Apoptotic parasites silence macrophages by misusing the autophagy machinery

P. Crauwels,* S. Gottwalt,* F. Jäckel,* M. Thomas,* E. Bank,* P. Walther,† M. Bastian‡ & G. van Zandbergen*
**Immunology, Paul-Ehlich-Institut, Langen, Germany, †Electronmicroscopy Facility, University Ulm, Ulm, Germany, ‡Veterinary Medicine, Paul-Ehlich-Institut, Langen, Germany*

Purpose/Objective: An appropriate T cell response to *Leishmania* (Lm) infection is critical for an effective immune response. Human macrophages (MF) can present antigen to T lymphocytes and at the same time serve as host cells. Upon macrophage infection the virulent inoculum of Lm promastigotes consists of apoptotic and viable promastigotes. The viable promastigotes enter a maturing phagolysosome were they can survive and grow as amastigotes; the fate of apoptotic parasites is unclear.
Materials and methods: In this study, we hypothesize that the apoptotic promastigotes use the MFs«autophagy machinery to down regulate MF antigen presentation and T cell activation.
Results: Upon promastigote uptake by human primary MFs, we found apoptotic promastigotes to enter a compartment positive for the autophagy marker LC3. This LC3 compartment matured over time and became LAMP positive. 24 h later the compartment resolved after highly efficient parasite degradation. When co-incubated with autologous T lymphocytes, MFs infected with viable promastigotes induced a strong CD4-positive T cell proliferation. Compared to viable parasites a significantly lower T cell reactivity was observed in response to MFs inoculated with apoptotic or a mixed population of apoptotic and viable parasites. Subsequently, preliminary results suggest that only in the presence of apoptotic promastigotes and human T cells Lm infection could be sustained in human MF over a period of 7 days.
Conclusions: We found that apoptotic promastigotes enter a maturing LC3 compartment. Our data suggest that degradation of parasites in this compartment could be involved in a down regulation of T cell activation. We now further investigate and characterize the proliferating T cell subsets and how the autophagy machinery and apoptotic promastigotes may dampen immune responses in human primary macrophages.

Autophagy is activated in the B cells of patients with SLE and correlates with disease activity

A. J. Clarke, U. Ellinghaus & T. J. Vyse
Medical and Molecular Genetics, King's College London, London, UK

Purpose/Objective: Autophagy is increasingly appreciated as an important immune surveillance and effector mechanism, but understanding of its dynamic function in human autoimmune disease is limited. We sought to evaluate its role in the B and T lymphocytes of patients with SLE compared with healthy controls.

Materials and methods: Patient samples were collected with informed consent, and disease activity quantified by the SELENA-SLEDAI index. Multispectral imaging flow cytometry was performed using an Amnis ImageStream^X instrument. LC3-positive autophagosomes were enumerated in viable, non-apoptotic cells using the Bright Detail Intensity algorithm implemented in IDEAS 6. Autophagic flux was determined by incubation with chloroquine. As an alternative measure of autophagy, uptake of the novel autophagosomotropic dye CytoID (Enzo) was analysed using conventional flow cytometry. Autophagy was assayed in negatively selected B cells stimulated with combinations of anti-IgM and anti-CD40 antibodies, and interferon-α.
Results: Autophagy was significantly increased in the CD19$^+$ B cells of patients with SLE compared with healthy controls

($P = <0.001$, $n = 22$ patients, 15 controls), and there was a positive correlation with SLEDAI score ($r = 0.67$, $P = <0.002$). There was however, no association in CD4$^+$ T cells ($P = 0.49$). There was no statistical evidence of confounding due to patient age or medication use. Assessment of autophagic flux using the autophagosome-lysosome fusion inhibitor chloroquine revealed an accumulation of autophagsomes following treatment.

Analysis of *ex vivo* viable, annexin V negative human B cells demonstrated a significant increase in autophagy in unstimulated compared with anti-IgM stimulated cells, with further decreases observed with the addition of anti-CD40 and interferon-α.
Conclusions: The process of autophagy has not been previously examined in *ex vivo* human B cells from patients with systemic autoimmune disease. We demonstrate that autophagy is enhanced in this context. Given our *in vitro* data, we may advance the hypothesis that autophagy is acting as a survival mechanism for auto reactive B cells lacking adequate survival signals. An alternative explanation requiring further investigation is that autophagy is acting to promote presentation of self-antigens by B cells. Autophagy is readily inhibited by many common pharmaceutical agents and may therefore represent a new treatment target in SLE.

P0003

Role of autophagy in the immunopathogenesis of leprosy

B. J. Andrade Silva,* P. R. Andrade,* T. P. Amadeu,* V. Diniz,† S. Côrte-Real,† V. C. Valentim,* H. Ferreira,* J. A. C. Nery,* E. N. Sarno* & R. Olmo Pinheiro*
**Leprosy Laboratory, Oswaldo Cruz Institute, Rio de Janeiro, Brazil, †Structural Biology Laboratory, Oswaldo Cruz Institute, Rio de Janeiro, Brazil*

Purpose/Objective: Leprosy is a chronic infectious disease that can present different clinical forms and there is evidence that the establishment of different clinical forms is driven by host innate mechanisms. Macrophages from tuberculoid (BT) and lepromatous (LL) patients seem to have a different behavior in relation to the mycobacteria. While in LL patients there are highly infected macrophages, in BT rare or few bacilli are found. Electron microscopy studies showed the presence of phagosomes with double membrane in macrophages exposed to *M. leprae* (ML), suggesting a possible involvement of

autophagy in the immunomodulatory response. In the present study we evaluated the role of autophagy in the immune response to ML.
Materials and methods: THP-1 monocytic cell line, monocytes from healthy subjects and BT and LL macrophages isolated from skin lesions were used. For evaluate autophagy we used transmission electron microscopy, western blotting, immunohistochemistry and immunofluorescence techniques.
Results: Ultrastructural analysis showed a higher number of autophagosomes in cells from skin lesions of BT patients compared to LL patients or normal tissue. Immunoperoxidase and western blotting analysis revealed a greater tissue expression of the autophagosome marker LC3 in BT patients when compared with LL. Additionally, there was an increase on LC3-puncta expression in *ex vivo* macrophages from BT patient, in the presence or absence of IFNγ. ML stimulation induced autophagy in THP-1 macrophages. IFNγ treatment in ML-stimulated cells increased LC3-puncta expression compared with stimuli alone or non-stimulated monocytes and THP-1 macrophages. The pre-treatment with autophagic inhibitors wortmannin (Wm) or 3-methyladenine (3-MA) was able to reduce IFNγ-induced LC3 expression. IFNγ treatment promotes ML-LC3 colocalization in THP-1 macrophages. In addition, in the presence of both IFNγ and ML, there was a higher expression of Atg3. IFNγ treatment in ML-stimulated cells was able to increase IL-15 secretion in relation to non-stimulated cells, but not IL-10. Autophagic blockage by 3-MA led to decreased IL-15 levels in response to stimulation with IFNγ and ML, but did not affect the IL-10 production.
Conclusions: Together, these data indicate that in ML-stimulated macrophages, IFNγ induces the production of proinflammatory cytokines including IL-15, which contribute to host cell increase in microbicidal activity by autophagy induction. These findings may contribute to a better understanding of the mechanisms associated with leprosy immunopathogenesis.

P0004

Transient Receptor Potential Vanilloid 1 activation induces autophagy in thymocytes through ROS-regulated proteasome inhibition, UPR and AMPK/ATG4C pathways

V. Farfariello,* C. Amantini,† M. Nabissi,† M. B. Morelli,† S. Liberati,‡ A. M. Eleuteri,§ L. Bonfili,§ V. Cecarini,§ M. Sorice¶ & G. Santoni**

**Urology and Andrology, University of Perugia, Perugia, Italy, †School of Pharmacy, University of Camerino, Camerino, Italy, ‡Molecular Medicine, Sapienza University of Rome, Rome, Italy, §School of Biosciences and Biotechnologies, University of Camerino, Camerino, Italy, ¶Experimental Medicine, Sapienza University of Rome, Rome, Italy, **School of Pharmacy, University of Camerino, Rome, Italy*

Purpose/Objective: Autophagy is a highly conserved process involved in lymphocyte development and differentiation. Herein, we evaluated the effects of Transient Receptor Potential Vanilloid 1 (TRPV1) activation in mouse thymocytes.
Materials and methods: Western blot and flow-cytometric analyses were performed to assess whether TRPV1 activation by 10 μM capsaicin, a specific agonist, could induce autophagy in mouse thymocytes. We used flow cytometry to investigate calcium influx and ROS generation and western blot was to elucidate the signalling pathways. Modification of CD4 and CD8 expression and DNA fragmentation were assessed by flow cytometry. Proteasome inhibition was evaluated by proteasome peptidase activity using fluorogenic peptides. UPR induction was assessed by using RT- profiler PCR array.
Results: Triggering of TRPV1 induces autophagy in mouse thymocytes. Autophagy is activated as pro-survival process since its inhibition triggered apoptotic DNA fragmentation. TRPV1 activation induced the development of a DP subpopulation expressing lower levels of both CD4 and CD8 receptors (DP^{dull}).We found that CPS induces autophagy of DP^{dull} cells, and inhibition of autophagy by 3-MA triggers apoptosis of DP^{dull} cells. Probably via the generation of oxidative stress, TRPV1 activation induces proteasome inhibition, as shown by the reduced chimotrypsin- and trypsin-like activity. Since proteasome inhibition often induces ER stress and activates the unfolded protein response (UPR) we performed a RT-PCR array in CPS-treated thymocytes to verify UPR induction. We found a significative upregulation of calreticulin and Insulin induced gene 2, that bind to misfolded proteins and prevents the export from the Endoplasmic reticulum. Moreover, both Derlin-1 and Homocysteine-inducible, ER stress-inducible, ubiquitin-like domain member 1 that are part of a complex mediating UPR, were upregulated.
Conclusions: Overall, our data indicate that TRPV1 activation in thymocytes impairs the ubiquitin-proteasome degradation pathway. As consequence, autophagy is activated in response to UPR in order to eliminate unfolded proteins and rescue cells from apoptotic death. DP^{dull} cells constitute a distinct thymocyte subpopulation involved in the responses to stress signals during thymocyte maturation, via regulating autophagy and apoptosis in a TRPV1-dependent manner.

P0005
CCX-CKR deficiency alters thymic stroma impairing thymocyte development and promoting autoimmunity

I. Comerford, M. D. Bunting & S. R. McColl
Microbiology/Immunology, University of Adelaide, Adelaide, SA, Australia

Purpose/Objective: The ligands for the atypical chemokine receptor CCX-CKR (CCL19, CCL21 and CCL25) play an important role in the development of a self-tolerant adaptive immune system by directing migration of specific subsets of developing thymocytes to appropriate developmental niches through interactions with the chemokine receptors CCR7 and CCR9. However, despite high affinity binding of these chemokines and an apparent chemokine scavenging function, the contribution CCX-CKR makes to regulation of autoreactive T cell development remains to be clearly established.
Materials and methods: We have analysed CCX-CKR-deficient mice compared with WT C67Bl6 mice and performed detailed analysis of appearance of spontaneous peripheral autoimmune-like lesions and examined T cell development in the thymus using both immunofluorescent microscopy and flow cytometric approaches.
Results: CCX-CKR-deletion increases incidence of a spontaneous Sjögren's syndrome-like pathology, characterised by lymphocytic infiltrates in salivary glands and liver of CCX-CKR$^{-/-}$ mice, suggestive of a defect in self-tolerance when CCX-CKR is deleted. Analysis of the thymus revealed that negatively selected mature SP cells were less abundant in CCX-CKR$^{-/-}$ thymi, yet expansion of both DP and immature SP cells was apparent. Deletion of CCX-CKR profoundly reduced frequencies of DN3 thymocyte precursors and caused DN2 cells to accumulate within the medulla. These effects are likely driven by alterations in thymic stroma as CCX-CKR$^{-/-}$ mice have impaired expansion of cTECs, the cell population that expresses the highest level of CCX-CKR in the thymus. A profound decrease in CCL25 within the thymic cortex was observed in CCX-CKR$^{-/-}$ thymi, likely accounting for their defects in thymocyte distribution and frequency.
Conclusions: These findings identify a novel role for CCX-CKR in regulating cTEC expansion, which promotes optimal thymocyte development and selection important for self-tolerant adaptive immunity.

P0006
Chemokine CCL21 Expression in Macrophages is Regulated by Nuclear Factor of Activated T Cells (NFATc4) Pathways in Murine Inflammatory Arthritis

V. Adarichev,* M. Ramez,* M. T. Shekhani,* C. W. Chow,† P. A. Kenny,‡ O. D. Loudig§ & T. S. Forde*
**Department of Medicine, Albert Einstein College of Medicine, Bronx, NY, USA, †Department of Molecular Pharmacology, Albert Einstein College of Medicine, Bronx, NY, USA, ‡Department of Developmental & Molecular Biology, Albert Einstein College of Medicine, Bronx, NY, USA, §Department of Epidemiology & Population Health, Albert Einstein College of Medicine, Bronx, NY, USA*

Purpose/Objective: Nuclear factors of activated T cells (NFAT) is a family of transcription factors critical in regulating genes expression in development and disease. The pathway is an important target for cyclosporine immunosuppression in transplant rejection and in autoimmune diseases such as rheumatoid arthritis (RA). We aimed to study a functional significance and mechanisms of NFATc4 regulation of inflammatory arthritis.
Materials and methods: In genome-wide association study (GWAS), we correlated susceptibility to antibody (Ab)-mediated arthritides (serum transfer-induced arthritis and collagen Ab-induced arthritis, CAIA) of inbred murine strains with all available DNA polymorphisms/SNPs. CAIA was induced in NFATc4-ko gene deficient and in wild-type (WT) C57BL/6J mice.Differential gene expression analysis of RNA isolated from arthritic paws was performed using Affymetrix GeneChip® Mouse Gene 1.0 ST Array followed by statistical analysis, functional and unsupervised hierarchical clustering (Ingenuity Pathway Analysis, Partek).Significantly dysregulated genes were replicated using TaqMan® RT-PCR with independent RNA samples. Immunohistochemical staining of tissue sections and chemokine production in isolated macrophages were studied.
Results: Using GWAS, NFATc4 gene was discovered to be significantly associated with arthritis severity, $P < 0.000003$. Biological effect was confirmed in NFATc4-ko gene deficient mice that exhibited significantly weaker CAIA (55% downregulation, $P < 0.01$) when were compared to wild-type. The most significantly downregulated gene in paws of NFATc4-ko mice was chemokine CCL21 (11.55-fold, $P < 0.00006$).Using RT-PCR and ELISA, we showed that production of CCL21 was blocked in LPS-stimulated peritoneal macrophages from NFATc4-ko mice. Cells isolated from articular cartilage of gene-deficient mice showed significantly lower production of collagen type I and aggrecan (twofold, $P < 0.01$). LPS- and TNF-stimulated RAW-264.7 monocyte/macrophage cells produced CCL21, and chemokine expression correlated with osteoclastogenesis.
Conclusions: Transcriptome and proteome analyses confirmed *in silico* genetic association between severity of inflammatory arthritis and polymorphisms within the Nfatc4 gene. We showed that activation of macrophages is under the strong control of NFATc4 regulatory pathways.

P0007
Chemokine citrullination reduces *in vitro* and *in vivo* inflammatory activity

P. Proost, A. Mortier, E. Moelants, T. Loos, M. Gouwy, S. Struyf & J. Van Damme
Rega Institute Lab. Molecular Immunology, Katholieke Universiteit Leuven, Leuven, Belgium

Purpose/Objective: Chemokines are modified by posttranslational modifications (PTM) that may affect their biological activity. Recently we identified a novel PTM on chemokines, i.e. deimination of specific peptidylarginines to peptidylcitrullines. Moreover, protein citrullination is known to play a prominant role in autoimmune diseases such as rheumatoid arthritis and multiple sclerosis. The biological effects of this PTM were investigated on the inflammatory chemokines CXCL5, CXCL8, CXCL10, CXCL11 and CXCL12. In addition, an ELISA was developed to quantify specific citrullinated chemokines.
Materials and methods: Citrullinated arginines were identified by protein sequence analyses and mass spectrometry. Affinity of chemokines for their respective receptors and glycosaminoglycans was analysed on receptor transfectants or human leukocytes. Biological activity of citrullinated chemokines was tested *in vitro* in receptor signaling and chemotaxis assays and adhesion molecule expression was evaluated on fresh human blood. *In vivo* chemotaxis was evaluated by intraperitoneal injection of chemokines in mice and quantification of extravasated leukocytes. The influence of truncation and citrullination of CXCL8 on its angiogenic activity was tested in the cornea assay in rabbits.
Results: Human peptidylarginine deiminase (PAD) 2 and 4 modified 1 specific Arg in CXCL5, CXCL8 and CXCL10 and multiple Arg in CXCL12. Citrullination of leukocyte-derived CXCL8 depended on the presence of neutrophils. Citrullination resulted in reduced binding to glycosaminoglycans and citrullinated CXCL8 was resistant to proteolytic activation. Citrullination reduced the receptor binding properties of CXCL5, CXCL10 and CXCL12. Moreover, receptor-dependent signalling properties of CXCL5, CXCL10, CXCL11 and CXCL12 were

lower resulting in reduced neutrophil and lymhocyte chemotactic properties. Although citrullination of CXCL8 moderately reduced reduced its signaling properties, no difference in chemotactic activity was detected *in vitro*. However, upon intraperitoneal injection, both citrullinated CXCL5 and CXCL8 had a highly reduced ability to attract neutrophils to the peritoneal cavity. Citrullinated CXCL8 retained its angiogenic activity and efficiently mobilized neutrophils upon intraveneous injection.

Conclusions: PAD-dependent citrullination of chemokines dampens their inflammatory activity.

P0008

Chemokine receptor CCR7 on $CD4^+$ T cells plays a crucial role in the induction of experimental autoimmune encephalomyelitis

P. Belikan, F. Zipp & V. Siffrin
Department of Neurology, University Medical Center of the Johannes Gutenberg University of Mainz, Mainz, Germany

Purpose/Objective: Experimental autoimmune encephalomyelitis (EAE) is the animal model for the human disease multiple sclerosis. EAE is mediated by myelin-specific $CD4^+$ helper T cells. The chemokine receptor CCR7 is an important factor for immune cell trafficking and recirculation not only in the secondary lymphoid organ, but also within target organs of an inflammatory attack. Previous data suggested that CCR7 deficiency influenced clinical disease by altering dendritic cell biology.

Materials and methods: Using different animal models for multiple sclerosis and *in vivo* imaging technique within the CNS, we investigated the role of T cells in animals which lack the CCR7 on T cells.

Results: We demonstrate here that $CD4^+$ T cell-specific constitutive deletion of CCR7 led to an impaired clinical course in EAE. In adoptive transfer EAE, mice receiving $CCR7^{-/-}$ myelin antigen T cell receptor transgenic 2d2 TH17 cells showed an earlier disease onset compared to mice adoptively transferred with $CCR7^+/^+$ 2d2 TH17 cells. Thus CCR7-deficiency on TH17 cells caused an increased encephalitogenicity in adoptive transfer EAE. We monitored the trafficking of $CCR7^{-/-}$ and $CCR7^+/^+$ 2d2 Th17 cells within the CNS by two-photon laser scanning microscopy in living anaesthetized mice and identified distinct motility patterns. In contrast to the findings in adoptive transfer EAE, CCR7 deficiency on $CD4^+$ cells led to a delayed disease onset in active EAE induced with MOG in lymphopenic $RAG^{-/-}$ mice, which had been grafted with $CCR7^{-/-}$, $CCR7^+/^+$ or $CCR7^+/^-$. This could be attributed to impaired T cell priming in secondary lymphoid organs, which most likely resulted from reduced lymph node homing potential.

Conclusions: Taken together these findings underline a crucial and paradoxic role of CCR7 in neuroinflammation.

P0009

Chemokine-mediated innate immune responses to mosquito bites and their viruses

C. McKimmie,* A. Kohl,* J. K. Fazakerley† & G. J. Graham*
**Institute of Infection Immunity and Inflammation, University of Glasgow, Glasgow, UK, †Institute of Animal Health, Pirbright, UK*

Purpose/Objective: Diseases spread by mosquitoes have a significant impact on human health and include disease caused by viruses such as Chikungunya and West Nile virus. There remains a need to understand the complex interplay between these viruses, their mosquito vectors and their mammalian hosts.The early events of infection are critically important for disease outcome in the host. Strikingly, arbovirus inoculated via bites or accompanied by arthropod saliva induces a more rapid viraemia, higher mortality and higher pathogen load, compared to inoculation via a needle. Although, how virus disseminates from the inoculation site and what role arthropod saliva have in facilitating this process are not understood.

Chemokines have pivotal functions in the immune system, without which coordinated immune responses would not occur. We have studied chemotactic responses during key stages of infection, from the mosquito bite site to target CNS tissue.

Materials and methods: We have used a relevant, tractable *in vivo* model system to study the effects of bites and arbovirus infection on the chemokine system and other key innate immune processes.We have carefully mapped the kinetics of virus spread from skin inoculation sites and assayed the expression of chemokines and innate immune genes during these early stages of infection.

Results: Surprisingly, virus spreads within hours from skin to draining lymph nodes followed by viraemia at 48 h, suggesting that virus primarily disseminates away from bite sites via lymph fluid.Mosquito bites trigger chemotactic responses in the skin and lymph nodes that are qualitatively and temporally distinct from those triggered by virus infection. Bites induce a chemokine response dominated by neutrophil attracting chemokines whilst virus infection induces a later response dominated by the ligands for CXCR3.

Conclusions: In summary, we have developed a new model for studying chemotactic processes *in vivo* and defined a key aspect of innate anti-viral immunity in the initiating stages of a mosquito-borne virus infection.

P0010

Cloning of atypical chemokine receptors CRAM-A and CRAM-B for comparative functional analysis

P. Sarmadi & G. Esendagli
Department of Basic Oncology, Institute of Oncology, Hacettepe University, Ankara, Turkey

Purpose/Objective: Atypical chemokine receptors play an important role in the termination of inflammatory responses. Upon binding to their cognate ligands, chemokine gradient drops and immune cell migration is hampered. CCRL2 is the newest member of atypical chemokine receptor family. The human CCRL2 gene has two transcript variants CRAM-A (Chemokine Receptor on Activated Macrophages) and CRAM-B. The aim of this study is to compare the effect of these different variants on the chemokine gradient.

Materials and methods: Total cDNA was synthesized using RT-PCR. CRAM-A and CRAM-B protein coding cDNAs, specific primers and *Pfu* DNA polymerase were used in amplification and site-directed cloning (*Nhe*I and *Xma*I restriction enzyme sites). CRAM-A and -B amplicons, pIRES2-EGFP and pcDNA3.1/CT-GFP eukaryotic expression vectors were digested, isolated, ligated, and then transformed into *E.coli* competent bacteria.

Results: The resulting constructs were confirmed by restriction analysis and DNA sequencing.The recombinant clones pCRAM-A-IRES2-EGFP and pCRAM-B-IRES2-EGFP enabled the bicistronic expression of CRAM and EGFP, whereas pcDNA3.1/CRAM-A-CT-GFP and pcDNA3.1/CRAM-B-CT-GFP produced a hybrid GFP-tagged protein. The recombinant plasmids and empty vectors were delivered into HEK293T cell line via liposomal transfection. Transfection efficiency (GFP expression) and recombinant CRAM expression were analyzed by flow cytometry.

Conclusions: In conclusion, the transcript variants of human CCRL2 gene were cloned into different recombinant DNA constructs and *de novo* expression of recombinant CRAM proteins were determined. Next, the ligand binding assays will be performed with CRAM-A or CRAM-B-expressing cells.

P0011

Combining classical and NKT-cell-mediated DC licensing not only enhances, but also accelerates CD8$^+$ T cell responses

A. Heine, V. Semmling, D. Wohlleber, P. Knolle & C. Kurts
Institutes of Molecular Medicine and Experimental Immunology, University of Bonn, Bonn, Germany

Purpose/Objective: Dendritic cell (DC) licensing is a requisite for the induction of efficient CD8$^+$ T cell responses to extracellular antigens. Classically, DCs are licensed by CD4$^+$ helper cells. As an alternative, NKT cells can replace CD4$^+$ help. We have shown previously that combining both licensing systems results in synergistically enhanced CD8$^+$ T cell responses, by mechanisms involving the chemokine receptors CCR4 and CCR5. Here we asked whether this chemokine synergism impacts the kinetics of CD8$^+$ T cell induction.
Materials and methods: We performed *in vivo* kinetic studies using the OT-I mouse model, as well as an endogenous T cell repertoire, to analyse the initiation of CD8$^+$ T cell activation and the clearance of an adenoviral infection. Classical DC licensing was initiated by the application of the TLR-9-ligand CpG, whereas NKT-cell-mediated DC licensing was induced by the NKT-cell-ligand α-Galactosylceramide (GC).
Results: After applying the model antigen Ovalbumin (OVA) together with both CpG and GC, specific CD8$^+$ T cells proliferated faster and produced earlier more cytokines than when only one licensing system was engaged. The combination of OVA$^+$GC$^+$CpG resulted in higher antigen-specific cytotoxicity *in vivo* at earlier time points and a faster clearance of adenoviral infection in contrast to mice treated with OVA plus either adjuvant alone. This acceleration was chemokine receptor-dependent.
Conclusions: Combining classical and NKT-cell-mediated DC licensing allowed faster activation of CD8$^+$ T cells and accelerated clearance of adenoviral infection. These findings provide a novel approach for designing better vaccines against rapidly proliferating microbes.

P0012

Conditional knockout of chemokine receptor CXCR5 in antigen presenting (CD11c$^+$) cells

B. M. Bradford,* M. A. Helsby,* B. Reizis† & N. A. Mabbott*
**Neurobiology Division, The Roslin Institute and R(D) SVS the University of Edinburgh, Edinburgh, UK, †Department of Microbiology and Immunology, Columbia University, New York, NY, USA*

Purpose/Objective: The aim of this study was to generate a conditional CXCR5 knockout transgenic mouse model using the Cre/LoxP system. Using this model we can delete CXCR5 from various cells of the immune system, preventing their localising to lymphoid follicles. These models can then be used to study the possible loss of function of specific follicular localising cells.
Materials and methods: LoxP sites were gene-targeted to surround the CXCR5 gene in C57Bl/6 mice. To assess the efficacy of this model we have introduced the CD19-Cre(1) transgene to delete CXCR5 from B-cells. To study the role of antigen-presenting cells we have combined the CXCR5 floxed allele with CD11c-Cre(2) transgenic mice.
Results: We have generated and are currently characterising the CXCR5 floxed transgenic mouse model. Following CD11c-Cre mediated recombination we observed no alteration in lymphoid organogenesis, suggesting that removal of CXCR5 expression by potential CD11c$^+$ lymphoid tissue inducer cells had no effect on their ability to promote or maintain development of lymphoid organs including spleen, lymph nodes, intestinal Peyer's patches or isolated lymphoid follicles. Investigation of lymphoid microarchitecture revealed retention of CD11c$^+$ve cells within T-cell areas.
Conclusions: Generation of CD11c-restricted CXCR5 knockout had no effect on lymphoid organogenesis but has impaired the ability of CD11c$^+$ cells from entering the B-cell follicle. These cells have recently been reported to regulate the development of T_H2 responses within this locale (3) using complex mixed bone marrow chimeric and cell deletion based models. We present here a refined genetically-regulated cell-specific model to study the role of antigen presenting cells in lymphoid follicles and data on effects upon immune function.

Inducible tertiary lymphoid structures formation in a novel model of sialoadenitis in wild-type mice is preceded by ectopic expression of lymphoid chemokines

D. Lucchesi,* M. Bombardieri,* F. Barone,† S. Nayar,† G. Proctor,‡ C. D. Buckley† & C. Pitzalis*
**Experimental Medicine and Rheumatology, William Harvey Research Institute, London, UK, †Rheumatology Research Group, University of Birmingham, Birmingham, UK, ‡Oral Medicine and Pathology, King's College, London, UK*

Purpose/Objective: Salivary glands of patients with Sjögren's syndrome (SS) develop ectopic lymphoid structures (ELS) characterized by B/T cell compartmentalization, the formation of high endothelial venules (HEV), follicular dendritic cell networks (FDCs), functional B cell activation with expression of activation-induced cytidine deaminase (AID) as well as local differentiation of autoreactive plasma cells. The mechanisms triggering ELS formation, autoimmunity and exocrine dysfunction in SS are largely unknown. Here we present a novel model of inducible ectopic lymphoid tissue formation, breach of humoral self-tolerance and salivary hypofunction following delivery of a replication-deficient adenovirus-5 (AdV5) in submandibular glands of C57BL/6 mice through retrograde excretory duct cannulation.
Materials and methods: Luciferase- or LacZ-encoding Ad5 were delivered in C57BL/6 mice salivary glands (SG) through retrograde cannulation. SGs were collected at various time-points 1, 2 and 3 weeks post-cannulation (pc) and frozen sections were graded for infiltration and stained for T/B cell segregation, FDCs and HEV markers. Submandibular salivary flow was induced by pilocarpine stimulation and the amount of saliva measured. Expression of TLS-related genes was investigated by TaqMan-PCR. Anti-viral antibodies and autoantibodies were detected by IF and western blot.
Results: In this model, inflammation rapidly and consistently evolves from diffuse infiltration towards the development of SS-like periductal lymphoid aggregates within 2 weeks from AdV delivery. These infiltrates progressively acquire ELS features and support functional GL7$^+$ /AID$^+$ germinal centers. Formation of ELS is preceded by ectopic expression of lymphoid chemokines CXCL13, CCL21 and CCL19 as well as lymphotoxin-β and is associated with development of antinuclear antibodies in 75% of the mice. Finally, reduction in salivary flow was observed over 3 weeks post AdV infection consistent with exocrine gland dysfunction as a consequence of the inflammatory response.
Conclusions: This novel model has the potential to unravel the cellular and molecular mechanisms regulating ELS formation and their role in exocrine dysfunction and autoimmunity in SS.

P0015

Influence of placental secretory factors to endothelial cell functional activity and monocyte-endothelial interaction

O. I. Stepanova, T. U. Lvova, K. N. Furaeva, D. I. Sokolov & S. A. Selkov

Laboratory of immunology, Scientific Research Institute of Obstetrics and Gyneacology named after Ott, St-Petersburg, Russia

Purpose/Objective: Such complication of pregnancy as preeclampsia is accompanied by trophoblast differentiation and placental angiogenesis disruption and local placental inflammation. Macrophages and endothelial cells are the main source of cytokines and angiogenic factors in placenta. Those factors have an autocrine and paracrine effect. The goal of this investigation was to evaluate the influence of placental secretory factors to endothelial cells (ECs) functional activity and monocyte-endothelial interaction.

Materials and methods: Placental tissue samples were taken from healthy pregnant women on 9−11 weeks (abortion) and 38−39 weeks of gestation, pregnant women with gestosis on 38−39 weeks of gestation (both after Cesarean section) and were incubated in DMEM/F12, 10% FBS. The ECs line EA.hy926 was grown in DMEM/F12, 10% FBS. Monocyte cell line THP-1 was grown in RPMI-1640 medium, 10% FBS. ECs were incubated with placental supernatants to characterize its influence to ECs phenotype and activity.

Results: Angiogenic factors secretion was decreased in third trimester in comparison with first trimester normal pregnancy; preeclamptic pregnancy is characterized with increased placental secretion of antiangiogenic factors in comparison with normal pregnancy. Third trimester placental supernatants caused a decrease of ECs angiogenic receptors and adhesion molecules expression, ECs proliferation and migration, monocyte transendothelial migration in comparison to first trimester placental supernatants. It can be turned to placental growth limitation to the end of pregnancy. Preeclamptic placental supernatants caused increase of CD119 ECs expression and bFGF ECs secretion, decrease of ECs proliferation and migration in comparison to normal pregnancy supernatants. Monocyte transendothelial migration activity was higher to preeclamptic placental supernatants in comparison to normal pregnancy one and was accompanied with increased monocyte CD11b expression.

Conclusions: Discovered ECs and monocyte cells phenotype and functional alterations can contribute to angiogenic abnormalities and local placental inflammation initiation during preeclamptic pregnancy.

Inhibition of neutrophil chemokine receptor CXCR2 profoundly suppresses inflammation-driven and spontaneous tumorigenesis

M. Clarke,* T. Jamieson† C. Steele,† M. Olson,‡ M. Samuel,‡ S. Das,* O. Sansom† & R. Nibbs*

**Immunology, Institute of Infection Immunity and Inflammation, Glasgow, UK, †Colorectal Cancer and WNT Signalling, Beatson Institute for Cancer Research, Glasgow, UK, ‡Molecular Cell Biology, Beatson Institute for Cancer Research, Glasgow, UK*

Purpose/Objective: Certain properties of the chemokine receptor CXCR2 suggest pro-tumorigenic potential: others, such as reinforcing senescence, could block tumor progression.However, it is unclear whether CXCR2 plays any indispensable role in *de novo* tumorigenesis *in vivo*.To definitively address this, we investigated CXCR2 function in inflammation-driven and spontaneous mouse models of intestinal and skin neoplasia, including benign and malignant tumor models.

Materials and methods: Skin inflammation was induced by applying TPA (Sigma) to shaved dorsal skin. Skin papillomas were induced with a single application of 25 mg of DMBA (Sigma) followed by tri-weekly TPA treatments for up to 22 weeks.Colitis was induced by providing *ad libitum* with 2% or 3.5% (w/v) DSS (MP Biomedicals, MW 36−50 kDa) in place ofdrinking water for 5 days.

Transcripts were measured by Q-RT-PCR on a 7900HT Fast-Real Time PCR System (Applied Biosystems), using TaqMan gene expression assays (Applied Biosystems)

For pepducin treatments, $Apc^{Min/+}$ mice were injected s.c. with 2.5 mg/kg × 1/2pal-i3 pepducin [Genscript, RTLFKAHMGQKHR, palmitoyl N-terminal, amidation C-terminal (21)] or control × 1/2pal-i3CONT pepducin in sterile saline, and then daily with 1 mg/kg.For neutrophil depletion, 35 day-old $Apc^{Min/+}$ mice were injected i.p. 3× a week with 200 mg of 1A8 or 2A3 isotype control 3× weekly.

Results: All tumors developing in these models had substantially elevated expression of chemokine ligands for CXCR2. Moreover, CXCR2 deficiency profoundly suppressed inflammation-driven tumorigenesis in skin and intestine and spontaneous adenocarcinoma formation in *AhCreER* $APC^{fl/+}$ $PTEN^{fl/fl}$ mice, while 'pepducin'-mediated CXCR2 inhibition reduced tumorigenesis in $Apc^{Min/+}$ mice. Established tumors contained CXCR2-dependent neutrophil infiltrates. CXCR2 deficiency dramatically attenuated neutrophil recruitment, and concomitant epithelial proliferation, during tumor-promoting inflammation.Moreover, neutrophil depletion suppressed growth of established skin tumors and reduced adenoma formation in $Apc^{Min/+}$ mice.

Conclusions: CXCR2 is a potent pro-tumorigenic chemokine receptor in skin and intestine due, at least in part, to its ability to direct neutrophil recruitment during tumor-inducing and tumor-driven inflammation.Our data suggest that CXCR2 antagonists may have utility as cancer therapeutics, or as prophylactics in patients at high risk of colorectal cancer.

Inhibition of neutrophils recruitment to the lung in the course of pneumonic plague is associated with suppression of pulmonary KC, MIP-2 and G-CSF production

Y. Vagima*, Y. Levy†, A. Tidhar‡, D. Gur§, M. Aftalion§, Y. Flashner§, A. Zauberman§, A. Shafferman* & E. Mamroud¶

**iibr, Biochemistry and molecular genetics, Modiin, Israel, †iibr, Biochemistry and molecular genetics, Rehovot, Israel, ‡iibr, Biochemistry and molecular genetics, Hod hasharon, Israel, §iibr, Biochemistry and molecular genetics, Ness Ziona, Israel, ¶iibr, Biochemistry and molecular genetics, Ashdod, Israel*

Purpose/Objective: Bacterial infection of the lung triggers a prompt innate immune response mainly characterized by infiltration of neutrophils into the infected tissue. Recruitment of neutrophils from the blood to the site of infection is mediated by several key effector molecules, including KC (CXCL1), MIP-2 (CXCL2) and G-CSF. These soluble factors are locally produced in the lung and diffuse to the blood ensuring effective neutrophil migration and function upon demand. Pneumonic plague, initiated by *Yersinia pestis* (*Y. pestis*) airway-infection, is a fatal and rapidly progressing disease. The pathogen replicates initially in the lung, causing substantial damage to the tissue followed by dissemination to internal organs and blood. In this study we monitored neutrophil recruitment to the lung concomitant with cytokines production, in the course of pneumonic plague.

Materials and methods: C57BL/6 mice were intranasally inoculated with a lethal dose of the virulent *Y. pestis* Kimberley53 strain (100LD50). Disease progression was monitored at various time points post infection (p.i.).

Results: Infected mice exhibit attenuated neutrophil infiltration from the blood to the lung in the first 24 h p.i. Accordingly, levels of KC, MIP-2 and G-CSF were not elevated in the blood at this early time point. However, at a late stage of disease progression − 48 h p.i., a

significant elevation of KC, MIP-2 and G-CSF levels in the blood and lung was accompanied by neutrophil accumulation in the lung. By using a trans-well migration assay, we evaluated whole-lung supernatants obtained from infected mice, for their potential to support neutrophil migration. Only supernatants from mice which were sacrificed 48 h p.i. indeed augmented neutrophils trans-well migration. Real-time PCR analysis of whole-lung mRNA revealed delayed expression of KC, MIP-2 and G-CSF at 48 h p.i. In contrast, infection with an avirulent strain was characterized by immediate up-regulation of KC, MIP-2 and G-CSF mRNA, neutrophils infiltration and inhibition of bacterial proliferation and dissemination.
Conclusions: The data suggests that during early stages of pneumonic plague neutrophil chemoattractans expression is suppressed therefore leading to an ineffective immune response against the *Y. pestis* pathogen.

P0018
Investigation of signaling mediators which control bone marrow memory T cell migration

M. McGrath, K. Tokoyoda, J. Dong, O. Okhrimenko, O. Sercan, H. D. Chang & A. Radbruch
Cell Biology, German Rheumatism Research Centre Berlin, Berlin, Germany

Purpose/Objective: We have previously identified a population of memory $CD4^+$ T cells which preferentially reside in the bone marrow of mice and can be classified as resting in terms of their proliferation state and major transcriptional activity. However, after activation by antigen, these cells are extremely capable cytokine producers and support the production of high affinity antibodies, proving that they are highly effective memory cells. The major objective of this study is to investigate whether such memory cells in the bone marrow of mice and humans can be further classified as resting in terms of their migratory capacity, and if so, what are the molecular mechanisms which mediate this phenotype.
Materials and methods: Chemokine receptor expression on memory ($CD44^{hi}$) CD4 and CD8 T cells from bone marrow and spleens of mice were assessed by flow cytometry. *In vitro* migratory potential was assessed using transwell migration assays. Migration was also examined in more detail using confocal microscopy based methods (3D chemotaxis slide) and polarisation assays. For analysis of signaling molecules involved in mediating migration of memory T cells, global transcriptional microarray profiles were analysed and genes related to migration were grouped using gene set enrichment analysis.
Results: Murine memory bone marrow T cells were found to exhibit differential chemokine receptor expression, as assessed by transcriptome analysis and on the protein level by flow cytometry. In particular, CCR2 and CXCR6 levels were increased on bone marrow memory T cells. *In vitro* transwell migration assays revealed that bone marrow T cells migrated less than splenic T cells when no stimulus was added to the chambers. However, when the cells were exposed to chemokines, the bone marrow counterparts were found to be more responsive to stimuli such as CXCL12 than splenic T cells.
Conclusions: Bone marrow memory T cells differ from splenic memory T cells in terms of their chemokine receptor expression and migration patterns. A variety of candidate molecules are currently being tested to identify their roles in the control of bone marrow memory T cell migration.

P0019
Macrophage migration inhibitory factor regulates neutrophil chemotactic responses in bacterial infection

M. Schiwon, L. Franken, S. Gutweiler, C. Kurts & D. R. Engel
Institute of experimental Immunology, University Clinic of Bonn, Bonn, Germany

Purpose/Objective: Polymorphonuclear neutrophils mainly facilitates the defense against invading uropathogenic *E.coli* (UPECs) within the urinary tract and are rapidly recruited into the infected urinary bladder. Although the macrophage inhibitory protein-2 (MIP-2) is considered the major chemokine responsible for this recruitment, the role of other chemokines involved in this recruitment are currently unknown.
Materials and methods: Wild type (C57/B6) and CCR5 knockout mice were infected 3h h before analysis with UPECs. If indicated MIF, KC and MIP-2 were blocked before using 125 ng blocking antibody per gram mouse weight. Cells were isolated from the bladder tissue by collagenase/DNAse digestion and analyzed by flow cytometry.
Results: We could show that the initial recruitment of neutrophils into the *E.coli*-infected murine bladder is induced by tissue resident macrophages. Such macrophages produced the CXCR2 ligands MIP-2, MIF and KC. Blockade of the neutrophil chemokine KC, MIP-2 and the macrophage inhibitory factor (MIF) demonstrated, that KC and MIF, but not MIP-2 mainly reduced neutrophil infiltration into the bladder. Apart from these CXCR2-ligands also CCR5 seems to contribute to neutrophil recruitment into the inflamed bladder as the number of neutrophils was decreased in CCR5-deficient animals. Of note, chemokines that recruit neutrophils did not influence the number of inflammatory $Gr1^+$ macrophages, which shows the specificity of these chemokines for neutrophils and suggests that the subsequent recruitment of inflammatory macrophages are independent of neutrophils.
Conclusions: These data demonstrates that a plethora of different chemokines specifically regulate the recruitment of neutrophils into the infected bladder and might be crucial for the innate immune repsonse against UPECs.

P0020
Myosin Vb mobilizes the chemokine decoy receptor D6 from recycling endosome for adaptive upregulation and chemokine degradation

C. Cancellieri, A. Vacchini, E. M. Borroni, C. Buracchi, A. Anselmo, A. Mantovani, R. Bonecchi & M. Locati
Medical Biotechnologies and Translational Medicine, Istituto Clinico Humanitas, Rozzano (Milan), Italy

Purpose/Objective: The decoy receptor D6 is a chemokine scavenger with a non-redundant role in the control of inflammation. D6 degradative properties refer to as ligand-induced increase of receptor membrane levels through a rapid mobilization from recycling endosomes but the mechanisms by which this adaptive up-regulation is achieved are still undefined. Given the importance of cytoskeleton dynamics in regulating chemokine receptors intracellular trafficking, here we investigate the role of actin and microtubules on D6 trafficking and scavenging properties.
.
Materials and methods: Confocal microscopy analysis has been used to evaluate D6 intracellular localization and actin/microtubule organization, using depolymerizing and stabilizing agents of actin filaments and microtubules. D6 membrane expression was measured with FACS, and chemokine degradation by ELISA test.
Results: In basal conditions D6 colocalizes with both microtubules and myosin Vb but not actin filaments. Perturbations of microtubule dynamics do not affect D6 constitutive endocytosis, however disrup-

tion of recycling endosomes by nocodazole increases D6 surface levels and this effect is reverted by dominant negative Rab11, indicating that intact microtubule network is required for the correct sorting of D6 to slow recycling endosomes. On the contrary, inhibition of actin turnover increases D6 expression on cell surface as a consequence of impaired receptor constitutive endocytosis. Interestingly, the actin depolymerization agent latrunculin A increases D6 membrane expression without modifying receptor internalization rate and this effect is reverted by dominant negative Rab4, indicating that D6 is missorted to rapid recycling endosomes. After chemokine exposure, actin fibres and microtubules rearrange at plasma membrane where strongly colocalized with D6-myosin Vb complexes. Microtubules depolymerization and myosin Vb inactivation impair D6 up-regulation and scavenging, suggesting that intact microtubules and myosin Vb are required to mobilize D6 from recycling endosomes.

Conclusions: Cytoskeletal dynamics sustain D6 constitutive endocytosis and its correct sorting to Rab4/Rab11 recycling endosome, and myosinVb-dependent control of cytoskeletal rearrangement is required for the adaptive up-regulation of D6 allowing optimal degradation of chemokines.

P0021
Peripheral monocyte expression of CCR2 is altered by pregnancy

S. Björkander,* G. Heidari-Hamedani,* K. Bremme,† I. Gunnarsson,‡ E. Sverremark-Ekström* & U. Holmlund*
**Immunology, Stockholm University, Stockholm, Sweden, †Department of Women and child health-Division of Obstetrics and Gynecology, Karolinska Institute, Stockholm, Sweden, ‡Medicine-Unit of Rheumatology, Karolinska Institute, Stockholm, Sweden*

Purpose/Objective: Purpose: Peripheral monocytes are chemotactically recruited to the decidua during pregnancy where they differentiate into macrophages clearing cellular debris and facilitating trophoblast invasion. Previous studies suggest that monocyte phenotype, behaviour and activation are affected by pregnancy. The purpose of this study was to investigate how pregnancy affects monocyte surface expression of CCR2, PBMC-secretion of the CCR2 ligand CCL2/MCP-1 and migratory behaviour of monocytes. In addition, we investigated placental expression of CCR2 and how *in vivo* CCL2/MCP-1 concentrations vary during and after pregnancy.

Materials and methods: Material and methods: PBMCs from women at labour and non-pregnant women were cultured *in vitro*. Monocyte surface markers were evaluated with flow cytometry and transwell-experiments were performed to study monocyte migratory response to CCL2/MCP-1. Placental expression of CCR2 was performed using immunohistochemistry and CCL2/MCP-1-concentrations in supernatants and serum were measured with CBA.

Results: Results: This study demonstrates that women at labour have significantly reduced percentages of CD16-CCR2$^+$ and CD16$^+$ CCR2$^+$ monocytes compared to non-pregnant women. Further, we show that CD16- and CD16$^+$ monocytes from women at labour and non-pregnant women have a similar migratory capacity towards CCL2/MCP-1 *in vitro*. In addition, CCR2$^+$ cells were abundant in the deciduas of all placentas. Finally, we found that PBMCs from women at labour release more CCL2/MCP-1 compared to non-pregnant women, while the *in vivo* concentrations of CCL2/MCP-1 was lower during pregnancy compared to after pregnancy.

Conclusions: Conclusions: We demonstrate that pregnancy significantly reduces the percentage of CCR2$^+$ monocytes in both CD16- and CD16$^+$ subpopulations, which might be explained by migration towards the decidua during pregnancy. Indeed, the monocytes from pregnant women readily migrated towards CCL2/MCP-1 *in vitro* and a strong expression of CCR2 was found on cells in the placental decidua. Uncontrolled placental infiltration of monocytes has been associated with pregnancy complications and our results suggest that monocyte migration is tightly regulated during pregnancy.

P0022
The biochemical properties of the D6 N-terminus and its therapeutic potential

K. D. Hewit, A. Fraser, R. J. B. Nibbs & G. J. Graham
Chemokine Research Group Level 3, Institute of Infection Immunity and Inflammation, Glasgow, UK

Purpose/Objective: D6 is an 'atypical chemokine receptor' and the N-terminal region (D6-N) is thought to act as part of the binding site for inflammatory chemokine ligands. A synthetic peptide analogue of D6-N may therefore have the capability to bind a broad spectrum of inflammatory chemokines, and consequently inhibit receptor binding. Thus D6-N may have the potential to be used therapeutically as a non-immunogenic, broad-based chemokine scavenger that would be beneficial in the treatment of chronic inflammatory conditions. Binding-affinity studies using different experimental techniques suggest a strong interaction between D6-N and different inflammatory chemokines.

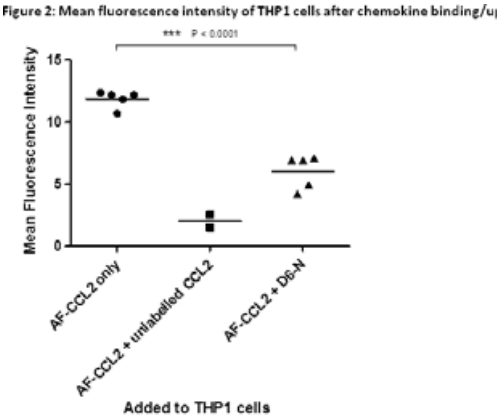
Materials and methods: A chemically synthesised version of the N-terminal of D6 (D6-N) has been used in these experiments.

Assessment of the ability of D6-N to bind inflammatory CC chemokines: Mixtures of biotinylated and native chemokines were incubated with D6-N and streptavidin beads used to 'pull-down' the chemokines. 'Pull-down' samples were then run on SDS gels and western blotted to examine any co-pull down of D6-N.

Assessing the ability of D6-N to interfere with CCL2/CCR2 interactions: CCL2 labelled with Alexafluor-647 (AF-CCL2) was added to THP1 cells with either unlabelled CCL2 or D6-N (as binding competitors) for 1 h. Cells were then analysed by FACS to measure CCL2 binding and uptake.

Results: i) D6-N binding properties: Bands corresponding to D6-N were apparent on western blots when CCL2 and CCL22 were used to 'pull down' D6-N. There was virtually no D6-N detected in samples when the non-D6 ligand, CCL19 was used therefore confirming specificity of D6-N for inflammatory chemokines.

ii) D6-N and CCL2/CCR2 binding: Addition of AF-CCL2 to THP1 cells resulted in an increase in the mean fluorescence intensity associated (MFI) with AF-CCL2 binding and uptake by the cells. As expected, this could be 'competed out' by adding a 20-fold molar excess of un-labelled CCL2. Importantly, the addition of D6-N also significantly reduces MFI associated with AF-CCL2 binding to, and internalisation by, the THP1 cells.



Chemokine(s) used	Relative density of D6-N band on western blot
Negative control	1
Biotinylated CCL2	10.42
Biotinylated CCL2$^+$ CCL22	36.09
Biotinylated CCL19	1.84
Biotinylated CCL19$^+$ CCL22	32.85
CCL22	31.05

Conclusions: The D6-N peptide is capable of binding to the inflammatory chemokines CCL2 and CCL22 but not to the homeostatic chemokine CCL19.

Addition of D6-N inhibits AF-CCL2 uptake by CCR2 on THP1 cells, suggesting that D6-N can bind to AF-CCL2, and thus prevent it from binding to its receptor.

P0023

The chemokine receptor CX3CR1 mediates homeostatic DC-colonization of the kidneys and leukocyte infiltration in Nephrotoxic Nephritis

K. Hochheiser, D. R. Engel, F. Hoss, T. Urcyniczok & C. Kurts
Institutes of molecular Medicine and Experimental Immunology, University Clinics of Bonn, Bonn, Germany

Purpose/Objective: Dendritic Cells (DCs) span the tubulointerstitium of the kidneys and monitor the renal parenchyma. Although renal DCs (rDCs) form a contiguous network, the anatomy of the kidney suggests that DCs located in the renal cortex, where most food antigens are reabsorbed, will differ from DCs located in the hyperosmotic and hypoxic medulla. Here, we investigated phenotypical and functional differences between cortical and medullary DCs, as well as the role of the chemokine receptor CX3CR1, which is expressed by most rDCs, in homeostasis and Nephrotoxic Nephritis (NTN).
Materials and methods: Renal cortex and medulla were macroscopically separated prior to DC isolation. DC phenotype and function were investigated by flow cytometry and functional assays. To study rDCs under inflammatory conditions, NTN, in which rDCs are protective at the onset of disease but are rendered pathogenic by the inflammatory environment induced by macrophage driven DTH responses, was induced. The role of CX3CR1 in NTN was investigated, using CX3CR1$^{GFP/GPF}$ transgenic mice.
Results: Under homeostatic conditions, DCs were more abundant in the renal cortex as compared to the medulla. Medullary DCs took up antigen more efficiently than cortical DCs. However, expression of costimulatory markers and the ability to stimulate T cells were similarly low in DCs isolated from either compartment.

Upon NTN induction, antigen uptake increased in both rDC subsets. Nevertheless, only cortical, but not medullary, DCs became competent to drive CD4 T cell proliferation and production of IFN-γ and IL-17.

In CX3CR1$^{GFP/GPF}$ transgenic mice, we discovered a reduction of rDCs under homeostatic conditions, which was more pronounced in the cortex. Interestingly, in these mice, NTN was attenuated as compared to control mice, as shown by histological and functional parameters. Flow cytometric analysis of the kidneys after NTN induction revealed reduced infiltration of DCs and macrophages in CX3CR1$^{GFP/GPF}$ transgenic mice as compared to heterozygous controls.
Conclusions: These findings suggest that cortical DCs may be more immunostimulatory as compared to medullary DCs, and drive Th1 as well as Th17 responses in NTN. Furthermore, CX3CR1 seems to play a role in DC-colonization of the homeostatic kidneys, especially in the cortical compartment, as well as in the recruitment of pro-inflammatory cells in NTN.

P0024

The microRNA miR-223 controls pulmonary trafficking of leukocytes in tuberculosis by targeting innate cytokines

A. Dorhoi,* M. Iannaccone,* M. Farinacci,* K. C. Faè,* J. Schreiber,* P. Alves,* H. J. Mollenkopf,* F. Del Nonno,† D. Goletti,† R. Capparelli‡ & S. H. E. Kaufmann*
**Immunology, Max Planck Institute for Infection Biology, Berlin, Germany, †Pathology, National Institute L. Spallanzani (INMI), Rome, Italy, ‡Faculty of Biotechnological Sciences, University of Naples 'Federico II, Naples, Italy*

Purpose/Objective: Tissue recruitment of immune cells during infection is critical for efficient eradication of pathogens. Yet, excessive accumulation of inflammatory cells is deleterious due to subsequently induced tissue damage. Recruitment of leukocytes at infection site is tightly regulated by chemoattractants. While regulation of chemoattractants by cellular and soluble immune mediators was described, a role for micro RNAs (miRs) was sparsely studied so far. We aimed at understanding how miRs regulate trafficking of immune cells in tuberculosis (TB), a chronic, non-resolving inflammation.
Materials and methods: Lung specimens from TB patients and experimentally infected mice were profiled for miRs expression using microarrays and subsequently miR candidates were confirmed by qPCR. Relevance of selected miRs in TB control was further tested by analysing responses to infection in gene knock-out mice. MiR targets and their effects on inflammation, lung cell trafficking and disease outcome were evaluated by combining *in silico* approaches with molecular and cellular investigations.
Results: We identified microRNA-223 (miR-223) as one of the most abundant noncoding RNAs in lung biopsies of TB patients. A similar pattern of expression was detected in TB-susceptible mice. Deletion of miR-223 rendered resistant mice highly susceptible to TB due to aberrant neutrophil-driven inflammation. MiR-223 tailored lung recruitment of innate cells by targeting the chemokines CXCL2, CCL3 and the cytokine IL-6.
Conclusions: Our study demonstrates that miR-223 is an essential regulator of inflammation in TB. By identifying innate cytokines as novel targets, we ascribe new biological functions to miR-223, namely control of leukocyte chemotaxis. The miR-dependent regulation of cell trafficking could be a general mechanism in inflammatory diseases.

P0025

The role of the atypical chemokine receptor CCRL2 (CRAM) in shaping local chemokine gradients

A. Haerzschel,* M. Leick,† J. Catusse,* E. Hinterseer,‡ T. Hartmann‡ & M. Burger*
**Department of Hematology/Oncology, University Clinic of Freiburg, Freiburg, Germany, †Institute for Anatomy & Vascular Biology, Westfälische Wilhelms-Universität, Münster, Germany, ‡Laboratory for Immunological and Molecular Cancer Research (LIMCR), Paracelsus Medical University Salzburg Austria, Salzburg, Austria*

Purpose/Objective: The correct localistation of immune cells during development, homeostasis and pathogenesis is an important prerequesite for the correct function of the immune system. The temporal and spatial control of this localisation is achieved by a complex and tightly regulated network of signalling molecules, among which chemokines play a prominent role. Besides the classical chemokine receptors, atypical, non-signalling receptors have been found to be important for the finetuning of the chemokine network by regulating

chemokine availability as well as interfering with the signaling of classical receptors. The most recently identified member of this atypical family is CCRL2, also called CRAM. We have shown in previous work that CCRL2 binds the homeostatic chemokine CCL19, which plays a pivotal role in the development and function of B and T cells through its classical receptor CCR7. When coexpressed with CCR7, CRAM interferes with the classical CCR7 responses.

Materials and methods: We used in-vitro transwell systems to simulate migration and transmigration of lymphocytes in response to chemokine gradients, as well as cell-cell adhesion assay. Furthermore, the subcellular localisation of CRAM was analysed by immune fluorescence (IF) and confocal microscopy. CRAM expression in human tissue sections was analysed by immunohistchemistry.

Results: We demonstrate that CRAM is able to efficiently internalise and re-express its ligand CCL19, without inducing significant degradation. CRAM expressing cells can subsequently present CCL19 to CCR7 expressing cells and induce classical responses such as calcium mobilisation and chemotaxis as efficiently as direct application of the chemokine. Furthermore, CRAM was shown to be involved in the transport of CCL19 across a polarised cell monolayer.

Conclusions: Our results suggest a role for CRAM in the finetuning of CCL19 gradients. By internalising, transporting and presenting CCL19, CRAM expressing cells locally enrich CCL19, thus creating gradients and ensuring the attraction of CCR7 expressing cells.

TNFa modulates chemokine expression and leukocyte influx during alveolar bone repair process in mice

A. E. Vieira*, C. E. Repeke,* E. M. Silveira,* C. C. Biguetti,* C. F. Francisconi,* A. P. Campanelli,† A. P. F. Trombone,* G. F. Assis,* R. Taga* & G. P. Garlet*

**OSTEOimmunology Lab, Bauru School of Dentistry University of São Paulo, Bauru, Brazil, †Immunology Lab, Bauru School of Dentistry University of São Paulo, Bauru, Brazil*

Purpose/Objective: Although the migration of innate immunity related leukocyte subsets, especially macrophages, have been implicated in bone repair process, the molecular mechanisms underlying such process remains unknown. Thus the aim of this study was to characterize the role of TNF-α (pro-inflammatory cytokine) in the modulation of chemokine expression and in leukocyte influx in alveolar bone repair process after tooth extraction in mice.

Materials and methods: C57Bl/6 (WT) and TNFp55KO strains had the right upper incisor was extracted and the maxilla containing the remaining alveolus was collected 0, 7, 14, 21, 28 and 42 days after extraction for molecular (RealTimePCR) and histomorphometric analysis.

Results: The results demonstrated that in C57Bl/6WT mice the expression of CCL2, CCL25 and CX3CL1 was associated with the development of the inflammatory infiltrate and a granulation tissue; TNF-α expression peaked at 7 days while the chemokines peaked with 14 days. Besides, growth factors as BMP2, BMP4, BMP7, TGFb1 and VEGFa had a gradual increase reaching its peak with 7 days. Afterward the granulation tissue was gradually (7−42 days) replaced by connective tissue, blood vessels and bone. These processes were associated with higher expression of matrix markers (COL1a1, COL1a2, COL2a1, MMP1α) and bone markers RUNX2 (CBFA-1) and ALP, and subsequently by OCN, DMP1 and PHEX), concomitant with lower expression of AHSG and AMBN. Subsequently, bone remodeling features were detectable, in parallel with increased expression of osteocyte marker SOST. TNFp55KO strain presented an increased number of leukocytes in repair sites despite a slight decrease in CXCL1, CCL-2 and CCL3 expression. TNFp55KO also presented a delay in angiogenesis and in transition of granulation to bone tissue, a discreet presence of newly formed bone tissue associated with decreased CBFA-1, ALP, OCN and PHEX expression, in opposite of the higher proportion of osteoclasts in the late periods of the repair process.

Conclusions: The results presented demonstrate that the absence of TNF-alpha interferes in alveolar bone repair through mechanisms that involve the modulation of osteogenic markers and chemokines expression, as well the modulation of inflammatory cell migration along the course of alveolar bone repair.

Atypical Hémolytique and Uremique Syndrom by MCP defenciency diagnosed at a teenager

M. Hedouas
Néphrologie, Hospital Pr Nefissa Hamoud, Algiers, Algeria

Purpose/Objective: The relation between the atypical H*mlytique-Uremiquse Syndrom and the deficits in fractions of complement.
Materials and methods: We report the observation of a 17-yaer-old teenager, whose first symptom appeared in january 2011.She has brutally, without a triggering factor, presented anaemia, a severe hypertention and anuric acute renal failure.On the biological plan, we are noticed:hemlytic anaemia with scizocytes, very high LDL and rate of haptoglobin collapsed, the studdy on the activity of the complement was realized and it objectified a deficit in MCP (CD46) with factor H and I normal. A transjugulaire renal biopsy was performed, it shows throbotic microangiopathie. The patient has benifit of plasma exchanges with conventional hemodialysis. The answer of plasma exchange was partial and not sustainable. She benifed later of the ECULIZUMAB, our patient got back a renal function (35 ml/Mn), with normal rate of platelet and hemoglobulin. The genetic study finds that parents as well as her small sister are heterozygous it should be noted that her first cousin dialysis chronic for an indefinite renal disease and benefited from two kidney transplantation.
Results: It is the first case of atypical HUS with MCP deficiency diagnosed in Algeria, the patient answered partially the sessions of plasma exchanges and she reponded well to treatment with ECULIZUMAB with partial recovery of renal function. It is possible that his first cousin is wearing the same affection.
Conclusions: The MCP defenciency is an anomaly of the complement associeted with the atypucal HUS. A therapeutic hope was born with ECULIZUMAB.

C5a drives the cutaneous lesions in experimental epidermolysis bullosa acquisita, which can be targeted by highly galactosylated IgG1 immune complexes

R. Kilchenstein,* C. M. Karsten,* J. Figge,* G. D. Brown† & J. Koehl*
**Institute for Systemic Inflammation Research, University of Luebeck, Luebeck, Germany, †Section of Infection and Immunity, University of Aberdeen, Aberdeeen, UK*

Purpose/Objective: Epidermolysis Bullosa Acquisita (EBA) is a chronic autoimmune disease, causing subepidermal blistering of the skin. Autoantibodies targeting type VII collagen are critical for disease development. Previous data suggest that immune complex formation in the skin leads to activation and deposition of complement. Further C5-deficient mice were protected in experimental EBA indicating that complement fragments downstream of C5 may be important for EBA development. Of note, IgG IC can differ in their potential to activate complement and to promote inflammation. In line with this view, we recently uncovered a novel anti-inflammatory pathway by which highly galactosylated IgG1 IC can block C5a-mediated effector functions by an FcgRIIB and Dectin-1-dependent signalling pathway.
Materials and methods: EBA was induced in C57Bl/6J wt, $C5aR^{-/-}$ and Dectin-$1^{-/-}$ mice by repeated transfer of purified rabbit IgG specific to murine collagen type VII. The clinical phenotype was determined by assessment of the affected body surface area. Skin C3b and IgG deposition was determined by immunohistochemistry. To block C5a effects, high and low galactoslyated OVA/anti-OVA IgG1 IC (HiGal-IC and LoGal-IC) were administered prior to the injection of pathogenic typy II collagen antibodies.
Results: We found that $C5aR^{-/-}$ mice are protected from the development of cutaneous lesions. Further, treatment with HiGal- but not with LoGal-IC prior to disease initiation reduced number and size of cutaneous lesions, whereas deposition of collagen type VII-specific antibodies and of C3b was not affected in the two treatment groups. Importantly, HiGal-IC had no protective effect in Dectin-$1^{-/-}$ mice.
Conclusions: C5a promotes the inflammatory responses underlying the inflammatory skin lesions in experimental EBA. The C5a effector functions can be reduced by treatment with HiGal-IC. The galactosylation level of the IgG1 ICs is critical for the inhibitory effects as LoGal-IC are not protective. The missing effect of HiGal-IC in Dectin-$1^{-/-}$ mice suggests an important role for Dectin-1 in in the control of C5a-mediated regulation of autoimmunity.

P0029

C5a receptor signalling in dendritic cells controls the development of maladaptive Th2 and Th17 immunity in allergic asthma

I. Schmudde,* Y. Laumonnier,* H. Ströver,* T. Vollbrandt,† P. König,‡ C. M. Karsten* & J. Köhl*
**Institute for Systemic Inflammation Research, University Medical Center Schleswig-Holstein, Luebeck, Germany, †Clinical and Experimental Research Facility, University Medical Center Schleswig-Holstein, Luebeck, Germany, ‡Institute for Anatomy, University Medical Center Schleswig-Holstein, Luebeck, Germany*

Purpose/Objective: The mechanism underlying dendritic cell (DC)-mediated induction of maladaptive Th2 and Th17 responses to inhaled allergens in the lung are incompletely understood. Mice lacking C5 or the C5a receptor (C5aR) suffer from maladaptive Th2 immunity in models of experimental asthma suggesting that C5a exerts immunoregulatory properties at the DC/T cell interface. To directly assess the role of C5aR signalling in DCs, we assessed the impact of ovalbumin (OVA) stimulation on DC maturation *in vitro* and DC-mediated experimental allergic asthma induction *in vivo*.
Materials and methods: We characterized DC differentiation from wildtype (wt) and C5aR-deficient BM precursors using GM-CSF by flow cytometric staining. To assess antigen uptake and processing, we incubated DCs with fluorescently labelled OVA. T cell activation and survival were tested in *in vitro* cocultures of wt or C5aR-deficient DCs and OVA-responsive DO11.10 $Rag2^{-/-}$ T cells. To assess the role of C5aR on DC-mediated development of maladaptive immunity in asthma, we adoptively transferred naïve or OVA pulsed wt or C5aR-deficient BM-derived DCs into wt BALB/c mice. Three days before analysis, mice were challenged by intratracheal administration of OVA.
Results: *In vitro*, antigen uptake and processing as well as CD11b expression were reduced in C5aR-deficient DCs. Further IL-1$, IL-6 and IL-23 production were impaired resulting in reduced Th17 differentiation, associated with accelerated T cells death. Additionally we found an increased frequency of $CD11b^{hi}CD11c^{int}Gr\text{-}1^{+}$ $F4/80^{+}$ cells that shared functional characteristics like arginase 1 and nitric oxide synthase 2 expression with myeloid-derived suppressor cells (SC). *In vivo* administration of pulsed wt BM-DCs induced a clear asthmatic phenotype characterized by airway hyperresponsiveness, eosinophilic and neutrophilic infiltration, mucus production and secretion of Th2/Th17 cytokines. In contrast, transfer of C5aR-deficient DCs failed to promote a strong asthmatic phenotype. Further, combined transfer of wt DCs and C5aR-deficient SCs reduced airway inflammation and Th2 cytokine production.
Conclusions: We uncover novel roles of C5aR in Th17 differentiation, T cell survival and differentiation of a SC population controlling Th2 immunity in experimental allergic asthma.

P0030

Comparison of fully activated complement and C5a on the response of retinal pigment epithelial cells

S. Wasmuth,* K. Lueck,† M. Busch,* A. Lommatzsch‡ & D. Pauleikhoff‡

**Ophtha-Lab, Ophthalmology at St. Franziskus Hospital, Muenster, Germany, †Cell Biology, Ophthalmology at University College Londonl, London, UK, ‡Ophthalmology, St. Franziskus Hospital, Muenster, Germany*

Purpose/Objective: Retinal pigment epithelial (RPE)-cells undergo cell death during age-related macular degeneration (AMD). This possibly blinding eye disease is related to an enhanced activation of the complement cascade but the influence of the important anaphylatoxin complement 5a (C5a) is unclear. Therefore, in this study complement treated RPE cells were compared to RPE cells treated with isolated C5a.
Materials and methods: Human ARPE-19 cells as a model for RPE cells were treated with increasing concentrations of human complement serum (HCS) or with recombinant C5a. In some experiments zymosan was added to stimulate complement activation. Terminal complement complex C5b-9 was stained by immunocytochemistry. Reactive oxygen species (ROS) were measured by a nitroblue tetrazolium assay. The production of vascular endothelial growth factor (VEGF) in the cell culture supernatants was quantified by ELISA. Polarized RPE cells were grown in transwell inserts.
Results: After 24 h even low amounts of HCS induced a strong C5b-9 specific staining, generated an increase in ROS and clearly raised the VEGF production by ARPE-19 cells. The strongest effects were observed with combined HCS and zymosan treatment. In contrast, C5a treated ARPE-19 showed no C5b-9 staining. There were only slight augmentations in ROS and in the secreted amount of VEGF. Elevated concentrations of C5a and prolonged time of incubation failed to provoke elevated effects. Independent of HCS and C5a treatment, VEGF was mainly secreted towards the basal side.
Conclusions: The influence of C5a induced only minor changes in confluent ARPE-19 cells. In contrast, HCS showed clear effects. These RPE cells may either be relatively resistant against C5a or the effect of C5a may be more transient. In AMD pathology a second trigger might be necessary. For future therapeutic intervention in AMD the inhibition of the complement complement cascade might be more effective than C5a inhibition.

P0031

Influence of mannose-binding lectin (MBL) deficiency on the clinical presentation of patients with antibody deficiencies

M. Speletas,* G. Iordanakis,* A. Mamara,* Z. Florou,* E. Papadopoulou-Alataki† & A. E. Germenis*

**Department of Immunology and Histocompatibility, University of Thessaly, Larissa, Greece, †Pediatric Clinic, Aristotle University of Thessaloniki, Thessaloniki, Greece*

Purpose/Objective: MBL deficiency, characterized by low MBL plasma levels and/or low-producing *MBL2* genotypes, has only a minor influence on the morbidity of otherwise healthy people, but it becomes symptomatic if other defense defects are present. In this study, we investigated the role of MBL deficiency in the clinical presentation of patients with antibody deficiencies.
Materials and methods: 65 patients with antibody deficiencies were enrolled, including 19 patients with common variable immunodeficiency (CVID), 23 with IgA deficiency (IgAD), 19 with selective IgG4 deficiency (sIgG4D) and 4 with transient hypogammaglobulinemia of infancy. The detection of *MBL2* alterations (-221: X/Y, rs7096206; cod52: A/D rs5030737; cod54: A/B, rs1800450; cod57: A/C, rs1800451) was performed by PCR-RFLP and direct sequencing. Allele and genotype frequencies of *MBL2* compared with those observed in 153 healthy controls.
Results: We did not observe any significant difference on the prevalence of MBL deficiency between patients and controls, except of a higher frequency of the X allele (rs7096206) in patients with IgAD. *MBL2* deficient genotypes were significantly correlated with severe respiratory complications, especially bronchiectasis, in CVID, but did not affect the clinical presentation of IgAD and sIgG4D.
Conclusions: Our findings demonstrate that *MBL2* deficient genotypes might potentiate the clinical symptoms of patients with CVID and are mainly correlated with severe respiratory complications, especially bronchiectasis formation.

Investigation of the factors that influence complement-dependent cytotoxicity (CDC) following ofatumumab treatment in chronic lymphocytic leukaemia

O. Middleton,* E. Cosimo,* E. Dobbin,* A. M. McCaig,* C. Clarke,† A. M. Brant,† M. T. Leach,‡ A. M. Michie* & H. Wheadon*

**Paul O'Gorman Leukaemia Research Centre, University of Glasgow, Glasgow, UK, †GlaxoSmithKline UK Ltd., Stockley Park West, Uxbridge, UK, ‡Haematology, West of Scotland Cancer Centre, Glasgow, UK*

Purpose/Objective: CLL patients exhibiting progressive disease often become refractory to standard first line therapies, underpinning the need for novel drugs. An emerging field is targeted monoclonal antibody (MAB) development. In this study we evaluated the ability of the next generation anti-CD20 MAB ofatumumab (OFA), against current first-line anti-CD20 MAB rituximab (RIT), to induce CDC and determined whether complement defects are an issue in CLL MAB treatment regimes.
Materials and methods: CLL cells and serum were taken from patients with confirmed B-CLL diagnosis. Flow cytometric analysis was performed for CDC levels (PI staining) and surface marker expression. Complement activity and levels were verified using CH100 assay, immunonephelometry and ELISA-based assays.
Results: OFA induced significantly higher CDC in CLL primary cells than RIT, with levels of CDC positively correlated with expression levels of CD20. CLL serum sample analysis revealed that >40% of patients were either deficient, or had reduced expression of, one or more complement components, which impacted on their ability to elicit a CDC response to OFA-bound CLL cell line, HG3. Patients with complement levels bordering on normal initially induced a high level of CDC, however on secondary challenge CDC activity in sera was significantly reduced, compared with normal human serum (NHS; $P = <0.0001$; $n = 24$). Importantly, supplementing CLL serum with individual complement components was sufficient to restore CDC activity and protect against exhaustion.C2 deficiency was particularly important, with re-addition of C2 restoring CLL patient serum activity back to NHS levels, ($P = <0.0001$; $n = 11$). Furthermore, high CLL cell burden also contributed to more rapid complement exhaustion.
Conclusions: Our studies demonstrate that OFA is more effective at inducing CDC than RIT and correlates with intensity of CD20 expression on CLL cells. In addition, complement deficiencies in CLL serum suggest that supplementing MAB treatment with fresh frozen plasma, or more specifically C2, may help maintain normal CDC levels, particularly in patients with a high white blood cell count. This study has important implications for CLL patients receiving MAB therapy.

P0035

Polymorphisms causing deficiency in lectin pathway genes: frequency in the Icelandic population

M. Arnardottir,* H. Bjarnadottir† & B. R. Ludviksson*
*Department of Immunology & Faculty of Medicine, Landspitali University Hospital & University of Iceland, Reykjavík, Iceland,
†Department of Immunology, Landspitali University Hospital, Reykjavík, Iceland

Purpose/Objective: The complement system has a pivotal role in innate immunity. The lectin complement activation pathway is initiated by either mannan-binding lectin (MBL), or one of three ficolins through associated serine proteases (MASPs). MASP-2 has a central role in initiating the lectin pathway. It is known that homozygotes with the *MASP2* gene mutation *p.D120G* have no functional MASP-2. It is estimated that 1:1000 healthy Danish individuals are homozygous for this mutation *(G/G)*. We evaluated the frequency of *p.D120G* mutation in healthy Icelandic blood donors.
Materials and methods: A total of 453 blood donor samples were genotyped for the mutation *p.D120G* in the *MASP2* gene. Genomic DNA was extracted from EDTA treated blood using salting out procedure and genotyped using 'sequence-specific primer' PCR (PCR-SSP) method.
Results: A total of 37 blood donor samples were found to be heterozygous for this mutation or 8.2%.
Conclusions: Our results show that the frequency of the *p.D120G* mutation is 0.041 in Icelandic population, which is comparable with Danish population (0.039). Next step is to screen for *p.D120G* in variable disease associated populations in Iceland, including individuals with repeated unexplained infections.

P0036

Role of complement regulatory protein CD46 in rheumatoid arthritis

R. Pahwa,* U. Kumar† & N. Das*
*Biochemistry, All India Institute of Medical Sciences, New Delhi, India,
†Medicine, All India Institute of Medical Sciences, New Delhi, India

Purpose/Objective: Rheumatoid Arthritis (RA) is a chronic inflammatory disease characterized by pain, swelling and progressive destruction of multiple joints, affecting approximately 1% of the adult human population. The growing importance of Membrane cofactor protein (MCP; CD46) not only as central membrane bound complement inhibitor but also as critical regulator of T-cell immunity, suggests that regulation of its expression may have significant effects on health and disease. Studies on animal models suggest disease modulating activity of CD 46 in autoimmune disorders. We conducted a case-control study to explore the role of CD 46 in human RA. Till now, only few reports on the expression of CD 46 on circulating cells in RA are present.
Materials and methods: In this study, the surface CD 46 expression on lymphocytes, monocytes and neutrophils of 40 healthy controls and 30 DMARD naïve RA patients were monitored using Flow cytometer. The Circulating Immune Complex (CIC) levels in serum of controls and patients were determined spectrophotometrically. Disease activity scores (DAS28) were monitored in RA patients using swollen and tender joint counts (SJC & TJC), the patient global assessment and the ESR. The correlations of CD46 expression with clinical parameters (DAS28, SJC and CIC) were calculated using Spearman's rank correlation test.
Results: The mean fluorescence intensity values of CD 46 on leukocyte sub-populations were in the order of monocytes >neutrophils > lymphocytes both in controls and patients. In patients, the surface CD 46 expression reduced significantly on lymphocytes followed by monocytes as compared to controls. The mean value of CD 46 expression on neutrophils was comparable between the patients and controls. Significant negative correlations of the monocyte and lymphocyte cell surface CD 46 with DAS28 and SJC were observed in patients. Only lymphocyte CD 46 correlated negatively with CIC.
Conclusions: Decline in the levels of CD 46 expression differentially on different leukocyte subpopulations in patients may contribute not only to the aggravation of complement mediated tissue injury but also to immune deregulation in rheumatoid arthritis. The negative correlations of CD 46 with disease activity indices suggest significant association of CD 46 with the disease state. The role of CD 46 as disease activity marker is envisaged.

P0038

Specificities for microorganisms by Ficolins and Mannan-binding lectin – complement-activating soluble pattern recognition molecules

S. Thiel, J. C. Jensenius, U. S. Sørensen & T. Kjær
Department of Biomedicine, Institute of Biomedicine, Århus C, Denmark

Purpose/Objective: We wish to expand the knowledge of soluble pattern recognition molecules (sPRMs) initiating the lectin pathway of complement. This pathway is initiated by the binding of the proteins: mannan-binding lectin (MBL) or one of the three ficolins, H-ficolin, M-ficolin or L-ficolin. These proteins bind to pathogen-associated molecular patterns (PAMPs) displayed by microorganisms. The binding of the sPRMs promotes the activation of associated proenzymes, termed MBL-associated serine proteases, (MASPs). The MASPs then mediate the down-stream activation of complement.
Materials and methods: We have screened a large number of microorganisms (bacteria, viruses and fungi) for binding in serum by H-ficolin, L-ficolin, M-ficolin and Mannan-binding lectin. Quantification of ficolins and MBL was by time-resolved immuno-fluorometric assays (TRIFMA) in serum samples exposed to various microorganisms.
Results: We find a huge difference in binding to different microorganisms by these four sPRMs and a remarkably specificity for certain serotypes of pneumococci and fungi. As another example we find that M-ficolin binds to encapsulated but not to unencapsulated *Streptococcus Agalactiea*, while the reverse was true for MBL.
Conclusions: A highly specified biological role of MBL and ficolins in activation the innate immune system when different microorganisms is exposed to the body is indicated.

P0039

Transcriptomic 'portraits' of transient inflammatory arthritis in C5 complement component deficient mice

V. Adarichev, J. Brucker, E. T. Lyons, M. T. Shekhani & T. S. Forde
Department of Medicine, Albert Einstein College of Medicine, Bronx, NY, USA

Purpose/Objective: C5 complement component is a central molecule that is essential for leukocytes activation in inflammation. C5 encoding gene is located within the Pgis2 chromosome 2 interval linked to murine proteoglycan-induced spondylitis (PGIS). The goal of the study was searching for genes that rescue the inflammatory phenotype in C5-deficient BALB/c.DBA/2-Pgis2 congenic mice.

Materials and methods: Collagen antibody-induced arthritis (CAIA) was induced in BALB/c, DBA/2 and congenic mice. Mice were sacrificed at the acute inflammation, and collected synovial joints were subject for histopathological analysis. Total RNA was isolated from arthritic paws and analyzed for genechip expression. Serum C5a levels were measured using ELISA. Ingenuity Pathways Analysis and hierarchical clustering of expression patterns were performed.

Results: DBA/2 mice carry natural C5 deficiency and were resistant to CAIA, while C5-suffcient BALB/c were highly susceptible for CAIA. C5-deficient Pgis2-congenic mice demonstrated an intermediate phenotype of transient inflammatory arthritis. Statistical analysis of differential gene expression in the congenic arthritic paws revealed $n = 27$ genes that expression were significantly deregulated ($P < 0.01$) and greater than ±1.5-fold change when compared to arthritic paws of wild-type BALB/c mice.Empirical false discovery rate (FDR) tested for these comparison criteria using 500 permutations was 0% for median FDR and 18.5% for 90-th percentile FDR. Most significantly down-regulated genes include FK506 binding protein 5 (-2.58-fold, $P < 0.0003$), raftlin lipid raft linker 1 (-2.38-fold, $P < 0.008$), serine peptidase inhibitor clade A isoform 3C (-2.18-fold, $P < 0.0008$). Top upregulated genes in Pgis2 mice with attenuated CAIA were sphingosine kinase 2 (2.8-fold, $P < 0.00001$) and defensin beta 3 (2.92-fold, $P < 0.007$). According to IPA, differentially expressed genes showed the enrichment with messages that are specific for macrophages and effector T cells.

Conclusions: The early, transient arthritis in Pgis2-congenic C5-deficient mice is due to multifactorial by committee gene expression and may lead to the identification of novel targets for therapeutic intervention in inflammatory arthritis models.

Activities of histamine H2- and H4-receptors on granulocytes

D. Neumann,* T. M. Reher,* I. Brunskole,† A. Buschauer† & R. Seifert‡
*Hannover Medical School, Institute for Pharmacology, Hannover, Germany, †Department of Pharmaceutical and Medicinal Chemistry II, University of Regenburg, Regensburg, Germany, ‡Hannover Medical School, Institute for Pharmacology, Hannover, Germany

Purpose/Objective: Eosinophils and neutrophils are involved in the two major lung diseases, allergic asthma and chronic obstructive pulmonary disease (COPD), respectively. The biogenic amine histamine plays a role in allergic diseases as well as in inflammatory diseases, such as COPD. Histamine is recognized on target cells by four different receptors, histamine H_1-receptor (H_1R), H_2R, H_3R, and H_4R. Of these, H_1R, H_2R, and H_4R are expressed on eosinophils, while neutrophils express only H_1R and H_2R. In this study, our objectives were to functionally examine the H_XR subtypes on human eosinophils and to compare the effects of histamine on eosinophils and neutrophils with special emphasis on the regulatory H_2R.
Materials and methods: Granulocytes were isolated from peripheral human blood by density gradient centrifugation followed by hypotonic lysis of erythrocytes. The obtained cell suspension contained at least 95% viable neutrophils. Eosinophils were enriched from the granulocyte suspension by CD16-directed magnetic bead-assisted cell sorting, resulting in preparations consisting of 98% eosinohils. H_XR were targeted by histamine and selective ligands, such as the H_4R-selective agonist UR-PI376, the H_4R-selective antagonist JNJ7777120 and the H_2R-selective ligands amthamine (agonist) and famotidine (antagonist). Intracellular calcium concentrations ($[Ca^{2+}]_i$) were measured by the Fura-2 method and *in vitro* chemotaxis was quantified in a Boyden chamber. Finally, reactive oxygen species (ROS) production was analyzed by reduction of cytochrome c.
Results: Histamine and UR-PI376 induced $[Ca^{2+}]_i$ mobilization and chemotaxis of eosinophils, which were inhibited by JNJ7777120. In contrast, blockade of the H_2R enhanced histamine-induced chemotaxis. Formation of ROS was induced in eosinophils and neutrophils by the formyl peptide fMLP, but not by histamine. In both granulocytes subsets, the induction of ROS formation was reduced by histamine in a H_2R antagonist-sensitive manner.
Conclusions: On eosinophils, histamine has both activating and reducing effects on differing cellular functions. In contrast, on neutrophils histamine via the H_2R mainly reduces activation, probably due to the absence of H_4R expression.

P0041
An evaluation of neutrophil function: a new approach to the chemiluminescent analysis

I. V. Obraztsov
Faculty of Fundamental Medicine Chair of Biophysics, Lomonosov Moscow State University, Moscow, Russia

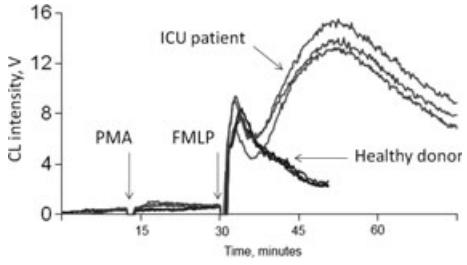
Purpose/Objective: Neutrophils as a part of nonspecific immunity factors play a crucial role in antimicrobial resistance. Reactive oxygen species (ROS) are important compound of the neutrophils' microbicidal action. Analysis of neutrophils' ROS production could provide valuable data on a phagocyte link of immunity. Chemiluminescent (CL) assay being highly sensitive allows evaluating oxidative output of the cells in dynamics.

There were published many controlled studies on neutrophil CL in humans with different diseases. However the results often vary between authors because of the lack of standardized method of CL analysis. So we tried to develop a methodology of neutrophils' CL analysis according to principles of the evidence-based medicine.
Materials and methods: 95 healthy donors and 3 ICU patients with second-third degree burns participated in the study.

To dilute blood samples we used Henks Balanced Salt Saline (HBSS) with glucose, pH = 7.4 supplemented with 2 mM HEPES. Luminol (Sigma-Aldrich) was dissolved in double distillated water at 1 mM. N-formyl-methionyl-leucyl-phenylalanine (FMLP, Sigma-Aldrich) and 4-phorbol-12-myristate-13-acetate (PMA, Sigma-Aldrich) were diluted in DMSO (MP Biomedicals, LLC) to make stock solutions that were dissolved in HBSS on the day of experiment. CL was evaluated by means of a chemiluminometer Lum-12 (Chair of Biophysics, Moscow State University).
Results: We have obtained curves of CL-response of whole blood neutrophils in healthy donors under conditions ofPMA, FMLP and their combination. A statistical analysis has shown optima for their concentrations and for time interval between blood sampling and CL assay. We have also analysed a blood dilution impact to a CL response. We have developed a method on the evaluation of a neutrophil function that is based on a step-by-step stimulation of the cells by PMA and FMLP.

Using this method, we compared the distributions of CL characteristics for the population of 95 healthy donors.

We also held a CL assay ICU patients (Fig.1) and then compared the results with data from clinical observations and laboratory tests.



Conclusions: As a result we suggest reliable and replicable method on the evaluation of a neutrophil function applicable in clinical practice. We argue that to interpret reference means of the adjusted CL characteristics distributions it is important to foresee future tendencies on septic complications.

P0042
Co-operation between innate CCR3-expressing granulocytes and macrophages in controlling early establishment of Brugia malayi infection

J. Turner,* A. de Castro Guimaraes,* A. Steven,* D. Cook,* N. van Rooijen† & M. J. Taylor*
Molecular and Biochemical Parasitology, Liverpool School of Tropical Medicine, Liverpool, UK, †Molecular Cell Biology, Vrjie Universiteit, Amsterdam, The Netherlands

Purpose/Objective: The mouse is a non-permissive host for the human lymphatic filarial parasite, *Brugia malayi*. Experimental infection with third stage infectious larvae (L3) induces a rapid recruitment and / or expansion of eosinophils and macrophages and >95% of larvae are killed by a host granulomatous response within the first 2 weeks of infection. We investigated the early immune events that govern resistance to primary filarial infection.
Materials and methods: Experimental *B. malayi* infections were undertaken by infection with 50 L3 larvae into the peritoneal cavities of interleukin(IL)-4 receptor alpha$^{-/-}$ IL-5$^{-/-}$ mice, Severe Combined ImmunoDeficient (SCID) mice or WT mice all on a BALB/c

background. Administration of anti-C-C chemokine receptor 3 (CCR3) antibody and clodronate encapsulated liposomes 1 day before infection selectively depleted eosinophils and macrophage populations, respectively. Larvae and peritoneal exudate cells were recovered at between^{+}2 and^{+}14 days. More long-term infections (+12 weeks) were used to examine impact of manipulation of the host response on the establishment of patent adult infections.

Results: We report that severely impaired type 2 signalling (IL-4, -5 and -13) in IL-4Ra$^{-/-}$/IL-5$^{-/-}$ mice produces a susceptible phenotype able to host long-term *B. malayi* fecund infections both in the peritoneal cavity and lymphatics accompanied by a complete ablation of eosinophils at the infection site. Resistance is dictated by early immune events as significantly higher parasite burdens can be discerned in IL-4Ra$^{-/-}$/IL-5$^{-/-}$ mice as little as^{+}2d after infection. By tracking larval attrition during the first 2 weeks following temporal ablation of eosinophils or macrophages, we show both cell types are necessary for resistance to early larval establishment. Increased susceptibility is also apparent in SCID mice following anti-CCR3 targeted ablation of eosinophils indicating the mechanism of early larval attrition is independent of adaptive immunity.

Conclusions: The presence of both CCR3^{+} granulocytes and macrophages are important for optimum resistance to larval *B. malayi* infection. We speculate that recruited CCR3^{+} eosinophilic granulocytes may mediate larval killing by regulating macrophage effector function.

P0043

Expression of HPV16-E7 oncoprotein in skin exacerbates the contact hypersensitivity response to DNCB

A. S. Bergot,* S. Le Tran,* D. Mittal,* M. A. Grimbaldeston† & I. H. Frazer*

**Epithelial Cancer Division, University of Queensland Diamantina Institute, Brisbane, Qld, Australia, †Division of Human Immunology, Centre for Cancer Biology, Adelaide, SA, Australia*

Purpose/Objective: Cervical cancer is the second most common cancer of women worldwide and is the first cancer described to be entirely induced by a virus, the human papillomavirus. This study is aimed to better understand the immunopathology of pre-cancerous skin lesions associated with HPV infection.

Materials and methods: We use C57BL/6 mice expressing HPV16-E7 oncoprotein as a transgene from a keratin 14 promoter in mouse skin (E7 mice). The inflammatory response to DNCB was investigated after application to ear skin of E7 and control mice.

Results: E7 mouse ears undergo increased swelling relative to control ears within the first 8 h (early) following DNCB exposure, and also exhibit increased swelling at day 5 (late) which resolves by10 days after DNCB exposure. E7 skin has two to three-times more mast cells than control, and there were more degranulated mast cells in the basal layer of the epidermis. Mast cells in E7 mouse skin were found to have a greater capacity to degranulate during a passive cutaneous anaphylaxis response. The early response induced by DNCB was accompanied by substantial mast cell degranulation in E7 mouse ear skin, which was not observed in control ear skin. The increased late response to DNCB in E7 mice was accompanied by elevated levels of IL-1b and IL-19, but not IL-33, in the skin.

Conclusions: E7 transgenic skin shows exaggerated swelling in response to a contact sensitising agent, in association with mast cell degranulation and IL-19 release.We are now investigating a possible link between mast cells and IL-19 in the immunopathology of HPV infected skin, particularly as mast cells have been associated with HPV positive intraepithelial neoplasia in humans, and as IL-19 plays a role in psoriasis lesions where skin thickening similar to that in HPV16-E7 skin is observed.

P0044

Functional responses of basophils to endogenous danger signals

C. Stoeckle, A. Thomet, U. Gurzeler, T. Rabachini de Almeida, T. Kaufmann & H. U. Simon

Institute of Pharmacology, University of Bern, Bern, Switzerland

Purpose/Objective: Cellular injury, necrosis or stress that might occur during inflammatory responses or mechanical injury leads to release of damage associated molecular patterns (DAMPs), intracellular molecules that are normally retained inside the cell. These molecules include ATP, uric acid, S100A proteins and HMGB1, which are interpreted as danger signals by the immune system when present in the extracellular milieu. Several DAMPs have been shown to have differential (usually pro-inflammatory) effects on immune cells, including neutrophils and eosinophils, but whether and how basophils respond to endogenous danger signals is unknown.

Since basophils are important players in allergic immune responses and these often involve cellular damage, we aimed to understand how human and mouse basophils react to different DAMPs and how this might contribute to an inflammatory response.

Materials and methods: We cultured human *ex vivo* isolated or mouse *in vitro* differentiated basophils in the presence or absence of different DAMPs and assessed viability, chemotaxis, surface expression of activation markers CD63 and CD203c, and chemotactic responses.

Results: We found that basophils are capable of responding to a variety of different DAMPs and that different DAMPs affect a variety of basophil functions, including survival, migration and cytokine release.

Conclusions: Our results suggest that endogenous danger signals modulate inflammation also through their action on basophils.

P0045

Hsp70 and Hsc70 dynamics in human neutrophils under heat shock conditions

A. Boyko, A. Sapozhnikov & E. Kovalenko

Lab of Cell Interactions, Immunology Department, Shemiakin-Ovchinnikov Inst of Bioorganic Chemistry RAS, Moscow, Russia

Purpose/Objective: Neutrophils are short lived cells characterized by low biosynthetic activity, however they are inducible for synthesis of heat shock proteins 70 kDa (HSP70s) possessing cell protective functions. The aim of this study was to analyze the dynamics of HSP70 content in human neutrophils in response to heat shock (HS), and to investigate factors affecting the dynamics.

Materials and methods: Neutrophils isolated by density gradient from heparinized venous blood of healthy volunteers were stained intracellularly with monoclonal antibodies (mAbs) directed to constitutive Hsc70 (SPA815, Stressgen) or inducible Hsp70 (SPA810, Stressgen) proteins, or with HSP70 antibody not distinguished between Hsc70 and Hsp70 (BRM-22, Sigma). Detection of intracellular HSP70 levels was performed by flow cytometry.

Results: In most cases after short-term heating (43°C, 10 min) we registered an increase and following decrease in 15−30 min after the end of HS of HSP70 levels with all three mAbs (BRM-22, SPA810, SPA815). We did not detect any increase phase by Western blotting. Pre-incubation with cycloheximide, inhibitor of protein synthesis, did not change the dynamics of intracellular HSP70 levels revealed by flow cytometry. This fact indicates that the HSP70 increase phase is not mediated by de novo protein synthesis, but is possibly related to the availability of epitopes of HSP70s for binding with mAbs. The decrease phase of HSP70 level was confirmed by Western blotting normalized with β-actin. This phase can be connected with release of HSP70s into extracellular space phenomenon described mostly for Hsp70. Treatment of neutrophils with glybenclamide, ATP sensitive potassium

channel blocker, resulted in the HSP70 decrease stage reduction detected with all mAbs suggesting that Hsc70 but not only Hsp70 was released from the cells. Treatment of neutrophils with NH_4Cl, lysosomotropic compound, resulted in greater increase of intracellular HSP70 level, possibly, through impairment of vesicle maturation.
Conclusions: Thus, our data suggest that both Hsp70 and Hsc70 are released from neutrophils under the HS conditions through the endolysosomal pathway involving ATP-sensitive mechanism.

P0046

Human neutrophils establish cellular interaction with natural killer cells to enhance their interferon-gamma production

A. Micheletti,* C. Costantini,* F. Calzetti,* W. Vermi† & M. A. Cassatella*
*Pathology and Diagnostics, University of Verona, Verona, Italy, †Pathology, University of Brescia, Brescia, Italy

Purpose/Objective: The role of neutrophils in the orchestration of immune responses has been increasingly recognised by their functional interactions with various immune cells, such as dendritic cells, monocytes as well as lymphocytes. Herein, we aimed at defining whether human neutrophils establish a functional cross-talk with natural killer (NK) cells too. In fact, it has been clearly recognised that NK cell activation is finely tuned by accessory cells which provide them with activating signals such as membrane molecules or soluble factors. Based on these premises, the aims of this study were: (i) to evaluate the ability of human neutrophils to activate NK cells in terms of IFN-γ production; (ii) to characterize the cell-cell interactions that could eventually occur between human neutrophils and NK cells.
Materials and methods: Human neutrophils and autologous NK cells were isolated from buffy-coats of healthy donors. NK cells were then cultured alone or with neutrophils at 1:1 ratio and stimulated in the presence of LPS in combination with IL-15 and IL-18, for 18 h. IFN-γ production was then assessed by ELISA. Cell-cell interactions and cell identity were characterized by confocal microscopy and immunohistochemistry.
Results: NK cells showed an enhanced capacity to secrete IFN-γ when cultured in the presence of neutrophils under our stimulatory conditions. Such an increased IFN-γ production by NK cells was found to be dependent on the contact between the two cell types. By the use of specific neutralizing antibodies, we could then identify the specific membrane molecules involved in the NK cell-neutrophil interactions, specifically the CD11d/CD18 integrin on the NK cell, and the ICAM-3 immunoglobulin family member on neutrophil side. The potential *in vivo* occurrence of a neutrophil/NK cell cross-talk was uncovered in the lesions of patients with psoriasis, Crohn's disease and Sweet's syndrome disease, in which a neutrophil-NK cell colocalization is present.
Conclusions: The present work reports the capacity of human neutrophils to potentiate the IFN-γ release by NK cells *via* contact-dependent mechanisms. These data may have potential implications in the pathogenesis of diseases where a neutrophil/NK cell colocalization is observed.

P0047

Mast cell-specific NFATc1-deficiency drives overexpression of the transcription factor NFATc2 in murine bone marrow-derived mast cells

P. Friedrich, A. Michel, G. Manz & M. Stassen
Institute for Immunology, University Medical Center Johannes Gutenberg University, Mainz, Germany

Purpose/Objective: To investigate the function of the transcription factor NFATc1 in murine mast cells we generated mast cell-specific NFATc1-deficient mice by crossing Mcpt5Cre mice with $NFATc1^{fl/fl}$ animals.
Materials and methods: We produced bone marrow-derived mast cells from these animals and looked after their ability to express the cytokines IL-6 and IL-9 *in vitro*. For this we used qRT PCR and ELISA. Via Western Blotting we checked the expression of the transcription factors IRF-4 and NFATc2.
Results: According to the expectations based on our previous work, the expression of IL-6 was unaffected in the absence of NFATc1. However, the production of IL-9 was enhanced. Detailed analyses revealed the overexpression of the closely related NFATc2 in NFATc1-deficient mast cells. Concomitantly, the expression of the transcription factor IRF-4 and of IL-1β was also strongly enhanced. Thus, the increased expression of IL-9 in the absence of NFATc1 might be explained by the autocrine effect of IL-1β or by IRF-4-mediated transactivation of the IL-9 promotor. How NFATc1 modulates the expression of NFATc2 and the influence of the latter on the production of IRF-4 and IL-1β is currently unknown.
Conclusions: The model used in this study to examine the specific function of NFATc1 in mast cells is not suitable, since the absence of this transcription factor can be compensated by an overexpression of NFATc2. These results, however, show a possible influence of NFATc1 on the production of NFATc2 as part of an intracellular network modulating the expression of IL-9.

P0048

Mast cells phagocyte Candida albicans via Toll-like 2 receptor without TNF-a and IL-10 production

K. H. Pinke, H. G. Lima & V. S. Lara
Department of Stomatology, Area Pathology, Bauru School of Dentistry, University of São Paulo, Bauru, Brazil

Purpose/Objective: The pattern recognition receptors of innate immunity are important in defense against pathogens by recognizing of surface molecules and triggering important signaling pathways. *Candida albicans* (*C. albicans*) is recognized by cells of innate immunity by Toll-like 2 receptors. Mast cells have this receptor on cellular membrane and its immune mechanisms include synthesis and secretion of mediators, antigen presentation, as well as phagocytic and microbicidal activities. So, this study evaluated *in vitro* the TNF-α and IL-10 production and phagocytosis by mast cells challenged with *C. albicans* and the involvement of TLR2 in these mechanisms.
Materials and methods: Murine bone marrow cells (BMMC) wild type ($TLR2^{+/+}$) or TLR2 knockout ($TLR2^{-/-}$) were cultured for 21 days in presence of stem cell factor (SCF) and interleukin-3 (IL-3). Mast cells were challenged with FITC-labeled *C. albicans* by 30 or 60 min and the phagocytosis analyzed by confocal laser scanning microscopy. TNF-α and IL-10 production was measured by ELISA after 24 h of challenge with *C. albicans*.
Results: BMMC $TLR2^{+/+}$ did not produce TNF-α or IL-10 after stimulation or not with *C. albicans*. However, these cells challenged with zymosan produced detectable levels of TNF-α, but not IL-10. After 30 min, 30% of BMMC $TLR2^{+/+}$ showed internalized *C. albicans*, approximately four yeasts per cell. Besides, the BMMC $TLR2^{-/-}$ did not produced TNF-α or IL-10 irrespective of experimental conditions and their phagocytosis was also impaired. After 30 and 60 min, 98.4% and 99.6% of mast cells, respectively, had not internalized fungi. The percentage of zymosan phagocytosis by mast cells was also very low (2.7%).
Conclusions: Data demonstrated the phagocytic capacity of BMMC against *C. albicans* yeasts and the strong involvement of the TLR2 receptor in this mechanism. Still, the absence of TNF-α and IL-10 production after fungal challenge may represent an immune escape of the *C. albicans* after their internalization by mast cells.

P0049
Neutrophil chemotaxis is impaired in celiac disease

K. M. Lammers
Mucosal Biology Research Center, University of Maryland School of Medicine, Baltimore, MD, USA

Purpose/Objective: Celiac disease (CD) is triggered by the ingestion of gliadin, the immunogenic component of gluten-containing grains. We have observed that exposure to gliadin induces rapid and massive influx of neutrophils to the murine gut mucosa, suggesting it is a chemoattractant factor for neutrophils. Aims of this study; has gliadin also chemoattractant properties for human neutrophils, and do neutrophils from healthy individuals (HC) and CD patients respond differently to gliadin.
Materials and methods: Neutrophils were isolated from venous blood of HC and CD patients and applied in an under-agarose assay to monitor neutrophil chemotaxis to pepsin-trypsin-digested gliadin (PTG) or N-formyl-methionyl-leucyl-phenylalanine (fMLP) as a positive control. Resting neutrophils and PTG- or fMLP-stimulated neutrophils were analyzed by flow cytometry for CD62L surface expression.
Results: Human neutrophils migrated towards PTG and fMLP. However, compared to the chemotactic response of HC neutrophils to PTG (5.7 ± 1.3 net neutrophil migration), the chemotactic response of CD neutrophils was markedly reduced (0.4 ± 0.3 net neutrophil migration, $P < 0.001$). A similar, albeit non-significant difference was also observed in CD versus HC neutrophil migration to fMLP (4.8 ± 1.1 versus 11.9 ± 2.9 net neutrophil migration, respectively, $P = 0.067$). The percentage of CD62L-expressing neutrophils (resting 67 ± 15) diminished after fMLP- (52 ± 22) and PTG-stimulation (44 ± 19) in HC, but remained unchanged in CD (resting 86 ± 5, fMLP (61 ± 24), PTG (90 ± 6).
Conclusions: These results suggest that PTG is also a chemoattractant factor for human neutrophils. Compared to HC, the CD neutrophil chemotactic response to PTG and fMLP is impaired in the under-agarose assay, suggesting that CD neutrophils have reduced chemotactic potential that possibly involves L-selectin.

Redox regulation of degranulation in human neutrophils

N. Vorobjeva
Department Immunology, Lomonosov Moscow State University, Moscow, Russia

Purpose/Objective: The NADPH oxidase of neutrophilic granulocytes is a complex enzyme consisting of membrane and cytosolic subunits. After activation of the cells the cytosolic subunits translocate to the membrane where the functioning oxidase complex is formed. The active enzyme carries out the transfer of one electron from cytosolic NADPH oxidase to molecular oxygen, generating thereby superoxide anion in the exterior of the cell or in the phagocytic vacuoles and H^+, $NADPH^+$ in the cytosol. It was demonstrated by Jankowski and Grinstein (1999) that NADPH oxidase is able to transfer electrons against a potential gradient. Thus, the activity of NADPH oxidase is not only restricted to destruction of invading microorganisms, but it can rapidly change the membrane potential causing a depolarization.

The degranulation plays a principal role in most proinflammatory functions of neutrophils. However the relationships between a membrane potential and degranulation was not investigated completely. In order to investigate the regulatory role of redox potential on degranulation, we tested the inhibitors of NADPH oxidase, diphenylene iodonium (DPI) and apocynin, in the *in vitro* model of CB/fMLP-activated human neutrophils.
Materials and Methods: Exocytic insertion of CD63 and CD66b into the cell membrane was determined by flow cytometry. Radical oxygen species (ROS) production was measured using luminol chemiluminescence method.
Results: Activation of neutrophils with CB/fMLP resulted in a high release of azurophil and specific granules. Adding the DPI in several concentrations before activation of the cells resulted in inhibition of azurophil and specific granules release, while a specific inhibitor of enzyme complex, apocynin, caused a dose-dependent suppression of degranulation of CB/fMLP-activated cells.
Conclusions: The present study showed that inhibition of NADPH oxidase, responsible for the depolarization of membranes, resulted in downregulation of degranulation of activated cells that can be caused by the deterioration of fusion proteins interaction with the membranes.

P0051
Role of the CREB transcription factor in inflammatory cytokine production by human neutrophils

P. McDonald, F. A. Simard, T. Z. Mayer & A. Cloutier
Medicine Faculty Pulmonary Division/Research, Université de Sherbrooke, Sherbrooke, QC, Canada

Purpose/Objective: Neutrophils influence innate and adaptative immunity by generating numerous mediators whose regulation largely depends on transcription factors typically associated with inflammation, such as NF-kB and C/EBP factors. Here, we show that this functional response also involves the CREB transcription factor.
Materials and methods: Protein analyses by immunoblot and ELISA; gene regulation analyses by EMSA, qPCR, ChIP assays, and luciferase assays. Most studies in primary neutrophils, except those featuring transient overexpressions or luciferase assays, which were carried out in DMSO-differentiated, granulocytic human PLB-985 cells.
Results: Neutrophil stimulation with physiological agonists (LPS, TNF) led to a rapid and transient CREB DNA-binding activity, and concurrent phosphorylation of CREB1 on S133. Accordingly, the same stimuli elicited the transactivation of a CREB-driven luciferase reporter in neutrophil-like PLB-985 cells. Functionally, overexpression of a dominant negative CREB mutant (K-CREB) or of a point mutant (S133A) resulted in a decreased ability of neutrophilic PLB-985 cells to generate inflammatory cytokines (CXCL8, CCL3, CCL4, TNFa). In primary neutrophils, CREB DNA binding and S133 phosphorylation were found to occur downstream of the p38 MAPK/MSK1 axis. The parallel phosphorylation of another bZIP transcription factor, C/EBPb, was similarly affected. Inhibition of p38 MAPK or MSK1 prevented cytokine generation in neutrophils, as well as the recruitment of either P-CREB or P-C/EBPb to chemokine promoters in ChIP assays.
Conclusions: Collectively, our data show the involvement of CREB in neutrophil cytokine production, the key role of its S133 residue, some of the molcular mechanisms involved, some of the upstream signaling events, and the parrallel activation of another bZIP factor. Our study also identifies potential molecular targets that could be exploited in the context of several chronic inflammatory diseases that prominently feature neutrophils and their products.

P0052

Signal Inhibitory Receptor on Leukocytes-1 (SIRL-1) negatively regulates the oxidative burst in human phagocytes

T. A. M. Steevels,* K. van Avondt,* G. H. A. Westerlaken,* J. Walk,† L. Bont,‡ P. J. Coffer‡ & L. Meyaard*
**Immunology, UMC Utrecht, Utrecht, The Netherlands, †Pediatrics, UMC Utrecht, Utrecht, The Netherlands, ‡Pediatrics and Immunology, UMC Utrecht, Utrecht, The Netherlands*

Purpose/Objective: The production of reactive oxygen species (ROS) is an important effector mechanism mediating intracellular killing of microbes by phagocytes. Inappropriate or untimely ROS production can lead to tissue damage, thus tight regulation is essential. We recently characterized Signal Inhibitory Receptor on Leukocytes-1 (SIRL-1) as an inhibitory receptor expressed by human phagocytes. We now set out to study its role in the regulation of these cells.
Materials and methods: Primary human monocytes and neutrophils were used to study bacterial killing, oxidative burst and SIRL-1 expression upon activation with various stimuli. SIRL-1 signalling was analyzed in transfectants of wild type and mutated SIRL-1. In a cohort of RSV-infected infants, we studied SIRL-1 expression on neutrophils in BAL and peripheral blood.
Results: We demonstrate that ligation of SIRL-1 dampens Fc receptor-induced ROS production in primary human phagocytes. In accordance, SIRL-1 engagement on these cells impairs microbicidal activity of neutrophils, without affecting phagocytosis. The inhibition of ROS production may result from reduced activation of extracellular signal-regulated kinase (ERK), since co-ligation of Fc receptors and SIRL-1 on phagocytes inhibited phosphorylation of ERK. Importantly, we demonstrate that microbial and inflammatory stimuli cause rapid down-regulation of SIRL-1 expression on the surface of primary neutrophils and monocytes. In accordance, SIRL-1 expression levels on neutrophils in bronchoalveolar lavage fluid from patients with neutrophilic airway inflammation are greatly reduced.
Conclusions: We propose that SIRL-1 on phagocytes sets an activation threshold to prevent inappropriate production of oxygen radicals. Upon infection, SIRL-1 expression is down-regulated, allowing microbial killing and clearance of the pathogen.

P0053

Subpopulations of blood cells forming the mast cells — lymphocytes rosettes

T. Sydorenko, Y. U. Serezhko & O. Melnikov
Immunology and Pathophysiology, Institute of Otolaryngology, Kyiv, Ukraine

Purpose/Objective: Lymphoid cells are able to contact with mast cells.
Materials and methods: In the investigation the methods of MLR-forming and CD-determination were used.
Results: Lymphoid cells of peripheral blood in patients with cancer of larynx forms increased number of so-called mast-lymphocytes rosettes (MLR) in comparison with patients with precancer diseases and healthy donors. Herewith the number of $CD5^+$, $CD11^+$, $CD16^+$ and $CD54^+$ blood lymphocytes was decreased in patients ofboth groups plus decreased level of $CD25^+$ cells in larynx cancer patients and the number of CD 20^+ , $CD95^+$ and $CD3^+$ lymphocytes was (had) at the normal level. Analysis of subpopulations of lymphocytes that forms the contacts with mast cells revealed the predominant participation in MLR-forming $CD3^+$ and $CD25^+$ cells in patients with larynx cancer and $CD19^+$ and $CD11^+$ in patients with precancer diseases.
Conclusions: So the subpopulation compositions of lymphoid cells contacting with mast cells are varied in different diseases.

P0054

T4 phages head proteins do not induce production of reactive oxygen species by granulocytes

P. Miernikiewicz, K. Dabrowska, A. Piotrowicz, K. Hodyra, B. Owczarek, G. Figura, A. Kopciuch, K. Macegoniuk & A. Gorski
Bacteriophage Laboratory, Institute of Immunology and Experimental Therapy, Wroclaw, Poland

Purpose/Objective: Phages are viruses specific to bacteria. Their application in drug-resistant bacterial infections has become significant alternative for antibiotics. However, phage therapy still evokes discussion due to its safety. Studies of phage influence on immunological system are necessary to provide more profound understanding of their safety and effectiveness. In this work we evaluated the effect of T4 head proteins on reactive oxygen species (ROS) production by granulocytes.
Materials and methods: Highly purified, by two-step affinity and size-exclusion chromatography (<1 Eu/ml LPS), recombinant T4 phage head proteins gp23, gp24, gphoc and gpsoc were used with controls: PBS, albumin (alb), LPS, PMA. LPS content was assessed by the Chromogenic End point LAL test. Granulocytes (PMN) were isolated from buffy coats of human healthy volunteer blood using double gradient Histopaque. ROS formation was measured using luminol-dependent chemiluminescence (CL) assay in microplate reader. The reaction mixture (100 μl) for CL in each well contained: 10^6 cells/ml, 10 μg/ml protein preparation or 500 Eu/ml LPS or 1 μM PMA, 10 mM luminol. Measurements were carried out at 37°C for 1.5 h.
Results: Highly purified T4 phage proteins: gp23, gp24, gphoc, gpsoc did not induce ROS production (the same level as negative controls) during the whole period of the test. As expected, PMA and LPS highly increased ROS formation.
Conclusions: PMN are known to respond immediately after a virus infection, e.g. HCV core protein evokes intensive ROS production by blood cells initiating inflammatory process. Excessive ROS production may cause cellular damage and induce inflammatory reactions which may be dangerous to patients.Our results indicating that phage proteins do not induce ROS provide good argumenst for the safety of phage therapy.

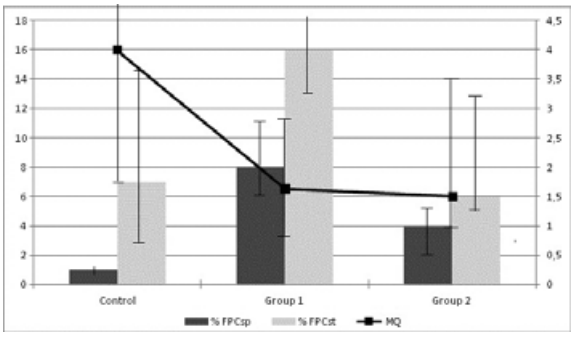
P0055

The functional features of neutrophils in sportsmen with different level of training loadings

I. Shvydchenko,* V. Romenskaya,* E. Bykovskaya,* G. Rozhkova,* A. Kapustin,† V. Yatsyk† & A. Tambovtseva*
**Physiology, Kuban State University of Physical Education Sport and Tourism, Krasnodar, Russia, †Theories and Techniques of Winter Kinds Bicycle Sports and Sports Tourism, Kuban State University of Physical Education Sport and Tourism, Krasnodar, Russia*

Purpose/Objective: To investigate the influence of training loadings on phagocytic, oxidized activity and the production of cytokine by neutrophils.
Materials and methods: Functional activity of neutrophils was studied in two groups of sportsmen: group 1 ($n = 9$) — highly qualified sportsmen with high level of training loadings (6—12 times a week for 2 h); group 2 ($n = 11$) — sportsmen with low level of training loadings (<3 times a week). The untrained volunteers served as the control ($n = 96$). Research spent to the intercompetitive season of a year training cycle. We defined the quantity of neutrophils, their capacity to ingest zymosan in phagocytosis assay, oxidized activity in spontaneous and zymosan-stimulated NBT-test, and their ability to secrete cytokines IL-1b, IL-6, IL-8, IL-10 and IL-1RA at rest or upon subsequent stimulation with LPS or zymosan. ELISAs were used to measure cytokine levels in neutrophil-derivated supernatant.
Results: Highly qualified sportsmen had a lower relative quantity of blood neutrophil compared with the controls ($P < 0.05$). The neutro-

phil phagocytic capacity was on 31.11% lower ($P < 0.01$) in highly qualified sportsmen and on 24.44% lower ($P < 0.01$) in group 2 compared with the controls. Neutrophils of sportsmen from both groups had considerably raised spontaneous oxidized activity. Quantity of formazan-positive cells (FPC) was raised after stimulation by zymosan too, however mobilisation quotient (ratio %FPC in stimulated NBT-test to %FPC in spontaneous NBT-test) was more than in two times below compared with the controls ($P < 0.05$). Neutrophils of sportsmen from group 2 possessed the raised ability to secrete cytokines as it is spontaneous, and at stimulation. Spontaneous production IL-1b, IL-8 and IL-1RA by neutrophils was above control value in 10.6 ($P < 0.01$), 4.3 ($P < 0.001$) and in 2.7 times ($P < 0.01$), accordingly. They also produced considerable quantity IL-6 which was not defined in neutrophil-derivated supernatant in untrained subject. Quantity of produced cytokines by neutrophils of highly qualified sportsmen did not differ from control (except for secretion IL-1RA by neutrophils of some sportsmen).



Conclusions: The revealed functional features of neutrophils in sportsmen with different level of training loadings and, especially, distinctions in their capacity to produce cytokines, possibly, are reflectance of a various degree of manifestation of adaptive processes, directed on prevention of pathophysiological inflammatory reactions.

P0056

The inflammatory effect of *ORMDL3* and trimellitic anhydride on mast cells

K. Ogi,* M. Sakashita,† T. Yamada,† Y. Manabe* & S. Fujieda†
**Otorhinolaryngology, Shinseikai Toyama Hospital, Toyama, Japan, †Otorhinolaryngology Head and Neck Surgery, Fukui University, Fukui, Japan*

Purpose/Objective: Allergic rhinitis has a multi-factorial origin, including genetic and environmental factors. *ORMDL3* is a genetic factor associated with asthma and allergic rhinitis. Occupational rhinitis, which develops in the work place, is an environmental factor. The causative agents are divided into low molecular weight (LMW) and high molecular weight (HMW) substances. In this study, we investigated the mechanism by which *ORMDL3* and trimellitic anhydride (TMA), an LMW substance, affected the release of chemical mediators from mast cells.

Materials and methods: We evaluated the β-hexosaminidase release from stable cloned rat basophilic leukemia (RBL-2H3) cell lines overexpressing *ORMDL3*. To examine the effect of LMW substances, we examined LMW substances-induced β-hexosaminidase release. In addition, we incubated the cells with TMA and analyzed the cell lysates and mRNA by immunoblotting and real-time polymerase chain reaction (PCR) to determine whether TMA affected cellular signal transduction.

Results: The overexpression study revealed that *ORMDL3* enhanced degranulation on stimulation by antigens at low concentrations. We found that among LMW substances, only TMA induced β-hexosaminidase release. Further, TMA elicited degranulation in the absence of Ca^{++}, suggesting that this phenomenon was independent of FcεRI-mediated signal transduction. Immunoblotting analysis revealed that TMA completely blocked the phosphorylation of extracellular signal regulated kinases (ERKs). Thus, there was a possibility that TMA affected mast cells through an unknown signaling pathway.

Conclusions: We concluded that overexpression of *ORMDL3* and TMA exposure resulted in increased inflammation. The effect of TMA exposure was lower than FceRI-mediated degranulation. However, persistent chronic inflammation induces asthma. Therefore, occupational rhinitis should be diagnosed as soon as possible.

P0057

The oxidative burst, but not elastase is essential for fungal clearance *in vivo* in a mouse model of Aspergillus fumigatus pneumonia

S. Prüfer,* M. Weber,* P. Stein,* H. Schild* & M. P. Radsak†
**Johannes Gutenberg-University Medical Center, Institute for Immunology, Mainz, Germany, †Third Department of Medicine, Johannes Gutenberg-University Medical Center, Mainz, Germany*

Purpose/Objective: The fungus *Aspergillus fumigatus* and its conidia are ubiquitously present in the environment. In immunocompromised individuals, i.e. during tumour treatments and transplantations, inhaled conidia cause invasive aspergillosis (IA) with a mortality rate over 50%. Polymorphonuclear neutrophils (PMN) are the main innate immune effector cells responsible for clearance of such fungi. For this they employ their potent effector mechanisms, i.e. phagocytosis, the oxidative burst and releasing intracellular granules containing antimicrobial proteins like cathepsin G or elastase (ELA) and inflammatory mediators.

Materials and methods: To study the role of PMN and the contribution of oxidative or non-oxidative effector functions in IA, we analysed knockout mice after infection with the *A. fumigatus* wild type strain ATCC 46645. Anesthetized mice were infected intratracheally with 10×10^6 conidia that were sublethal to wild-type (WT) mice. The infected animals were observed over a period of 14 days, and clinical performance and survival were monitored. Some mice were sacrificed 24 h after inoculation, and fungal outgrowth was determined in lung homogenates.

Results: As a positive control, PMN of WT mice were depleted with a Gr-1 specific antibody (clone RB6-8C5) resulting in a sustained neutropenia and a death within 3 days post infection. In $p74^{phox-/-}$ and $gp91^{phox-/-}$ mice, the NADPH oxidase complex is not functional due to a lack of the cytosolic $p47^{phox}$ or membrane $gp91^{phox}$ subunits, respectively. Infected $p47^{phox-/-}$ and $gp91^{phox-/-}$ mice died within the first 3–4 days and had significant higher numbers of fungal colony-forming units in lung homogenates compared to WT mice. These results indicate an essential role of the oxidative burst for fungi clearance *in vivo*. Surprisingly, in neutrophil ELA deficient ELANE mice the survival after infection was unimpaired and comparable to WT mice indicating that ELA is not essential for immunity against IA. Nevertheless, a delayed *A. fumigatus* clearance was detected in the lung homogenates indicating a partial contribution of ELA to fungal immunity.

Conclusions: Taken together, PMN are essential in *A. fumigatus* elimination. The main effector function for fungi clearance require the oxidative burst whereas ELA as a major component of azurophilic granules is not essential for survival after infection with this pathogen.

P0058

The pathogenesis of the anti-phospholipid syndrome: Toll-like receptor mediated signals in participating neutrophils

P. Stein,* G. Gladigau,* P. Haselmayer,* I. Scharrer† & K. Lackner‡

**Institute for Immunology, Johannes Gutenberg – University Medical Center, Mainz, Germany, †Third Department of Medicine, Johannes Gutenberg – University Medical Center, Mainz, Germany, ‡Institute of Clinical Chemistry and Laboratory Medicine, Johannes Gutenberg – University Medical Center, Mainz, Germany*

Purpose/Objective: The anti-phospholipid syndrome (APS) is a systemic autoimmune disease characterized by an adaptive immune response against self phospholipid (PL)-binding proteins. Patients are suffering from recurrent thrombotic or thrombembolic events and fetal losses. Although APS is considered as an autoantibody-mediated disease, there is growing evidence that anti-phospholipid antibodies (aPL) are necessary but not sufficient for the clinical manifestations of the syndrome. Analyzing the participation of aPL in pregnancy loss during APS revealed that aPL have a direct impact on complement activation. Beyond this, a role for neutrophil activation by the tissue factor/PAR2 axis has been demonstrated to play an additional role. Finally, microbial infections have been reported to act as triggers for the production of autoantibodies cross-reacting with PL-binding proteins as well as inflammatory stimuli that potentiate the aPL thrombogenic effect. Altogether, these findings suggest a role for the innate immunity in APS pathogenesis. Recently, also Toll-like receptor (TLR) mediated signals have been implicated in the activation cascade of aPL induced thrombus formation. There is evidence that aPL may activate endothelial cells and monocytes through TLR-4-dependent signalling. Whether or not TLR in conjunction with aPL may influence the activation status of neutrophils is not known and is the focus of this project.
Materials and methods: To address this question, we purified polymorphonuclear neutrophils (PMN) from healthy donors and analysed the impact of a purified human monoclonal aPL in the presence or absence of a TLR agonist on neutrophil effector functions.
Results: We found that aPL alone were only able to induce minor activation of PMN effector functions. However, in the additional presence of LPS the activation threshold was markedly lowered shown by an elevated production of ROS, increased phagocytic activity and L-selectin shedding as well as enhanced IL-8 production.
Conclusions: These results suggest that PMN as important innate immune effector cells are directly activated by aPL under inflammatory conditions and therefore may be important contributors to the pathophysiology of APS.

P0059

The role of the small GTPase RhoH in eosinophil development and eosinophilic disorders

C. Stoeckle, B. Geering, N. Andina & H. U. Simon

Institute of Pharmacology, University of Bern, Bern, Switzerland

Purpose/Objective: The small atypical GTPase RhoH is highly expressed in eosinophils and further upregulated in patients with hypereosinophilic syndrome (HES), a condition characterised by chronically elevated eosinophil levels and tissue damage with sometimes fatal outcome. The function and regulation of RhoH in eosinophils is unknown. We therefore wished to determine the role of RhoH in eosinophil function and development under normal and pathological conditions.
Materials and methods: Eosinophils were isolated from peripheral blood of healthy donors or HES patients. Expression of RhoH in eosinophils with or without IL-5 stimulation was analysed by Western blot. Transcription factors expression was analysed in an eosinophilic HL60 subline stably transduced with inducible RhoH. Human bone marrow cells were differentiated into eosinophils and RhoH expression was analysed by Western blot. Human or mouse bone marrow from $RhoH^{-/-}$ or wild type mice was differentiated *in vitro* into eosinophils. Cells were analysed by light microscopy or flow cytometry.
Results: We find RhoH is upregulated in some HES patients and that IL-5 upregulates RhoH in eosinophils from normal donors but not patients. Furthermore, it is upregulated during *in vitro* differentiation of eosinophils. $RhoH^{-/-}$ mice have elevated eosinophils levels in blood and bone marrow and *ex vivo* bone marrow eosinophils appear to be more mature, with altered expression of several functionally important surface receptors. *In vitro* differentiation into eosinophils with IL-5 is also enhanced in $RhoH^{-/-}$ bone marrow cultures. Enforced expression of RhoH alters the expression of transcription factors involved in eosinophil development.
Conclusions: The results suggest a regulatory role of RhoH in eosinophil development and function, possibly via negatively regulating IL-5 signalling and/or by affecting the balance of transcription factors regulating eosinophil development.

A murine air pouch model to study group A streptococcal pathogenesis and protective immunity

N. Chiappini,* A. Seubert,† D. Serruto,* J. L. Telford,* G. Grandi,‡ I. Margarit‡ & R. Janulczyk*

*Microbial Molecular Biology, Novartis Vaccines and Diagnostics, Siena, Italy, †Immunology, Novartis Vaccines and Diagnostics, Siena, Italy, ‡Research Center, Novartis Vaccines and Diagnostics, Siena, Italy

Purpose/Objective: Group A Streptococcus (GAS) is a major human pathogen worldwide, responsible for both local and systemic infections. In this work we apply a novel murine model to study GAS infection, in particular the role of a well-known virulence factor the chemokine-degrading protease SpyCEP. Moreover, we extended the application of the air pouch model to evaluate protective immunity.
Materials and methods: Dorsolateral air pouches were inflated in CD1 mice by subcutaneous injection of 3 ml air on day 1 and day 4. On day 6, 1×10^7 CFU of exponential phase 3348 wild type or 3348Δ*spyCEP* knock out strains were injected into the pouch. At 2, 4 or 24 h after infection, the animals were euthanized, and an air pouch lavage was performed. Lavage samples were processed for the parallel analysis of bacteria, cell recruitment and chemokines. Bacterial load was determined by viable counts. Cells were stained with a combination of different cell markers and analyzed by flow cytometry. Chemokine concentrations were measured by a bead-based immunoassay. For protective immunity experiments mice were immunized with adjuvant only, M protein, or a combination of GAS antigens (including SpyCEP) recently shown to be protective in traditional models. After air pouch inflation mice were infected with 3348 strain and bacterial viable counts were performed after 24 h.
Results: To investigate SpyCEP action *in vivo*, we adapted a mouse air pouch model of infection for parallel quantification of bacterial growth, host immune cell recruitment and chemokine levels *in situ*. Mice infected with 3348Δ*spyCEP* showed a tendency to have more neutrophils and monocytes compared to mice infected with the wild type 3348 strain. Concomitantly, the chemokines KC, LIX, and MIP-2 were drastically increased in mice infected with the SpyCEP knockout strain, and growth of this mutant strain was reduced compared to the wild type. We also adapted the model to evaluate protective immunity, and observed that vaccinated groups showed significant bacterial growth reduction compared to the group immunized with adjuvant only.
Conclusions: Taken together, our data suggest that the air pouch model promises broad application in the study of immune system response after streptococcal infection.

P0061

Candida albicans evades protective immunity by promoting the expansion of induced $CD4^+$ $CD25^+$ $FoxP3^+$ Helioslo regulatory T cells that enhance Th17 responses

N. W. Whibley,* D. M. MacCallum,† M. A. Vickers,† H. Waldmann,‡ S. Hori,§ N. A. R. Gow,† R. N. Barker* & A. M. Hall*

*Medicine & Dentistry, University of Aberdeen Institute of Medical Sciences, Aberdeen, UK, †Aberdeen Fungal Group, University of Aberdeen Institute of Medical Sciences, Aberdeen, UK, ‡Sir William Dunn School of Pathology, University of Oxford, Oxford, UK, §Research Unit for Immune Homeotasis, Riken Research Center for Allergy & Immunology, Yokohama City, Japan

Purpose/Objective: Regulatory T cells (Treg) play a central role in limiting helper T cell (Th) responses and maintaining immune homeostasis during infection through their ability to inhibit immune responses. Two distinct subsets of $FoxP3^+$ Treg have been identified; natural Treg (nTreg) are generated in the thymus and appear to be important in self tolerance, whilst induced Treg (iTreg) differentiate from naïve T cells in the periphery in response to invading microorganisms in an antigen-specific manner. *Candida albicans* is found harmlessly on up to 80% of humans, however, superficial infections can become debilitating whilst more serious systemic infections are a common problem within intensive care units. The fungus induces the expansion of both Th1 and Th17 that limit, but do not clear infection. The aim of this work was to investigate the role of Treg cells that may prevent sterilising immunity during *C. albicans* infection.
Materials and methods: C57BL/6 mice or hCD2FoxP3 reporter mice were infected with *C. albicans* for 7 days. Splenic Th cells were isolated and stimulated with C. albicans antigens for a further 5 days. Proliferation and cytokine production were measured by 3H-thymidine incorporation, cellular ELISA and flow cytometery.
Results: We demonstrate for the first time, in a murine model of disseminated *C. albicans* infection, that both yeast and hyphae induce MHC class II dependent Th differentiation towards a Treg phenotype and that these Treg inhibit *C. albicans*-induced Th1 and Th2 cells, but enhance Th17 responses. The expanded Treg cells are largely derived from a FoxP3 negative population, confirming that they are not Treg in origin. Furthermore, these cells are negative for Helios, a transcription factor reportedly expressed in nTreg but not iTreg. Interestingly, *C. albicans* induced $FoxP3^+$ cells co-express ROR-γt suggesting that they may contribute to both Treg and Th17 responses. Importantly, mice depleted of $FoxP3^+$ Treg *in vivo* showed reduced kidney burdens compared to mice with normal $FoxP3^+$ Treg numbers.
Conclusions: These results show that *C. albicans* induces the expansion of iTreg cells that may prevent an effective immune response. We hypothesise that *C. albicans* can escape immune clearance by inducing the conversion of Th17 to Treg cells that limit protective Th1 responses.

P0062

Dynamic induction of immune escape by activated T cells via regulation of B7-ligands on myeloid leukemia cells

G. Esendagli & Y. Dolen

Department of Basic Oncology, Institute of Oncology, Hacettepe University, Ankara, Turkey

Purpose/Objective: The costimulatory molecules belonging to B7 ligand superfamily can be expressed by acute myeloid leukemia (AML) cells. The significance of B7 ligands in disease progression has been demonstrated by independent clinical studies. Interestingly, presence of the most potent costimulatory molecules B7-2 (CD86) and B7-H2 (ICOS-L) on AML cells has been associated with bad prognosis and disease severity. Here, we aimed to modulate the expression of B7 molecules on myeloid leukemia cells and used them as a model to study the interaction between helper T cells and leukemic blasts.
Materials and methods: The model was established with HL-60 AML cell line and iHL-60 cells generated after protein kinase C (PKC) induction. Flow cytometric analyses, cell sorting, and CFSE-based proliferation assays were used for the determinastion on T cell and/or myeloid leukemia cells immunophenotype and proliferation. ELISA arrays were also performed for the determination of proinflammatory cytokine production.
Results: PKC induction increased B7-2 on HL-60 cell line (designated as iHL-60). The expression of other critical costimulatory molecules such as CD70, TRAIL, CD58, and OX40L expression was not significantly modulated. In the ELISA arrays of human proinflammatory cytokines, only IL-8 differed between HL-60 and iHL-60. The majority (>80%) of HL-60 and iHL60 cells was B7-1^-, B7-$H1^-$, B7-$H2^+$, B7-$H3^+$, and B7-$H4^-$. B7-2 and B7-DC expression was upregulated upon PKC induction. $CD4^+$ T cell responses (CD154,

CD25, CD69 expression and proliferation) were supported by HL-60 and to a higher extend by iHL-60. The presence of B7-2 was not critical for immune stimulation. Intriguingly, especially iHL60 cells expressed B7-H1 (PD-L1), increased B7-DC (PD-L2), and decreased B7-H2 levels soon after the engagement with activated T cells. In the co-cultures, T cells expressed PD-1. In the presence of activated T cell-conditioned iHL-60, T cell activation and proliferation were significantly hampered. Addition of an ICOS-stimulating mAb did not enhance T cell proliferation whereas blockage with PD-1-Fc did. In addition, the expression of CD25 and CD127 on $CD4^+$ T cells was also significantly modulated with different co-culture partners.
Conclusions: In conclusion, immune escape of $B7\text{-}2^+$ and $B7\text{-}H2^+$ myeloid leukemia cells can be triggered by helper T cell responses and potential targeting of PD-1 ligands may be considered for leukemia immunotherapy.

P0063

Evasion of human innate immunity without antagonizing TLR_4 by mutant Salmonella enterica serovar Typhimurium having penta-acylated lipid A

M. Matsuura,* K. Kawasaki,† K. Kawahara‡ & M. Mitsuyama*
**Microbiology, Kyoto University Graduate School of Medicine, Kyoto, Japan, †Pharmaceutical Science, Doshisha Women's College, Kyotanabe, Japan, ‡Engineering, Kanto Gakuin University, Yokohama, Japan*

Purpose/Objective: Bacterial lipopolysaccharide (LPS), a cell wall component of Gram-negative bacteria, is a good target for mammalian cells to recognize bacterial invasion and trigger innate immune responses. Lipid component of LPS called lipid A plays a critical role in interaction with a mammalian TLR4/MD-2 receptor complex. A hexa-acylated type of lipid A which is relatively conserved among a wide variety of Gram-negative bacteria is strongly recognized by mammalian cells and elicit robust immunological activity but less-acylated types of lipid A isolated from some bacterial species have been shown to have weaker stimulatory activity. Modification of a lipid A to a less acylated form is therefore suggested to facilitate bacterial evasion of host innate immunity. In this study, we have investigated the contribution of less-acylated lipid A to interactions of whole bacterial cells with host cells (especially in humans).
Materials and methods: Mutant strains of *Salmonella enterica* serovar Typhimurium having fewer Lipid A acyl groups were generated by deletion of genes for acyltransferases participating in the biosynthesis of lipid A. LPS, formalin-killed bacteria and live bacteria preparations of these strains were used to stimulate human U937 macrophages. Productions of pro-inflammatory cytokines in the culture supernatants were assayed by ELISA.
Results: The major lipid A type in wild-type (WT) and the mutant KCS237 strain is hexa-acylated; in mutant strains KCS311 and KCS324 it is penta-acylated; and in KCS369 it is tetra-acylated. WT and KCS237 formalin-killed and live bacteria, as well as their LPS, strongly stimulated production of pro-inflammatory cytokines in human U937 cells; this stimulation was suppressed by TLR4 suppressors. LPS of other mutants produced no agonistic activity, but strong antagonistic activity, while their formalin-killed and live bacteria preparations had weak agonistic and no antagonistic activity. Moreover, these less-acylated mutants had increased resistance to phagocytosis by U937 cells.
Conclusions: Our results indicate that a decrease of one acyl group (from 6 to 5) is enough to allow *Salmonella* to evade human innate immunity and that the antagonistic activity of less-acylated lipid A is not utilized for this evasion.

P0064

Investigating the impact EBVs immune strategies have on antigen presentation and $CD8^+$ T cell recognition during lytic cycle replication

L. Quinn
School of Cancer Science, University of Birmingham, Birmingham, UK

Purpose/Objective: During lytic cycle replication Epstein-Barr virus (EBV) expresses at least three immune evasion genes, BNLF2a, BGLF5 and BILF1. In this study we aim to assess the impactthese genes have on antigen presentation and cytotoxic T-lymphocyte (CTLs) recognition of EBV infected cells.
Materials and methods: Lytically replicating EBV infected cells, in which the expression of these genes is silenced, were used to probe recognition by CTLs, of antigens expressed at different phases of lytic cycle replication.
Results: BNLF2a deficient cells were more efficiently recognised by CTLs specific for immediate early and early expressed antigens, relative to those lacking BGLF5 and BILF1. Whereas, BILF1 deficient cells were more efficiently recognised by CTLs specific for late antigens, relative to BNLF2a and BGLF5 lacking cells.
Conclusions: This suggests BNLF2a plays a dominant role in interfering with antigen presentation at IE and E stages of lytic cycle, while BILF1 plays the dominant role at L stages.

P0065

Role of CD163 in the mycobacterium leprae survival and persistence in lepromatous macrophages

R. Olmo Pinheiro,* D. F. Moura,* K. A. Mattos,† T. P. Amadeu,* P. R. Andrade,* J. S. Sales,* V. Schmitz,* J. A. C. Nery* & E. N. Sarno*
**Leprosy Laboratory, Oswaldo Cruz Institute, Rio de Janeiro, Brazil, †Cellular Microbiology Laboratory, Oswaldo Cruz Institute, Rio de Janeiro, Brazil*

Purpose/Objective: Lepromatous (LL) macrophages possess a regulatory phenotype that contributes to the immunosuppression observed in leprosy. CD163, a scavenger receptor that recognizes hemoglobin-haptoglobin complexes, is expressed at higher levels in lepromatous cells although its functional role in leprosy is not yet well-established.
Materials and methods: Skin biopsies from LL ($n = 6$) or tuberculoid ($n = 6$) patients were used for immunohistochemistry, immunofluorescence and Western blotting analysis. Sera from LL ($n = 5$), tuberculoid ($n = 5$) and healthy volunteers were used to assess sCD163 levels. Human monocytes were isolated from PBMCs obtained from healthy donors ($n = 6$) and infected with *M. leprae* (ML, MOI 5:1). Cytokine concentrations in cell supernatants were evaluated by ELISA. IDO, CD209 and CD163 expression were evaluated by flow cytometry. Alternatively, HEK293 transfected with cDNA for CD163 was used.
Results: We herein demonstrate that LL lesions are microenvironments rich in CD163 − IDO positive cells. Isolated cells from these lesions are $CD68^+$ IDO^+CD163^+ while higher levels of sCD163 in lepromatous sera correlate positively with IL-10 levels and IDO activity. Different ML concentrations in healthy monocytes likewise revealed a positive correlation between increased concentrations of the mycobacteria and IDO, CD209, and CD163 expressions. The regulatory phenotype in ML stimulated monocytes is accompanied by increased TNF, IL-10, and TGF-β levels whereas the IL-10 blockade reduces ML − induced CD163 expression. The CD163 blockade also reduces ML uptake in human monocytes. ML uptake was higher in HEK293 cells transfected with the cDNA for CD163 than in non transfected cells. At the same time, increased CD163 expression in lepromatous cells seems to be dependent on ML uptake besides contributing to augmented iron storage levels in lepromatous macrophages.

Conclusions: Altogether, these results suggest that CD163 expression induced by ML modulates the host cell phenotype to create a favorable environment for mycobacterial entry and survival.

The transcription factor Nrf2 inhibits autoimmune neuroinflammation via heme oxygnease-1 expression in dendritic cells

A. Cunha, I. Marguti, A. Cunha, S. Cardoso, A. Chora & M. P. Soares
Inflammation Laboratory, Instituto Gulbenkian de Ciencia, Oeiras, Portugal

Purpose/Objective: The transcription factor NF-E2-related factor 2 (Nrf2) orchestrates a protective response against autoimmune neuroinflammation, via a mechanism that remains to be established. We hypothesized that Nrf2 acts via a mechanism involving the expression of heme oxygenase-1 (HO-1/*Hmox1*) gene, which inhibits the pathologic outcome of autoimmune neuroinflammation.

Materials and methods: C57BL/6 *Nrf2*-deficient ($Nrf2^{-/-}$), myelin oligodendrocyte glycoprotein peptide 35−55 (MOG_{35-55}) specific T cell receptor transgenic (2D2) crossed with $Nrf2^{-/-}$ and $Nrf2^{+/+}$, IFN-g receptor-deficient ($Ifngr1^{-/-}$) mice and *CD11c-Cre* crossed with $Hmox1^{lox/lox}$ were used. For EAE induction, mice were immunized with MOG_{35-55} (100 mg) emulsified in CFA (100 ml; 4 mg/ml) subcutaneously on each side of the lower abdomen and received Pertussis toxin (PTx) intravenously (200 ng in PBS; 100 ml) after immunization (i.e. 4h and 2 days). 2D2$Nrf2^{+/+}$ and 2D2$Nrf2^{-/-}$ mice received PTx intravenously (200 ng in PBS; 100 ml) twice at 48h interval. Clinical signs of experimental autoimmune encephalomyelitis (EAE) were evaluated daily for 40 days and scored as described elsewhere. For the IL-12/23p40 *in vivo* neutralization assay, 2D2$Nrf2^{+/+}$ and 2D2$Nrf2^{-/-}$ mice received PTx intravenously (200 ng in PBS; 100 ml) twice with a 48h interval. At day-1 and 6 post-PTx administration, mice received either anti-IL12/23p40 neutralizing antibody (C17.15, 1 mg/mouse) or a rat isotype-matched IgG2a control antibody (YKIX-302; 1 mg/mouse) i.p. dissolved in PBS.

Results: When immunized withMOG_{35-55}, $Nrf2^{-/-}$ mice develop a more severe form of EAE, as compared to wild type ($Nrf2^{+/+}$) controls. This is also the case for 2D2 $Nrf2^{-/-}$ versus $Nrf2^{+/+}$ mice, without MOG_{35-55} immunization. The protective effect of Nrf2 is exerted in leukocytes, as demonstrated by the adoptive transfer of leukocytes from MOG_{35-55}-immunized 2D2 $Nrf2^{-/-}$ versus $Nrf2^{+/+}$ mice into naïve recipients. Expression of Nrf2 in DC inhibits IL-12 production, revealed by increased IL-12 expression in $Nrf2^{-/-}$ versus $Nrf2^{+/+}$ DC. This favors myelin-reactive T helper (T_H) cell priming towards a T_H1 phenotype secreting IFN-g. Inhibition of IL-12, using a neutralizing anti-IL-12/23p40 monoclonal antibody, reverts this effect and suppresses the development of EAE in 2D2 $Nrf2^{-/-}$ or $Nrf2^{+/+}$ mice. This is also the case when the IFN-g biologic activity is suppressed in $Ifngr1^{-/-}$ mice. Specific deletion of the *Hmox1* allele in DC enhances IL-12 secretion by DC as well as T_H1 cell priming and EAE severity in MOG_{35-55} immunized *CD11c-Cre/*$Hmox1^{-/-}$ versus $Hmox1^{lox/lox}$ mice.

Conclusions: In conclusion, we propose that Nrf2 counters the pathogenesis of autoimmune neuroinflammation via an immunoregulatory mechanism exerted in DC and involving the expression of HO-1.

Tim-3 and PD-1 are differently expressed on exhausted T cells in HIV infected patients

K. Grabmeier-Pfistershammer,* J. Leitner,† A. Rieger* & P. Steinberger†
**Dermatology, Medical University Vienna, Vienna, Austria, †Immunology, Medical University Vienna, Vienna, Austria*

Purpose/Objective: Progressive loss of T cell function is an important mechanism of chronic HIV-1 infection. PD-1 has been primarily used to describe exhausted T cells. Recently Tim-3 has been identified as additional marker for dysfunctional T cells in chronic virus infections. Tim-3 positive cells were reported to differ from PD-1 positive T cells, but these cells have not been defined in detail.

Materials and methods: In this study we have investigated the expression of PD-1 and TIM-3, two markers implicated in immune exhaustion on T cells from HIV-1 infected individuals.

Results: Interestingly we found that even in the viremic patients only a small percentage of T cells expressed Tim-3 (mean: 4.1%). In contrast, a significant amount of T cells were PD-1 positive (mean 36.8%) and furthermore PD-1 was expressed at much higher levels than Tim-3. Nevertheless we found a trend to higher numbers of Tim-3 positive cells in viremic than in aviremic HIV infected and even lower numbers in healthy individuals. When analysing CD8 T cells of viremic and aviremic patients regarding CD45RA expression we found a striking difference between Tim-3 and PD-1 positive T cells: the Tim-3 expressing cells were found in the CD45RA positive subset ($P < 0.5$) whereas PD-1 expression was nearly exclusively found on the CD45RA negative subset ($P < 0.5$). To further characterize the Tim-3 positive subset we performed multicolour staining using antibodies to various T cells markers including CD28 and CD57. Although CD57 expression and loss of the CD28 molecule are both associated with T cell senescence, Tim-3 expressing cells were exclusively found in the CD57 positive subset whereas is was not restricted to CD28 negative T cells.

In contrast to the PD-L/PD-1 pathway, blockingTim-3 did not enhance HIV specific T cell proliferation or IFN g secretion.

Furthermore, whereas PD-1 positive cells have previously been shown to be increased in HIV infected patients with discordant immune response, Tim-3 expression did not differ between patients with or without immune restoration on HAART.

Conclusions: Taken together our data implicate that Tim-3 defines a novel subset of terminally differentiated T cells.

A role for the pattern recognition receptor Nod2 in recruitment of CD103$^+$ DC to the gut in helminth infection

R. Bowcutt,* P. J. Murray,† C. Booth,‡ R. K. Grencis* & S. M. Cruickshank*

**FLS, University of Manchester, Manchester, UK, †Departments of Infectious Diseases and Immunology, St. Jude Children's Research Hospital, Memphis, UK, ‡Epistem, Incubator, Manchester, UK*

Purpose/Objective: The ability of the colon to generate an immune response to pathogens, such as the whipworm *Trichuris muris*, is a fundamental and critical defence mechanism. Our previous work demonstrated that resistance to infection is associated with the rapid recruitment of dendritic cells (DCs) to the colonic epithelium via epithelial production of CCL5 and CCL20. However, the epithelial-parasite interaction that drives chemokine production is not known. Here, we address the role of the cytosolic pattern recognition receptor Nod2, the location of which within the crypts correlates with the *T.muris* niche.
Materials and methods: *Nod2*$^{-/-}$ and WT mice were infected with T.muris and DCs in the large intetsine anlaysed by flow cytometry and immunohistochemistry. DC migration was analysed using bone marrow chimeras and chemotaxis assays. Epithelial chemokine production was assesed by qPCR and ELISA.
Results: There was a rapid influx of CD103$^+$ CD11c$^+$ DCs into the colonic epithelium in WT mice whereas DC recruitment was impaired in *Nod2*$^{-/-}$ animals. Strikingly, the number of colonic CD11c$^+$CD103$^+$ DCs in *Nod2*$^{-/-}$ mice remained low until D7 post-infection. Macrophage recruitment was unaffected. Migration assays revealed no difference between the migration of *Nod2*$^{-/-}$ and WT colonic DCs in response to chemokines. Furthermore, bone marrow chimeras of wildtype mice reconstituted with *Nod2*$^{-/-}$ cells unequivocally demonstrated that *Nod2*$^{-/-}$ DCs recruitment was restored in the presence of a WT epithelium. *In vivo* and *in vitro* experiments showed that epithelial production of chemokines, CCL2, CCL3 and CCL5 by *Nod2*$^{-/-}$ epithelial cells was markedly reduced. In addition, Nod2$^{-/-}$ was upregulated in WT epithelial cells 24 h pos-infection.
Conclusions: Collectively, these data indicate a role for Nod2 in recognition of the helmith *T.muris* via epithelial chemokine production and recruitment of CD103$^+$ DCs to the colonic epithelium.

P0070

An investigation of the capacity of colonic macrophages to proliferate in CX3CR1$^+$ /eGFP mice infected with the parasitic nematode *Trichuris muris*

M. C. Little,* C. C. Bain,† A. Mowat,† S. J. Jenkins,‡ J. E. Allen‡ & K. J. Else*

**Faculty of Life Sciences, University of Manchester, Manchester, UK, †Institute of Infection Immunity and Inflammation, University of Glasgow, Glasgow, UK, ‡Institute of Immunology and Infection Research, University of Edinburgh, Edinburgh, UK*

Purpose/Objective: *Trichuris muris* is a nematode parasite of the mouse which dwells in the large intestine. It is a natural mouse model of *Trichuris trichiura*: a prevalent and debilitating parasite of humans worldwide. A Th2 immune response is essential for the expulsion of worms. However, the nature of the ensuing inflammatory response (and its regulation) is not fully understood. Previous studies in this laboratory have shown that macrophages are the predominant type of inflammatory cell in the large intestine post-infection. Recently, macrophages have been shown to proliferate during certain inflammatory responses. This study aims to determine the capacity of colonic macrophages to proliferate (by analysing the incorporation of BrdU into DNA) during infection with *T. muris*.
Materials and methods: Mice were injected i.p. with BrdU. Four hours later, leukocytes were isolated (by enzymatic digestion) from the large intestine of CX3CR1$^{+/eGFP}$ mice and the macrophages were analysed by multi-colour flow cytometry. In this mouse, cells expressing the chemokine receptor CX3CR1 also express eGFP.
Results: Two contrasting populations of CX3CR1$^+$ macrophages were identified. The first, F4/80^{high}CX3CR1^{high} and predominantly Ly6C$^-$, was relatively abundant in uninfected mice. This phenotype is consistent with resident macrophages. In contrast, the second, F4/80^{low}CX3CR1^{low} and Ly6C$^+$ was relatively abundant post-infection. This population is consistent with inflammatory macrophages. Less than 7% of either population of macrophages expressed RELMa, a marker of alternative activation, and there was no significant difference post-infection. In naïve mice, <2% of the resident or inflammatory macrophages had incorporated BrdU into their DNA. However, there was a twofold increase post-infection, but only in the resident macrophages. A relatively high proportion (approximately 30%) of these BrdU$^+$ resident macrophages also expressed RELMa.
Conclusions: In contrast to other models of inflammation, only a small proportion of colonic macrophages proliferates during *T. muris* infection. These cells were resident-type macrophages, some of which were alternatively activated. Compared to the accumulation of inflammatory macrophages derived from blood monocytes, the proliferation of resident macrophages makes only a small contribution to the inflammatory response.

P0072

Bladder-resident phagocytes in the response to luminal bacteria

M. A. Ingersoll,* A. M. Platt,† C. Biot,* L. Colineau,* M. Albert* & G. Randolph‡

**Immunology, Institut Pasteur, Paris, France, †Institute of Infection Immunity and Inflammation, University of Glasgow, Glasgow, UK, ‡Department of Pathology and Immunology, Washington University School of Medicine, St Louis, MO, USA*

Purpose/Objective: The bladder is a unique mucosal barrier devoid of microbiota. The most prevalent diseases of the bladder are urinary tract infection (UTI and bladder cancer. One common feature between the diseases is the introduction of bacteria into the lumen, uropathogenic *E. coli* (UPEC) in the case of UTI or BCG as immunotherapy for bladder cancer. UPEC and BCG instillation into the bladder have different outcomes, where BCG induces CD8$^+$ T cell cross-priming, while immunity to UPEC appears to be primarily antibody-mediated. We hypothesized that the basis for this difference is due in part to differential bacterial uptake by phagocytes in the bladder mucosa.
Materials and methods: To assess uptake by bladder phagocytes, we developed a fluorescent particulate model antigen coated with bacterial adhesin to overcome the complication that material instilled intravesically is quickly expelled during micturition. We employed flow cytometric analysis, immunohistochemistry, and functional assays to investigate uptake following instillation of model antigen, UPEC, or BCG in mouse models of urinary tract infection and BCG immunotherapy.
Results: We characterized four subsets of dendritic cells (DCs) and macrophages resident in naïve bladders. We observed that model antigen was taken up by bladder-resident macrophages. By contrast, UPEC, which induces bladder cell exfoliation, was phagocytized by macrophages and CD103$^+$ DCs. As the number of BCG in the bladder is significantly reduced compared to UPEC, we used a functional assay to measure uptake, observing that CD86 expression was increased on the surface of CD11c$^+$ cells enriched from the bladder and these cells presented antigen. Interestingly, despite very low CFU in the bladder,

BCG disseminated to the lymph nodes and spleen of treated mice while UPEC remained bladder-localized.
Conclusions: These studies suggest that different bladder APC populations take up UPEC and BCG, perhaps ferrying BCG to distal sites of the host, resulting in distinct immune responses. This may be due to bacteria localization in relation to resident APC. These findings contribute to the understanding of the disparity in adaptive immune responses initiated by BCG or UPEC, which may translate to mechanisms to enhance clearance of UPEC and improve the efficacy of BCG immunotherapy for bladder cancer.

$CD161^{++}CD8^{+}$ T cells express IFNgamma in response to TLR8 stimulation in an IL-12^{+} IL-18 dependent, TCR independent, manner

C. B. Willberg, M. Bilton, A. Kurioka, E. Attwood, J. Shadwell, R. Townsend, E. Mettke, J. Ussher & P. Klenerman
Peter Medawar Building for Pathogen Research, Nufflied Department of Medicine, Oxford, UK

Purpose/Objective: The high expression of CD161 is a characteristic of the human mucosal-associated invariant T (MAIT) cells / Tc17 subpopulation. T cells expressing the invariant V-alpha7.2 TCR make up ~85% of the adult $CD161^{++}CD8^{+}$ T cell population. A further characteristic of this population is the high expression of the IL-18 receptor, which correlated with CD161 expression in T cells. This suggested that these cells were potentially strong responders to IL-18 and IL-12 stimulation, which has long been known to induce IFN-gamma in both NK and T cells in a TCR independent manner.
Materials and methods: Human peripheral blood mononuclear cells (PBMC) from healthy individuals were stimulated with IL-12 and/or IL-18, TLR agonists. Cytokine expression by $CD161^{++}CD8^{+}$ T cells was assessed by FACS.
Results: Here we show that in humans $CD161^{++}CD8^{+}$ T cells were the primary T cell population to respond to IL-12^{+} IL-18 stimulation, without prior activation or CD3 cross-linking. This response was restricted to IFN-gamma secretion, which was delayed compared to TCR triggering, although the delay was reduced with prior IL-12 priming, and was enhanced by IL-15 co-stimulation. TLR8 agonist stimulation of PBMCs resulted in IFN-gamma production specifically by the $CD161^{++}CD8^{+}$ T cell and NK cell populations. This response could be blocked by either anti-IL-12 or anti-IL-18 antibodies, or inhibition of TLR8 or caspase-1. This is of particular interest as MAIT-cells have been previously described to be restricted to an as-yet unidentified bacterially derived ligand/s, presented on the MHC-like protein, MR1.
Conclusions: These data show, for the first time, that $CD161^{++}CD8^{+}$ T cells are the major T cell population that responds to directly IL-12^{+} IL-18 stimulation in humans without TCR triggering. Moreover, $CD161^{++}CD8^{+}$ T cells could also respond rapidly *in vivo*, in a TCR independent fashion, to cytokines, and potentially, via TLR8, to viral infections by single-stranded RNA viruses, such as HIV, HCV or Dengue.

P0074

Characterization of tonsil infiltration and gene expression profile of innate sensors in PFAPA patients

S. Chiesa,* R. Caorsi,* F. Penco,* A. Bertoni,* S. Borghini,† A. Omenetti,* A. Sementa,‡ R. D'Agostino,§ A. Martini* & M. Gattorno*
**Laboratory of Immunology and Rheumatic Diseases, G.Gaslini Institute, Genoa, Italy, †Laboratory of Molecular Genetics, G.Gaslini Institute, Genoa, Italy, ‡Anatomic Pathology, G.Gaslini Institute, Genoa, Italy, §UO Otorinolaringoiatria, G.Gaslini Institute, Genoa, Italy*

Purpose/Objective: Periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis (PFAPA) syndrome is the most common periodic fever disease in young children classified in the group of autoinflammatory syndromes. The etiology of this disorder is still unknown. Palatine tonsils are sites where innate immunity leads to onset of the adaptive immunity, mediated by B and T lymphocytes. Three families of pathogen sensors mediate the recognition of microbes: Toll-like receptors (TLRs), NOD-like receptors (NLRs) and RIG-I-like receptors (RLRs). We aimed to investigate differences in leucocytes subpopulations and innate receptors gene expression of palatine tonsil cells from patients with PFAPA in order to understand the pathogenesis of this inflammatory condition.
Materials and methods: We have collected tonsil tissue from two groups of pediatric patients undergoing tonsillectomy: PFAPA patients whose genetic testing excluded hereditary periodic fevers (HPFs) during flares and asymptomatic intervals ($n = 20$), and patients undergoing to tonsillectomy due to recurrent bacterial tonsillitis (control group, CG) ($n = 16$). We have performed staining of subpopulations on tonsil cells and tissues using flow cytometry and immunohistochemistry. We have analyzed TLRs, NLRs, and RLRs gene expression by quantitative real-time RT-PCR.
Results: The histology of tonsils in PFAPA patients shows a preservation of tonsillar architecture without specific chronic inflammation with respect to CG. FACS analysis demonstrate a higher number of naïve and a significantly lower percentage of effector memory $CD4^{+}$ and $CD8^{+}$ T cells in PFAPA patients compared to CG. Moreover, we observe a significantly recruitment of NK cells in PFAPA patients with respect to CG. Tonsil cells express a broad repertoire of TLRs variably represented in both PFAPA and CG. Of note, in PFAPA patients we discover a significant increase in the gene expression of NALP1 and NALP3 and higher levels of RIG-1 expression when compared to CG.
Conclusions: In summary, these results indicate a possible involvement of NK cells and of innate receptors (NLRs and RLRs) in pathogenesis of PFAPA supporting the crucial role of the innate immunity. Nonetheless, the high numbers of undifferentiated naïve T cells in PFAPA patients suggest that adaptive immune responses might *be implicated in these autoinflammatory* disorders.

P0075

COX-2 Modulates IL-36γ Expression by HPV6/11^{+} laryngeal keratinocytes' in patients with recurrent respiratory papillomatosis

V. Bonagura,* J. DeVoti,* L. Hatam,* A. Lucs,† A. Abramson† & B. Steinberg†
**Center for Immunology and Inflammation, The Feinstein Institute for Medical Research, New York, NY, USA, †Center for Oncology and Cell Biology, The Feinstein Institute for Medical Research, New York, NY, USA*

Purpose/Objective: Determine why HPV6/11 chronically infected laryngeal keratinocytes (LKs) from recurrent respiratory papillomatosis (RRP) patients that over-express COX-2 and IL-36γ fail to activate resident, immature Langerhans cell (LCs) in papillomas.

Materials and methods: Affymetrix HG-133A gene expression arrays identified differential expression IL-36g between papillomas and unaffected autologous laryngeal tissues from RRP patients ($P < 0.001$, paired t-test), and COX-2 was over expression by both tissues. Cultured HPV^+ papilloma cells or HPV^- LK from patients were studied for IL-36γ expression by qPCR and western analysis, after IL-36β or IL-36γ treatment,$^{+/-}$COX-2 inhibition (celecoxib, 5 μM) and$^{+/-}$ 500 pg/ml PGE_2. IL-36γ release was detected by ELISA (Adipobiotech).
Results: We asked if IL-36γ stimulation of HPV^+/HPV^- laryngeal cells affected mRNA expression of IL-1β, TNF-α or IL-36γ following by IL-36γ itself, and if pretreatment with celecoxib that eliminate PGE_2 effects secretion of these proinflammatory cytokines. LK IL-36γ treatment showed little effect on HPV^+/HPV^-LK IL-1β expression. TNF-α was elevated in untreated papilloma cells, versus HPV^- cells, and was increased in IL-36γ treated HPV^-, and more so in papilloma LKs ($P < 0.05$).Basal and IL-36γ-stimulated TNF-α levels were suppressed by celecoxib pretreatment.Thus, PGE_2 enhances TNF-α expression in LKs. However, IL-36γ treatment of HPV^- LKs showed a 14-fold increase in IL-36γ after IL-36γ exposure ($P = 0.03$), and greater in LKs pretreated with celecoxib (46.6-fold; $P = 0.0003$). IL-36γ treated papilloma cells increased IL-36γ expression 15-fold ($P = <0.01$), similar to HPV^- LKs.IL-36γ expression by papilloma cells was 20-fold higher to begin with ($P = 0.006$). Pretreatment with celecoxib increased IL-36γ in HPV^- LKs treated, but did not further upregulate IL-36γ in papilloma LKs, possibly because IL-36γ expression was so high after IL-36γ treatment. However, IL-36γ was not found in culture medium.We also tested monocyte-derived Langerhans cell (iLCs) responses to IL-36γ; they expressed IL6, IL-12p40.
Conclusions: HPV infection drives very high levels of IL-36γ expression in HPV^+ LKs. PGE_2 modulates this.While celecoxib decreased IL-36γ-induced TNF-α expression, it increased IL-36γ expression in HPV^+ LKs. Thus, IL-36γ has a positive feed-back loop. IL-36γ release by RRP-derived LKs is not spontaneous.A secondary signal may be needed, such as poly(I:C)/another Toll-like signal/ATP/IL-17. Control LKs are under study to determine if they can release IL-36γ. IL-36 papilloma cells/HPV^+ cells can mature iLCs and support effective adaptive anti-HPV immunity.

P0076
Critical role of type III interferons during rotavirus infection

J. Pott,* M. Mordstein,† T. Mahlakoiv,† C. U. Duerr,‡ S. Stockinger,‡ P. Staeheli† & M. W. Hornef‡
**Dunn School of Pathology, University of Oxford, Oxford, UK, †Department of Virology, University of Freiburg, Freiburg, Germany, ‡Medical School Hannover, Institute for Medical Microbiology, Hannover, Germany*

Purpose/Objective: Type I and type III interferons (IFN) bind to different cell surface receptors but induce identical signal transduction pathways leading to the expression of antiviral host effector molecules. Although IFN-λ has been shown to predominantly act on mucosal organs such as the lung and gastrointestinal tract, studies using IFN-λ receptor-deficient mice have failed to define a non-redundant function. Here we analyse the role of IFN-λ during infection with an epithelial tropic enteric virus to elucidate the contribution to antiviral protection at mucosal surfaces.
Materials and methods: IL28Rα-deficient, IFNAR-deficient and IL28Rα/ IFNAR-double deficient mice were analysed during oral rotavirus infection. Viral titer in the intestine was determined by ELISA. The response of the intestinal epithelium was analysed by quantitative PCR and simultaneous immunostaining of virus-infected cells and the antiviral Mx1 protein were performed.
Results: Reduced expression of IFN response genes were found in type III interferon signalling deficient mice in contrast to IFNAR-deficient or wild type mice. In accordance, enhanced virus replication and tissue damage was found in the absence of IFN-λ signalling, whereas no significant contribution of IFN-α/β signalling to the antiviral host defence was detected.
Conclusions: These findings identify a critical role of IFN-λ to induce an antiviral response and to restrict virus replication in the intestinal epithelium.

P0077
Dectin-1 is required for control of systemic, but not gastrointestinal, infections by *Candida albicans*

S. Vautier,* R. A. Drummond,* P. Redelinghuys,* G. I. Murray,† D. MacCallum* & G. D. Brown*
**Infection and immunity, University of Aberdeen Institute of Medical Sciences, Aberdeen, UK, †Pathology, University of Aberdeen Institute of Medical Sciences, Aberdeen, UK*

Purpose/Objective: *Candida albicans* is a human fungal commensal, commonly colonising the gastrointestinal tract. However, *C. albicans* can cause both mucosal and systemic infections if the host immune response becomes compromised. In mice and humans the innate pattern recognition receptor Dectin-1 is involved in the control of fungal infections. However, the role of Dectin-1 during colonisation of the gastrointestinal tract remains to be defined. Here we investigated the role of Dectin-1 in systemic candidiasis as well as mucosal colonisation of the gastrointestinal tract following oral infection.
Materials and methods: For systemic infections, mice (C57/BL6 wild-type and Dectin-$1^{-/-}$) were infected I.V. with 2×10^5CFU *C. albicans* SC5314 via the lateral tail vein. For colonisation of the gastrointestinal tract, mice were pre-treated with antibiotics before exposure to 1×10^7 CFU/ml *C. albicans* SC5314 (for 5 days) in the drinking water. Colonisation was maintained using antibiotics and monitored via stool fungal burdens. Mice were analysed at various time points for tissue fungal burdens, cytokine responses and pathology via histology.
Results: Dectin-1 deficiency correlated with increased fungal burdens and dysregulated cytokine production in gastrointestinal tract tissues during systemic infection. Surprisingly, following oral infection via the drinking water, there was no Dectin-1 involvement in inflammation, fungal burdens or cytokine responses to GI colonization with *C. albicans*.
Conclusions: Here we demonstrate in mice that Dectin-1 is essential for controlling dissemination to the tissues of the gastrointestinal tract during systemic infection with *C. albicans*; however this receptor appears to be redundant for controlling colonisation of the gastrointestinal tract following oral infection.

P0078
Deviant expression of defensins in sera and saliva of patients with autoimmune polyendocrine syndrome type I

A. S. B. Wolff, A. Østre, B. E. V. Oftedal & E. S. Husebye
Endocrinology, Institute of Medicine, Bergen, Norway

Purpose/Objective: Patients with autoimmune polyendocrine syndrome type I (APS I) have high titer neutralization IgG autoantibodies against Th17-expressed cytokines. Autoantibodies against IL17F and IL22 are present in up to 90% of APS I patients, and their presence in sera correlate to chronic *Candida* infections. We have further previously reported that APS I patients exhibit lower secretion of IL17F and IL22 than healthy controls. In an attempt to elucidate the mechanisms behind these phenomena, we have characterized the IgA and IgG autoantibody profiles against Th17-expressed proteins in sera and saliva from APS I patients and controls. Since especially IL22 can influence the expression of antimicrobial peptides (AMPs), which mediates the destruction of invading pathogens (including *Candida*),

we have also examined the expression of key set of key AMPs and anti-fungi agents in sera and saliva from APS I patients and controls.
Materials and methods: We have measured IgA and IgG antibodies aganst Th17-mediators in sera and saliva using RIA and an in-house ELISA. We have further examined the expression of alpha-defensins (HNP 1−3), beta-defensin 1, 2 and 4, calprotectin, LL-37, Bactericidal permeability increasing protein and Myeloperoxidase in saliva and sera from Norwegian APS I patients and healthy controls using commercial ELISA.
Results: We confirm the high prevalence of serum IgG autoantibodies against IL17F and IL22 in APS I patients. A significantly higher level of IgA autoantibodies against IL22 were also found in both sera and saliva from these patients compared to healthy blood donors. This kind of response could be important in mucosal immunity and prone APS I patients to resistance against Candida clearance. Our results further indicate an imbalance of both alpha-defensins and beta-defensins in APS I patients compared to healthy controls. Importantly, the actual profile of autoantibodies and AMP expression varied a lot between patients.
Conclusions: We conclude that a high level of IgG and/or IgA autoantibodies against cytokines involved in AMP expression could be correlated to a deviant level of AMPs, which again may mediate chronic candidiasis. Further studies will be necessary to confirm our findings.

P0079
Differential functional contributions of monocyte descendants to gut homeostasis and inflammation as effector monocytes, macrophages and dendritic cells

S. Jung,* E. Zigmond,* G. Shahhar,* J. Farache,* C. Varol† & Z. Halpern†
**Immunology, Weizmann Institute, Rehovot, Israel, †Immunology, Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel*

Purpose/Objective: Based on specific growth and transcription factor requirements, as well as results of adoptive precursor transfers, mononuclear phagocytes are currently divided into two sublineages, with MDPs (i) giving rise to dedicated precursors of classical Flt3L-dependent dendritic cells and (ii) differentiating into monocytes that are called to sites of inflammation to yield macrophages.The healthy intestinal lamina propria is unique in that it constantly recruits Ly6C^{hi} monocytes, presumably attracted by tonic low-grade inflammation resulting from exposure to the commensal microflora. Once extravasated monocytes give rise to resident macrophages that contribute with their distinct non-inflammatory gene expression signature critically to maintain gut homeostasis.
Materials and methods: Our study uses DSS-challenged mice as colitis model and employs adoptive monocyte transfers, flow cytometry and gene expression analysis and and two photon imaging to establish monocyte fates in the inflamed colon.
Results: Here we report on monocyte fates in the inflamed colon. Specifically we show that infiltrating Ly6C^{hi} monocytes gain in this tissue context effector functions that render them responsive to bacterial products and as a result pro-inflammatory. Moreover, monocyte ablation established these cells as critical drivers of acute DSS-induced gut inflammation. Interestingly though, with time monocytes differentiate into migratory antigen-presenting cells, reminiscent of dendritic cells.
Conclusions: Collectively, our results highlight cellular dynamics in the inflamed colon and the plasticity of Ly6C^{hi} monocytes singling them out as potential targets for IBD therapies.

P0081
Enteropathogenic *Escherichia coli* engages in temporal regulation of the inflammasome by interaction with NLRC4 and NALP3

N. Pramanik,* M. Lucas,* N. Klein,* C. Bryant† & M. Bajaj-Elliott*
**Immunology and Infectious Disease, UCL Institute of Child Health, London, UK, †Department of Veterinary Medicine, University of Cambridge, Cambridge, UK*

Purpose/Objective: Enteropathogenic *Escherichia coli* (EPEC) is a leading cause of acute and chronic diarrhoea in developing nations, principally affecting children <2 years of age. The interaction of EPEC with the gastrointestinal (GI) mucosal immune system remains largely uncharacterised. A recent study by Lebeis *et al* 2011 indicated a critical role for IL-1 receptor signalling in *Citrobacter rodentium* (murine model for EPEC) mediated disease pathogenesis. In the present study we investigated the signalling events that regulate IL-1β production in response to EPEC infection. Better understanding of this complex pathway may highlight novel therapeutic targets for infection control and highlight strategies for vaccine development for this major enteropathogen.
Materials and methods: Murine Bone Marrow derived Dendritic cells (BMDC) from mice lacking various inflammasome components (NLRC4$^{-/-}$, NALP3$^{-/-}$, ASC$^{-/-}$, CASPASE$^{-/-}$) were infected with EPEC Wild Type (WT) E69 strain and isogenic mutant strains deficient in the flagella and structural and effector protein(s) of the T3SS (Type III secretion system). Inflammasome activation was assessed by gene and protein expression, flow cytometry and confocal microscopy.
Results: WT E69 strain induced marked increase in bioactive IL-1β in a caspase-1 dependant manner. This effect required the presence of the T3SS component in EPEC. In contrast to published work by Miao *et al* 2010, we found a minimal role for flagella-mediated IL-1β as ΔFliC a mutant strain lacking the flagella elicited IL-1β to levels seen during infection with WT strain in NLRC4$^{-/-}$ DC. ASC (an essential adaptor required for regulating mature caspase-1 by the inflammasome) speck formation and IL-1β secretion was significantly decreased in NLRC4$^{-/-}$and NLRP3$^{-/-}$suggesting involvement of both proteins in ASC mediated caspase-1 activation.
Conclusions: An intact T3SS was found to be necessary for optimal IL-1β release. Our experiments indicate potential role of ASC in EPEC-mediated IL-1β release especially in the presence of the inflammasome NLRC4. Our study is the first to highlight temporal involvement of NLRC4 and NALP3 in EPEC-mediated inflammasome activation.

P0082
Epithelial responses to pathogenic or commensal oral biofilms

E. Millhouse,* G. Ramage,* A. Jose,* S. Rawling† & S. Culshaw*
**Infection and Immunity Group, University of Glasgow, Glasgow, UK, †Microbiology, GlaxoSmithKline, Weybridge, UK*

Purpose/Objective: Periodontal disease is the result of chronic inflammation mediated by the host immune response to bacterial biofilm (plaque) on the root surface, leading to destruction of supporting structures of the teeth and ultimately tooth loss. In health, commensal oral biofilms form without notable disruption of the tooth supporting tissues. However, introduction of 'keystone pathogens' such as *P. gingivalis* creates a pathogenic biofilm which evokes a damaging inflammatory response with local tissue destruction.

To compare the response of oral epithelial cells to pathogenic and commensal biofilms and investigate the mechanisms by which pathogenic species alter the epithelial cell inflammatory response *in vitro*.
Materials and methods: OKF6-TERT2 oral epithelial cells were stimulated with different species of bacteria (*S. mitis, P. gingivalis, F. nucleatum and A. Actinomycetemcomitans*). Bacterial stimulations were prepared as planktonic bacteria, mixed or single species biofilms.

Changes in mRNA and protein expression of multiple chemokines and cytokines were then assessed by Taqman® low density array or ELISA.
Results: Significant differences between epithelial cell cytokine and chemokine in response to pathogenic or commensal biofilms were observed at both protein and mRNA level. *P. gingivalis* degraded IL-8 and demonstrated strain dependent variation in epithelial cell stimulation. These results demonstrate that oral bacteria may modulate the epithelial cell response to allow persistence of the biofilm.
Conclusions: Periodontal disease associated bacteria are able to modulate epithelial cell chemokine and cytokine expression both at a gene and protein level. The subversion of the host response, such as cytokine degradation by *P. gingivalis,* may contribute to the chronicity of infection and subsequent progression of periodontal disease.

P0083
Essential role for type I interferons in the regulation of T cell mediated colitis

A. Kole,* J. He,† A. Rivollier,† K. Kitamura,† K. Maloy* & B. Kelsall†
**Sir William Dunn School of Pathology, University of Oxford, Oxford, UK, †National Institutes of Health, National Institute of Allergy and Infectious Disease, Bethesda, MD, USA*

Purpose/Objective: We explored the role of type I interferons (IFN-1) in the regulation of intestinal homeostasis.
Materials and methods: We used the T cell adoptive transfer model of colitis to study intestinal homeostasis *in vivo*. We also isolated various cell populations from the colon lamina propria to study the dependence of their functions on type I interferon by employing methods of *in vitro* stimulation.
Results: Colon mononuclear phagocytes (MP) constitutively produced IFN-1 that was dependent on TRIF but not MyD88-signaling. Transfer of $CD4^+$ $CD45RB^{hi}$ T cells from wild type (WT) or interferon a/b receptor-deficient ($IFNAR1^{-/-}$) mice into $RAG^{-/-}$ hosts resulted in similar colitis development. In contrast, $RAG^{-/-}$/$IFNAR1^{-/-}$ double knockout (DKO) mice developed accelerated severe colitis compared to $RAG^{-/-}$ hosts transferred WT $CD4^+$ $CD45RB^{hi}$ T cells. Enhanced colitis was associated with increased T cell proliferation in the mesenteric lymph nodes and subsequent accumulation in the colon lamina propria and was suppressed by IFNAR signaling on host hematopoietic cells. Additionally, blockade of IFN-1 by a neutralizing monoclonal antibody against IFNAR1 resulted in exacerbated colitis. Finally, we show that colon mononuclear phagocytes (MP) from $IFNAR1^{-/-}$ mice produced less IL-10 than from WT mice upon *ex vivo* stimulation.
Conclusions: These data are the first to demonstrate an essential role for IFN-1 in controlling the production of IL-10 by gut MP and the indirect maintenance of intestinal T cell homeostasis.

P0084
Ex vivo imaging of free radicals reveals robust immune activity in the distal small intestine in NOD mice

R. Emani,* M. N. Asghar,† R. Toivonen,* L. Lindholm,* M. Söderström,‡ R. van Tol,§ D. Toivola† & A. Hänninen*
**Department of Medical Microbiology and Immunology, Turku University, Turku, Finland, †Department of Bioscience/Cell Biology, Äbo Acedamy University, Turku, Finland, ‡Department of Microbiology and Pathology, Turku University, Turku, Finland, §Mead Johnson Nutrition, R&D, Amsterdam, The Netherlands*

Purpose/Objective: Environmental influence on autoimmunity in type 1 diabetes is thought to be ascribed to dietary and microbial factors, most of which affect the gastrointestinal tract. In the nonobese diabetic (NOD) mouse, signs of enteropathy and increased immune activity are present in both small and large intestine.
Materials and methods: We evaluated inflammatory activity in the whole gut in prediabetic NOD mice by *ex vivo* imaging of reactive oxygen intermediates (ROI) with a chemiluminescent probe and In-vivo imaging system (IVIS), cytokines and bacterial 16s RNA were measured using QPCR and cells were characterised with flow cytometry.
Results: Young NOD mice displayed high ROI activity in the distal small intestine, ileum. *In vivo* staining with dihydroethidium revealed that the major ROI producers were intestinal epithelial cells. Anti-diabetogenic casein hydrolysate diet diminished ROI activity, expression of IL-17 and proinflammatory cytokines, T-cell activation and total bacterial load in ileum. Despite all this, gut permeability to oral FITC-dextran was not reduced.
Conclusions: Our findings suggest that secondary to an underlying permeability disorder, diet-dependent bacterial colonisation induces epithelial ROI production and local T-cell activation in the ileum of NOD mice. These findings establish a new link between diet, microbial factors and dysbalanced gut homeostasis in the NOD mouse, with possible implications for the immune pathogenesis of type 1 diabetes.

P0085
Function and differentiation of intestinal macrophages in oral tolerance

A. Schridde, U. Hadis, M. Ugur & O. Pabst
Basic Immunology, Immunology, Hannover, Germany

Purpose/Objective: $CD11b^{-/-}$ and $CX3CR1^{-/-}$ mice fail to establish oral tolerance. This defect can be rescued by the adoptive transfer of wild type macrophages, suggesting a central role of intestinal macrophages in intestinal tolerance generation. We have previously shown that CX3CR1 drives the Interleukin-10 (IL-10) secretion by gut resident macrophages and thereby the local expansion of regulatory T (Treg) cells. Here we analysed the role of CD11b in intestinal tolerance induction and macrophage differentiation.
Materials and methods: The myeloid compartment of $CD11b^{-/-}$ mice was compared to wild type mice using flow cytometry and iterative Chipbased Cytometry (iCBC). Cytokine production by intestinal macrophages was analysed and adoptive transfer experiments were performed to follow Treg induction and expansion *in vivo*. The differentiation of intestinal macrophages was studied by photoconversion and iCBC.
Results: Treg were readily induced in the gut draining mesenteric lymph nodes of wild type and CD11b-deficient mice. In contrast, the local expansion of Treg was impaired in the absence of CD11b. CD11b deficient mice showed a wild type-like composition of intestinal myeloid cells and gut resident macrophages secreted normal amounts of IL-10. To track the local differentiation from incoming progenitors to tolerogenic $CX3CR1^{high}CD11b^+$ macrophages, we compared the myeloid compartment as a function of local residence time in the gut lamina propria by photoconversion and iCBC.
Conclusions: The expression of CX3CR1 and CD11b affect the expansion of Treg cells in the gut lamina propria. Yet, in contrast to CX3CR1, the lack of CD11b does not affect the cytokine profile of intestinal macrophages. Elucidating the differentiation process of intestinal macrophages, its regulation in inflammation and steady state and the function of CX3CR1 and CD11b will help for the further understanding of oral tolerance.

P0086

Generation and phenotypic analysis of murine beta defensin knockout mice

C. R. Walker,* M. Boniotto,† F. Pisano,† B. Cooper,* H. Te Riele‡ & W. Muller*

*Faculty of life Science, University of Manchester, Manchester, UK, † Inflammation and Immunity, Helmholtz Centre for Infection Research, Brauschweig, Germany, ‡Division of Molecular Genetics, The Netherlands Cancer Institute, Amsterdam, The Netherlands

Purpose/Objective: Defensins are thought to play a role in the protection against infection and immunological homeostasis, however their role is not completely characterised. Experimental induced mutations of defensin genes may enhance our understanding of their microcidal and immunological activity. We have generated mice that lack murine beta defensin 14 (mBD14), which was recently identified as the orthologue of human beta defensin 3 (HBD3). As the defensin genes are in close proximity to one another, we used oligonucleotide-mediated gene modification (oligo targeting), which created a specific mutation by inserting a 4bp sequence in the *Defb14* gene creating a stop codon and a frameshift. This mouse mutant was then phenotypically analysed.
Materials and methods: HBD3 has been associated with ulcerative colitis, as patients with ulcerative colitis exhibit increased expression of HBD3 mRNA. Therefore the ability of mBD14 to maintain the immunological homeostasis of the gut, was investigated by DSS induced colitis. Additionally, to determine if the microbiota of the mBD14$^{-/-}$ mice is different to WT and mBD14$^{+/-}$ mice, a 16s rRNA PCR was performed and PCR products were run on a denaturing gradient gel electrophoresis (DGGE) gel.
Results: The mutation in the *defb14* gene has been confirmed in the homozygous mice at the genomic, RNA and protein level. There was no difference in the severity of colitis in the colon of the mBD14$^{-/-}$ mice compared with mBD14$^{+/-}$ mice. Additionally, no difference in the DGGE profiles of caecal contents and skin were observed for WT, mBD14$^{+/-}$ and mBD14$^{-/-}$ mice.
Conclusions: No phenotype was established for the mBD14$^{-/-}$ mice, therefore further defensin genes (*Defb18*, *Defb41*, *Defb7*, *Defb40*, *Defb20*) will be inactivated by TALEN technology, to create single, double and defensin cluster mutants. These mutants will be phenotyped with the same methods used to analyse the mBD14 mutant mice. These experiments may help clarify the role of defensins in immunological homeostasis.

P0087

Humoral and cellular immunity to food antigens in patients with leukemia

M. Djordjevic,* A. Vidovic,† D. Tomin,† B. Mihaljevic,† Z. Juranic,* S. Ristic,‡ N. Grozdanic* & M. Djordjic*

*Laboratory for Biological Response Modifiers, Institute of Oncology and Radiology of Serbia, Belgrade, Serbia, †First Department, Medical Faculty of Belgrade, Clinical Center of Serbia, Institute of Hematology, Belgrade, Serbia, ‡Department of Hematology, Medical Faculty of Belgrade, Clinical Hospital Dragisa Misovic Dedinje Belgrade, Serbia

Purpose/Objective: Patients with food allergy have well known abnormal immune response to various food antigens. Abnormal and dysfunctional response of immune cells may represent a predisposition for the development of hematological malignancies, especially leukemia. Chronic stimulation of dysfunctional immune cells in leukemia patients with some antigen that is constantly present in a daily diet can lead to increased number of malignantly transformed cells. The aim of this study was to determine the humoral immunoreactivity to food antigens (gliadin, cow's milk proteins – CMP and phytohaemagglutinine – PHA) and cellular immunoreactivity to those antigens in leukemia patients.
Materials and methods: Study involved 35 patients with different types of leukemia. The control group consisted of 72 healthy volunteers. The Home Made ELISA test to gliadin, CMP and PHA were done to determine humoral immunity. For the assessment of cellular immunity PBMC were isolated and incubated in RPMI with 10% autologous plasma without and with different food antigens: gliadin, CMP and PHA. Index of PBMC stimulation was determined using MTT test. Cut-off for both tests, ELISA ant MTT, was determined as mean ($X \pm 2SD$)%.
Results: The most pronounced stimulation of PBMC was detected with gliadin 12/35 patients had increased growth of PBMC. Among them, 2 had enhanced IgA immunoreactivity to gliadin, one patient had increased IgG immunoreactivity and 3/12 had increased IgE immunoreactivity. Only one patient had suppression of growth of PBMC with gliadin but without increased humoral immunoreactivity to tested antigens. 2/35 patients had suppression of growth of PBMC with CMP and both of them had enhanced IgA immunoreactivity to CMP. 11/35 patients had suppression of growth of PBMC with PHA, amongst them three patients had enhanced IgA immunoreactivity to PHA and one had enhanced IgM immunoreactivity to PHA.
Conclusions: These preliminary results showed that enhanced humoral immunoreactivity to some of the tested antigens is present together with the suppression of growth of PBMC to the same antigen in some of the examined leukemia patients. This point to the need to elucidate clinical importance of those findings in these particular leukemia patients, i.e. to give the answer could stimulation of mucosal immunity with food antigens affect the survival of the malignant cell clone.

P0088

IL-17E: a negative regulator of periodontal inflammation?

C. Nile, R. Awang, D. Lappin & S. Culshaw

Dental School, University of Glasgow, Glasgow, UK

Purpose/Objective: IL-17E (IL-25) has a key role in promoting Th2-driven pathologies but has also been demonstrated to down regulate destructive localised inflammatory responses in conditions such as rheumatoid arthritis. Periodontal disease is a chronic inflammatory disease which left untreated leads to tooth loss. At present the role of IL-17E in periodontal disease pathogenesis is completely unknown. Therefore, the purpose of this study was to investigate the expression of IL-17E within the periodontoium and begin to delineate the role IL-17E may play in the pathogenesis of periodontal disease.
Materials and methods: Real time PCR was employed to compare the expression of IL-17E mRNA in healthy and diseased periodontal tissue. The cell types within the periodontium responsible for expression of IL-17E and its receptors (IL-17RA and IL-17RB) were then determined by immunohistochemistry. Using a live biofilm of the periodontal pathogen, *P. gingivalis*, combined with ELISA technologies and real time PCR, the ability of IL-17E to modulate the oral keratinocyte immune response was then investigated *in vitro*.
Results: Real time PCR analysis showed that IL-17E mRNA levels are up-regulated in periodontal disease. Immunohistochemical analysis of diseased periodontal tissue demonstrated the cellular sources of IL-17E to be endothelial cells and infiltrating leukocytes. No expression of IL-17E was detected in oral keratinocytes. However, oral keratinocytes were demonstrated to express both IL-17RA and IL-17RB and therefore identified as a target for IL-17E signaling. Indeed, using an *in vitro P. gingivalis* biofilm model, IL-17E was found to negatively regulate the *P. gingivalis* induced expression of neutrophil pro-chemotatic chemokines; CXCL5 (ENA-78) and CXCL8 (IL-8).
Conclusions: IL-17E derived from endothelial cells and invading leukocytes play a role in the pathogenesis of periodontal disease. IL-17E has been demonstrated to be a negative regulator of oral

immunity. IL-17E can down regulate the expression of key neutrophil chemo-attractants and therefore possibly inhibit neutrophil chemotaxis into the periodontium. As neutrophils play a key role in the early events associated with periodontal disease progression, the data suggests IL-17E is a rational target for therapeutic intervention.

P0089
Impaired pulmonary immunity after cerebral ischemia

C. Dames,* L. Akyüz,* O. Engel,† K. Winek,† H. D. Volk,* A. Meisel† & C. Meisel*
**Institute for Medical Immunology, Charité – Universitätsmedizin, Berlin, Germany, †Department of Experimental Neurology, Charité – Universitätsmedizin, Berlin, Germany*

Purpose/Objective: Severe cellular immunodepression is a frequent phenomenon in stroke patients, which is associated with a high rate of infectious complications and worse clinical outcome. Up to 20% of stroke patients develop pneumonia with worse recovery and high mortality. Clinical and experimental studies have shown that stroke induces a long-lasting suppression of cell-mediated immune responses in blood and lymphatic organs. The dynamics of quantitative and functional changes in lung immune cells has not been studied so far. Here we analysed, in a clinically relevant mouse model, the pulmonary immune response at different time points after stroke.
Materials and methods: In a well-established mouse stroke model (middle cerebral artery occlusion for 60 min) we characterized quantitative and functional changes of myeloid and lymphoid immune cell populations *ex vivo* in lung and spleen at different time points after stroke. The early pulmonary host response during bacterial pneumonia was analyzed in a model of aspiration-induced pneumonia. Phenotypic and functional analyses were done by flow cytometry, multiplex cytokine analysis of BAL fluid, plasma and cell culture supernatants after *ex vivo* TLR-ligand stimulation, and by assessing phagocytic activity.
Results: Analysis of cellularity showed decreased numbers of lymphocytes, dendritic cells and macrophages in lungs at different time points after stroke. Functional analyses indicated an impaired cytokine production in both lung cells and splenocytes after *ex vivo* TLR and T cell mitogen stimulation. First results of the *in vivo* host response to aspiration of low dose *Streptococcus pneumonia* that does not induce infection in naïve mice indicate an early and prolonged hyperinflammatory response with increased cytokine production in stroke mice.
Conclusions: Our data suggest that similar to the changes in lymphoid organs and peripheral blood also pulmonary immune cells show signs of impaired function after cerebral ischemia. The precise mechanisms of altered pulmonary immunity including the recruitment of peripheral immune cells during bacterial lung infection after acute CNS injury needs to be further investigated and may lead to new therapeutic strategies to prevent infections and improve outcome in stroke patients.

P0090
In vitro, induction of BAFF and APRIL expression by A549 and BEAS-2B airway epithelial cells

W. Alturaiki, A. Fonceca, C. Broughton, P. S. McNamara & B. F. Flanagan
Immunology, Institute of Infection and Global Health, Liverpool, UK

Purpose/Objective: The production of BAFF and APRIL by epithelial cells contributes to local accumulation, activation, class switch recombination, and antibody production by B cells in the airways. Here we aimed to characterise BAFF and APRIL production by the cultured airway epithelial cells, A549 and BEAS-2B.

Materials and methods: §The total RNA was extracted and collected from A549 cells and Beas- 2b and RT-PCR was applied. Human BAFF ELISA and Il-8 were used to measure the protein.

§ *in vitro*, we investigated if cultured epithelial cellseither A549 or Beas-2b can be stimulated to produce BAFF or APRIL by viral infection, dsRNA or cytokines stimulation.

Results:

1 Induction of BAFF and APRIL mRNA in A549 cells after 12h stimulation
Induced expression of BAFF and APRIL mRNA in A549 cells varied according to the stimuli used. For example, BAFF mRNA was observed at 12hrs post INF β stimulation and IFN α and there was no expression for APRIl
2 Induction of BAFF mRNA in Beas-2b cells after 12h stimulation
Expression of mRNA BAFF has been detected post stimulation with IFN β and IFN α.
3 I INF $\boldsymbol{\beta}$ time course
Among the stimulantsfactors used, we have found that IFN §was significantly induced BAFF expression. Thus, weaimed to see in which time point.
4 RSV infection of cultured BEAS-2B cells induces BAFF expression by an interferon $\boldsymbol{\beta}$ dependantmechanism.

Conclusions: Collectively our results indicate that airway epithelial cells can produce BAFF in an interferon dependant manner. Suggesting that the Airway epithelial could help support B cell growth development and Ab production in the Lung.

P0091
Increased hyaluronic acid in the airway following influenza infection contributes to heightened susceptibility to secondary bacterial infection

T. J. Bell,* R. J. Snelgrove* & T. Hussell†
**Imperial College London, National Heart & Lung Institute, London, UK, †Manchester Collaborative Centre for Inflammation Research, The University of Manchester, Manchester, UK*

Purpose/Objective: Severe respiratory viral infections are often associated with bacterial complications. We have previously demonstrated the importance of the regulation of innate immunity in this altered susceptibility. This current work aims to elucidate the influence of airway hyaluronic acid (HA) on the innate immune rheostat following respiratory viral infection.

Materials and methods:

1 C57BL/6 mice were infected with 2–15 PFU/mouse A/PR8/34 (H1N1) influenza. HA content in bronchoalveolar lavage (BAL) fluid was determined by ELISA. Cell surface marker expression was determined by flow cytometry.
2 Lung integrity was altered by intranasal administration of MIP-2 or histamine.
3 Alveolar macrophages isolated from naïve mice were incubated with HA fragments for 4 h, allowed to recover for 18 h, then stimulated with LPS for 20 h. Cytokine levels in cell culture supernatants were determined by ELISA.
4 Mice were treated with 50 $\boldsymbol{\mu}$g HA 2 h prior to infection with 10^4 CFU/mouse D39 *Streptococcus pneumoniae*. Organ homogenates were cultured to determine the number of recoverable bacteria.

Results: HA content in the airway was increased by four log units following influenza infection, with a significant increase in the amount of HA persisting for more than 6 weeks. There was a substantial loss of integrity in the lung post viral infection, as determined by airway albumin content and staining of epithelial damage markers. Replicating this damage, however, by inducing infiltration of neutrophils or by disrupting endothelial tight junctions did not result in a substantial increase in HA.

CD44 is one of the major cellular receptors for HA on leukocytes and is highly expressed by alveolar macrophages (AM). CD44 has been previously shown to play a key role in the resolution of inflammation, and can trigger expression of the TLR negative regulator A20 when complexed with HA. Here we demonstrate that *ex vivo* exposure of AM to HA results in a significant desensitisation to LPS challenge. *In vivo*, introduction of HA into the airway of mice prior to bacterial challenge markedly reduced bacterial clearance and was associated with reduced cellular recruitment to the site of infection.
Conclusions: Following influenza-induced inflammation, increased hyaluronic acid in the airway contributes to the desensitisation of alveolar macrophages to TLR stimuli with a resultant increase in susceptibility to secondary bacterial infection.

P0092
Induction of pro-inflammatory cytokines in human NALT and peripheral blood by domain 4 pneumolysin

C. Gray,[*] A. Kasnekar,[†] P. McNamara,[†] H. Beer,[‡] M. McCormick,[‡] T. Mitchell[§] & Q. Zhang[*]
[*]Department of Clinical Infection Microbiology and Immunology, Institute of Infection and Global Health, Liverpool, UK, [†]Alder Hey Children's Hospital, Liverpool, UK, [‡]ENT Department, Royal Liverpool University Hospital, Liverpool, UK, [§]Infection and Immunity, University of Glasgow, Glasgow, UK

Purpose/Objective: Pneumococcal infection causes significant morbidity and mortality worldwide. Currently available vaccines are either not effective in young children or limited in serotype coverage. Pneumolysin (Ply) is a protein toxin that is conserved in virtually all serotypes of pneumococci. Ply has four domains, which together induce pore formation on cell membranes. The fourth domain (D4Ply) is important in cell binding. Our previous studies have shown that D4Ply is a potent activated of T cell proliferation. We have studied the induction of cytokines in immune cells from both human nasal-associated lymphoid tissue (NALT) and peripheral blood.
Materials and methods: Mononuclear cells (MNC) from adenotonsillar tissues and peripheral blood mononuclear cells (PBMC) were isolated from children and adults undergoing adenotonsillectomy. $CD14^+$ monocyte and $CD3^+$ T lymphocytes were isolated from PBMC using MACS magnetic cell separation. Recombinant domain 4 Ply (D4Ply), which lacks toxicity was co-cultured with adenotonsillar MNC, purified monocytes or T cells. Expression of different cytokines including TH1, TH2 and TH17 cytokines was analysed by cytometric bead array, intracellular cytokine staining and ELISA. Activation of Toll-like receptor signaling was examined by RT-PCR array.
Results: D4Ply induced a predominant pro-inflammatory cytokine profile including IL-1β, Il-6, TNF-α (monocytes), IL-17 and INF-γ (T cells). D4Ply induced a stronger INF-γ response in PBMC, mainly by $CD8^+$ T cells, whereas there was a stronger IL-17 response in $CD4^+$ adenotonsillar MNC. The RT-PCR array showed that D4Ply stimulation of monocytes induced up-regulation of key genes in Toll-like receptor signaling pathway.
Conclusions: D4Ply activates both T cells and antigen presenting cells and can induced significant pro-inflammatory cytokine expression. Further studies are underway to examine the immunological pathway of cell activation by D4Ply and explore its potential as a human vaccine against pneumococcal infection.

P0093
Infiltration of ROR gamma t positive lineage negative lymphocytes into the lung during lipopolysaacharide-induced acute lung injury

R. Muir, D. McAuley & R. Ingram
Centre for Infection and Immunity, Queens University Belfast, Belfast, UK

Purpose/Objective: The hallmark features of acute lung injury (ALI) include neutrophilic infiltration with the release of inflammatory cytokines causing damage to the alveolar epithelial-capillary endothelial barrier leading to pulmonary oedema. IL-17 produced by lymphocytes is known to enhance recruitment of neutrophils by promotion of other inflammatory cytokines, including IL-8 and IL-6. However, detailed characterisation of the lymphocytes infiltrating the lung in the early phase of ALI has not been reported.
Materials and methods: Lung tissue cells were characterised by flow cytometry in a murine model of ALI induced by intratracheal lipopolysaacharide (LPS).
Results: We observed increased numbers of lymphocytes in the lung 24 h after LPS treatment, including an increase in retinoic acid-related orphan receptor-gamma t $(ROR\gamma t)^+$ lymphocytes. $ROR\gamma t^+$ lung lymphocytes were observed to be predominantly $CD4^+$ T cells (18%), $CD8^+$ T cells (20%) cells and a Lin^- population (40%). Furthermore, we characterised the expression of a variety of cell surface markers associated with the innate lymphoid cells in the $ROR\gamma t^+Lin^-$ population in the lung and ex-vivo stimulation of cells was used to confirm IL-17 production. Using an IL-17KO mouse we have demonstrated a key role for this cytokine in the recruitment of neutrophils into the lung, as we observed a significant reduction in neutrophil numbers in the absence of IL-17.
Conclusions: These results identify a key role for innate cells, more specifically a $ROR\gamma t^+Lin^-$ population in the lung that contribute to IL-17 production and therefore inflammation in ALI.

P0094
Influence of metals onto sIgA, IgA1 and IgA2 production in saliva in patients undergoing implantation therapy in dentistry

Y. Lyuya-Mi, S. Podzimek, M. Tomka, P. Sommerova & J. Prochazkova
First Faculty of Medicine and GUH Prague, Institute of Clinical and Experimental Dental Medicine, Charles University, Praha, Czech Republic

Purpose/Objective: Purpose of the study: The aim of this study was to compare sIgA, IgA1 and IgA2 production in saliva before, during and after implantation therapy in patients undergoing implantation therapy in dentistry.
Materials and methods: Material and methods: Saliva from 19 patients was collected before implantation therapy, from 15 patients after implatation and before prosthesis and from 16 patients after implantation and prothetic therapy. Secretory IgA, IgA1 and IgA2 antibody production was established using RID method.
Results: Results: The levels of all three types of IgA antibodies (secretory IgA, IgA1 and IgA2) in saliva of patients were increasing during implantation process, significantly increased levels after implantation and prosthetic therapy in comparison to levels before implantation therapy were found in secretory IgA and IgA2 antibodies.
Conclusions: Conclusion: Increased levels of type A antibodies during implantation therapy in saliva of patients show that defence immune reactions were already started.
Acknowledgement: The study was supported by research projects SVV 2012 nr. 264501 and PRVOUK-P28/LF1/6 ofMinistry of Education, Youth and Sports, Czech Republic and by project NT 13087-3 of the Internal Grant Agency, Ministry of Health, Czech Republic.

Intravaginal cell recruitment and upper genital tract pathology in mice pretreated with hyaluronic acid and infected with *Chlamydia muridarum*

E. Koroleva, N. Kobets & N. Zigangirova
Medical Microbiology, Gamaleya Research Institute for Epidemiology and Microbiology, Moscow, **Russia**

Purpose/Objective: Chlamydia is a widely spread chronic urogenital infection that essentially affects reproductive health worldwide. There is well acknowledged evidence that Chlamydia infection induces a range of immunopathological reactions, while the components of early immune response that might lead to protection from upper genital tract pathology and re-infection require further elucidation. In this study we evaluated early intravaginal cell recruitment in response to *Chlamydia muridarum* infection in mice pretreated with high molecular weight hyaluronic acid (HA) as a prospective delivery agent to assess how it effects both intravaginal cell recruitment and Chlamydia induced upper genital tract pathology.
Materials and methods: BALB/c mice were pretreated with 0.1% HA intravaginally (i.v.). Three weeks later they were infected i.v. with 10^6 IFU of *C. muridarum* and numbers and phenotypes of cells from vaginal washes were analyzed 48 h post infection (PI) by flow cytometry. Vaginal shedding and Chlamydia DNA in lower and upper genital tract were assessed at different time points post infection. Upper genital tract pathology (hydrosalpinx) was evaluated 4 weeks post infection.
Results: We found that HA induced a dramatic change in numbers and phenotypes of cells recruited to vagina in response to *C. muridarum* compared to untreated mice. Three fold increase in total cell numbers in HA treated mice was a accompanied with fivefold increase in $CD4^+$ T cells, while $CD8^+$ T cells predominated in vaginal washes of untreated mice. There was also an increase in neutrophils, macrophages and dendritic cells in HA-treated mice. We did not find a statistically significant difference in either vaginal shedding of bacteria or the levels of Chlamydia DNA in upper or lower tract between the groups, however a dramatic increase in incidence and severity of hydrosalpinx was observed in mice pretreated with HA. Possible correlations between the repertoire of cells recruited to the vagina in response to Chlamydia and Chlamydia induced genital pathology are currently under the study.
Conclusions: Our results demonstrate that introvaginal repertoire of cells recruited in response to Chlamydia can differ in mice with moderate or severe upper genital tract pathology even if they have the similar levels of pathogen DNA and vaginal shedding. Potential predictive value of this observation needs further elucidation.

P0096

Macrophage development in the neonatal mouse intestine

A. Bravo-Blas & C. C. Bain
Immunology, Institute of Infection Immunity and Inflammation, Glasgow, UK

Purpose/Objective: Macrophages (mϕ) are essential for both homeostasis and inflammation in the intestine. Adult gut mϕ are derived from pro-inflammatory monocytes, but acquire high phagocytic ability and production of IL10, allowing them to scavenge commensal bacteria without provoking inflammation. Aberrant mf reactions to microbiota drive inflammatory bowel disease (IBD), suggesting that the usual adaptation processes have been disrupted. The most important period for establishing the mucosal mϕ pool is likely to be during early life when the microbiota is becoming established. Here we have explored how intestinal mϕ acquire their normal pattern during the perinatal period.
Materials and methods: Intestine from CX3CR1-GFP reporter mice was analysed from E19.5 to adulthood using multi-parameter flow cytometry.
Results: Intestinal mϕ express very high levels of CX3CR1 before and around birth, but unlike adult mϕ, they are class II MHC^{neg} and are heterogeneous for expression of F4/80 and CD11b. One group is $F4/80^{hi}$ $CD11b^{int}$ and is similar to the yolk sac derived mf described in other tissues. The other subset is $F4/80^{int}$ $CD11b^{hi}$ and may be derived from foetal liver. These populations remain constant in number during the first 2 weeks of life, but $F4/80^{hi}$ $CD11b^{int}$ mf acquire class II MHC. Around weaning an influx of classical $Ly6C^{hi}$ monocytes gives rise to adult-type $CX3CR1^{hi}$ $F4/80^{hi}$ $CD11b^{hi}$ mϕ, presumably reflecting the increasing numbers of commensal bacteria.
Conclusions: Mϕ in neonatal intestine are a complex mix of cells of different origin, whose composition changes as the gut and its microbiota mature. These processes are likely to have important implications for future health and may contribute to susceptibility to IBD.

P0097

Methanoarchaea activate innate host defense mechanisms

C. Bang,* K. Weidenbach,* T. Scholzen,† H. Heine‡ & R. A. Schmitz*
**Institute for General Microbiology, Christian-Albrechts-Universität zu Kiel, Kiel, Germany, †Division of Fluorescence Cytometry, Research Center Borstel, Borstel, Germany, ‡Division of Innate Immunity, Research Center Borstel, Borstel, Germany*

Purpose/Objective: The methanoarchaea Methanosphaera stadtmanae and Methanobrevibacter smithii are known to be part of the indigenous human gut microbiota. Although few studies focusing on the immunogenic effect of these strains are available, data for methanoarchaeal activation of innate host defense mechanisms are rare.
Materials and methods: We studied and report here on the cytokine response of peripheral blood mononuclear cells (PBMCs) and monocyte-derived DCs after incubation with *M. stadtmanae* and *M. smithii*.
Results: High cytokine release of TNF-a, IL-1-b, IL-8 and IL-6 was obtained after 20 h of stimulation with *M. stadtmanae*, whereas stimulation with *M. smithii* only lead to minor cytokine release. Moreover, phagocytosis of methanoarchaea by PBMCs and monocyte-derived dendritic cells (moDCs) was demonstrated by confocal microscopy and shown to be required for cellular activation by application of specific inhibitors. Western-Blot analysis demonstrated activation of MAP-kinases of stimulated moDCs after 90 min. Transfection of HEK293 cells with several common innate immune receptors did not reveal activation by the methanoarchaeal strains via TLRs or NLRs, thus pointing towards a different recognition mechanism.
Conclusions: This first comprehensive study of the inflammatory response of human immune cells to M. stadtmanae and M. smithii strongly suggests that methanoarchaea are specifically recognized by components of the human innate immune system and hence most likely have an effect on the immunomodulation within the human gut.

P0099

Myeloid activators of RORγ t- innate lymphoid cells

C. A. Connor & A. Diefenbach
Institute for Medical Microbiology & Hygiene, AG Diefenbach, Freiburg, Germany

Purpose/Objective: Inflammatory Bowel Diseaseisaheterogeneous group of inflammatory disordersarising from defects inmucosalpermeability coupled with unregulated, hyperresponsive effector cells. Theroleofadaptive immunity in IBD has been focusofmuch investigation, but the part played by innateimmunesystemremainspoorly defined. The innateimmune systemisanevolutionarily ancient componen to fmammalianimmunity and, as such, may provide important clues to

the aetiopathogenesis of IBD. It has previously been determined that an IFN-y producing, RORγt$^-$ subpopulation of innate lymphoid cells (ILC) is a potent inducer of innate colitis in mice. RORγt$^-$ ILC cells differentiate from RORγt$^+$ ILC as a result of largely unknown molecular signalling. We report here on the myeloid populations responsible for activating these colitogenic LTi-like cells and on the cytokines involved in the activation process.

Materials and methods: CD40-mediated colitis was induced in Rag2$^{-/-}$ mice on a C57BL/6 background. Mice were sacrificed 6 or 7 days post-injection. Lamina propria lymphocytes were analysed for expression of cell surface markers and intracellular cytokines using the MoFlo analysis, FACS analysis and real-time PCR.

Results: Anti-CD40 stimulation led to the induction of proinflammatory cytokines, with IL-12, IL-27 and IL-6 production peaking at 0.5 days postinjection (p.i.), TNF at 2 days p.i. andI L-23 at 7 days p.i. CD11b$^+$CD11c$^-$ (MHC II$^+$ Ly6C$^+$ F4/80$^+$ CD103$^+$ Ly6C/G$^+$) cells were the main producers of IL-12, IL-27 and IL-6. TNF was produced mainly by CD11b$^+$CD11c$^+$ (MHC II$^+$ Ly6C$^-$ F4/80^{lo} CD103$^+$ Ly6C/G$^-$) cells. CD11b$^+$CD11c$^+$ cells also secreted the greatest amount of IL-23 overall. IFN-γ production by RORγt$^-$ ILC correlated with the kinetic of IL-12, IL-27 and IL-6 production.

Conclusions: Activation of RORγt$^-$ ILC occurs rapidly upon CD40-crosslinking of myeloid cells and correlates to the onset of systemic wasting. CD11b$^+$CD11c$^-$ cells are the main myeloid population involved in the transition of ILC to a RORyt$^-$ phenotype. IL-6, IL-12 and IL-27 contribute to the induction of IFN-γ production by RORγt$^-$ ILC. The delayed production of TNF raises the possibility that activated RORyt$^-$ ILC subsequently stimulate myeloid cells. Although IL-23 is required for colitis development, the kinetic of IL-23p19 expression does not correlate with IFN-γ expression. Thus, IL-23 may instead be required to maintain IFN-γ expression at later stages.

P0100
Neutrophils are rapidly recruited by PT-gliadin itself

K. M. Lammers,* M. Chieppa,† L. Liu,‡ C. A. Parent‡ & A. Fasano*
**Mucosal Biology Research Center, University of Maryland School of Medicine, Baltimore MD, USA, †Lymphocyte Biology Section Lab Immunology, NIAID/NIH, Bethesda, MD, USA, ‡Lab Cellular and Molecular Biology Center for Cancer Research, NCI/NIH, Bethesda, MD, USA*

Purpose/Objective: Gliadin, a component of gluten-containing cereals, triggers celiac disease (CD) in genetically predisposed individuals. We have shown that gliadin induces a profound increase in gut permeability. Histology of CD gut mucosa consistently shows massive influx of neutrophils. We aimed at studying the early immunological changes evoked by pepsin-trypsin digested-gliadin (PTG) to understand its role in neutrophil influx in CD.

Materials and methods: Ten C57BL/6 mice were given PTG or PBS by gavage. After 2h mice were sacrificed and duodenal tissue was examined for PTG effects on tight junction (TJ) integrity and immune cell subsets by fluorescence microscopy and flow cytometry. Neutrophil recruitment was monitored *in vivo* after luminal exposure to PTG or PBS for 2h by intravital microscopy using five Lys-GFP mice that have green-fluorescent neutrophils. Neutrophils were isolated from bone marrow of eight C57BL/6 mice, and chemotaxis to PTG, or fMLP as positive control, was monitored *in vitro* using a Taxi-scan assay.

Results: PTG caused redistribution of E-cadherin and ZO-1 TJ proteins, a measure of TJ disassembly, and increased numbers of GR1$^+$ granulocytes. Intravital microscopy revealed a rapid and massive neutrophil tissue influx within 2h after luminal challenge with PTG. This observation was confirmed in Taxi-scan assay.

Conclusions: PTG induces a massive neutrophil recruitment in the mouse intestinal mucosa. *In vivo* and *in vitro* models that allow real-time monitoring of neutrophils movements strongly suggest that PTG itself is a chemo-attractant factor for neutrophils.

P0102
Resident and pro-inflammatory macrophages in the colon represent alternative context dependent fates of the same Ly6Chi monocyte precursors

C. C. Bain, C. L. Scott & A. M. Mowat
Centre for Immunobiology, Institute of Infection Immunity and Inflammation, Glasgow, UK

Purpose/Objective: Macrophages (mϕ) are essential for intestinal homeostasis, but are also central to the pathology of inflammatory bowel disease. It is not clear whether distinct populations of mϕ are responsible for these different functions, or if the resident mϕ change during inflammation. We set out to investigate the phenotypic and functional characteristics of mϕ present in the steady state colon and during acute experimental colitis, and sought to determine the origin of these cells.

Materials and methods: CX3CR1-GFP reporter mice were used for phenotypic analysis of colonic mϕ. Acute colitis was induced by feeding 2% DSS in drinking water for up to 6 days. For adoptive transfer studies, Ly6C^{hi} BM monocytes from CX3CR1-GFP mice were transferred into unmanipulated CCR2$^{-/-}$ mice.

Results: We show here that most resident mϕ in resting mouse colon express very high levels of CX3CR1, are avidly phagocytic and MHCII^{hi}, but are desensitised to TLR stimulation and produce IL10 constitutively. A smaller population of CX3CR1^{int} cells is present in resting colon which is phenotypically heterogeneous, responds robustly to TLR ligation and expands dramatically during experimental colitis. Using a combination of gene profiling, immunophenotyping and adoptive transfer experiments, we demonstrate that rather than representing independent mϕ populations, CX3CR1^{int} and CX3CR1^{hi} cells in the steady state intestine represent cells at different stages of a progressive differentiation continuum. Under normal conditions, 'inflammatory' Ly6C^{hi} CCR2$^+$ monocytes enter the mucosa and differentiate into CX3CR1^{hi} mϕ through a CX3CR1^{int} intermediary stage. This phenotypically identifiable process is accompanied by a switch in cytokine production, TLR responsiveness and gene expression. Importantly, during inflammation this differentiation process is disrupted, leading to an accumulation of TLR-responsive TNFa-producing CX3CR1^{int} mϕ.

Conclusions: These results provide the first evidence that 'resident' and 'inflammatory' mϕ in the colon may be derived from the same monocyte precursor whose ultimate fate is determined locally and depends on the presence or absence of inflammation. Targeting these events could offer routes for therapeutic intervention in IBD.

P0103
Role of glucocorticoid receptor in regulation of pulmonary dendritic cells gene expression

M. Weitnauer,* L. M. Schmidt,† N. Ng Kuet Leong,* S. Huebner,‡ J. Tuckermann‡ & A. Dalpke*
**Department of Infectious Diseases Medical Microbiology and Hygiene, University of Heidelberg, Heidelberg, Germany, †Institut of Pathology Biobanking DCIF, University of Heidelberg, Heidelberg, Germany, ‡Leibniz-Institute for Age Research, Fritz Lipmann Institute, Jena, Germany*

Purpose/Objective: Since the lung is constantly challenged with antigens, airway epithelial cells are important to control local immunity in order to avoid chronic inflammation. Recently we could demonstrate a role of epithelial cell derived prostaglandin E2 (PGE2)

in modulating IL12 and TNFalpha synthesis of respiratory tract dendritic cells (DC).
Materials and methods: In order to further investigate the involved pathways we analyzed the gene expression of murine bone marrow derived dendritic cells (BMDC) treated with airway epithelial cell conditioned medium (ECCM-DC) using microarray.
Results: Among the 97 genes being regulated by airway epithelial cells 61 were up- and 36 were down-regulated. The two most upregulated genes were Ms4a8a (18.914-fold) and Chi3l3 (18.513 fold). Both genes are known to be highly expressed in alternatively activated macrophages (M2). Surprisingly Ms4a8a and Chi3l3 gene expression was not affected by PGE2. When analyzing transcription factor binding site over representation in genes regulated by epithelial conditioning, clustering of sites for nuclear receptors was observed, e.g. glucocorticoid receptor (GR). Since glucocorticoids are known to be important for the induction of M2 macrophages we investigated the potential role of GR in modulating Ms4a8a and Chi3l3 expression in ECCM-DCs. Application of Dexamethasone to BMDCs induced the expression of Ms4a8a and Chi3l3 which was further potentiated by treatment with ECCM. In line with this, pharmacological inhibition of GR by RU486 as well as genetic deletion of GR could inhibit ECCM mediated induction of Ms4a8a and Chi3l3 in BMDCs.
Conclusions: Our results indicate a physiological role of glucocorticoids in regulation of pulmonary dendritic cell gene expression and function via GR.

P0104
TAM receptors and their role in the regulation of lung innate immunity

T. Fujimori, R. Snelgrove & T. Hussell
Imperial College London, National Heart and Lung Institute, London, UK

Purpose/Objective: The role of TAM receptors are well characterised in autoimmunity, developmental biology and cancer biology. Their role in infectious diseases is now being elucidated. We have strong preliminary data showing that TAM receptors (Axl and MerTK in particular) become significantly up-regulated on alveolar macrophages following primary influenza infection, and this may account for the high rate of bacterial co-infection in hospitalised patients. In this study, the role of TAM receptors in various infection models was investigated and de-sensitisation of airway macrophages to bacterial infection following influenza infection was assessed.
Materials and methods: Using murine model, we extensively characterised TAM receptor expression profiles on various innate immune populations over 6 weeks post primary influenza infection. We have also characterised the expression of both Axl and MerTK following bacterial and fungal infections. We also manipulated Axl-GAS6 (Axl ligand) axis and monitored subsequent alteration in inflammatory cytokine production profile and phagocytic ability of alveolar macrophages.
Results: The expression profile of Axl on both alveolar macrophages and on neutrophils following influenza infection became significantly up-regulated, remaining higher than at its homeostatic level even 6 weeks after initial infection. Furthermore, Axl also becomes up-regulated during bacterial infection, and Axl expression shows 'Dose-response' to bacterial burden. Preliminary data also showed that the pre-treatment of alveolar macrophages with the Axl ligandGAS6 reduces production of inflammatory cytokines and TLR desensitisation.
Conclusions: This study has elucidated information into the behaviour of Axl and MerTK expression following various infection models. Sustained up-regulation of Axl following primary influenza infection has significant clinical implications as it is involved in the desensitisation of TLRs, which may cause patients to have a predisposition to secondary bacterial complications. Moreover, the manipulation of Axl-GAS6 axis has allowed us to gain insight into the phenotypic changes of alveolar macrophages brought about by influenza infection. The results of this study would allow us to develop a new approach in the intervention of secondary bacterial complications via the antagonism of Axl in the later stages of diseases.

P0105
The role of cathelicidins in protection against pathogenic lung infections

E. Gwyer Findlay,* S. M. Logermann,* P. Beaumont,* P. G. Barlow,* A. Mackellar,* R. L. Gallo,† J. R. W. Govan,‡ P. M. Fitch,* J. Schwarze* & D. J. Davidson*
**CIR, University of Edinburgh, Edinburgh, UK, †UCSD, Department of Medicine, San Diego, USA, ‡CID, University of Edinburgh, Edinburgh, UK*

Purpose/Objective: Cathelicidins are cationic host defence peptides with key roles in innate immunity. The sole human cathelicidin gene *CAMP* encodes the human antimicrobial protein of 18kDa (hCAP18), that is proteolytically cleaved to active peptides, with the predominant form being LL-37. LL-37 has been shown to perform a diverse array of microbicidal and immunomodulatory roles during infection. Mice deficient in the murine orthologue of *CAMP* (*Camp*) have increased susceptibility to bacterial infection in multiple systems, demonstrating the critical and non-redundant nature of cathelicidin-mediated protection in host defence against infection. However, the mechanisms underpinning this protection remain unclear, and the role of cathelicidins in host defence against viral infections has not been well characterised.
Materials and methods: Using *in vitro* and *in vivo* models of pulmonary infection with human respiratory pathogens *Pseudomonas aeruginosa*, respiratory syncytial virus (RSV) and influenza A virus (IAV), we demonstrate key antimicrobial and host immunomodulatory properties of cathelicidins.
Results: We report a number of different mechanisms by which cathelicidins promote pathogen clearance and protect against pulmonary infection, including: 1) direct anti-viral activity against both RSV and IAV, and induction of an antiviral state in airway epithelial cells, and 2) modulation of the cellular inflammatory response to infection; with diminished pathogen clearance and neutrophil influx in cathelicidin knockout animals (*Camp*$^{-/-}$) which could be both corrected in *Camp*$^{-/-}$ mice and enhanced in wild-type animals by therapeutic cathelicidin administration.
Conclusions: These data demonstrate key roles for cathelicidins in host defence against pathogenic bacterial and viral pulmonary infections and have the potential to inform the development of synthetic analogues as novel immunomodulatory antimicrobial therapeutics.

P0107
The role of dendritic cells in the initiation and maintenance in a pre-clinical model of ulcerative colitis

U. Wenzel,* A. Rydström† & M. J. Wick*
**Biomedicine, Microbiology and Immunology, Gothenburg, Sweden, †Clinical Virology/Infectious Diseases, Sahlgrenska Cancer Center, Gothenburg, Sweden*

Purpose/Objective: The mucus layer is an important component of an intact intestinal barrier and combined with appropriate immune regulation ensures that reactivity to luminal flora is kept at bay and intestinal tolerance is maintained. Evidence supports that a barrier breach results in an inappropriate immune response towards commensals inducing pathogenic T cells. In this study we analyze the role of dendritic cells in the initiation and maintenance of colitis in mice

lacking the protective mucus layer in the colon, thus the normal flora is in direct contact with intestinal cells, a situation that mimics the events triggering ulcerative colitis in humans.
Materials and methods: Single cells suspensions form $Muc2^{-/-}$ mice, lacking the gene for mucin 2 and thus lacking the protective mucus layer specifically in the colon are studied by multicolor flow cytometry as well as whole tissue lysates are analyzed by cytometric bead arrays.
Results: Single cell suspensions of colon LP were analyzed in regards to innate cell populations. These analyses revealed a significant increased of neutrophils in $Muc2^{-/-}$ mice. A 'cut off value' discriminating inflamed from non-inflamed $Muc2^{-/-}$ mice was established using the relative amount of neutrophils detected. According to this separation we further identified differences in dendritic cell subpopulations in the colon, revealing that the colon of inflamed animals had higher percentages of $CD11b^+$ DC, while at the same time the number of $CD103^+$ $CD11b^-$DC decreased though the relative amount of $CD103^+$ $CD11b^+$ DC did not alter in inflamed colon LP. Cytometric bead arrays of whole tissue lysates of parallel colon samples revealed a local increase in typical pro-inflammatory cytokines specifically a significant increase in IL-6, IL-17a and IFN-γ in later stages of the inflammation.
Conclusions: Together these findings suggest that the infiltration of neutrophils and monocytes initiate a cascade of events resulting in a Th17 biased immune response against luminal antigens.

P0108

The role of Th17 response towards a protein-based *Streptococcus pneumoniae* vaccine

M. Cortese,* E. Bizzarri,† A. Corrado,† G. Bensi,† P. Ruggiero,† M. Moschioni,† V. Masignani,† S. Bertholet,† E. De Gregorio† & A. Seubert†
**DiSCAFF, University of Piemonte Orientale 'A.Avogadro', Novara, Italy, †Immunology, Novartis V&D, Siena, Italy*

Purpose/Objective: Current vaccines to prevent *S.pneumoniae* infection are based on the induction of antibodies (Ab) against some of the more than 90 serotype-specific capsular polysaccharides. A different strategy to a successful vaccine could be based on broadly cross-protective protein antigens. Additionally, this strategy offers the possibility to exploit both arms of the immune system, coupling Ab-mediated to cell-mediated immunity. This is important as several findings suggest that natural immunity to *S.pneumoniae* might be acquired independently of anticapsular Ab and implicate IL17-producing $CD4^+$ T helper (Th17) cells. With our study we set to unveil the contribution of Th17 responses to the resolution of pneumococcal infection in mice.
Materials and methods: We assessed quantity and quality of T cell responses in mice immunized with different vaccine formulations and via different routes. Then, we adoptively transferred serum or CFSE-labeled $CD4^+$ T cells from vaccinated mice to naïve recipients prior to bacterial challenge. We closely followed infection kinetics and assessed weight loss/ survival of mice, bacterial counts in lung and blood, as well as recruitment of immune cells into the lung.
Results: Intranasal (i.n.) vaccination with a mucosal adjuvant induces higher Th17 responses than subcute (s.c.) administration with alum. Yet, s.c. induced responses can be enhanced by co-formulation with TLR agonists. Vaccine-induced CFSE-labeled $CD4^+$ T cells rapidly accumulate in the lung of infected mice and can contribute directly to protection. Accordingly, recruitment of other cell types is enhanced in actively or passively immunized mice, leading to lower bacterial counts and greater survival of mice.
Conclusions: The role of Th17 cells in pneumococcal infection was studied so far only after direct vaccination in different mouse knockout models. Applying adoptive transfer of vaccine induced $CD4^+$ T cells, we could unequivocally confirm their protective potential. This underlines the added value of a protein-vaccine that can induce both antibodies and T cells over a solely Ab-inducing glycoconjugate. Application of optimized vaccine formulations and administration routes for the induction of T cell and antibody responses should allow to exploit the combined potential of both arms of the immune system.

A novel model of MHC class I-related (MR1)-mediated activation of MAIT cells

J. E. Ussher, M. Bilton, A. Kurioka, C. B. Willberg & P. Klenerman
Nuffield Department of Medicine, Peter Medawar Building for Pathogen Research, Oxford, UK

Purpose/Objective: Mucosal associated invariant T (MAIT) cells are an innate-like T cell populationthat comprise ~10% of the $CD8^+$ T cell compartment, express a semi-invariant (Vα7.2) T cell receptor and are restricted by the non-polymorphic, highly evolutionarily conserved MHC class I-related 1 (MR1) protein. While MAIT cells are activated by bacteria in an MR1-dependent manner the ligand(s) presented by MR1 and how it is processed are yet be defined. We sought to develop an *in vitro* model of MR1-dependent MAIT cell activation that would enable us to address these questions.
Materials and methods: Human PBMC or THP-1 cells were incubated overnight with *E. coli* and MAIT cell activation was assessed by intracellular cytokine staining and flow cytometry. The effect of blocking antibodies (MR1, IL-12, IL-18), pharmacological inhibitors, or siRNA-mediated gene knockdown was investigated. Co-localisation of MR1 with other cellular markers was assessed by confocal microscopy.
Results: Overnight stimulation of PBMC with *E. coli* lead to specific activation of MAIT cells, as assessed by CD69 and interferon-γ expression. This was partially inhibited by antibody blockade of MR1 but not IL-12 and IL-18. In contrast stimulation of purified $CD8^+$ T cells by *E. coli*-exposed THP-1 cells was entirely MR1-dependent within the first 6 h but by 20 h was mediated by both MR1 and IL-12 and IL-18. In both systems, inhibitors of endosomal acidification and of lysosomal cathepsins inhibited MAIT cell activation. Confocal microscopy revealed partial co-localisation of MR1 with lysosomes and surface expression of MR1 following exposure to *E. coli*. Furthermore, siRNA-mediated knockdown confirmed the requirement of β-2-microglobulin for efficient MR1-dependent activation of MAIT cells.
Conclusions: We describe a novel model MR-1-dependent activation of primary human MAIT cells. This model reveals that MR1-dependent activation is more rapid than cytokine-mediated activation and is dependent upon endosomal acidification, cathepsins, and β-2-microglobulin. This model will assist in further dissection of the MR1 pathway and identification of the microbial ligand(s) that it presents.

A search for non glycosphingolipid ligands as self lipids, causing CD1d-autoreactivity of type II Natural Killer T (NKT) lymphocytes

S. Rhost,* L. Löfbom,* B. M. Rynmark,† B. Pei,‡ J. E. Månsson,† S. Teneberg,§ M. Blomqvist† & S. L. Cardell*
**Biomedicine, Microbiology and Immunology, Gothenburg, Sweden, †Neuroscience and Physiology, Psychiatry and Neurochemistry, Gothenburg, Sweden, ‡Allergy and Immunology, Developmental Immunology, La Jolla, CA, USA, §Biomedicine, Medical Biochemistry and Cell Biology, Gothenburg, Sweden*

Purpose/Objective: NKT cells make up a potent immunomodulating subset of T lymphocytes that is activated by self-lipids presented by CD1d molecules. So far, the identity of most self-lipids presented by CD1d underlying the autoreactivity of NKT cells are unknown. In this study, we set out to identify self-lipids causing autoreactivity of a sulfatide reactive, CD1d restricted, murine type II NKT cell hybridoma, XV19.
Materials and methods: To this end we fractionated lipids from a highly stimulatory antigen presenting cell (APC), A20CD1d TD and tested the stimulatory capacity of the type II NKT cell hybridoma, XV19.
Results: Two active glycoshpingolipids (GSL); glucosylceramide (Glcβ1-1′Cer) and galactosylcermide (Galβ1-1′Cer) were identified as active ligands for XV19 cells. The most potent isoform of the GSL was the lysoforms, lacking the fatty acid chain, followed by isoforms with the long fatty acid chain of C24. Thus, one NKT cell hybridoma could recognize sulfatide, GlcCer and GalCer both as presented by APC in a CD1d-dependent manner, and when presented on plate bound CD1d. Furthermore, we show that XV19 cells were not dependent on GSL for natural CD1d autoreactivity, using APC deficient in all GSL.
Conclusions: These results suggesting that self ligands that determine CD1d-autoreactivity of XV19 cells are non GSL. Preliminary data suggest reactivity to non GSL, and investigations are ongoing to determine the role of non GSL in CD1d autoreactivity. Identifying endogenous lipid ligands that activate type II NKT cells will be of fundamental importance for our understanding of NKT cell activation in autoimmunity and tumor immunity.

Decreased IL-17$^+$ CD16$^+$ and IL-10$^+$ CD16$^+$ NK cells in Behçet's disease

F. Cosan,* E. Aktas Cetin,† N. Akdeniz,† Z. Emrence,‡ A. Cefle* & G. Deniz†
**Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, Kocaeli University, Kocaeli, Turkey, †Department of Immunology, The Institute of Experimental Medicine (DETAE), Istanbul University, Istanbul, Turkey, ‡Department of Genetics, The Institute of Experimental Medicine (DETAE), Istanbul University, Istanbul, Turkey*

Purpose/Objective: Behcet's disease (BD) is a multi-system inflammatory disorder with recurrent inflammation attacks. BD pathogenesis includes genetical, environmental and immunological factors. The main genetic susceptibility is HLA-B*51, but the mechanism is unknown. HLA molecules play a key role with the interaction with natural killer (NK) cells. NK cells are also critical components of the innate immune response by virtue of their capacity to produce a variety of cytokines and have to ability to both lyse target cells and serve as regulators of immune responses by releasing Th1, Th2 and Th17 type cytokines. In this study, cytokine secretion and cytotoxic activity of NK cells in BD were investigated.
Materials and methods: The study group consists of BD patients (n = 26, mean age = 37.2 ± 9.7) with mucocutaneous involvement and healthy subjects (n = 12, mean age = 32.5 ± 8). The patients have not received any immunsupresive treatment. Peripheral blood mononuclear cells (PBMC) were used as effector cells and K562 cell line was used as target cell. PBMCs stained with CD107a were incubated with K562 cells with an effector: target (10:1) for 4 h. Cells were stained with anti-CD16 antibody for the determination of CD107a expression by flow cytometry. Cytotoxic activity (by using CFSE-labeled K562 as target cells), expression of NK cell receptors and surface markers, intracellular IL-5, IL-10, IL-17 and IFN-γ levels in $CD16^+$ NK cells were also determined by flow cytometry. Statistical analyses were performed by Mann Whitney U test.
Results: The percentages of NK, $CD16^{bright}CD56^{dim}$, $CD16^{dim}CD56^{bright}$ subsets, NKp46 and NKG2D expressions were found similar in both groups. However there was a significant difference in cytokine secretion.Although IFN-γ secreting NK1 cell subsets were found to be higher(P = 0.001), IL-5$^+$ CD16$^+$ NK2, IL-17$^+$ CD16$^+$ NK17 and IL-10$^+$ CD16$^+$ NKregulatory cells significantly decreased in BD patients. (P = 0.001). Even CD107a expression was significantly decreased in BD, cytotoxic activity did not show any difference between groups with CFSE (P = 0.03).

Conclusions: Our findings revealed that increased NK1 cell subsets and also decreased numbers of NK17 and NK regulator cell subsets might play role in BD pathogenesis.

P0112

Effect of T follicular helper cells on regulation of mucosal immunity to influenza haemagglutinin by novel immunological adjuvants

A. Aljurayyan,* A. Kasbekar,† H. Beer,‡ M. McCormick,‡ P. McNamara,† S. Gordon§ & Q. Zhang*
**Department of Clinical Infection Microbiology and Immunology, Institution of Infection and Global Health, The University of Liverpool, Liverpool, UK, †NHS, Alder Hey Children's Hospital, Liverpool, United Kingdom, ‡ENT Department, Royal Liverpool University Hospital, Liverpool, UK, §Liverpool School of Tropical Medicine, The University of Liverpool, Liverpool, UK*

Purpose/Objective: Stimulation of the innate immune system is known to have an important role in the initiation and regulation of adaptive immunity. Therefore, inclusion of some immunological adjuvants such as Toll-like receptor ligands, which trigger early innate responses to enhance the adaptive responses, is crucial to vaccine effectiveness. T follicular helper cells (T_{FH}) have recently been shown to be crucial in germinal centre function and in regulation of adaptive immunity. The aim of the study is to investigate whether and how TLR ligands regulate T and B cell immunity to some respiratory tract pathogens through T_{FH} cells.
Materials and methods: Peripheral blood, nasopharyngeal swab and adenotonsillar tissues were collected form children and adults undergoing adenotonsillectomy. B cell antibody production analysed ELISA. T_{FH} cells and effect of TLR ligands on their function were analysed by flowcytometry and intracellular cytokine staining. Kinetics of antibody and cytokine production will also be analysed by ELISA.
Results: The proportion of T_{FH} cells in adenotonsillar tissue was significantly higher in children than that in adults. Stimulation of adenotonsillar cells by CpG-DNA was shown to increase the numbers of T_{FH} cells and this was consistent with the finding that CpG-DNA significantly enhance the antibody production to haemoglutinin (HA) of seasonal influenza virus H1N1 (sH1N1) antigen in adenotonsillar cells. However, TLR-2 ligand (BLP) seems to downregulate both the proportion of T_{FH} cells and the antibody level to sH1N1.
Conclusions: CpG-DNA promotes T_{FH} cells in nasal-associated lymphoid tissue which is correlated with the enhancement of influenza HA-specific antibody production. Understanding the mechanisms by which TLR ligands regulate adaptive immunity through T_{FH} cells may lead to novel vaccines against respiratory infections.

P0113

IL-33 induces innate lymphoid cell-dependent airway inflammation by activating mammalian target of rapamycin

R. J. Salmond, A. Mirchandani & F. Y. Liew
Immunology, Institute of Infection Immunity and Inflammation, Glasgow, UK

Purpose/Objective: Recently, novel type 2 innate lymphoid cells (ILCs) have to been shown to be important mediators of anti-parasitic immunity in the gut and allergic inflammation in the airways. The IL-1 family cytokine IL-33 is a potent activator of ILC function yet the mechanisms by which this cytokine modulates their activation are not clear. The purpose of this study was to determine the role of mammalian target of rapamycin(mTOR) signalling pathways in the activation of ILC responses and the induction of airway inflammation by IL-33.
Materials and methods: We determined the effect of IL-33 on mTOR activation and examined the impact of the mTOR pathway *in vivo* using a model of IL-33-induced lung inflammation.
Results: IL-33 induced mTOR activation via p110d phosphoinositide 3-kinase in ST2-(IL-33 receptor)-positive Th2 cells and ILCs. Furthermore, treatment with the mTOR inhibitor rapamycin reduced IL-33-induced IL-5 and IL-13 production by both T_H2 cells and ILCs *in vitro* and *in vivo*. Administration of IL-33 to wild-type (WT) mice induced airway inflammation whilst *ex vivo* analysis analysis of lung digests identified ILCs as the predominant IL-5 and IL-13-producing cell type. Furthermore, adoptive transfer of WT ILCs to ST2-deficient mice recapitulated IL-33-driven airway inflammation. Importantly, co-administration of rapamycin reduced IL-33-dependent ILC-mediated inflammation, cytokine secretion and mucus deposition in the airways.
Conclusions: These data reveal a previously unknown and critical role for mTOR in IL-33-driven, ILC-dependent inflammation. Furthermore, our results suggest the possibility that manipulation of this signalling pathway might represent a target for therapeutic intervention of airway inflammation.

P0114

Innate lymphoid cells in models of IBD

C. Pearson,* S. Tung,† B. Seddon† & F. Powrie*
**Nuffield Department of Medicine, University of Oxford, Oxford, UK, †Immune Cell Biology, National Institute for Medical Research, London, UK*

Purpose/Objective: The increasing prevalence of inflammatory bowel diseases (IBD) in the developed world reinforces the need to understand the mechanisms that lead to onset of inflammation in the gut. Previous work from our lab identified a population of RORgt-dependent, IL-23-responsive innate lymphoid cells (ILCs). These could drive inflammation in innate models of IBD. Subsequent IBD studies identified equivalent populations in humans. ILCs may therefore represent a novel target for therapy in some IBD subtypes, and understanding survival and functional aspects may be useful in this regard. We have investigated further differences between innate models of colitis, focusing on the role of and differences between ILC populations.
Materials and methods: We used the *Helicobacter hepaticus*-induced and αCD40-induced mouse models of innate colitis. Both models share requirements for IL-23, RORg and ILCs. However these innate models also differ as the former is a bacterially driven, chronic colitis and typhlitis, and the latter is bacterially independent, acute, and is primarily restricted to the proximal colon. We investigated the ILC populations in the absence of cytokines including IL-7 in addition to measuring the colitis.
Results: We show a difference between our models in the requirement for IL-7, a typical homeostatic cytokine, to promote colitis, as the αCD40 model was not IL-7-dependent. Similar to lymphoid tissue inducer cells, other ILCs also express the IL-7R. However, we show that signaling through IL-7 is not necessary for the presence of all ILC populations *in vivo*. Furthermore, in a model where IL-7 is important to promote disease, this is not due to a requirement of the cytokine for ILC development. IL-7 can modulate the pro-inflammatory cytokine milieu associated with disease.
Conclusions: We have used the differences between animal models of colitis to try to understand the relative importance of ILC populations and cytokines such as IL-7 in the development of colitis. The gut is a major source of IL-7, and we have shown that IL-7 is not just a

homeostatic cytokine but can also influence the inflammatory environment during disease.

P0115

Lymphocytes but not Rorgamma$^+$ cells are the source of LTb in ectopic lymphoid structures in inflammatory conditions

S. Nayar,* T. Cloake,* D. Affram,* M. Coles,† D. Withers,‡ P. Lane,‡ C. Buckley* & F. Barone*

**Rheumatology, University of Birmingham, Birmingham, UK, †Immunity and Infection, University of York, York, UK, ‡Immunity and Infection, University of Birmingham, Birmingham, UK*

Purpose/Objective: Lymphoneogensis is critically dependent on the interaction between LTβR expressed on mesenchymal cells and LTβ produced by RORg$^+$ LTi. Presence of tertiary lymphoid structures (TLS) that resemble lymph nodes in organization and local production of lymphoid chemokines (CKs) and cytokines have been reported in various chronic inflammatory diseases. Emerging evidence highlight the role of various stimuli and cytokines in supporting TLS formation, however it is not clear the role that LTβ/LTbR interaction plays in this process and it is still debated the role od adult LTi in driving TLS during inflammation. We used a model of ectopic lymphoneogenesis, in adenoviral infected murine salivary glands to dissect the role of LTβ/LTβR axis and identify the source of LTβ in the inflammatory aggregates.
Materials and methods: Quantitative RT-PCR and immunofluorescence was performed at different time points post viral cannulation (pc) in WT and knockout mice (LTβRKO, RAGKO, RORgKO, CD3eKO, IgHKO) in order to investigate the role of these molecules in TLS development.
Results: WT animals are characterized by the formation of TLS in the salivary glands with T/B cell segregation and FDC (follicular dendritic cell) network formation which recapitulates the events happening in lymphoid organogenesis including expression of LTβ and CKs (CXCL13, CCL21 and CCL19). LTβRKO displayed disorganisation of the inflammatory aggregates, lack of FDC and significantly decreased expression of the lymphoid CKs both at protein and mRNA level. Surprisingly, absence of LTi (RORgKO mice) did not significantly affect CKs production and aggregates organization. Conversely, severe impairment in the expression of lymphoid CKS and LTβ was observed in RAGKO mice, accordingly both T and B knockout showed a similar (though milder) phenotype to the RAG, suggesting that both T and B cells express LTβ and synergistically contribute to the production of this cytokine.
Conclusions: This data demonstrated that full maturation and maintenance of TLS is dependent on LTβR/LTβ axis and that the source of LTβ in the inflamed tissue, differently from the embryonic secondary lymphoid organs, is not provided by RORg$^+$ LTi but by infiltrating T and B lymphocytes.

P0116

Natural aryl hydrocarbon receptor ligands control organogenesis of intestinal lymphoid follicles

E. A. Kiss,* C. Vonarbourg,* S. Kopfmann,* D. Finke,† C. Esser‡ & A. Diefenbach*

**Institute of Medical Microbiology and Hygiene, University of Freiburg, Freiburg, Germany, †Developmental Immunology, University of Basel, Basel, Switzerland, ‡Leibniz-Institute for Research in Environmental Medicine (IUF), University of Düsseldorf, Düsseldorf, Germany*

Purpose/Objective: Intestinal lymphoid follicles such as cryptopatches and isolated lymphoid follicles (ILFs) are lymphoid organs that develop postnatally under the influence of the intestinal microflora and other as of yet unidentified cues. The cells forming cryptopatches are RORγt (retinoic acid orphan receptor γ t)-expressing innate lymphoid cells (ILCs) believed to have lymphoid tissue inducing (LTi) function. Furthermore, RORγt$^+$ ILCs are an important source of interleukin-22, a cytokine essential for the defense against bacterial pathogens. In this study, I investigated the role of the aryl hydrocarbon receptor (AhR) for development and function of RORγt$^+$ ILCs.
Materials and methods: *Ahr*-deficient mice and mice fed with diet lacking natural AhR ligands were used to study the role of AhR for the development and function of RORγt$^+$ ILC. The effect of deficient AhR signaling in RORγt$^+$ ILC for the intestinal homeostasis was studied by using *Citrobacter rodentium* infection, a mouse model of attaching and effacing infections such as those with enterohemorrhagic *E. coli* strains.
Results: Mice lacking AhR had substantially reduced numbers of RORγt$^+$ ILCs and failed to develop cryptopatches and ILFs. In contrast to *Ahr*-proficient mice, RORγt$^+$ ILCs from mice lacking the AhR had very low levels of Kit expression. Kit is known to promote cell survival and proliferation in various cell types and Kit was recently reported to be required for the development and/or maintenance of intestinal RORγt$^+$ ILCs. Interestingly, dietary AhR ligands were found to control the pool size of RORγt$^+$ ILCs by maintaining the high Kit expression. In addition, consistent with the failure to expand the IL-22 producing RORγt$^+$ ILCs, *Ahr*-deficient mice were highly susceptible to *Citrobacter rodentium* infection.
Conclusions: Collectively, the data shows that AhR signals are indispensable for the expansion and/or maintenance of RORγt$^+$ ILC with LTi function required for the postnatal formation of intestinal lymphoid follicles.

P0118

TLR2 mediated propionibacterium acnes adjuvant effect on B-1 cell and on its phagocyte differentiation

M. Gambero,* M. E. Ishimura,* C. C. Squiella-Baptistão,† D. Teixeira* & I. M. Longo-Maugeri*

**Division of Immunology, Federal University of Sao Paulo, São Paulo, Brazil, †Immunochemistry Department, Butantan Institute, São Paulo, Brazil*

Purpose/Objective: B1 lymphocytes, like macrophages, are predominant in the peritoneal cavity. These cells are responsible for natural IgM and they are involved in innate immunity. They simultaneously express macrophages (CD11b/CD18) and lymphocytes (IgM, CD19, CD5) markers and are classified according to surface molecules, as B1a ($IgM^+/CD19^+$ $/CD11b^+/CD5^+$), B1b ($IgM^+/CD19^+$ $/CD11b^+$). Enriched B1b cell cultures can be obtained from mouse peritoneal adherent cells. When re-cultivated, they differentiate into a phagocyte derived from B1b (B1CDP) that expresses F4/80, CD11b and CD19 on membrane and also shows phagocytic activity. Recently, we demonstrated *in vivo* and *in vitro* the ability of heat-killed *Propionibacterium acnes* suspension and their soluble polysaccharide (PS) to increase B1b subtype and B1CDP on mice peritoneal cavity. Bacteria also induced *in vitro* and *in vivo* early phagocyte differentiation. The aim of this study was to verify if *P. acnes* effects are mediated by TLR2 and TLR4 on B1 and B1CDP.

Materials and methods: C57BL/6 wild type, $TLR2^{-/-}$ and $TLR4^{-/-}$ received a single injection of *P. acnes*, PS or saline. After 24 h, the cells from peritoneal exudatewere analyzed for B1 subtypes and B1CDP by flow cytometry. *Saccharomyces cereviseae* was labeled with CFSE to evaluate phagocytosis Internalized yeast by B1 or B1CDP was detected by flow cytometry.

Results: Bacteria decreased B1 $TLR2^+$ and it did not modify B1 $TLR4^+$ absolute number. *P. acnes* also elevated $TLR4^+$ absolute number and TLR2 expression/cell in B1CDP. PS increased only B1b $TLR2^+$. We demonstrated that the increasing in B1b and the phagocyte differentiation was mediated by TLR2, after bacterial stimulus, once in $TLR2^{-/-}$ mice we did not detected this effect.

The analysis of the phagocytic function in $TLR2^{-/-}$ and $TLR4^{-/-}$ mice revealed increasing B1b absolute number with internalized yeasts in *P. acnes* group; in contrast, these effect was observed in B1a subtype in the wild type group. Bacteria stimulus decreased B1CDP and also their phagocytic function on $TLR2^{-/-}$ group. Any effect was observed in PS treated groups.

Conclusions: The adjuvant effects induced by *P. acnes* on B1 cells, mediated undoubtly by TLR2, such as: increasing absolute number, differentiation into phagocytes and phagocytic activity, re-inforce the importance of this adjuvant and also the role of these cells on innate immune response.

Poster Session: Micro RNA

P0119

Functional role of microRNAs in the regulation of alternative activation in macrophages

D. Malik, D. Rückerl, S. J. Jenkins, G. Thomas, A. H. Buck & J. E. Allen

Institute of Immunology and Infection Research, University of Edinburgh, Edinburgh, UK

Purpose/Objective: Macrophages play a key role in maintaining the balance and efficiency of the immune response. T_H2 cytokines IL-4 and IL-13 trigger a state of alternative activation that is involved in the control of extracellular parasites such as helminths. Alternatively activated macrophages (AAMΦ) have also been implicated in tissue repair. However, inflammatory disorders like asthma and fibrosis are a result of a T_H2 weighted imbalance. Hence, macrophage responses must be tightly regulated. MicroRNAs, a short (~22nt) class of non-coding RNA, are one such immunomodulatory feedback mechanism that can regulate gene expression by targeting the 3' UTR of mRNA resulting in destabilization of the mRNA and/or inhibition of translation. We believe that with their ability for vast gene regulation, microRNAs could play a crucial role in the regulation of AAMΦ's by targeting genes and pathways critical for their induction and/or maintenance, thereby opening up new avenues for therapeutic intervention.

Materials and methods: To investigate the functional role of microRNAs in alternative activation, we have been using a murine model of filarial infection, *Litomosoides sigmodontis*, in which the nematode migrates to the pleural cavity and induces a T_H2 type response.

Results: Following parasite entry, the resident pleural cavity F4/80$^+$ macrophages proliferate and express the alternative activation markers, Arginase1, Relm- α and Ym-1. We have previously identified microRNAs associated with AAMΦ and in this study followed their expression in F4/80$^+$ macrophages over the course of *L. sigmodontis* infection, relating microRNA expression to alternative activation markers and cell division. We have also been evaluating alternative activation and miRNA expression profiles in IL-4-treated RAW 264.7 versus J774.1 MΦ cell lines.

Conclusions: We aim to establish these cell lines as lentiviral transduction targets for cross-linking and analysis of cDNA (CRAC), a technique that will provide in depth information on miRNA-mRNA interactions in AAMΦ.

P0120

Localized and generalized granulomatosis with polyangiitis nasal tissue displays specific disease associated micro-RNA profiles

S. Schinke,* M. Laudien,† A. Müller,* A. Jüngel,‡ W. L. Gross* & R. Häsler§

**Rheumatology, University Medical Center Schleswig-Holstein, Lübeck, Germany, †Department of Otorhinolaryngology Head and Neck Surgery, University Medical Center Schleswig-Holstein, Kiel, Germany, ‡Experimental Rheumatology, University Hospital Zürich, Zürich, Switzerland, §Clinical Molecular Biology, University Medical Center Schleswig-Holstein, Kiel, Germany*

Purpose/Objective: To characterize miRNA profiles associated with localized and generalized GPA and to identify new miRNA targets of pathophysiological relevance. Disease specific alteration of miRNA expression has been found in chronic inflammatory diseases such as RA, Sjögren's, SLE or chronic inflammatory bowel disease. Yet, no investigations in vasculitides have been described.

Materials and methods: Nasal tissue samples of 14 patients with generalized and six patients with localized GPA, 10 disease controls (CRS: chronic rhinosinusitis with polyps) and 10 healthy controls (HC) were genome-wide screened (Affymetrix® miRNA-microarray chip 1.0). Differential expression was calculated by Mann-Whitney U-test; fold changes were based on the ratios of the medians of each experimental group. Results were visualized using TIBCO Spotfire®. Putative miRNA targets were predicted by combining three different computational methods: (i) PubMed search, (ii) Tarbase 5.0 (Diana labs), an algorithm for experimentally validated targets and (iii) microRNA Data Integration Portal (mirDIP).

Results: 1. From 847 human miRNAs screened, 24 displayed a GPA-specific expression pattern at cut-off level of a twofold change. For localized GPA 11 miRNAs were differentially regulated compared to generalized GPA. Further 7 miRNAs were unspecifically changed in GPA as well as in CRS.

2. Target prediction revealed previously experimentally validated targets involved in proliferation and differentiation of T- and B-cells, dendritic cells, fibroblast and of osteoblasts as well as apoptosis, hypoxia, angiogenesis and cellular adhesion. These are known pathways implicated in the pathogenesis of GPA. Potential targets also include proteinase-3, the specific GPA autoantigen, and lysosomal membrane protein-2, only recently described as an alternative autoantigen in GPA.

Conclusions: For the first time, this explorative survey compares disease associated miRNA profiles in nasal tissue samples of localized and generalized GPA patients. Predicted GPA specific miRNA targets belong to known pathological pathways of GPA. Considering the promising diagnostic, prognostic and therapeutical applications of miRNAs in other diseases, validation of the clinical relevance of our data will help to understand GPA on a molecular level as a key element in developing new therapies.

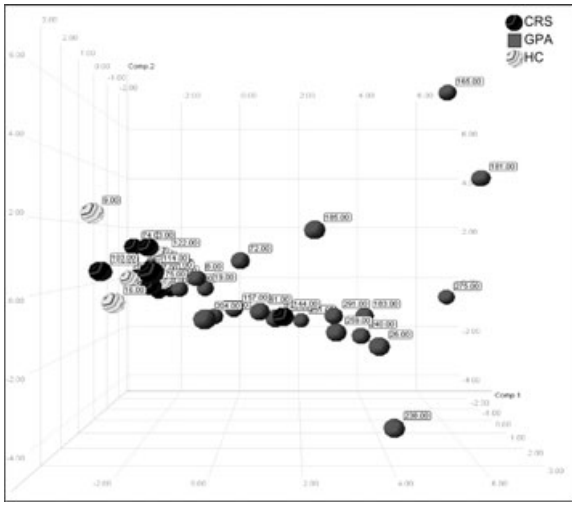

Figure 1. Principal component analysis: GPA patients form a different group from HC and CRS patients.

P0121

miR-142-3p, miR-185 and miR-181a, b, c and d control levels of the GARP protein, which in turn regulates processing and secretion of latent TGF-b1 in human T lymphocytes

E. Gauthy, J. Stockis, N. Dauguet, P. G. Coulie & S. Lucas

Génétique Cellulaire, de Duve Institute – Université catholique de Louvain (UCL), Brussels, Belgium

Purpose/Objective: How regulatory T lymphocytes (Tregs) suppress other immune cells is not completely understood. We previously proposed that human Tregs suppress at least in part through transformation of latent TGF-§1 into the active, immunosuppressive

cytokine. TGF-§1 activation by Tregs is confined to the cell surface, possibly by means of GARP, a transmembrane protein that binds latent TGF-§1 on Tregs. What controls GARP expression in T lymphocytes and the precise roles it plays in the TGF-§1 processing pathway are currently not known. In a collection of stable human T cell clones, we detected the GARP protein in stimulated Tregs, but not in T helper (Th) clones, some of which nevertheless expressed substantial amounts of the *GARP* mRNA. This suggests the existence of a post-transcriptional control of *GARP* expression in human T lymphocytes. Here, we set out to examine whether microRNAs (miRs) contribute to such a regulation.

Materials and methods: Using publicly available bioinformatics programs, we identified miRs predicted to target the 3′UTR of the *GARP* mRNA. Candidate miRs were tested by co-transfection with a reporter plasmid in 293T cells. Levels of miR expression in stable human T cell clones were quantified by RT-qPCR. The impact of miRs overexpression or inhibition was assessed in human T cells transfected with mimics or antagomirs, respectively.

Results: We identified 6 miRs, namely *miR-142-3p*, *miR-185* and *miR-181a*, *b*, *c* and *d*, that directly target the *GARP* 3′UTR in 293T cells, decrease endogenous GARP protein levels when transfected in Tregs and are expressed at higher levels in human Th clones by comparison to Tregs. Inhibition of *miR-142-3p* and *miR-185* in Th cells induced GARP protein expression. In Th cells transduced with GARP-encoding viruses, presence of the 3′UTR region targeted by the 6 miRs decreased GARP protein levels. Importantly, this correlated with reduced cleavage of pro-TGF-§1 and reduced secretion of latent TGF-§1.

Conclusions: We identified a miR-dependent mechanism of post-transcriptional control of GARP levels, which could play a role in regulating the amounts of latent TGF-§1 available for activation at the surface of human Tregs.

P0122

miR-182 and miR-10a are key regulators of treg specialisation and function during Th2 and Th1-associated inflammation

S. Kelada,* P. Sethupathy,* I. Okoye,† Y. Belkaid,‡ S. Porcella,‡ S. Czeiso,† T. Wynn‡ & M. Wilson†

**NIH, Human Genome Centre, Bethesda, USA, †Molecular Immunology, MRC National Institute for Medical Research, London, UK, ‡NIH, LPD, Bethesda, USA*

Purpose/Objective: $CD4^+$ $Foxp3^+$ regulatory T cells are critical components of the immune system, required to control immune responses. The molecular identity of $CD4^+$ $Foxp3^+$ cells has been assumed to be largely independent of the immune environment.However, the recent identification of genes differentially expressed among $CD4^+$ $Foxp3^+$ cells is suggestive of functional heterogeneity.

Materials and methods: To investigate comprehensively whether $CD4^+$ $Foxp3^+$ cells are tuned to different responses and to identify regulatory pathways involved, $CD4^+$ $Foxp3^{gfp+}$ cells were isolated from Th1-rich or Th2-rich environments following *Leishmania major* or *Schistosoma mansoni* infection. Whole genome expression profiling and next generation sequencing revealed unique and dissimilar mRNA and miRNA profiles in $CD4^+$ $Foxp3^+$ cells from the different environments.

Results: *In silico* analyses, with extensive molecular validation demonstrated that distinct miRNAs are involved in determining the gene expression profile. MiR-10a was the strongest candidate 'master regulator' of $CD4^+$ $Foxp3^+$ cells in type-1 environments, whereas miR-182 was the most critical in type-2 environments. *In vitro* and *in vivo* systems further demonstrate that tight regulation of miR-182 and miR-10a is required for $CD4^+$ $Foxp3^+$ function.

Conclusions: These data support the notion that $CD4^+$ $Foxp3^+$ cells are specialized for different immune responses and identifies novel upstream miRNA pathways which influence Treg specialisation and function.

P0123

MiR-30* family negatively regulates BAFF synthesis in rheumatoid synoviocytes

G. Alsaleh,* A. Francois,* L. Philippe,* J. Sibilia,* J. E. Gottenberg,* P. Georgel† & D. Wachsmann*

**Laboratoire Physiopathologie des Arthrites, Faculté de Pharmacie Université de Strasbourg, Ilkirch Cedex, France, †Laboratoire d'ImmunoGénétique Moléculaire Humaine, Faculté de Médecine Université de Strasbourg, Strasbourg Cedex, France*

Purpose/Objective: In rheumatoid arthritis (RA) resident cells of the joint, fibroblast-like synoviocytes (RA FLS) acquire an aggressive phenotype in response to extrinsic factors such as PAMPs or DAMPs and intrinsic factors such as microRNAs. They produce large amounts of cytokines and among them the B cell-activating factor (BAFF) which allows them to collaborate with auto-immune B cells. We found that the miR-30* family of microRNAs (miR-30a*, d* and e*) was predicted to potentially target the 3'-UTR region of BAFF. As BAFF is also up-regulated in the skin and the serum of systemic sclerosis patients, the aim of this study was to evaluate the role of miR-30* in the regulation of BAFF synthesis in fibroblasts isolated from either RA or SSc patients.

Materials and methods: FLS and HDF were isolated from RA synovial tissues or from skin from SSc patients and were stimulated with TLR3 ligand (poly I:C) and IFN-γ for 3 days. RT-qPCR was performed to evaluate miRNA and mRNA expression. Transient transfection of RA-FLS and SSc-HDF with mimic miR-30* was performed using the Human Dermal Fibroblast NucleofectorTM kit from Amaxa. All assays were performed 24h post transfection.

Results: We first showed by qRT-PCR that like RA-FLS, SSc-HDF synthesize and released BAFF in response to poly I:C and IFN-γ. Conversely, HDF from normal subjects released BAFF only in response to IFN-γ. Using qRT-PCR, we demonstrated that miR-30a* and miR-30e* expression was strongly down regulated in RA-FLS, SScHDF and NHDH stimulated with either poly I:C or IFN-γ. Interestingly, NHDF which did not release BAFF in response to poly I:C expressed higher levels of miR-30a* and miR-30e* in response to poly I:C. MiR-30d* was not expressed constitutively or after activation by poly I:C and IFN-γ by each cell type. To evaluate whether miR-30* regulates BAFF expression in poly I:C and IFN-γ-activated RA-FLS and HDF, we transfected cells with miR-30* mimics. Transfection of the mimics induced a strong down-regulation of BAFF synthesis and release in response to poly I:C and IFN-γ. Using a luciferase test, we showed that miR-30* regulated directly BAFF mRNA 3'-UTR.

Conclusions: Our data strongly suggest a critical role of miR-30* in the regulation of the expression of BAFF which could play an important role in the regulation of the auto-immune response in RA and SSc.

P0124

Regulated expression of microRNA-21 is involved in the memory T-cell survival

K. Smigielska,* A. van den Berg,* H. Maat,* P. G. Jellema,* R. J. van der Lei,* A. M. H. Boots,† E. Brouwer† & B. J. Kroesen*
*Pathology & Medical Biology, University Medical Center Groningen (UMCG), Groningen, The Netherlands, †Rheumatology & Clinical Immunology, University Medical Center Groningen (UMCG), Groningen, The Netherlands

Purpose/Objective: MicroRNAs (miRNAs) are important post-transcriptional gene regulators required for proper development and function of immune cells. Although the dynamic expression of hematopoietic-specific miRNAs during consecutive phases of lymphocyte development in general is well documented, the specific role of single miRNAs in T cell activation and differentiation is still not well known. In this study we investigated the function of miR-21 in the process of T cell activation, and we report that miR-21 is a pro-survival factor in the context of memory T cell function.
Materials and methods: Using qRT-PCR we analyzed miR-21 expression in course of anti-CD3/CD28 stimulation of naïve ($CD4^+$ CD45RO-) and memory ($CD4^+$ $CD45RO^+$)-FACS sorted primary T cells, as well as in the Jurkat cell line. Viral vector harboring miR-21 inhibitor or scrambled-miR inhibitor sequence served to stably inhibit endogenous miR-21 in primary naïve and memory T cells as well as in Jurkat cells. Apoptosis rate was assessed by measuring mitochondrial potential. Immunoprecipitation of RISC complexes using mouse-anti-human-Ago2 monoclonal antibody followed by gene expression analysis was used to experimentally uncover T-cell specific miR-21 target genes.
Results: Resting memory $CD4^+$ T cells expressed five times more miR-21 than their naïve counterparts, suggesting involvement in the maintenance of the memory phenotype. Moreover, miR-21 was strongly upregulated upon TcR engagement in both primary and Jurkat cells, implicating it's contribution to the activation process. MiR-21 inhibition resulted in an increased rate of spontaneous apoptosis in *in vitro* activated T cell cultures, especially in the memory T cell population and induced massive spontaneous apoptosis in Jurkat cells. Immunoprecipitation of RISC complexes in Jurkat cells depleted of miR-21, followed by high throughput gene expression analysis allowed us to identify several potential miR-21 target genes relevant to T cell biology.
Conclusions: In conclusion, our data provide evidence that miR-21 is a key component in the process of T-cell activation by regulating T-cell survival signaling, especially in the memory T-cell population.

Regulation of microRNA 223 expression in a gouty arthritis

G. Statache,* A. Rainey,* L. Crawford,* S. Masters,* A. Balanescu,† I. McInnes* & M. Kurowska-Stolarska*
*Rheumatology, Institute of Infection Immunity and Inflammation, Glasgow, UK, †Rheumatology, SF Maria Hospital, Bucharest, Romania

Purpose/Objective: Introduction. Gout is an inflammatory chronic disease caused by deposition of uric acid crystals in the joint and connective tissues causing pain and disability. Current data suggest that gout is mediated by IL-1b that is produced due to the activation of the inflammasome pathway by uric acid crystals.In addition, neutrophil influx in the joint is the key initiator of a gout flare. miR-223 has been identified as a masterswitch molecule limiting neutrophil activation. In addition, we showed previously that this miR negatively regulates NLRP3 (an inflammasome component) and IL-1b production in human macrophages.

Objective. To investigate miR-223 expression and regulation in monocytes and neutrophils of gout patients.

Materials and methods: Methods. $CD14^+$ cells and neutrophils were isolated from gout patients ($n = 10$) and healthy donors ($n = 6$) peripheral blood using CD14 microbeads and polylymphoprep gradient buffer, respectively. $CD14^+$ from healthy donors were stimulated with LPS (10 ng/ml) IL-1beta (100−10 ng/ml), IL-6 (100 ng/ml), TNF alpha (10−100 ng/ml) or monosodium urate crystals MSU (1 mg−1 ug/ml) for different time points (24−72 h). Cells were harvested and miRNA extracted. Expression of miR-223 and endogenous control snRNA U1 was assessed by qPCR.
Results: Results. miR-223 expression in peripheral blood monocytes of patients withchronic gout was lower compared to healthy controls.This suggest that overproduction of IL-1b in chronic disease might be partially mediated by low levels of miR-223. *In vitro* studies revealed that MSU, IL-1b, TNFa and IL-6 significantly inhibited miR-223 expression in monocytes in all time points (24−72 h). In contrast, IL-10 strongly increased miR-223 expression. Interestingly, the levels of miR-223 in peripheral blood neutrophils were higher in gout patients compared to healthy controls.
Conclusions: A decrease in miR-223 expression in monocytes of chronic gout patients may contribute to uric acid crystals induced inflammasome activation and chronicity of disease. Upregulation of miR-223 expression in gout neutrophils may reflect the activation of mechanisms that limits neutrophils activation and lead to the resolution of gout flares.

P0126

Role of microRNAs in the differentiation of pro-inflamatory γδ T-cell subsets

A. Gomes, N. Schmolka & B. Silva-Santos
Molecular Imunology Unit, Instituto de Medicina Molecular, Lisbon, Portugal

Purpose/Objective: The cytokines interferon-gamma (IFN-γ) and interleukin-17 (IL-17) are critical mediators of the pro-inflammatory activity of T-cells in contexts of infection, cancer and autoimmunity. Gamma-delta (γδ) T-cells have been recently shown to contain distinct subsets that produce large amounts of either IFN-γ ($CD27^+$) or IL-17 ($CD27\text{-}CCR6^+$). However, the molecular mechanisms that underlie *Ifnγ* and *Il17* gene expression in γδ T cell subsets remain poorly understood. We aim at analysing the miRNA-mediated post-transcriptional regulation of *Ifnγ* and *Il17* expresssion in γδ T-cells.
Materials and methods: γδ T cells were analysed in wild type (wt) and lck-Dicer knockout (ko) mice (Merkenschlager lab). miRNA microarray analysis was performed on sorted peripheral γδ T cell populations ($CD27^+$ and $CD27\text{-}CCR6^+$) from wt B6 mice using the Exiqon miRCURY LNA™ microRNA Array. The expression of candidate miRNAs was validated in thymic and peripheral γδ T cell populations by miRNA RT-qPCR (using LNA primers from Exiqon).
Results: The analysis of lck-Dicer ko mice has revealed a strong impairement in IL-17 (but not IFN-γ) production by miRNA-deficiient γδ T cells. To identify specific miRNAs that might account for this phenotype we performed large scale miRNA studies on the γδ $CD27^+$ and the γδ $CD27\text{-}CCR6^+$ T cell subsets. RT-qPCR validation of two candidate miRNAs, miR-181 and miR-146a, confirmed their up regulation in the γδ $CD27^+$ and γδ CD27-CCR6 subsets, respectively. Interestingly, this differential expression was observed in both thymic and peripheral γδ T cell subsets.
Conclusions: miRNAs are required for the differentiation of IL-17 producing γδ T cells. Specific miRNAs seem to segregate between the IL-17 and the IFN-γ producing γδ subsets both in the thymus and in the periphery. This strongly suggests that the differential expression of miRNAs in γδ T cell subsets is set up in the thymus. Thus, future functional characterization of candidate miRNAs in fetal thymic organ cultures (FTOCs) will be crucial to assess their role in the development of pro-inflammatory γδ T cell-subsets.

P0127

Role of miR-146a-5p in Graft−versus − Host Disease

S. Atarod, W. Cope, J. Norden, M. Collin & A. M. Dickinson
Haematological Sciences, Newcastle University, Newcastle upon Tyne, UK

Purpose/Objective: A major complication of allogeneic (allo-) haematopoietic stem cell transplantation (HSCT) is Graft-versus-Host Disease (GvHD). GvHD has been classically divided into acute GvHD (aGvHD) and chronic GvHD (cGvHD) depending on the time-point of disease manifestation. Recently, it was shown that miRNAs play a role in GvHD (miR-155) and kidney graft rejection. In this study, we investigated miR-146a-5p which functions in both the innate and adaptive immune system. The aim was to quantify the expression of miR-146a-5p and its validated targets (*TRAF6*, *IRAK1*, *STAT1-α* and *IRF5*) in the whole blood of both aGvHD and cGvHD patients pre- and post-transplantation.

Materials and methods: Whole blood was collected in PAXgene tubes from allo-HSCT patients ($n = 60$) at various time-points pre- (Day-7) and post-transplant (up to 12 months). Expression of miR-146a-5p and its validated targets; *TRAF6*, *IRAK1*, *STAT1-α* and *IRF5* were studied by q-PCR using Taqman miRNA and gene expression assays, respectively. Significance was determined by Mann Whitney *U* test and set at $P < 0.05$.

Results: At 28 days post-transplant, miR-146a-5p expression was significantly down-regulated in II-IV aGvHD patients in comparison to 0-I aGvHD patients ($P = 0.001$). No significant variation was observed between the no cGvHD and cGvHD patient cohort. Likewise, mRNA expression of the targets; *TRAF6*, *IRAK1*, *STAT1-α* and *IRF5* did not vary at any time-point in neither the aGvHD nor the cGvHD cohorts.

Conclusions: We hypothesize that the low expression of miR-146a-5p at 28 days post-transplant in whole blood of II-IV aGvHD patients could be an early indicator of aGvHD severity. We also postulate that miR-146a-5p has a post-transcriptional effect on its targets. This will be elucidated by detection of the targets at the protein level (ongoing).

Cytotoxic CD8$^+$ T cells regulate myelopoiesis via the bone marrow stromal cell niche

C. Schürch,* C. Riether† & A. F. Ochsenbein‡
Department of Clinical Research, Institute of Pathology, University of Bern, Bern, Switzerland, †Department of Clinical Research, University of Bern, Bern, Switzerland, ‡Medical Oncology and Department of Clinical Research, University of Bern, Bern, Switzerland

Purpose/Objective: Cytotoxic CD8$^+$ T effector cells (CTLs) are crucial for the protection against primary infection with viruses and other intracellular pathogens. Upon activation by antigen presenting cells, naïve CD8$^+$ T cells undergo clonal expansion, migrate to sites of infection and kill infected target cells via secretion of perforin/granzymes or Fas-ligand/Fas-interaction. However, the complete clearance of pathogens and restitutio ad integrum requires a regulated interplay of innate and acquired immunity. IFN-γ, secreted by activated CTLs, can directly regulate innate immune cells. In addition, IFN-γ was shown to affect hematopoiesis in mice and men; however, these studies yielded conflicting results. Therefore, we analyzed the role of CTL-secreted IFN-γ on hematopoiesis after adoptive transfer of TCR-transgenic T cells and during acute viral infection.
Materials and methods: To assess the effect of activated effector CTLs on myelopoiesis, we infected wild-type mice with the CD8 T cell-controlled lymphocytic choriomeningitis virus (LCMV). In another model, we injected TCR-transgenic p14 CTLs specific for the LCMV-gp33 into mice ubiquitously expressing LCMV-gp33 on MHC class I (H8 mice). Bone marrow (BM) HSCs and myeloid progenitors as well as peripheral blood cells were analyzed at different time points.
Results: Adoptive transfer of activated p14 CTLs into H8 mice did not affect the early hematopoietic stem cell (HSC) compartment but induced the proliferation of multipotent progenitor cells, resulting in increased production of mature myeloid cells. Similar results were obtained with LCMV-infection of wild-type mice. IFN-γ did not affect hematopoietic stem- or progenitor cells directly, but stimulated mesenchymal stromal cells of the BM stem cell niche to produce hematopoietic cytokines including interleukin-6.
Conclusions: BM stromal cells (BMSCs) have an important documented role in the regulation of HSC maintenance and quiescence. Our study demonstrates that BMSCs are central in the regulation of myelopoiesis in response to infection and that CTLs exert an indirect positive feedback on myeloid progenitors during clearance of acute viral infection.

P0130

Detection of TLR agonists by hematopoietic stem and progenitor cells programs macrophage function

H. S. Goodridge, A. Yanez, N. Hassanzadeh-Kiabi, A. Subramanian & M. Y. Ng
Cedars-Sinai Medical Center, Regenerative Medicine Institute, Los Angeles, CA, USA

Purpose/Objective: The function of mature macrophages is instructed by signals they receive from factors in their environment and interactions with other cells. For example, Toll-like receptors (TLRs) sense microbial components and the signals they generate coordinate the anti-microbial response. TLRs also detect endogenous danger signals to initiate a response to cell stress and tissue damage. Recent studies showed that TLR expression is not restricted to differentiated cells, but that hematopoietic stem and progenitor cells (HSPCs) also express TLRs. In this study we examined how exposure of HSPCs to TLR agonists alters the function of macrophages derived from them.
Materials and methods: The effects of exposing mouse and human HSPCs to TLR agonists during or prior to macrophage differentiation were examined. The responses of macrophages (adherent, CD11b$^+$ F4/80$^+$ cells) produced by culturing HSPCs with TLR2 and TLR4 agonists ('TLR-derived' macrophages) were compared to those of macrophages derived using M-CSF ('M-CSF-derived' macrophages). The effects of transient exposure of HSPCs to TLR agonists prior to macrophage differentiation driven by M-CSF ('TLR-programmed' macrophages) were also examined.
Results: TLR2 and TLR4 agonists stimulated HSPC proliferation and, depending on the timing, either induced or boosted macrophage differentiation. Upon stimulation of differentiated macrophages, both TLR-derived and TLR-programmed macrophages (mouse and human) exhibited reduced inflammatory cytokine production and oxidative burst activity. However, they were functionally different from 'TLR tolerized' macrophages, which had previously been exposed to TLR agonists but only after macrophage differentiation.
Conclusions: TLR signaling in HSPCs is a previously unrecognized mechanism of regulation of macrophage function, which may be important for limiting the damaging effects of inflammation, but could also impact immune function during/following infection and inflammatory disease. In addition, it might be possible to develop therapeutic approaches based on the concept of TLR programming of HSPCs, which could be applied to the treatment of a variety of diseases, by boosting myeloid cell responses to microbes or tumor cells, or suppressing their inflammatory activity.

P0131

Differentiation of myeloid progenitors is regulated by calcineurin/NFAT signaling

J. Fric, A. Mertes, C. Lim, T. Zelante & P. Riccardi-Castagnoli
Singapore Immunology Network (SIgN), Singapore, Singapore

Purpose/Objective: Haematopoiesis of myeloid cells is a tightly regulated process and complex regulatory mechanisms are in place to control the continuous self-renewal of progenitor cells and their differentiation. The plasticity of the myeloid cell lineage mirrors the diversity of the infectious agents and the diversity of the microenvironments that myeloid cell progenitors are seeding. Indeed the fast replenishment of myeloid progenitors is a key characteristic of innate immunity.
Materials and methods: Different types of haematopoietic progenitors (HSC, MPP, CMP and GMP) were sorted from lineage depleted samples of bone marrow and cultured in presence of SCF, IL-6, Flt3-L, while NFAT signaling was blocked by Cyclosporin A or tacrolimus. Both *in vivo* and *in vitro* proliferation of progenitors were assessed by BrdU staining. Global transcription was analyzed using c-Kit enriched progenitors treated with calcineurin/NFAT inhibitors.
Results: Here we report that calcineurin/NFAT pathway is a key player in the regulation of early stages of myeloid progenitor differentiation from haematopoietic stem cells. We have found a different calcium flux regulation during the development of myeloid progenitors and we have shown that this leads to differential engagement of the calcineurin/NFAT pathway. Our data provide the first evidence that the inhibition of the NFAT pathway *in vivo* enhances the proliferation of granulocyte-monocyte progenitors (GMP). *In vitro*, GMP cells also showed an increased proliferation rate during the differentiation towards dendritic cells when cultured with calcineurin/NFAT inhibitors, such as cyclosporine A and tacrolimus. This regulation can be explained through the interaction of NFAT with cell cycle regulating genes as shown by global transcription analysis of c-Kit enriched progenitors treated with cyclosporin A or tacrolimus.
Conclusions: Taken as a whole our data show that NFAT signaling is a new player in the homeostasis of the myeloid lineage and that immo-

suppressive drugs such as cyclosporin A or tacrolimus can affect the early stages of myeloid haematopoiesis.

P0132
Epigenetic regulation of IRF4 in human monocyte-derived dendritic cells

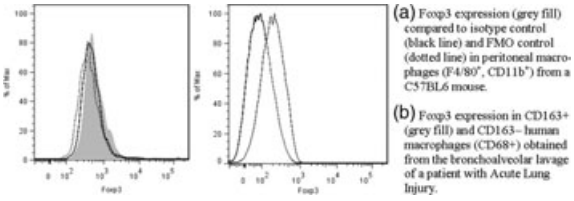
U. Haljasorg, L. Tserel, M. Laan, M. Kotkas & P. Peterson
Department of General and Molecular Pathology, University of Tartu, Tartu, Estonia

Purpose/Objective: Interferon regulatory factor 4 (IRF4) is a well-characterized transcriptional regulator involved in the differentiation of both, T- and B-lymphocytes as well as dendritic cells (DC) and macrophages. Mice deficient in IRF4 are completely devoid of plasma cells and lack functional $CD4^+$ DCs. Although multiple proteins have been shown to regulate IRF4 in different cell-types, including STAT6 (downstream of IL4), c-Rel, JMJD3, the epigenetic regulation of the IRF4 promoter, on the other hand, has received little attention. Here we have studied the activation, epigenetic changes in histone modifications and DNA methylation on IRF promoter during monocyte-derived dendritic cell differentiation.
Materials and methods: Peripheral $CD14^+$ monocytes were purified from the buffy coats of healthy blood donors and differentiated into DCs in the presence of IL4 and GM-CSF. mRNA, chromatin and genomic DNA were extracted from monocytes or DCs to carry out expression analysis, chromatin immunoprecipitation (ChIP) and DNA methylation analysis, respectively. In ChIP and DNA methylation analysis IRF4 promoter was analysed.
Results: We observed a significant increase in IRF4 expression in DCs compared to monocytes. ChIP analysis revealed that DCs had slightly elevated levels of trimethylated lysine in position 4 of the histone H3 (H3K4me3) on IRF4 promoter. More importantly, DCs had significantly lower levels of the repressing histone marker H3K27me3, indicating an active role for lysine demethylase JMJD3 also in human DC-specific IRF4 promoter activation. We also analysed CpG-methylation pattern of IRF4 promoter in monocytes and DCs.
Conclusions: In monocyte-derived dendritic cells IRF4 expression is tightly regulated by the epigenetic modifications in its promoter.

P0133
$Foxp3^+$ Macrophages, do they exist?

R. J. Ingram, S. Spence, S. Magorrian, M. Cross, D. F. McAuley & A. Kissenpfennig
Centre for Infection and Immunity, Queens University Belfast, Belfast, UK

Purpose/Objective: Forkhead box P3 (Foxp3) is the key transcription factor controlling T regulatory cell (Treg) development and function. Foxp3 expression by a subset of immunosuppressive macrophages is highly controversial. We will present data supporting the existence of this suppressive $Foxp3^+$ macrophages in both mice and humans.
Materials and methods: Flow cytometery was used to characterise the $Foxp3^+$ macrophage ($F4/80^+$ $CD11b^+$) cells using a combination of wild type C57BL6, Foxp3 eGFP and Foxp3 GFP DTR mice. Bone marrow derived macrophages (BMDM) were cultured conditions inducing a pro-inflammatory M1 or anti-inflammatory M2 phenotype and the expression of Foxp3 assessed using real time PCR. Mice with a myloid specific KO of suppressor of cytokine signaling proteins (SOCS)2 (M1 phenotype) or SOCS3 (M2 phenoytpe) were used to further assess the phenotype of $Foxp3^+$ macrophages. The expression of Foxp3 in human alveolar macrophages was also examined.
Results: A small but distinct population of $Foxp3^+$ macrophages was consistently identified by flow cytometry. A variety of approaches were used to demonstrate the validity of this population. An increased percentage of $Foxp3^+$ macrophages were detected in SOCS3KO mice which have been previously show to have exclusively M2 macrophages, in contrast no $Foxp3^+$ macrophages were detected in SOCS2 KO (M1) mice. $Foxp3^+$ expression was upregulated in M2 skewing conditions, most strikingly in SOCS3 KO mice. Foxp3 expression was also detected in human M2 ($CD163^+$) macrophages.



(a) Foxp3 expression (grey fill) compared to isotype control (black line) and FMO control (dotted line) in peritoneal macrophages (F4/80$^+$, CD11b$^+$) from a C57BL6 mouse.

(b) Foxp3 expression in CD163+ (grey fill) and CD163− human macrophages (CD68+) obtained from the bronchoalveolar lavage of a patient with Acute Lung Injury.

Conclusions: $Foxp3^+$ Macrophages are a contentious cell population. We have presented evidence that we believe establishes this is a genuine population, as opposed to auto-fluorescence, which is upregulated under M2 conditions. The increased expression of Foxp3 we observed in macrophages from SOC3 KO mice is consistent with previous findings in Tregs, which are deficient in SOCS3 protein expression. Upregulation of SOCS3 in Tregs reduces their suppressive function; we postulate that a similar mechanisms may regulate $Foxp3^+$ macrophages.

P0134
Identification of regulatory elements within the minimal promoter region of PRDM1β in myeloma cells

R. M. Mateos,* N. Pedreño-Horrillo,* F. Mora-López,* L. Gómez-Jaramillo,* E. Foncubierta,* G. Jiménez-Gómez,* M. C. Durán† & A. Campos-Caro*
**Hospital Universitario Puerta Del Mar, Unidad de Investigación, Cádiz, Spain, †Hospital Universitario De Puerto Real, Unidad de Investigación, Cádiz, Spain*

Purpose/Objective: PRDM1 is a transcriptional repressor required for the differentiation of plasma cells and short-lived effector T cells. PRDM1 exists as two isoforms, PRDM1α and PRDM1β. The repressor activity is associated mainly to PRDM1α isoform which control key target genes involved in growth control, apoptosis and differentiation. PRDM1β lacks the amino-terminal 101 amino acids of the full isoform PRDM1α which results in a loss of repressive function on multiple target genes. Both proteins are encoded by the same gene but PRDM1β uses an internal alternative promoter. In lymphoma and myeloma cells PRDM1β isoform is up-regulated and it is associated with an increased c-MYC expression. However, little is known about the transcriptional control of the alternative promoter regulating PRDM1β.

For this reason, our principal aim in the present work is to identify 'trans' and/or 'cis' regulatory elements that take part in the transcriptional regulation of this promoter.
Materials and methods: With this purpose different fragments upstream the PRDM1β promoter were cloned in the pGL3-Luc vector. The constructions were transfected in different cell lines and tested for luciferase expression. After that, a new combination of EMSA, SELDI-TOF and Mass Spectrometry techniques were used for the identification of transcription factors which bind to PRDM1β promoter in myeloma cells.
Results: The minimal promoter region with repressor activity was located between -522 to -474 relative to the ATG codon. An analysis of this sequence with Transfactor database revealed a possible binding site for TP53. EMSA assays show at least two prevalent retarded complexes but supershift assays do not identify it as TP53. Mutations affecting the binding site for these complexes increased the promoter activity to basal levels. Binding sites and molecular weights of at least two

transcription factors were defined by EMSA and SELDI-TOF. Actually, we are analyzing the sequence of these transcription factors by Mass Spectrometry.

Conclusions: Our data show a repressor 'cis' element in PRDM1β promoter regulated by at least two transcription factors. Considering that PRDM1β expression indicates poor disease outcome in patients with lymphomas and myelomas, the control of the expression level of PRDM1β in those cells could be used as a therapeutic target of these malignancies.

P0135
Influence of CD137L signaling in myelopoiesis during inflammation

Q. Tang* **& D. Jiang†**
**Department of Physiology National University of Singapore, Singapore, , †Department of Physiology, University of Ulm, Ulm, Germany*

Purpose/Objective: CD137 is a costimulatory molecule expressed on activated T cells. The signaling of CD137 into T cells upon ligation by its ligand, CD137L, which is expressed on antigen presenting cells (APC), can potently enhance the activation of T cells. It has been shown that CD137 can also induce signaling into APC via CD137L. The signaling of CD137L into the cells it is expressed on is termed reverse signaling to distinguish it from the signaling of CD137. The aim of this project is to investigate the role of CD137L on myelopoiesis under inflammatory condition.

Materials and methods:

1. Acute peritonitis was induced in mice by injection of LPS and *E. coli*. Myeloid population and T cell population were examined in the bone marrow and spleen. Proliferating populations were tracked by BrdU labeling.
2. Activated WT and CD137$^{-/-}$ T cells were cocultured with WT bone marrow cells *in vitro*. Proliferation of cells were determined by CFSE labeling.

Results: Our data show that when stimulated through CD137L murine monocytes become activated as evidenced by increased adherence; release of inflammatory cytokines. *In vivo* CD137 also represents a novel and potent growth and differentiating factor for murine myeloid cells during inflammation. In an acute peritonitis there is a significantly larger increase of myeloid cells, particularly of monocytes, in the bone marrow and spleen of wild type (WT) than of CD137$^{-/-}$ mice. This demonstrates that CD137*CD137L interactions significantly enhance myelopoiesis during inflammation. BrdU labeling experiments revealed that the increase in the number of myeloid cells is due to enhanced local proliferation instead of an influx from other organs. Further investigations revealed that the source of CD137, which drives this enhanced myelopoiesis during inflammation are CD4$^+$ T cells. *In vitro*, WT activated CD4$^+$ T cells induced higher expression of CD11b as well as enhanced proliferation of WT bone marrow cells than CD137$^{-/-}$ activated CD4 T cells, partly through the production of GM-CSF.

Conclusions: These data suggests that CD137$^+$ T cells play a pivotal role in myelopoiesis during inflammation. It is hypothesized that when inflammation is induced, T cells are activated and home to bone marrow and interact with CD137L-expressing progenitor cells and monocytes. Future experiments will focus on examining whether adoptively transferred activated CD4$^+$ T cells can restore the myelopoiesis in CD137$^{-/-}$ mice.

P0136
PAR-2 activation inhibits human osteoclast differentiation

L. McGavin,* R. Freeburn,* A. Crilly,* W. R. Ferrell,† C. S. Goodyear† & J. C. Lockhart*
**School of Science, University of the West of Scotland, Glasgow, UK, †Institute of Infection Immunity and Inflammation, University of Glasgow, Glasgow, UK*

Purpose/Objective: Osteoarthritis (OA) is a joint disease characterised by both cartilage degradation and increased subchondral bone formation (osteosclerosis). Osteoblasts and osteoclasts are the cells responsible for the maintenance of bone homeostasis[1]. As osteoclasts resorb bone, reduction in their number or function may be responsible for osteosclerosis in OA. PAR-2 is a G-protein coupled receptor known to be involved in inflammation. PAR-2 has recently been shown to play a critical role in experimental OA as a reduced disease phenotype occurs in mice lacking this receptor [2]. This study seeks to identify a role for PAR-2 in human osteoclast differentiation.

Materials and methods: CD14$^+$ monocytes were purified from the peripheral blood of healthy subjects and cultured for 14 days with M-CSF and sRANKL to promote osteoclast differentiation. In parallel experiments, osteoclast differentiation was performed in the presence of a selective PAR-2 activating peptide, SLIGKV-NH_2, or the reverse sequence peptide (RP) and the number of osteoclasts quantified by counting the TRAP$^+$ multinucleated ($\geq$3) cells in each well.

Results: CD14$^+$ monocytes have low levels of surface PAR-2, with cultured pre-osteoclasts displaying denser PAR-2 expression. Differentiation of pre-osteoclasts in the presence of SLIGKV-NH_2 resulted in a significant decrease ($P < 0.01$; $n = 3$) in osteoclast formation (80.8 ± 28.7; mean ± SEM) compared to vehicle (473 ± 68.8) or RP-treatment (481.8 ± 90.7; $P < 0.05$).Importantly, the PAR-2 activating peptide did not affect cell viability.

Conclusions: These findings suggest that PAR-2 activation can inhibit human osteoclast differentiation, potentially promoting osteosclerosis as observed in OA. This corroborates a previous study in murine cells [3] and importantly translates this finding to human osteoclast differentiation.

P0137
Role and function of microglia cells in autoimmune CNS inflammation

J. Bruttger,* S. Wörtge,* S. Jung,† A. Waisman,* Y. Wolf† & S. Yona†
**Institut for Molecular Medicine, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany, †Department of Immunology, The Weizmann Institute of Science, Rehovot, Israel*

Purpose/Objective: Unlike other glia cells, microglia originate from the myeloid cell lineage and therefore often are considered as resident brain macrophages. They act in the first response to direct injury or peripheral insults. However, the exact role microglia play during the process of autoimmune disease is not clear yet. Using the iDTR system microglia were depleted *in vivo*. After optimizing the efficiency of the depletion system, the role of microglia in health and disease (EAE) was analysed.

Materials and methods: The new microglia/ macrophage specific CX_3CR1^{CreER} strain was crossed to iDTR mice. Administration of tamoxifen lead to Cre-mediated excision of a loxP flanked DNA fragment in both cell types. Whereas macrophages have a fast turnover and are replaced by unaffected precursors, the microglia persist in the

modified stage. By crossing the CX_3CR1^{CreER} mice to the Rosa26-RFP reporter line we could investigate the efficiency of the system.

Then the CX_3CR1^{CreER} mice were crossed to iDTR mice to specifically express the diphtheria toxin receptor in microglia. To optimize the system for efficient microglia depletion we tested different DT administration protocols.

Results: By analyzing the reporter expression after tamoxifen treatment in the age of 2 weeks, mature mice exhibit no RFP positive macrophages whereas 70% of the microglia still expressed RFP. This phenotype was also observed during EAE progression.

With two Tamoxifen and three successive DT injections we could achieve an efficiency of 80% microglia cell ablation. Interestingly, we observed by histology 50% of repopulating microglia already 6 days after depletion. Approximately 2 weeks after depletion the microglia numbers were even increased compared to unaffected controls. In FACS analysis we found a CD45.2 high $Ly6C^+$ population on day 6, indicating a repopulation of microglia by peripheral monocytes.

During EAE the mice showed a more severe course of disease and exhibit a neurological phenotype.

Conclusions: Mice without microglia sustained a more severe EAE course, which was accompanied by showing neurological deficits. Furthermore microglia were rapidly repopulated after depletion and therefor they seem to play a critical role in homeostasis of brain functions and environment.

P0138

T cell immunoglobulin and mucin family members are expressed by hematopoietic cells, especially developing macrophages, in mouse and chicken embryo

R. Syrjänen, P. Petrov, V. Glumoff, O. Vainio & T. Uchida
Department of Medical Microbiology and Immunology, University of Oulu, Oulu, Finland

Purpose/Objective: T cell immunoglobulin and mucin domain containing (TIM) molecules are known regulators of the immune response, e.g. in asthma and autoimmunity. In adult mouse, TIM4 is known to be expressed by antigen presenting cells and TIM1, TIM2 and TIM3 by T cells in which they regulate the balance between T_{H1} and T_{H2} responses. In an earlier study, we reported *tim1* and *tim4* to be expressed differentially by $CD45^+$ hematopoietic cells in para-aortic (PA) region of chicken embryo. Chicken PA-region, as mouse fetal liver (FL), provides a microenvironment for HSC to further proliferate and differentiate into hematopoietic progenitor cells (HPC). Our aim is to study the expression and role of TIM molecules in fetal hematopoiesis.

Materials and methods: We have analysed TIM expression in chicken by PCR and *in situ* hybridization and in mouse by qPCR and FACS staining. We have also characterized mouse FL TIM expressing cells with antibodies to identify their developmental stages.

Results: PCR analysis of chicken embryonic day 4 (ED 4), ED 7 and ED 13 tissues revealed *tim1* to be expressed more widely in younger embryos, especially in PA-mesenchyme which is a known site for HSC differentiation and development. Chicken *tim4* transcripts were amplified from almost all studied embryonic tissues. It«s wide expression pattern was also evident in *in situ* hybridization suggesting *tim4* to be expressed by macrophages during development. In 12.5 dpc mouse, *tim3* and *tim4* transcripts were expressed highest in FL and mostly absent in non-hematopoietic tissues. *tim1* expression was shown to be high in lung.

Further characterization of 13.5 dpc mouse FL cells showed TIM4 to be expressed by $CD45^+$ $F4/80^{high}$ cells which are presumably macrophages. $TIM4^+$ $CD45^+$ $F4/80^{high}$ cells included populations expressing stem cell markers c-kit and/or SCA-1. TIM1 and TIM3 were also shown to be mainly expressed in $CD45^+$ hematopoietic cells. Both $CD45^+$ $TIM1^+$ and $CD45^+$ $TIM3^+$ populations included a subpopulation of $F4/80^+$ $c\text{-}kit^+$ immature macrophages. $CD45^+$ $TIM1^+$ $F4/80^-$ and $CD45^+$ $TIM3^+$ $F4/80^-$ cells contain few $c\text{-}kit^+$ and/or $SCA\text{-}1^+$ cell, possibly HSC or HPC.

Conclusions: In summary, TIM family molecules are expressed by mouse and chicken embryonic hematopoietic tissues. In mouse FL, TIM1, TIM3 and TIM4 expression was shown in hematopoietic cells, especially in immature macrophages suggesting a possible role in hematopoiesis.

P0139

T-cell specific deregulation of Notch3 receptor induces alterations in the development of myeloid compartment unveiled by the deletion of NF-kappaB/p50 expression

A. F. Campese,* P. Grazioli,* G. Scafetta,† C. Noce,* S. Verkhovskaia,* C. Mari,* A. F. Gulino* & I. Screpanti*
**Molecular Medicine, Sapienza University of Rome, Rome, Italy,*
†Medical-Surgical Sciences and Biotechnologies, Sapienza University of Rome, Rome, Italy

Purpose/Objective: T-cell specific deregulation of Notch3 in transgenic mice (*N3-tg*), induces the development of a T-cell acute lymphoblastic leukemia (T-ALL), sustained by the constitutive activation of NF-kB canonical pathway. Besides, Notch signalling modulation in bone-marrow stromal cells or in hematopoietic stem cells, has been related to alterations in differentiation/proliferation processes of myeloid cells. To clarify the Notch/NF-kB relationships in the progression of T-ALL and the effects of a T-cell specific deregulation of Notch on myeloid compartment, we decided to delete NF-kB canonical pathway in *N3-tg* mice.

Materials and methods: We generated *N3-tg/p50*$^{-/-}$ mice, deleted of the NF-kB/p50 subunit in a Notch3 transgenic background. The follow-up of double mutant versus *N3-tg* mice versus relative controls was conducted and immunophenotyping of hematopoietic cell subsets was performed at different age and in multiple tissues from the indicated animals by flow-cytometry tecniques. Total RNA and protein extract samples, derived from sorted T- or myeloid-cells of our mice models, were processed for RT-qPCR and Western blotting analysis, respectively, to test the expression of Notch-related molecules.

Results: The progression of T-ALL, as defined by the peripheral expansion of immature $CD4^+$ $CD8^+$ T cells, was strongly inhibited in *N3-tg/p50*$^{-/-}$ versus *N3-tg* mice. However, the double mutant mice succumb earlier than *N3-tg* counterparts displaying a dramatic increase of $Mac1^+$ $Gr1^+$ myeloid cells in both spleen and blood, as well as of granulocyte/monocyte progenitors in the bone marrow. The expansion of myeloid subsets was detectable at a lower extent also in *N3-tg* versus *wild-type* mice. Preliminary data indicate that $Mac1^+$ $Gr1^+$ cells do not express Notch3, suggesting that this receptor may influence the equilibrium of the myeloid compartment mainly *in trans*, possibly through its interaction with the Jagged-1 ligand.

Conclusions: Our results suggest that the NF-kB canonical pathway deletion inhibits the T-ALL progression, thus unveiling the influence of Notch signalling modulation on the behaviour of myeloid cells. We provide a useful model to extend our understanding of Notch/NF-kB interplay in driving the relationships between lymphoid and myeloid compartments in the context of hematological malignancy.

The Frizzled-like domain from Collagen XVIII (FZC18) controls hematopoiesis and myeloidogenesis *in vivo*

V. Izzi, D. G. Vicente, R. Devarajan, H. Ruotsalainen, R. Heljasvaara & T. Pihlajaniemi

Center for Cell-Matrix Research and Biocenter Oulu Department of Medical Biochemistry and Molecular Biology, University of Oulu, Oulu, Finland

Purpose/Objective: Collagen XVIII (Col18), characterized by the antiangiogenic / tumor-suppressive endostatin domain at its C-terminus, occurs as three N-terminal variants. The corresponding gene has two promoters, promoter 1 encoding the shortest variant and promoter 2 the middle and longest variants. The longest variant is characterized by a frizzled-like domain (FZC18), known to be shed from full-length Col18, and shown to act as a soluble inhibitor of the Wnt3a/b-catenin pathway. In view of the known importance of Wnt3a in hematopoietic stem cell (HSCs) development and myeloidogenesis, and the fact that Col18 is expressed in the bone marrow, we decided to investigate the effects of lack of Col18 on mouse hematopoiesis.

Materials and methods: Using total- and promoter-specific knockout mice for Col18, the HSCs isolated from adult bone marrow were fractionated into KLS and srHSCs populations basing on their expression of CD34, a master marker for HSCs/ multipotent progenitors discrimination. The same mouse cohorts were also screened for differences in peripheral leukocyte counts. Moreover, 12.5 and 13.5 days p.c.-old embryos were collected and HSCs in the liver screened for CD41 (a marker for yolk sac-derived HSCs) and CD45 (a marker for liver HSCs) expression.

Results: Our data show for the first time a role for Col18 on mouse hematopoiesis, as witnessed by a significant increase in HSCs in the knockout mice, and consequently a wide increase in monocyte and granulocyte counts. This effect was found to be specific for promoter 2 knockout mice.

Conclusions: Specific ablation of the middle and longest Col18 variants leads to an increase in srHSCs which reflects on peripheral monocyte and granulocyte accumulation, without any appreciable effect on the specific compartment of the immune response. These data thus provide evidence of novel roles for Col18 and possibly its FZC18 variant, capable of binding Wnt molecules, as endogenous controllers of myeloidogenic commitment during HSCs development.

P0141

The role of microRNA in microglia maintenance and function

D. Varol, Y. Wolf, A. Mildner & S. Jung

Department of Immunology, The Weizmann Institute of Science, Rehovot, Israel

Purpose/Objective: Microglia are macrophages populating the central nervous system (CNS). They continually survey the CNS and mediate phagocytosis during steady state (development, synaptic pruning) and contribute to neurodegenerative diseases. To protect the CNS from harmful inflammation, microglia activity is tightly regulated by various factors including microRNAs (miRs). To study microglia in context we take advantage of CX_3CR1-CreER mice that harbor a latent recombinase inducible upon drug application. In tamoxifen-treated mice, rearrangements in peripheral CX3CR1-expressing mononuclear phagocytes are progressively lost due to their renewal from BM-derived precursors. In contrast, the self-maintaining CX_3CR1^+ microglia remain permanently genetically manipulated. Here, we generated *in vivo* conditional miR deficiency in microglia by crossing CX_3CR1-CreER mice with mice harboring a conditional allele of Dicer, the miR processing enzyme yielding MG^{DDicer} mice.

Materials and methods: Flow cytometry measuring microglial numbers and activation; immuno-histochemistry assessing neurodegeneration, neuroinflammation and astrogliosis; behavioral studies measuring motoric functions.

Results: MG^{DDicer} mice display a progressive severe loss of microglia which is more pronounced in spinal cord than the brain. The remaining dicer-deficient microglia had elevated surface expression of CD11b and CD45, as well as CD86. Immunohistochemistry of microglia showed a classical pattern of activated microglia with increased cell body and amoeboid structure. Finally, preliminary behavioral locomotor studies revealed reduced motoric activity of MG^{DDicer} mice, when compared with their littermates.

Conclusions: Here we establish a critical role of miRNA in the maintenance of microglia. Spinal cord microglia are more sensitive than brain microglia, resulting in lower limb motoric deficiency. Ongoing experiments address whether motor neuron defect results from microglia activation and neuro-inflammation. Moreover, we are in the process of generating mice with deficiencies of specific candidate miRs to define the miR control of microglia homeostasis.

A new mechanism of resistance to NK cell attack in melanoma

M. Vitale,* M. Balsamo,† M. Parodi,† G. Pietra,† C. Manzini,† A. Moretta,† W. Vermi,‡ F. Facchetti,‡ L. Moretta§ & M. C. Mingari*
*Immunology, IRCCS-AOU San Martino-Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy, †DI.ME.S., Univaersità Genova, Genoa, Italy, ‡Spedali civili Brescia, Servizio Anatomia Patologica., Brescia, Italy, §Istituto G. Gaslini, Direz Scientifica, Genoa, Italy

Purpose/Objective: The efficiency of human NK cells in eliminating tumors is generally assessed by measuring their killing capability against a large number of tumor cell lines in cytolytic assays. The E/T ratios used *in vitro*, however, may be not consistent with the levels of NK cell infiltration of tumors. In this study, by the histological analysis of 28 melanoma samples, we first assessed the level of NK infiltration at the tumor site, and then set up NK-melanoma cell co-culture experiments in order to assess the possible functional interactions occurring between the two cell types at such low E/T ratio.
Materials and methods: Melanoma cells recovered from co-cultures were analyzed by FACS and in cytolytic assays in order to assess possible changes in their surface phenotype and their susceptibility to NK cell mediated lysis.
Results: The histological analysis of melanoma samples revealed that the NK/Melanoma cell (NK/M) ratio *in situ* is far lower than that generally used *in vitro* to evaluate the NK cell killing capability. In co-culture experiments performed at similar low NK/M ratio, we observed that a large part of melanoma cells survived and, more importantly, acquired strong resistance to NK cell-mediated killing. This effect was essentially due to an increased surface expression, in melanoma cells, of classical and non classical HLA-I molecules and was dependent on NK-mediated IFN-g release. NK-conditioned Melanoma cells also showed slight expression decreases of different NKG2D-Ligands and of GPR56 (a possible receptor for ECM components) but these changes didn't apparently affect melanoma cell susceptibility to NK cells. Further analysis on melanoma lesions revealed a higher HLA-I expression on tumor cells that were proximal to NK cell infiltrate thus suggesting that the acquisition of resistance could actually occur *in vivo*. Analysis of different NK-activating cytokines indicated that IL-15 might in part overcome this new phenomenon of tumor resistance.
Conclusions: This study provides new elements for a proper evaluation of NK cell efficacy to fight cancer *in vivo* and proposes IL-15 as valuable element to prevent from this newly described phenomenon of tumor resistance.

P0143
Accelerated effector: target conjugate formation and granule polarization in leukotriene B4-treated human NK cells

J. Stankova, M. Wang, S. Turcotte & M. Rola-Pleszczynski
Pédiatrie, Université de Sherbrooke, Sherbrooke, QC, Canada

Purpose/Objective: The natural killer (NK) cell is an important element of innate and adaptive immunity due to its strong cytotoxic response and cytokine production. Previously, we determined that leukotriene B_4 (LTB_4) augmented NK cytotoxicity and characterized the expression and contribution of LTB_4 receptors on NK cells. However, the mechanism of LTB_4-induced cytotoxicity augmentation is not yet clear. The killing of target cells by NK cells involves recognition, conjugation between NK and target cells, granule polarization and degranulation. Thus, we sought to investigate the effect of LTB_4 at these stages of cytotoxicity.
Materials and methods: Peripheral blood mononuclear leukocytes and purified NK cells were isolated from healthy donors. Calcium influx was measured with Fluo-4 stain. LFA-1 activation was determined with a specific antibody. The NK-target conjugates were determined as $CD56^+$ $CFSE^+$ after co-incubation of NK cells ($CD56^+$) and K562 cells ($CFSE^+$). CD107a (LAMP1) was chosen as marker for degranulation. The kinetics of granule polarization was evaluated by confocal microscopy in NK92MI. Cytotoxicity was measured with the 7AAD stain by flow cytometry.
Results: LTB_4 induces concentration-dependent calcium influx in NK cells. NK-target binding increases 1.5-fold after a 5-min stimulation with LTB_4, however, this increase is transient and returns to control levels within 30 min. In NK92MI cells, LTB_4 results in granule polarization to the synapse area within 12 min after NK-K562 conjugation, compared to 20 min in unstimulated cells. In addition, higher CD107a expression on the NK cell surface is observed within 30 min of stimulation with LTB_4.
Conclusions: Our findings suggest that a more rapid NK-target conjugation, granule polarization and increased degranulation may contribute to LTB_4-induced augmentation of NK cell cytotoxicity.

P0144
Acute myeloid leukemia cells evade from NK cells anticancer response by forming an impaired immunological synapse

Z. Khaznadar,* G. Henry,† N. Setterblad,‡ S. Agaugue,§ N. Boissel,¶ H. Dombret,¶ A. Toubert** & N. Dulphy**
*Univ Paris Diderot Institut Universitaire d'Hématologie, Institut National de la Santé et de la Recherche Médicale Inserm UMR940, Paris, France, †Laboratoire d'Immunologie et Histocompatibilité, Assistance Publique Hopitaux de Paris APHP Hopital Saint Louis, Paris, France, ‡Department d'Immagerie, Univ Paris Diderot Institut Universitaire d'Hématologie, Paris, France, §Immunologie, Institut National de la Santé et de la Recherche Médicale Inserm UMR940, Paris, France, ¶Assistance Publique Hopitaux de Paris APHP Hopital Saint Louis-Service d'Hématologie Adulte, Univ Paris Diderot, Paris, France, **Institut National de la Santé et de la Recherche Médicale Inserm UMR940, Univ Paris Diderot Institut Universitaire d'Hématologie – APHP Hopital Saint Louis Laboratoire d'Immunologie et Histocompatibilité, Paris, France*

Purpose/Objective: Natural Killer cells (NK) cells are largely studied as effectors cells in the anticancer immune response in patients with Acute Myeloid Leukemia (AML). AML blasts were shown to express ligands for NK cell activating receptors. We and others observed some defects in the expression of major activating receptors including NKG2D, DNAM-1 and NKp46, on patients NK cells. However little is known about the direct interaction between NK cells and leukemic cells.
Materials and methods: We used primary NK cells from healthy donors and AML cell lines THP1 and HL60, in comparison to the highly sensitive NK target K562. Interactions between NK and tumor cells were evaluated by flow cytometry and confocal microscopy, focusing on the polarization of actin, CD107a and LFA-1 toward the immune synapse. Long-term impact of the NK-AML tumor contact was evaluated after *in vitro* co-cultures.
Results: NK cells formed less conjugates with HL60 than with THP1, and in both cases less than with K562. Upon contact with THP1 and HL60, first steps of the lytic synapse were established: actin polymerized and the adhesion molecule LFA-1 was recruited to the contact area. However lytic granules polarization toward the synapse was defective: average percentage of conjugates showing polarized CD107a was 32% and 29% with THP1 and HL60 respectively, compared to 55% with K562 ($P = 0.001$ and 0.0007 respectively). Interactions with HLA-Cw*03:04 transfected and untransfected K562 lines were not different, ruling out a primary effect of inhibitory receptor ligands.

After 48h co-culture of PBMC with AML cell lines, the expression of DNAM-1 on all NK cells was down-regulated with both THP1 and

HL60. NKG2D expression was reduced only with THP1 and the decrease of NKp46 was significant on the CD56Bright subset only with both cell lines. NK cells retrieved from co-culture with THP1 showed a decreased activity in a CD107a degranulation assay (16.8% degranulation of THP1 co-cultured NK cells versus 43.4% for control cultured NK cells, $P = 0.03$).

Conclusions: Our observations show defects in lytic granule polarization and function during the early interaction between NK cells from healthy donors and AML cell lines. This engagement leads also to a decreased expression of activating receptors and thereby to sustained cytolytic activity impairment.

P0145

Alloreactive NK cells in haploidentical-HSCT (HAPLO-HSCT) upon infusion of either CD34$^+$ OR TCR alpha beta/CD19-depleted cells

R. Meazza,* M. Falco,† C. Tuberosa,‡ S. Marcenaro,* M. E. Bernardo,§ M. C. Mingari,* A. Moretta,‡ L. Moretta,¶ F. Locatelli§ & D. Pende*

**Lab. Immunologia, IRCCS-AOU San Martino-Istituto Nazionale per la Ricerca sul Cancro, Genova, Italy, †Lab Immunologia Clinica e Sperimentale, Istituto G. Gaslini, Genova, Italy, ‡Università degli Studi di Genova, Dimes, Genova, Italy, §Ospedale Bambin Gesù, Ematologia e Oncologia pediatrica, Roma, Italy, ¶Direzione Scientifica, Istituto G. Gaslini, Genova, Italy*

Purpose/Objective: We aimed to analyze the NK cell repertoire in pediatric leukemia patients transplanted from alloreactive haploidentical donors, comparing two different procedures: infusion of either CD34$^+$ or TCR $\alpha\beta$/CD19-depleted cells. This second graft manipulation provides a pool of stem cells in addition to effectors cells, potentially active against infections (i.e. NK and TCR $\gamma\delta$ T lymphocytes) and against leukemia cells (i.e. alloreactive NK cells).

Materials and methods: Clinimacs technology was used for either the positive selection of CD34$^+$ or the negative selection of $\alpha\beta$ T cells and CD19 B cells. The analysis of donor KIR gene profile and HLA-I typing of both donor and recipient may predict, in the case of KIR/KIR-ligand mismatch in GvH direction, the existence of alloreactive NK cells. Combinations of anti-KIR mAbs were used to define the size of alloreactive NK cell subset and the expression of activating KIR.

Results: Genetic, phenotypic and functional analyses have been performed to study the NK cell repertoire. In some cases, when two NK alloreactive donors were available, we have selected the most appropriate one taking into account features which have been correlated with a better clinical outcome (KIR genotype B/X better than A/A, higher B content score, larger size of alloreactive subset), considering the positive role that activating KIR can exert. Indeed, we have demonstrated that the presence of KIR2DS1 in C1$^+$ /C2$^+$ donors can be relevant in the lysis of C2$^+$ /C2$^+$ leukemias. At the 1st month post-transplant, while NK cells in CD34$^+$ grafts predominantly displayed an immature phenotype, in TCR $\alpha\beta$/CD19-depleted grafts we observed a high proportion of NK cells with a mature phenotype (CD56^{dim}, KIR$^+$/NKG2A$^-$ and CD57$^+$) and a detectable alloreactive NK cell subset.

Conclusions: These preliminary data suggest that, in patients transplanted with TCR $\alpha\beta$/CD19-depleted cells, mature donor-derived NK cells, including alloreactive NK cells, persist at 1st month. Longer follow-up and larger group of patients are necessary to clinically assess the potential beneficial effects of this graft manipulation in the control of infections and leukemia relapse.

P0146

Altered number and function in different subpopulations of NK cells from elderly

C. Campos,* A. Pera,* I. Gayoso,* R. Tarazona† & R. Solana*

**Department of Immunology, IMIBIC Reina Sofía Hospital, University of Córdoba, Córdoba, Spain, †Department of Physiology (Immunology Area), University of Extremadura, Cáceres, Spain*

Purpose/Objective: The process of immunosenescence affects both innate and acquired immune response. Previous studies show that NK cells are affected by ageing. The aim of this work is to study *in vitro* the effect of age on the phenotype and function of NK cell subpopulations through the quantification of the basal content of granzymes A and B.

Materials and methods: To determine *in vitro* the frequency of NK cells and their subpopulations, 32 young donors and 20 elderly donors were included. In order to analyze the changes associated with aging in the intracellular expression of granzymes on NK cells subpopulations, defined by the expression of CD56/CD16, the basal content of granzyme A ($n = 33$ young and 23 elderly donors) and granzyme B ($n = 29$ young and 24 elderly donors) was determined by multiparametric flow cytometry.

Results: The frequency of subpopulations CD56brightCD16- and CD56brightCD16low of the elderly compared with young people was decreased while the subpopulation CD56-CD16$^+$ was increased. The percentage of NK cell subpopulation CD56dimCD16$^+$ was maintained. Our results showed an increased expression of granzyme A and B in total NK cells from elderly individuals when compared with young donors. In relation with the NK cells subpopulations, we found an increased expression of granzyme A and granzyme B in CD56bright-CD16- and CD56brightCD16low of elderly relative of young people, while it was decreased in CD56dimCD16$^+$ of the elderly compared with young people. Similar expression rates of granzyme A and B were found in the subpopulation CD56-CD16$^+$ from elderly and young donors.

Conclusions: The results indicate that NK cells are among the lymphocyte populations affected by the process of 'immunosenescence' in phenotype and function. These changes affect differently the different subpopulations of NK cells. The CD56bright subpopulation is most affected in this process, becoming more cytotoxic capacity with age.

P0147

CD161 expression defines a phenotypically, functionally and transcriptionally distinct set of NK cells which are specifically depleted in HIV infection

A. Kurioka,* C. Willberg,* C. Cosgrove,* Y. Kang,* E. Young,* H. Güntard,† A. Rauch,‡ N. Khanna§ & P. Klenerman*

**Peter Medawar Building for Pathogen Research, University of Oxford, Oxford, UK, †Division of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, University of Zurich, Zurich, Switzerland, ‡Division of Infectious Diseases University Hospital Berne, University of Berne, Berne, Switzerland, §Division of Infectious Diseases and Hospital Epidemiology, University Hospital Basel, University of Basel, Basel, Switzerland*

Purpose/Objective: HIV-1 infection leads to a gradual loss of natural killer cells, which correlates with disease progression. CD161 is a C-type lectin molecule expressed on the majority of NK cells. CD161$^+$ NK cells have been previously observed to be reduced in HIV infected patients; however functional analyses according to CD161 expression have not been performed. In this study we have characterized the unique properties of NK cells expressing CD161 by defining their phenotype, transcriptional signature, and functional capacity in healthy donors, and for the first time present longitudinal data showing CD161 expression recovering with HAART treatment in chronic HIV patients.

Materials and methods: $CD161^+$ and CD161- NK cells were sorted from PBMCs isolated from healthy adult blood, and expression profiling was performed using the Agilent platform. Differentially expressed genes and functional properties were analysed using FACS and intracellular cytokine staining. The flux of these cells in chronic HIV was analysed using longitudinal samples from the Swiss HIV cohort study.
Results: We report that CD161 is expressed on the majority of $CD56^{bright}$ NK cells and $CD56^{dim}$ NK cells in adults (average 80.57% and 89.79%, respectively). $CD161^+$ NK cells are enriched for activating NK cell receptors and cytolytic molecules while CD161- NK cells express inhibitory NK cell receptors. Furthermore, there was a significant enrichment of cells producing IFNγ and with greater proliferative capacity in response to target cells and cytokines in the $CD161^+$ NK cell subset compared to the CD161-NK cell subset. Intriguingly, the frequency of $CD161^+$ NK cells was dramatically lower in HIV patients before HAART treatment compared to healthy controls (62.83% and 89.37% respectively, $P < 0.0001$), but showed a stepwise increase their CD161 expression after HAART initiation, correlating with a higher CD4 count ($r = 0.5013$, $P = 0.0107$).
Conclusions: These results suggest that CD161 expression on NK cells is a marker of a more activated and functional subset within both the $CD56^{bright}$ and $CD56^{dim}$ NK populations, displaying enhanced antiviral function. This highly functional subset of NK cells is reduced in chronic HIV, but recovers with HAART. Further understanding of the role of this NK cell subset in disease progression may provide new insights into HIV pathogenesis.

P0148
Characterization of mice with a deficiency in natural killer cell missing self reactivity

S. Wickstrom, L. Öberg, K. Kärre, M. H. Johansson
Karolinska Institute, MTC, Stockholm, Sweden

Purpose/Objective: In experiments with a KO mouse strain deficient for a nonclassical MHC class I like gene, but with otherwise normal MHC class I expression, we unexpectedly observed that the mice had severely impaired capacity for NK cell mediated rejection of MHC class I deficient cells. Control experiments with independently derived KO strains for the same gene as well as F1 and F2 intercrosses with B6 mice, indicated that the NK cell defect was not caused by the targeted gene and the two phenotypes segregated independently. This mouse strain represents an opportunity to study the mechanisms and regulation of missing-self rejection and other NK functions.
Materials and methods: *in vivo* studies of NK cell mediated rejection of normal and tumor cells. *In vitro* flow cytometry based assays to study the phenotype and functional capacity of NK cells. *In vitro* cytotoxicity assays. Construction of bone marrow chimeras.
Results: The mouse strain showed a normal number of NK cells and normal profiles for their cell surface phenotype. *In vivo*, the NK cells showed a severely impaired capability for missing self rejection of normal spleen (b_2m- versus b_2m^+) and tumor cells (RMA-S versus RMA). Kinetic studies and tumour outgrowth experiments revealed a profound defect rather than a delay in missing-self rejection. In contrast, there was a normal or partly impaired capacity with respect to other NK functions, such as positive allorecognition, CD107a/IFNγ production and ADCC. Genetic crosses suggested that the defect is under control of (a) recessive gene(s). Bone marrow chimeras indicated that the defect is bone marrow derived and not due to the host environment..
Conclusions: Our results indicate that this mouse strain has a genetically based, selective deficiency in the killing pathway used to sense missing self. This defect is intrinsic to bone marrow cells, possibly to the NK cells themselves. One possibility is a dysfunction that involves an unknown activating receptor or signaling molecule, most critical for missing self recognition. Alternatively, the defect may disturb education/licensing for missing self recognition, while leaving other NK functions relatively intact. Further studies of these mice may shed light on the regulation and the *in vivo* role of missing self recognition as compared to other NK cell functions, in different responses or diseases.

P0149
Characterization of NK cells infiltrating metastatic melanoma lymph nodes

M. Messaoudene,* G. Fregni,* E. Neves,* J. Chanal,* E. Maubec,† M. F. Avril‡ & A. Caignard§
**Immno-Hematology, Cochin Institute Inserm U1016, Paris, France, †Dermatology, Bichat Hospital, Paris, France, ‡Dermatology, Cochin Hospital, Paris, France, §Immno-Hematology, Cochin Institute INSERM U1016, Paris, France*

Purpose/Objective: Over the past decades, the incidence of melanoma has been constantly increasing. Malignant melanoma has a high metastatic potential and is difficult to cure. There are numerous arguments indicating that melanomas are immunogeneic and that the immune system can control the tumor growth in certain conditions. We focus our interest on Natural Killer (NK) cells, potent cytotoxic effectors that can control metastases in several murine tumor models.
Materials and methods: To study the NK cells that infiltrated lymph nodes, an early site of metastasis in melanoma, we have set up experimental methodology to characterize NK cells in metastatic lymph nodes (LN) from 25 stage III melanoma patients. We have analysed *ex vivo* by multicolor FACS analyses and functional assays in response to K562 stimulation the NK cells infiltrating lymph nodes. The tumor burden in the samples was estimated by the pathologist to determine the level of tumor invasion of the LN and distinguish metastatic (M) and non metastatic (nM) LN. We included mediastinal LN from five donors as controls.
Results: We first show that the $CD56^{dim}$ NK subset major circulating NK subset is less represented in LN. Our preliminary data show that compared to normal LN, the phenotype of NK cells from patient derived LN is different: however, NK cells from MLN and nMLN exhibit close phenotype and are characterized by increased expression of certain activating receptors. Chemokine receptors are also expressed by LN infiltrating NK cells from patients suggesting their migration from the periphery. LN infiltrating NK cells from patients are also characterized by decreased functionality in response to strong stimulation (PMA/$Iono^+$K562). We also determine the frequencies and distribution of NKp46 positive NK cells by immunohistochemistry in a series of sentinel lymph nodes from melanoma patients.
Conclusions: These results constitute a complete *ex vivo* characterization of NK cells infiltrating LN from melanoma patients.

P0150
CXCL8 production and absence of LFA-1 surface expression identify human NK cells at early stages of differentiation characterized by CD161 molecule with activating function

C. Vitale,* E. Montaldo,* F. Cottalasso,† R. Conte,‡ T. Glatzer,§ P. Ambrosini,* L. Moretta¶ & M. C. Mingari**
**Experimental Medicine Department (DIMES), University of Genoa, Genoa, Italy, †Immuno-hematology, IRCCS G. Gaslini, Genoa, Italy, ‡Oncology and Hematology, IRCCS AOUSM/IST, Genoa, Italy, §Innate Immunity, DRFZ Berlin, Genoa, Italy, ¶Scientific Direction, IRCCS G. Gaslini, Genoa, Italy, **Experimental Medicine Department (DIMES), University of Genoa and AOUSM/IST, Genoa, Italy*

Purpose/Objective: Human NK cell development is a step-by-step process characterized by phenotypically identified stages. To define

factors that involved *in vitro* NK cell differentiation and maturation from $CD34^+$ progenitors, we performed time course analysis of cytokine release and of acquisition NK cell markers expression.

Materials and methods: Umbilical cord blood $CD34^+$ stem cells were cultured *in vitro* with IL-7, IL-15, IL-21, SCF and Flt3-L in. Leucocytes were analysed for informative cell surface markers by cytofluorimetric assays and separated by cell sorting according to CD33, CD161, CD56 and LFA-1 surface expression. Cells were tested for cytolytic activity and/or cytokine production. Cytofluorimetric assays were used to analyse CD161-mediated signal transduction, cytokine or CD107 expression. We performed Real Time PCR for detection of CXCL8 mRNA.

Results: We demonstrated that LFA-1 expression allows discriminating between immature non-cytolytic $CD161^+$ $CD56^+$ LFA-1- NK cells (immNK) and more differentiated cytolytic $CD161^+$ $CD56^+$ $LFA\text{-}1^+$ NK cells (difNK). LFA-1 expression allowed distinguishing between $CD161^+$ $CD56^+$ LFA-1- immNK cells producing large amounts of CXCL8, but not IFN-γ, and $CD161^+$ $CD56^+$ $LFA\text{-}1^+$ difNK cells, producing IFN-γ, but not CXCL8. We could also identified *in vivo* immNK cells able to produce CXCL8. Indeed, CXCL8 mRNA expression was detected in fresh tonsil Lin-$CD56^+$ $CD117^+$ CD94/NKG2A- stage III immature NK cells and these cells expressed CXCL8 protein upon PMA stimulation. CXCL8 release was also induced upon crosslinking of NKp44 and CD161. The activating function of CD161 was confined to immNK cell subset, since it did not induce cytokine release or CD107a expression in $CD161^+$ $CD56^+$ $LFA\text{-}1^+$ difNK cells or in mature PB NK cells. CD161 crosslinking in immNK cells induced increase of Akt-pS473 expression and CD161-mediated CXCL8 expression was significantly reduced by the presence of Akt inhibitor XI. The addition of anti-CXCL8 neutralizing antibody led to a partial inhibition of NK cell differentiation suggesting a regulatory role of CXCL8 during early NK cell differentiation.

Conclusions: Altogether, these data provide novel information on NK cell development and may also offer clues to optimize NK cell maturation in hematopoietic stem cell transplantation.

De novo expression of CCR7 and acquisition of migratory properties by human $KIR2DS1^+$ NK cells interacting with allogeneic $HLA\text{-}C2^+$ monocyte-derived DC or T cell blasts

S. Pesce,* E. Marcenaro,* S. Sivori,* S. Carlomagno,* L. Moretta† & A. Moretta*

**Department of Experimental Medicine, University of Genoa, Genoa, Italy, †Department of Experimental Medicine and Laboratory, Istituto Giannina Gaslini, Genoa, Italy*

Purpose/Objective: In the present study, we investigated the ability of $KIR2DS1^+$ NK cells to de novo express CCR7 after interaction with allogeneic $HLA\text{-}C2^+$ mature dendritic cells (mDC) and T cell blasts.

Materials and methods: In order to better understand the correlation between KIR2DS1-mediated signaling and CCR7-expression, we used mDC from allogeneic donors expressing HLA-C alleles belonging to the C2-specificity and selected alloreactive NK cell clones expressing the activating C2-specific KIR2DS1 receptor and NKG2A (or, as control, clones expressing only NKG2A).

In co-culture experiments, NK cells were mixed with these targets at an effector-to-target cell (E/T) ratio of 1:1 in the presence or in the absence of anti-HLA-Cw4 or anti-NKG2A mAbs and incubated for 1 h at 37¡ C in 5% CO_2. Next, NK cells were directly assessed for surface phenotype, cytolytic activity, migration capacity and cytokine production.

Results: In transplantation, alloreactive NK cells by killing recipient DC play a crucial role in preventing donor's T cell priming and subsequent GvHD. We showed that alloreactive KIR^+ NK cells may *de novo* express CCR7 upon co-culture with allogeneic mDC. The acquisition of CCR7 by NK cells is due to receptor uptake from $CCR7^+$ cells and is negatively regulated by inhibitory KIR-mediated recognition of HLA class I molecules.

Recent data indicate that, KIR2DS1 expression confers alloreactive NK cell responses with potent cytotoxicity against $HLA\text{-}C2^+$ mDC and T cell blasts.

In this study, we analyzed the effects mediated by alloreactive $KIR2DS1^+$ NK cells in the acquisition of CCR7 upon interaction with $HLA\text{-}C2^+$ $CCR7^+$ cells. Analysis of NK cell clones revealed that NK cells expressing this activating KIR acquire CCR7 and that this mechanism is positively regulated by recognition of KIR2DS1-ligand on both allogeneic DC and T cell blasts.

Conclusions: These data may have important implications in haploidentical hematopoietic stem cell transplantation, in which donor $KIR2DS1^+$ NK cells acquire the ability to migrate to lymph nodes, where they can kill recipient's DC and T cells thus preventing GvH (and HvG) reactions.

P0152

Differential TLR3 expression and function in human newborns and adults

L. Slavica,* I. Nordström,* M. Nurkkala-Karlsson,* M. Kacerovsky,† B. Jacobsson† & K. Eriksson*

**Department of Rheumatology and Inflammation Research, University of Gothenburg Institute of Medicine, Gothenburg, Sweden, †Department of Obstetrics and Gynecology, University of Gothenburg, Gothenburg, Sweden*

Purpose/Objective: TLR3 is an innate immune system receptor that recognizes dsDNA and is responsible for viral sensing. Human newborns are more susceptible to pathogens then adults, including to viral infections, e.g. herpes simplex type 2. We therefore hypothesized that TLR3 expression, as well as of some other viral-sensing receptors, might differ between newborns and adults.

Materials and methods: We analyzed different leukocyte subsets of cord blood and adult blood, and measured TLR3 mRNA expression in the cells that showed the highest TLR3 expression, i.e. natural killer (NK) and T cells, as well as in placental NK cells. Also, functional characteristics of cord and adult blood NK cells in response to TLR3 ligands were analyzed and compared.

Results: We found a marked difference in TLR3 mRNA and protein expression in cord blood NK and placental NK cells compared to adult blood NK cells. The mRNA expression of TLR7, TLR8, TLR9, MDA-5, RIG-I, PKR and IFI-16 genes for viral-sensing receptors did not significantly differ between newborns and adults. Furthermore, cord and adult blood NK cells differed in their cytotoxicity and the ability to produce IFN-γ as a result of TLR3 activation, showing a functional discrepancy between newborn and adult NK cells.

Conclusions: Our data imply that cord and adult blood NK cells have different potential in the aspect of TLR3 activation which is manifested in a functional divergence of TLR3-mediated responses to viruses between newborns and adults. This contributes to a better understanding of immature immune system of newborns and consequently their higher vulnerability to viral infection.

P0153

Elucidating the role of the NK killer receptor Ncr1 in controlling melanoma using in-vivo reflectance confocal microscopy

A. Glasner,* A. Levi,† J. Enk,* T. Neuman,‡ C. D. Enk† & O. Mandelboim*

Department of Immunology, Hadassah – Hebrew University, Jerusalem, Israel, †Department of Dermatology, Hadassah – Medical Center, Jerusalem, Israel, ‡Department of Pathology, Hadassah – Medical Center, Jerusalem, Israel

Purpose/Objective: Natural killer (NK) cells play a crucial role in the early host response against viruses, bacteria and malignancies by lysing infected or transformed cells. NK cells are controlled by signals generated upon the engagement of various ligands to inhibitory and activating receptors. Among the later are proteins such as NKG2D, 2B4 and the natural cytotoxicity receptors [NCR (NKp44, NKp30 and NKp46)]. NKp46 is expressed almost exclusively on NK cells, and it is the only NK cell receptor with a mouse orthologue, the Ncr1.

Recently we demonstrated that Ncr1 plays an important role in regulating the growth of melanoma cells and their capacity to metastasize. However, the mechanism by which this is done is yet unclear.

In-vivo reflectance confocal scanning microscopy (RCM) is a novel, non-invasive imaging technique that permits real time visualization of cellular structures in the skin at a resolution close to that of conventional histology. It has been widely used in the diagnosis of both benign and malignant tumors in humans. Only few reports are available on the use of RCM in mice melanoma models.

Objectives(i) To asses the usefulness of *in vivo* RCM not only as a diagnostic tool in humans, but as a research tool capable of imaging mouse model malignancies. (ii) To clarify the mechanism by which Ncr1 is involved in melanocytic tumors and metastases development in mice.

Materials and methods: Using B16F10.9 tumors and an Ncr1 knockout mouse generated by our group we checked various melanoma indices of tumor development by means of RCM.

Results: (i) We determined that there is a very good correlation in many criteria used for diagnosis in human melanoma and the B16F10.9 mouse model. (ii) We showed that in the absence of Ncr1, tumors of the same developmental stage and size feature more aggressive properties, which are correlated with worst prognosis and metastasis.

Conclusions: Thus, we concluded that the Ncr1 is involved in the structural modulation of melanocytic tumors.

We plan to further investigate the mechanisms underlying these results *in vivo* and *in vitro*, using RCM, conventional histology and functional assays.

P0154

Expression of the NKC-encoded C-type lectin-related glycoprotein Clr-a

E. Rutkowski, S. Leibelt & A. Steinle

Institute for Molecular Medicine, Frankfurt am Main, Germany

Purpose/Objective: The 'C-type lectin-related' (Clr) molecules (Clr-a to Clr-h) are C-type lectin-like receptors encoded by *Clec2* genes in the mouse Natural Killer Gene Complex (NKC). Except for *Clec2d* encoding for Clr-b, little is known about expression and function of members of the *Clec2* gene family. Interestingly, Clr-b is a ligand of the inhibitory NK cell receptor Nkrp1d with genes of Nkrp1d and other Nkrp1 receptors interspersed with *Clec2* genes in the centromeric region of the mouse NKC. To unravel the immunological significance of Clr molecules we are aiming at the characterization of expression and function of Clr molecules, including the orphan receptor Clr-a encoded by the *Clec2e* locus.

Materials and methods: Clr-a cDNA and mutants thereof were transfected in 293T and CHO transfectants. Clr-a expression was characterized by immunoblotting, immunoprecipitation and flow cytometry. Tissue-specific abundance of Clr-a transcripts was studied by quantitative RT-PCR (qPCR) analysis of various tissues of C57BL/6 and BALB/c mice. By immunizing rats with soluble Clr-a ectodomains, Clr-a specific mAb were raised.

Results: Tissue-specific expression of Clr-a was delineated from qPCR data and confirmed by immunohistochemistry. Low cell surface expression of Clr-a on transfectants (as compared to other Clr transfectants) was attributed to certain Clr-a domains by domain swapping experiments.

Conclusions: Cell surface expression of Clr-a is impaired due to sequence-intrinsic characteristics of Clr-a. Clr-a expression confined to specific epithelia suggests involvement of Clr-a in modes of tissue-specific immunosurveillance. Attempts to identify the (yet unknown) receptor for Clr-a are ongoing and will aid in testing this hypothesis.

P0155

Functional dissection of the hemi-ITAM of the human NK receptor NKp80

A. Steinle, T. Rückrich & K. M. Dennehy

Institute for Molecular Medicine, Goethe-University Frankfurt am Main, Frankfurt am Main, Germany

Purpose/Objective: NKp80 is an activating NK cell receptor that binds to the genectically linked activation-induced C-type lectin (AICL) on myeloid cells. The NKp80-AICL interaction leads to mutual activation of NK cells and monocytes, and to cytolysis of malignant myeloid cells. Unlike other well-known activating receptors on NK cells, NKp80 seems not to associate with an accessory chain carrying an immunoreceptor tyrosine-based activation motif (ITAM), but signals via an hemi-ITAM like sequence motif in the cytoplasmic domain. In this study, we analysed effects of amino acid substitutions on phosphorylation of the hemi-ITAM and Syk recruitment by the hemi-ITAM as well as functional consequences thereof.

Materials and methods: NK-92MI cells were transduced with NKp80 and NKp80 mutants and resulting transductans used for biochemical und functional analyses.

Results: The tyrosine 7 residue (Y7) within the hemi-ITAM is phosphorylated upon stimulation of NKp80-transduced cells and is required for NKp80-mediated cytotoxicity. Replacement of Y7 by phenylalanine (Y7F) ablates phosphorylation of NKp80 and cytotoxicity upon triggering of NKp80. A peptide representing the phosphorylated hemi-ITAM-like sequence binds spleen tyrosine kinase (Syk) and Syk is phosphorylated upon cross-linking of NKp80, but not of the Y7F mutant. Phosphorylation and Syk recruitment is dependent on amino acids preceding tyrosine 7.

Conclusions: Taken together, we show that NK cell-activating signaling by NKp80 depends on the hemi-ITAM-like sequence and Syk, and that altered amino acids in the hemi-ITAM of NKp80 (as compared to the hemi-ITAM consensus) fine tune NKp80 phosphorylation and function as well as Syk recruitment.

P0156

Human alpha-1-antitrypsin transgenic mice exhibit reduced steady-state NK cell numbers, near lack of NK1.1$^+$ cells and intact responses to tumor cells

O. Guttman & E. C. Lewis

Clinical Biochemistry, Ben-Gurion University of the Negev, Ashdod, Israel

Purpose/Objective: Alpha-1-antitrypsin (AAT) is being increasingly regarded as an immune tolerogenic protein; AAT prevents rejection of islet allografts in mice, diminishes inflammation and facilitates T

regulatory cell differentiation. At the same time, AAT protects tissues from injury and enhances animal survival during live bacterial infections. Lung-specific hAAT transgenic mice exhibit constitutive circulating levels of hAAT (<250 ng/ml), and are islet allograft-protective in the absence of exogenous hAAT treatment. Natural killer (NK) cells partake in transplant rejection both by direct killing of target cells and by inflammatory cytokine release. Thus far, the cellular targets of AAT have been identified as non-T cells, and include neutrophils, dendritic cells, macrophages and B cells; little is known regarding the effect of AAT on NK cells.

Materials and methods: Here, steady-state NK population size was determined in hAAT-transgenic mice. *In vivo* NK cell responses were evaluated by introduction of (syngeneic) B16 tumor cells and (allogeneic) NIH-3T3 cells to the peritoneal cavity.

Results: According to our results, total NK population size in the peripheral blood of hAAT transgenic mice was 47 ± 6.7% from that found in WT mice. Similarly, bone marrow NK cell population was 32 ± 11% of that found in WT mice. Notably, $NK1.1^+$ cells were nearly absent in the above mentioned tissues as well as in lungs and inguinal lymph nodes of transgenic mice compared to WT mice. B16 cells evoked comparable infiltrates of NK cells between the transgenic and WT strains, while NIH-3T3 cells evoked an infiltrate that was 43 ± 8.7% of that obtained in WT transplant recipient mice.

Conclusions: These results suggest that NK cells are targets of AAT activity. Further studies are required to identify the stage of NK cell lineage that is affected by AAT, and whether the protective activities of AAT might, in part, be NK cell-mediated.

P0157

IFN-g production by neonatal and adult blood $CD56^+$ NK cells and NK-like T cells in response to Trypanosoma cruzi and IL-15: differential kinetics and cellular subset responses

A. Guilmot, Y. Carlier & A. Truyens
Laboratoire de Parasitologie, Free University of Brussels (ULB), Brussels, Belgium

Purpose/Objective: IFN-γ is a pro-inflammatory cytokine important for the control of infection by intracellular pathogens like *T. cruzi*, the protozoan parasite agent of Chagas disease. While it has been described for decades that $CD56^{bright}$ NK cells are the best early producers of IFN-γ, studies have recently shown that other subsets can be important like $CD56^{dim}CD16^+$ in a very early way, $CD56^{dim}CD16^-$ or NK-like $CD3^+$ $CD56^+$ cells. Since it is also known that cord blood cells produce less IFN-γ following pathogen contact, which has a role in the immune immaturity of the neonate, we investigated the differences in the early kinetic of IFN-γ production following *T. cruzi* and IL-15 stimulation and the cellular subsets responsible for this production in neonates and adults.

Materials and methods: Isolated cord blood and adult peripheral blood mononuclear cells were incubated with rhIL-15 (20 ng/ml) and/or live *T. cruzi* trypomastigotes in a 1:1 parasite-to-cell ratio for 2–48 h. After stimulation, cells were further processed in order to detect IFN-γ mRNA by quantitative RT-PCR, IFN-γ intracellular content by flow cytometry and IFN-γ levels in culture supernatants by ELISA.

Results: Our results show that whereas IFN-γ transcript levels rapidly increase during the first hours in response to *T. cruzi* associated with IL-15, the protein is not secreted before 12h and, globally, whatever the stimulus and the cell type, intracellular IFN-γ was not detected before 8–12 h of culture (though generally somewhat earlier in adult than in cord cells). After incubation with IL-15 and *T. cruzi*, $CD56^{bright}$ and $CD56^{dim}CD16^-$ NK cells were the best IFN-γ producers and this production peaked at 18h for adults and 24h for neonates. Besides, a low proportion of adult NK-like $CD56^+$ $CD3^+$ T cells also synthesized IFN-γ when parasites were combined with IL-15. Since, in adults, NK-like T cells constituted around 30% and $CD56^{bright}$ and $CD56^{dim}$ $CD16^-$ NK cells only 5 and 3% of $CD56^+$ cells respectively (versus respectively 1.5, 13 and 5% of $CD56^+$ cells in cord blood), their contribution to the global IFN-γ response is likely not negligible in relation to the size of their population.

Conclusions: These results indicate that the contribution of the various $CD56^+$ cell subsets to early IFN-γ production may vary in neonates and adults and these differences might contribute to the well-known immaturity of the immune system in early life.

P0158

Mapping the interaction site of the C-type lectin-like receptors KACL and NKp65

I. Vogler, B. Bauer, J. Spreu & A. Steinle
Institute for Molecular Medicine, Goethe University Frankfurt, Frankfurt am Main, Germany

Purpose/Objective: We previously reported the novel activating C-type lectin-like receptor (CTLR) NKp65. NKp65 is closely related to NKp80, an activating receptor expressed by human NK cells and a subpopulation of CD8 T cells. NKp65 was found to be a high-affinity receptor for KACL, a member of the human CLEC2 family of CTLR, encoded adjacently to NKp65 in the human Natural Killer Gene Complex (NKC). Strikingly, KACL expression is almost exclusively confined to human skin, i.e. keratinocytes. NKp65/KACL interaction has been shown to activate cytotoxicity and IFNg secretion of an NKp65- expressing NK cell line. From a delineation of the putative receptor binding site of NKp65 in the C-type lectin-like domain (CTLD) of KACL we expected further insights into the interaction mode of pairs of genetically linked C-type lectin-like receptors.

Materials and methods: Site-directed mutagenesis was employed to introduce mutations into the coding sequence of KACL. Mutated constructs were transfected into 293T and Cos7 cells and analysed by flow cytometry for KACL surface expression. Receptor binding was subsequently characterized using tetramerised ectodomains of NKp65 by flow cytometry.

Results: Based on the known crystal structure of the KACL-homologue CD69 (Natarjan et al, 2000; Llera et al, 2001), several amino acid residues exposed in the CTLD of KACL were selected for mutational analysis. KACL mutants were ectopically expressed on 293T or Cos7 cells and assayed for NKp65 binding. Certain amino acid substitutions in close proximity to the KACL C-terminus abolished NKp65 binding and thus likely define the NKp65 binding site.

Conclusions: Our results define KACL residues involved in the high-affinity interaction of KACL with NKp65 indicating that the membrane-distal KACL surface ligates NKp65.

P0159

Melanoma cells inhibit natural killer cell function by modulating their phenotype

C. Manzini,* G. Pietra,* S. Rivara,* M. Vitale,† C. Cantoni,‡ A. Petretto,‡ R. Conte,† R. Benelli,† L. Moretta‡ & M. C. Mingari*
**Dipartimento di Medicina Sperimentale/Laboratory of Immunology c/o IRCCS AOU San Martino-IST, University of Genoa, Genoa, Italy, † IRCCS AOU, San Martino-IST, Genoa, Italy, ‡G. Gaslini Institute, Genoa, Italy*

Purpose/Objective: Natural killer (NK) cells are a component of the innate immunity that play a fundamental role in cancer immune surveillance. Despite recent evidence suggests that NK cells can be considered promising effector cells in the adoptive immunotherapy of cancer, NK cell-based immunotherapy has resulted in limited clinical benefit. This may reflect the capacity of tumor cells to develop various escape mechanisms to avoid NK mediated killing. In this context, a number of cytokines, growth factors and enzymes synthesized by tu-

mor and/or stromal cells have been reported to exert suppressive effects on cells involved in immune response. In this study we analyzed the consequence of the *in vitro* interactions between melanoma cells and NK cells on NK cell phenotype and functional capability.
Materials and methods: Enriched NK cells were isolated from healthy donors using the Human NK Cell Enrichment Cocktail-RosetteSep and cultured for 6 days with irradiated melanoma cell lines in IL-2 (100 U/ml) at a Mel/NK ratio of 1:10. Specific inhibitors of the immunosuppressive factors IDO and PGE2 (1-methyl- DL-tryptophan, NS398) and the anti-IFN-γ-RI blocking mAb were added to the co-cultures. NK cells phenotype was analyzed on a FACSCalibur flow cytometer (BD Biosciences) and NK cells function was tested against melanoma cell lines in a ^{51}Cr release cytolitic assay.
Results: Our study shows that melanoma may interfere with NK cell function by down-regulating the surface expression of activating receptors including NKp30, NKp44 and NKG2D. Receptor modulation results in an impaired ability of NK cells to kill melanoma cells. This inhibitory effect is primarily mediated by indoelamine 2, 3-dioxygenase (IDO) and prostaglandin E2 (PGE2). In addition IFNγ-mediated signaling seems to play a role in the inhibitory effect of melanoma through the induction of IDO.
Conclusions: Our results help to better understand the molecular mechanisms responsible for the inhibition of NK cell function upon interaction with melanoma cells. In view of this immunosuppressive effect, new strategies might be developed to prevent inhibition of potentially efficient anti-tumor effector cells.

P0160
MHC-I modulation due to metabolic changes regulates tumor sensitivity to NK cells

E. Catalán,* J. I. Aguiló,* S. Charni,† J. Naval,* J. Pardo,* M. Villalba† & A. Anel*
**Biochemistry and Molecular and Cell Biology, University of Zaragoza, Zaragoza, Spain, †Institut de Recherche en Biothérapie, INSERM U1040, Montpellier, France*

Purpose/Objective: Tumoral cells have a tendency, known as 'the Warburg effect', to use glycolysis to obtain energy instead of mitochondrial oxidative phosphorylation (OXPHOS). In a previous work we demonstrated that, at least in leukemic cells, this glycolytic phenotype correlated with loss of ERK5 expression and/or activity and, in consequence, with reduced MHC class I expression levels (Charni et al., J. Immunol. 185: 3498, 2010). Those results suggested that tumor cells could use this mechanism to evade immunosurveillance, since lower MHC-I expression should result in lower sensitivity to cytotoxic T lymphocyte (CTL) control. However, the same scenario can also result in increased sensitivity to NK cell-mediated cytotoxicity, as clearly demonstrated in leukemic cells in which ERK5 was eliminated by genetic means and MHC-I expression substantially reduced (Charni et al., J. Immunol. 182: 3398, 2009).
Materials and methods: In the present study, we have evaluated these outcomes, *in vivo* and *in vitro*, using the murine leukemia EL4 (or EG7) cell line and its derived EL4-ρordm; cell line, which lacks mitochondrial DNA. EL4-ρordm; cells should be considered as an extreme case of the Warburg effect, since they are completely dependent on glycolysis for survival and their MHC-I expression level is lower than that of parental EL4 or EG7 cells.
Results: While EL4-ρordm; cells were equally sensitive to cytotoxicity exerted by CTL than parental cells, they were more sensitive to activated NK cell mediated cytotoxicity exerted through the perforin/granzyme system. The increase in MHC-I expression induced by dichloroacetate (DCA) in EL4 cells by forcing mitochondrial respiration resulted in turn in a decrease in sensitivity to activated NK cell cytotoxicity. These results correlate with the reduced ability of EL4-ρordm; cells to generate tumors in syngeneic mice as compared with parental EL4 cells and have been confirmed in *in vivo* cytotoxicity assays.
Conclusions: Our present results show on one hand the importance of NK cells in immune antitumor surveillance, and on the other that the absence of OXPHOS does not seem to confer tumor cells an advantage in the context of immunosurveillance at least at the tumor establishment stage.

P0161
Natural killer cell education and tolerance under conditions of mixed haematopoietic chimaerism

S. Salam, H. Brauner, M. Johansson & K. Kärre
Karolinska Institute, MTC, Stockholm, Sweden

Purpose/Objective: *Introduction.* The missing self phenomenon explains that natural killer cells are 'educated' via inhibitory interactions with ligands, especially MHC-I, to tolerate self. The rheostat model states that this is a reversible and quantitative phenomenon, depending on the amount of signals a cell receives. Assuming NK cells integrate this input over multiple cell encounters, it may also depend on the ratio between cells with and without a critical MHC class I ligand, influencing their specific responsiveness. This clinically translates into chimaerism after haematopoietic transplantation. We aim to address whether education for NK cell responsiveness and missing self rejection is influenced quantitatively by the frequency of cells with a given MHC class I ligand.
Materials and methods: *Methods.* Mouse models: (i) The DL6 mouse, having mosaic expression of the introduced MHC class I (D^d) gene on a B6 background, where all cells are K^{b+} D^{b+}, while a while the proportion of D^{d+} versus D^{d-} cells varies among mice. (ii) Mixed hematopoietic chimaeras, with one donor carrying an extra D^d transgene, compared to the other donor, B6 (K^bD^b). In both models, the mice were challenged with a mixture of differentially fluorochrome labelled target cells of the following MHC phenotypes: $D^dK^bD^b$; D^bK^b; b_2m^-. Rejection was followed over time (in blood) and finally after sacrifice (in spleens).
Results: All DL6 mice were completely tolerant to $D^{d-}K^{b+}D^{b+}$ spleen cells, however, varying degrees of impaired missing self reactivity in the mosaic mice upon challenge b_2m^- cells, was observed. The relation between this missing self reactivity and the ratio of D^{d+} versus D^{d-} cells in the two mouse models is being investigated, using normal as well as tumor target cells. The *in vitro* responsiveness of NK cells in these mice will also be reported.
Conclusions: So far, our results suggest that complete tolerance develops robustly even towards ligand deficient host cells present only at low frequency under mosaic/chimeric conditions. One possible explanation is that the cells deficient in the additional MHC-I, modulate NK cell responsiveness. It remains to be investigated whether a frequency dependent quantitative education can be revealed when using tumor cells as targets.

P0162
Natural killer cells and NK receptors in granulomatosis with polyangiitis disease

S. Tognarelli,* J. Gayet,* M. Lambert,* E. Guiard,† A. Karras,† P. Cohen,‡ A. Mahr,§ L. Guillevin,‡ M. de Menthon§ & S. Caillat-Zucman*
**Hôpital St. Vincent de Paul, Inserm U986, Paris, France, †Service de Néphrologie, AP-HP HEGP, Paris, France, ‡Service de Médecine Interne, AP-HP Hôpital Cochin, Paris, France, §Service de Médecine Interne, AP-HP Hôpital St. Louis, Paris, France*

Purpose/Objective: GPA (former Wegener's disease) is a rare autoimmune disease characterized by severe necrotizing vasculitis of small size

vessels associated with granulomatosis. There are two main forms of GPA: a localized form characterized by granulomas mostly in lungs and upper airways and a generalized or diffuse form characterized by disseminated necrotizing vasculitis often involving the kidneys. We and others have identified a peculiar subset of CD4 T cells expressing some Natural Killer (NK) cells receptors in GPA patients. These cells are mainly distinguished by the aberrant presence of NKG2D, but they can express also other activating NK receptors (NKR) such as DNAM-1, 2B4 and some Killer Immunoglobulin-like Receptors (KIR). Moreover these CD4 T lymphocytes contain cytotoxic granules and show cytolytic abilities. These cells are present in granuloma and, as shown in our previous work (1), can contribute to vasculitis since they are able to kill endothelial cells in a TCR-independent way. Aim of our study was to characterize $CD4^+$ NK-like T cells and NK cells in patients with a localized or diffuse form of GPA, compared to patients with vasculitis without granulomas [Microscopic polyangiitis (MPA)] or with granulomatosis without vasculitis [Sarcoidosis (SAR)] to better understand the role of NKR and NKR-bearing cells in these pathologies.

Materials and methods: We used multiparametric flow cytometry and quantitative Real Time PCR to characterize lymphocytes phenotype and gene expression (NKR, signaling molecules, activation markers) from the different groups of patients and healthy controls.

Results: We evidenced major differences both in CD4 T cells and Natural Killer cells, especially in patients affected by a diffuse GPA disease, compared with healthy controls. Notably, we observed a higher expression of DAP12, NKG2D and KIR receptors on CD4 T cells and found that NK cells from the same patients displayed an early activated phenotype ($CD69^+$ NKp44-) and expressed more DNAM-1 receptor, compared with the other groups.

Conclusions: The presence of the activating adaptor protein DAP12 in T cells may represent an indicator of the acquisition of an aberrant and likely dangerous phenotype by CD4 T cells. A higher expression of this molecule, together with the aberrant expression of other NKR in CD4 T cells and the presence of activated NK cells, might participate in the pathophysiology of the diffuse vasculitis in GPA.

Natural killer cells expressing the KIR2DS1 activating receptor efficiently kill T cell blasts and dendritic cells: implications in haploidentical HSCT

S. Carlomagno,* S. Sivori,* M. Falco,† E. Romeo,† L. Moretta† & A. Moretta*

**University of Genoa, DI.ME.S. – Dipartimento di Medicina Sperimentale, Genoa, Italy, †Istituto Giannina Gaslini, Dipartimento di Medicina Sperimentale e di Laboratorio, Genoa, Italy*

Purpose/Objective: In the present study we investigate whether the expression of KIR2DS1 receptor by human NK cells may confer an advantage in their ability to kill allogeneic DC and T cell blasts.

Materials and methods: To this aim we generated NK cells clones from a C1/C1 Bw4/Bw4 $KIR2DS1^+$ healthy volunteer and we evaluated the effect of different NKG2A/KIR repertoire on the control of cytolitic activity against myelomonocitic dendritic cells (DCs) and T cell blasts derived from HLA-typed human peripheral blood mononuclear cells (PBMC) isolated from healthy volunteers.

Results: In allogeneic hematopoietic stem cell transplantation (HSCT), NK-cell alloreactivity is determined by the presence in the donor of NK cells expressing inhibitory KIR that recognize HLA class I allotypes present in the donor but lacking in the recipient. Dominant KIR ligands are the C1 and C2 epitopes of HLA-C. All HLA-C allotypes have either the C1 epitope, the ligand for KIR2DL2/L3, or the C2 epitope, the ligand for KIR2DL1/S1.

Here we show that, in alloreactive NK cell responses, KIR2DS1 expression represents a remarkable advantage as it allows efficient killing of C2/C2 or C1/C2 myelomonocitic dendritic cells (DC) and T cell blasts. When DC or T cell blasts were derived from C2/C2, Bw4/Bw4 donors, the activating signals delivered by KIR2DS1 could override the inhibition generated by NKG2A or KIR2DL2/L3 expressed on the same NK cell clone. Furthermore, substantial lysis of C2/C2, Bw4/Bw6 targets was mediated by $KIR2DS1^+$ NK cells co-expressing KIR3DL1. Importantly, in the case of C1/C2 targets, $KIR2DS1^+$ NK cells were inhibited by the co-expression of KIR2DL2/L3 but not of NKG2A.

Conclusions: Thus, KIR2DS1 expression in HSC donors may substantially increase the size of the alloreactive NK cell subset leading to an enhanced ability to limit GvHD and improve engrafment.

New prognostic markers in acute myeloid leukemia patients

B. Sanchez-Correa,* J. M. Bergua,† I. Gayoso,‡ C. Campos,‡ H. Bañas,† M. J. Arcos,† S. Morgado,* J. G. Casado,* R. Solana‡ & R. Tarazona*

**Immunology Unit, University of Extremadura, Caceres, Spain, †Department of Hematology, Hospital San Pedro de Alcantara, Caceres, Spain, ‡Immunology Unit, IMIBIC-University of Cordoba-Hospital Reina Sofia, Cordoba, Spain*

Purpose/Objective: To predict clinical outcomes in patients with Acute Myeloid Leukemia (AML) several characteristics as older age, poorer-risk cytogenetics, and performance status are commonly used. In the present work we have analyzed other prognostic markers in AML patients as NK cell phenotype and cytokine levels.

Materials and methods: PBMCs were obtained from 42 patients diagnosed of AML. NK cell ($CD3^-CD56^+$) surface analysis was carried out by flow cytometry. Plasma cytokine levels were measured in 42 AML patients, prior to initiation of therapy, and 58 healthy controls (HC). The concentrations of IL-1β, IL-2, IL-6, IFN-γ, IL-17A, IL-12p70, IL-8, IL-10, IL-4, IL-5 and TNF-α were analyzed using fluorescent bead-based technology. TGF-β was analyzed by ELISA technique. Patients were divided into two age groups, <65 and ≥65 years and compared with age-matched HC. Survival analyses were performed by the Kaplan-Meier method, and survival curves were compared using the log-rank test.

Results: Regarding NK cells activating receptors the univariate analysis showed that there are three factors associated with the increase of OS: age <65 year, good risk karyotype, and high expression of NKp46. The analysis of plasma cytokines levels showed that TNF-α, IL-6 and IL-10 levels were higher in AML patients from both groups of age. IL-8 was found increased in AML patients <65 years while the plasma concentration of IL-4, IL-5 and IL-12p70 was significantly higher only in AML patients ≥65 years compared to aged-matched HC. Kaplan-Meier analysis showed that low levels of IL-6 and high levels of IL-10 were associated with longer survival. Low IL-6 levels were associated with increased event-free survival.

Conclusions: Our results showed an aberrantly production of several cytokines in AML patients that may represent prognostic factors for disease response and survival in patients with AML. In addition, we show that higher expression of NKp46 on NK cells at diagnosis is associated with strong NK cell-mediated responses to leukemia and can be considered a novel prognostic marker for overall survival in AML patients.

NKG2D is the main receptor involved in NK cell activation against NKG2D ligand-positive melanoma cell lines

S. Morgado,* B. Sanchez-Correa,* J. G. Casado,† J. Gordillo,* I. Gayoso,‡ M. E. Duran,§ R. Solana‡ & R. Tarazona*

**Immunology Unit, University of Extremadura, Caceres, Spain, †Stem Cell Therapy Unit, Minimally Invasive Surgery Centre, Caceres, Spain, ‡Immunology Unit, IMIBIC-University of Cordoba-Hospital Reina Sofia, Cordoba, Spain, §Histology and Pathology Unit, University of Extremadura, Cordoba, Spain*

Purpose/Objective: The role of Natural Killer (NK) cells in immune surveillance against tumours has been recently underlined. Recent studies have demonstrated the expression of ligands for activating NK cell receptors in tumour cells from different histological origin. The facts that NK cells are able to respond rapidly and exert their cytotoxic function without previous sensitization to antigen place NK cells as a key component of the immune response against cancer. Melanoma cells can be recognized and killed by NK cells; however contradictory findings have been reported regarding the major activating receptors implicated in NK cell recognition.

Materials and methods: In order to analyze NK cell activation against melanoma cell lines we performed degranulation assays using IL-2-stimulated NK cells from healthy donors and melanoma cells with different expression of ligands for activating receptor. To test the participation of different activating receptors on NK cell degranulation, we performed blocking experiments by incubating NK cells with monoclonal antibodies against NKG2D, natural cytotoxicity receptors (NCRs) NKp30, NKp46 and NKp44, or DNAM-1 separately or together before co-culture with melanoma cells.

Results: We observed a variable NK cell degranulation against different melanoma cell lines. Blockade of NKG2D decreased NK cell degranulation in most melanoma cell lines analyzed. The higher degranulation of NK cells was observed against melanoma cell lines expressing high levels of NKG2D ligands showing a positive correlation between the percentage of CD107a/b$^+$ NK cells and the expression of ligands for NKG2D. We also observed a decrease in NK cell degranulation after blocking DNAM-1 or NCRs. These receptors were more involved in lysis of melanoma cells with low expression of NKG2D ligands.

Conclusions: Our results point to NKG2D as the most important NK cell activating receptor involved in the NK cell response against melanoma. Additionally, the cooperation of DNAM-1 and NCRs in this process has been shown to be complementary.

Orchestration of NK cell phenotype and function by breast cancer-derived factors

M. Kreuzer,* G. A. Foulds,* G. Multhoff† & A. G. Pockley‡

**Department of Surgical Oncology, University of Sheffield, Sheffield, UK, †Department of Radiation Oncology, Technische Universität München, Munich, Germany, ‡John van Geest Cancer Research Centre, Nottingham Trent University, Nottingham, UK*

Purpose/Objective: NK cells are key components of protective anti-tumour immunity, as they recognise tumour associated antigens and stress-induced ligands in an MHC class I-independent manner. However, recent studies comparing NK cells from cancer patients with those from healthy donors have reported differences in the phenotype and function of NK cells in patients with cancer which could manifest as an impaired anti-tumour immune capacity. The involvement of tumour-derived factors in driving these effects is unclear and the aim of this study is to determine whether breast cancer-derived factors can influence NK cell phenotype and function.

Materials and methods: NK cells were isolated from peripheral blood of healthy donors by density gradient separation of PBMCs and subsequent negative isolation using magnetic beads. NK cells were incubated with 50% v/v supernatant derived from MDA-MB-436 human breast cancer cells for 24 h in the presence or absence of IL-2 (100 IU/ml). The expression of the serine protease granzyme B, CD8, the activating receptors NKp46, CD94 and NKG2D, and the inhibitory receptor CD158e1 by CD56^{low}CD16$^+$, CD56^{high}CD16$^-$ and CD56^{high}CD16$^+$ NK cell subsets was determined by multicolour flow cytometry. To assess function, NK cells were co-incubated with either K562 cells or MDA-MB-436 cells for 3 h following activation by IL-2 in the presence or absence of tumour cell-derived supernatants, and target cell death analysed by flow cytometry.

Results: In the presence of IL-2, incubation of NK cells with MDA-MB-436-derived supernatants significantly reduced CD56 expression (by 10–20% depending on NK subset), and this effect was more pronounced when NK cells were subsequently co-incubated with MDA-MB-436 cells (45–60% reduction). Expression of the other antigens was also influenced, although this was highly subject-dependent. CD8 expression was stable under all conditions. Incubating NK cells in MDA-MB-436 supernatant resulted in a 25% decrease in cytotoxicity against K562 cells.

Conclusions: Breast cancer cell-derived factors influence NK cells in a pro-tumourogenic manner. However, the effects appear to be subject-dependent and further work clarifying these effects is required. Current work is screening the immunoregulatory properties of factors derived from other breast cancer cells lines and identifying the molecules involved.

P0167

Recognition of human cytomegalovirus by NK cells

A. Muntasell,* M. Costa,† A. Vera,* N. Marina† & M. López-Botet†

**Immunology, IMIM Hospital del Mar Research Institute, Barcelona, Spain, †Department of Experimental and Health Sciences, Pompeu Fabra University, Barcelona, Spain*

Purpose/Objective: NK cells play a critical role in the defence against viral infections. Activation of NK cells is tightly controlled by both inhibitory and activating receptors and modulated by cytokines released along the anti-viral response. On the other hand, NK cells express several TLRs able to boost NK cell functions upon activation. The present study was undertaken to investigate whether NK cells could directly recognize Human Cytomegalovirus (HCMV).

Materials and methods: Human NK cells were purified from peripheral blood by negative selection using immunomagnetic techniques. After a 24h coculture with HCMV (TB40/E strain), NK activation was monitored by measuring CD69 expression and IFNg secretion by flow cytometry and ELISA, respectively. NK cell cytotoxic activity was measured by the CD107a-mobilization assay.

Results: HCMV recognition by NK cells resulted in the expression of CD69, increased IL-12-induced IFNγ secretion and improved cytotoxic response to infected fibroblasts and autologous monocyte-derived dendritic cells. Indeed, HCMV-primed NK cells showed increased activity of NKp46, NKp30 and CD16 activating receptors as measured in P815-based redirected degranulation assays. HCMV-induced activation was prevented by the pre-treatment of NK cells with bafilomycin A1 and by the addition of IFNAR and TLR2 blocking mAb along the coculture. Thus, indicating that sensing of HCMV by NK cells required a functional endocytic pathway and involved the production of type I IFNs and TLR2 activation.

Conclusions: Direct recognition of HCMV by NK cells results in the priming of NK cell effector functions, and could likely contribute to the anti-viral response *in vivo*.

P0168

Regulation of NK cell maturation and function by the actin-regulatory proteins Coronin1a and Coronin1b

A. Jenckel* & N. Föger†
**Immunology and Cell Biology, Leibniz Research Center for Medicine and Biosciences (FZB), Borstel, Germany, †Molecular Immunology, Leibniz Research Center for Medicine and Biosciences (FZB), Borstel, Germany*

Purpose/Objective: NK cells are large granular lymphocytes, which contribute as an early defense system to the clearance of viral infections and the elimination of transformed cells. Recent work has begun to appreciate an important role of actin cytoskeletal dynamics in NK cell activation and function. We here further explored the role of the actin cytoskeleton for NK cells by analyzing the role the actin-regulatory proteins Coronin1a (Coro1a) and Coronin1b (Coro1b) in NK cell differentiation and function.
Materials and methods: Utilizing a genetic system of Coro1a- and/or Coro1b-deficient mice our study followed a multidisciplinary approach, which involved biochemical, cell biological and immunological methods to analyze the impact of actin-regulatory coronin proteins on developmental and functional aspects of NK cells.
Results: The analysis of naïve peripheral NK cells from spleen and lung revealed clear developmental alterations of NK cells from coronin-deficient mice. The NK cell differentiation status, as defined by CD27 and CD11b surface expression, was significantly shifted to a more immature NK cell state in Coro1a-deficient and Coro1a/1b-double-deficient mice as compared to wild-type controls. As the absence of Coro1a and Coro1b may also influence actin-dependent cellular functions during NK cell activation, we next analyzed NK function upon contact with target cells. For these experiments we utilized IL-15-primed NK cells, which showed similar expression of maturation markers and displayed normal granule contents in all genotypes. Importantly, Coro1a deficient NK cells showed defects in cellular degranulation and exhibited reduced cytotoxicity, which was further exacerbated by the additional loss of Coro1b in Coro1a/1b double deficient NK cells. These defects in degranulation and cytotoxicity in Coro1a/1b deficient NK cells were associated with impaired granule polarization towards target cells in NK cell/target cell conjugates. Furthermore, activation-induced secretion of inflammatory cytokines and chemokines, such as IFNg and CCL5, was significantly reduced in Coro1a and Coro1a/1b-double deficient NK cells.
Conclusions: Together, our study emphasises the importance of actin-cytoskeletal regulators for NK cells by identifying novel roles of the actin-regulatory proteins Coro1a and Coro1b in the control of NK cell maturation and function.

P0169

Regulation of NK cell subset localization at site of tumor growth in a model of multiple myeloma

G. Benigni, G. Bernardini, A. Ponzetta, G. Sciumè, F. Antonangeli, A. Kettner & A. Santoni
Molecular Medicine, Sapienza University of Rome, Rome, Italy

Purpose/Objective: NK cells play a pivotal role in the defense against tumors, due to the ability to kill target cells and to instruct other immune cells through cytokine production. Multiple myeloma (MM) is a malignancy of terminally differentiated plasma cells that are predominantly localized in bone marrow (BM), the main site for NK cell development. Our aim was to characterize the influence of MM growth on NK cell homing/trafficking to the BM and how this could affect NK cell-based anti-tumor response.
Materials and methods: We used a model of syngeneic orthotopic MM in C57BL/KaLwRij mice established by i.v. injection of the 5TGM1 tumor cell line. Disease progression was quantified after mice sacrifice by FACS analysis of $IgG2b^+$ cells into BM and spleen. NK cell subsets were defined as $CD11b^{low}$, $CD11b^{high}KLRG1^-$ and $KLRG1^+$ NK cells. *In vivo* homing experiments were performed by transferring total splenocytes or purified splenic NK cells from healthy mice into control and tumor-bearing mice at 3 and 4 weeks of tumor growth.
Results: We first observed that MM growth was sensitive to NK cells *in vivo* as it was markedly accelerated in mice depleted of $NK1.1^+$ cells. In addition, we could show that NK cells underwent activation and degranulated *in vivo* at tumor sites, as shown by increase of CD69 expression and of splenic $CD107^+$ NK cells at 3 and 4 weeks following tumor cell injection. *Ex vivo* experiments showed that target cell lysis and NK cell degranulation capacity were maintained at 3 weeks, while decreased after 4 weeks. Although all subsets of NK cells started to decrease in BM after 3 weeks, $KLRG1^+$ NK cells were minimally affected. Conversely, all subsets were markedly reduced in BM and spleen after 4 weeks, when tumor growth progressed. This findings correlated with modulation of chemokine receptor expression by NK cells and with defective NK cell homing to BM in tumor-bearing mice as shown by adoptive transfer experiments.
Conclusions: Our results suggest that when MM growth is limited, selected subsets of NK cells are excluded from BM. This can be partly attributed to NK cell redistribution that correlated with a stable anti-tumor activity. Conversely, further disease progression led to a strong reduction of NK cells at the tumor sites, possibly affecting NK cell-mediated anti-tumor response.

P0170

Retuning of mature NK cells after change of MHC class I (MHC-I) environment

A. K. Wagner,* R. Tallerico,† H. Brauner,* E. Carbone,† P. Höglund,‡ M. H. Johansson* & K. Kärre*
**Department of Microbiology Tumor and Cell Biology, Karolinska Institute, Stockholm, Sweden, †Tumor Immunology, University of Catanzaro, Catanzaro, Italy, ‡Deprtment of Medicine, Karolinska Institute, Stockholm, Sweden*

Purpose/Objective: The ability of NK cells to reject cells lacking self MHC-I depends on an education process which confers functional competence to the individual NK cell. Education also skews the repertoire of NK subsets defined by Ly49R expression in an MHC-dependent way. This may be harnessed in immunotherapy settings, by transfer of NK or bone marrow cells (BMC) from a host whose MHC-I molecules educate them so that they have the potential to recognize and eliminate the recipients malignant cells. It is therefore important to study how the host educating environment influences developing or mature NK cells. We have studied this in hematopoietic reconstitution and in adoptive transfer of mature NK cells.
Materials and methods: We confronted cells from $MHC^{+/+}$ mice (D^bK^b, $D^bK^bD^d$) with an environment where MHC-I was missing by transferring either BMCs or mature, NK cells to irradiated $MHC^{-/-}$ mice. Missing self capacity was tested by challenging the mice with MHC-I-deficient target cells. Reconstitution of NK cells and phenotypic analyses of activating receptors and maturation markers as well as repertoire assessment based on inhibitory receptors was performed.
Results: NK cells maturing from transplanted BMCs showed missing self rejection capacity against $MHC^{-/-}$ spleen cells by 2 weeks after transfer to autologous hosts. In contrast, they appeared tolerant to $MHC^{-/-}$ spleen cells after transfer to a $MHC^{-/-}$ deficient environment. The subset repertoire based on the expression of inhibitory Ly49 receptors in the donor-derived NK cells showed skewing towards that

seen in the recipient already 2 weeks after transplantation. Mature NK cells lost their ability to reject MHC-I-deficient spleen cells when transferred to MHC$^{-/-}$ hosts, but retained this ability in the autologous transfer. However, when mice where challenged with MHC-I-deficient tumor cells the transferred NK cells were equally capable of rejecting the tumor cells regardless of the MHC environment.

Conclusions: These results show that developing as well as mature NK cells adapt to the MHC environment. This suggests that tuning to tolerate normal cells lacking critical MHC-I ligands may still allow NK cells to detect and efficiently eliminate tumor cells lacking the same ligands. This supports the notion that the outcome of NK cell education is quantitative and context-dependent.

P0172

Surface expression of 'activation-induced C-type lectin' (AICL) tags cytokine-stimulated human NK cells

Y. Bartel,* S. Klimosch,† S. Wiemann† & A. Steinle*

**Institute for Molecular Medicine, Frankfurt am Main, Germany, †Department of Immunology, Institute for Cell Biology, Tübingen, Germany*

Purpose/Objective: The 'activation-induced C-type lectin' (AICL) is encoded in the Natural Killer Gene Complex (NKC) adjacent to its receptor, the activating NK cell receptor NKp80. AICL is expressed by myeloid cells and NKp80/AICL interaction was shown to promote the cross-talk between NK and myeloid cells. Unexpectedly, we recently observed also substantial AICL expression by human NK cell lines and subsequently investigated regulation of expression, cellular localization, and functional recognition of AICL by resting and activated human NK cells.

Materials and methods: AICL expression by NK cells was assessed using qRT-PCR, immunoblotting and flow cytometry. Confocal microscopy revealed subcellular localization of AICL in NK cells. Functional assays included cytokine and degranulation assays. Hybrids of AICL and KACL proteins, the latter being a close AICL relative, were generated to map domains involved in intracellular AICL retention in 293 transfectants.

Results: Resting human NK cells contain intracellular stores of AICL glycoproteins associated with the Golgi complex. As evident from mutational analyses, the C-type lectin-like ectodomain of AICL determines intracellular AICL retention. However, upon exposure of freshly isolated NK cells to inflammatory cytokines, AICL expression is upregulated resulting in a substantial and prolonged cell surface expression. AICL on cytokine-stimulated NK cells is functionally recognized by resting autologous NK cells triggering their effector functions in an NKp80-dependent manner.

Conclusions: Our results show that AICL glycoproteins predominantly localize in the Golgi complex. While resting NK cells are devoid of surface AICL, there is substantial AICL cell surface expression following exposure to inflammatory cytokines facilitating recognition by autologous NK cells via NKp80. Hence, cytokine-stimulated NK cells become tagged by AICL surface expression for recognition by bystander NK cells.

P0174

The role of Natural Killer cells in Multiple Sclerosis pathogenesis

I. Tahrali,* U. C. Kucuksezer,* A. Yilmaz,* U. Uygunoglu,† A. Altintas† & G. Deniz*

**Immunology, The Institute of Experimental Medicine (DETAE), Istanbul University, Istanbul, Turkey, †Neurology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey*

Purpose/Objective: Multiple sclerosis (MS) is an autoimmune disease characterized by inflammation, demyelination, axonal/neuronal loss and gliosis of the central nervous system (CNS). The onset of disease occurs as a clinically isolated syndrome (CIS) which affects spinal cord, brain and optic nerves in 85% of young adults with MS. About 87% of MS patients exhibit a relapsing-remitting (RR) course of disease, characterized by acute attacks followed by partial or full recovery occurring at variable intervals. It is very well-known that immune system plays an important role in the pathogenesis of MS and natural killer (NK) cells is thought to be in part responsible for RR or progressive nature of the disease. Although many studies indicate the role of T cells in MS, surveys about NK cells are limited. In this study, cell frequency and effector functions of NK cells in untreated RR-MS patients, RR-MS patients treated with disease-modifying drugs (DMDs) and patients with CIS were investigated and the results were compared with age and gender matched healthy subjects.

Materials and methods: Primarily, surface expression of CD3, CD4, CD8, CD19, CD16 and CD56, and proportions of NK cell subsets were detected in peripheral blood samples of patient groups mentioned above. Peripheral blood mononuclear cells obtained from blood samples were cultured in the presence and absence of hrIL-2, hrIL-12 and hrIL-4. Following 24 h cell culture, IFN-g, IL-10 and IL-22 contents of CD56^{bright}CD16^{-} and CD56^{dim}CD16^{+} NK cell subsets were measured by flow cytometry. NK cell cytotoxic activity was measured using erythromyeloblastoid leukemia cell line K562, and the frequencies of NK cell subsets were detected after 72 h of culture.

Results:

Compared to healthy subjects:

1. Increased IFN-g levels were investigated in CD3^{-}CD16^{+} CD56^{dim} NK subsets of CIS, SP-MS and RR-MS patients receiving DMDs.
2. IL-10 levels were significantly increased in CD56^{dim}CD16^{+} and CD56^{bright}CD16^{-} NK cell subsets of unstimulated (US) SP-MS.
3. Increased IL-22 levels were observed in CD56^{bright}CD16^{-} subsets of USSP-MS patient.

Conclusions: Our first line of results shows that NK cells may contribute to the pathogenesis of different MS groups; however more patients are needed to underline their roles.

P0175

The role of NK cell – dendritic cell interactions during BCG vaccination

C. Hamilton,* G. Entrican† & J. Hope*

**Infection and Immunity, The Roslin Institute, Edinburgh, UK, †Ruminant Immunology, Moredun Research Institute, Edinburgh, UK*

Purpose/Objective: Bovine tuberculosis (TB), caused by *Mycobacterium bovis*, is an infectious disease of increasing incidence in the UK. Attenuated *Mycobacterium bovis* Bacille Calmette Guerin (BCG) has been successfully used to vaccinate humans against TB since 1921, however currently there are no available vaccines for cattle. Vaccination of neonatal calves with BCG provides significant protection against bovine tuberculosis. The increased efficacy of BCG may be attributed to the increased numbers of circulating innate effector cells observed in neonatal calves, particularly NK cells. Production of IFNg by NK cells and interactions with dendritic cells (DC) are hypothesised to polarise a Th1 immune response, thus interactions between NK cells

and DCs may be pivotal in driving protective immunity to bovine TB. Further understanding of the immune mechanism whereby BCG exerts protective immunity could allow targets for improved vaccination to be identified, leading to enhanced vaccine efficacy.
Materials and methods: Neonatal calves (BCG vaccinated and non-vaccinated age matched controls) were assessed for the frequency, phenotype and function of NK cells. NK cells and DCs from vaccinated and control animals were co-cultured *in vitro* to determine the way in which these two cell populations interact.
Results: Preliminary data obtained thus far shows an increase in NK cell populations and altered functional characteristics following BCG vaccination.
Conclusions: Further work to elucidate the reciprocal interaction between NK cells and DCs is currently underway in order to determine the effects this has on the adaptive immune response following BCG vaccination of neonatal calves.

P0176

Type I interferon gene expression by non-mucosal mononuclear phagocytes requires poising by the commensal microbiota

A. Diefenbach,[*] S. L. Sanos,[*] C. Kallfass,[†] C. Kirschning,[‡] S. Lienenklaus,[§] S. Weiss,[§] P. Staeheli,[†] P. Aichele[¶] & S. C. Ganal[*]
[*]Microbiology, Institute for Medical Microbiology & Hygiene, Freiburg, Germany, [†]Virology, Institute for Medical Microbiology & Hygiene, Freiburg, Germany, [‡]Microbiology, Institute for Medical Microbiology, Essen, Germany, [§]Molecular Immunology, Helmholtz Centre for Infection Research, Braunschweig, Germany, [¶]Immunology, Institute for Medical Microbiology & Hygiene, Freiburg, Germany

Purpose/Objective: Mononuclear phagocytes are an important component of an innate immune system perceived as a system ready to react upon encounter of pathogens. The role of the commensal microbiota for calibrating the activity of mononuclear phagocytes residing in non-mucosal lymphoid organs (e.g. spleen) is not well defined.
Materials and methods: Using mice that lack commensal microbiota, we have investigated the molecular program underlying the priming of NK cell responses by mononuclear phagocytes in the context of viral infections and in response to defined stimulation of Toll-like receptors.
Results: Here, we show that mononuclear phagocytes residing in non-mucosal lymphoid organs of germ-free mice fail to produce type I interferons (IFN-I) in response to microbial stimulation. Consequently, NK cell priming and anti-viral immunity are severely compromised. Pathogen-inducible expression of a set of inflammatory response genes, including the various IFN-I genes, require poising by signals from the commensal microbiota. While signaling downstream of various pattern recognition receptors and nuclear translocation of NF-κB p65 and IRF3 were normal in mononuclear phagocytes of germ-free mice, binding to their respective cytokine promoters was impaired, which correlated with the absence of activating histone marks such as trimethylated lysine 4 of histone protein 3 (H3K4me3).
Conclusions: Our data reveal a previously unrecognized role for postnatally colonizing microbiota in the introduction of chromatin level changes in the mononuclear phagocyte system, thereby poising expression of central inflammatory genes to initiate a powerful systemic immune response during viral infection.

A novel mechanism of action in dendritic cells for a tick salivary immunomodulatory cystatin

J. Lieskovska,* J. Sirmarova,† M. Kotsyfakis‡ & J. Kopecky†
*Laboratory of Parasite Immunology, Institute of Parasitology Biology centre of AS CR, Ceske Budejovice, Czech Republic, †Department of Medical Biology, University of South Bohemia Faculty of Science, Ceske Budejovice, Czech Republic, ‡Laboratory of Genomics and Proteomics of Disease Vectors, Institute of Parasitology Biology centre of AS CR, Ceske Budejovice, Czech Republic

Purpose/Objective: Sialostatin L (SialoL), a cysteine protease inhibitor of the cystatin superfamily is present in the saliva of the hard tick *Ixodes scapularis* and it has the ability to inhibit dendritic cell activation. Previous work has shown that it negatively affects the production of TNF-α and IL-12 by DCs, and the expression of the costimulatory molecules CD80 and CD86. Our aim was to illuminate a possible mechanism of these immuno-modulatory effects of sialostatin L.
Materials and methods: We used spleen dendritic cells activated by LPS or IFN-β. SialoL was prepared in *E.coli*, LPS decontaminated. Activation of signalling molecules was determined by Western blot. Expression of IFN receptor on the cell surface was analyzed by flow cytometry. Gene expression of IRFs was examined by qPCR.
Results: Type I IFNs are critical for DC maturation. We show here that SialoL attenuates Signal Transducer and Activator of Transcription 1 (STAT-1) activation but does not affect activation of nuclear factor-κB (NF-κB) or mitogen-activated protein kinase (MAPK) p38 signalling pathways. STAT-1 activation is mediated by secreted IFN-β. By using recombinant IFN-β, we demonstrate that SialoL inhibited IFN β -triggered STAT-1 and STAT-2 activation. IFN receptor (comprising of two chains -IFNAR1 and IFNAR2) is upon ligation internalized and this influences the strength of signal which is transduced further downstream. The number of IFNAR1 on DC surface upon IFN ligation was decreased in the presence of SialoL (by 50%) suggesting that SialoL inhibits IFN signalling at receptor level, by enhancing internalization rate of IFNAR1.

IRF are transcription factors linked to IFN and playing important role in the maturation of dendritic cells. We found that expression of IRF-4 is up-regulated and IRF-7 is down-regulated in the presence of SialoL.
Conclusions: We present here two possible mechanisms that mediate the modulation of DC function in the presence of SialoL: i) through inhibiting interferon (IFN) signalling, and ii) by changing gene expression of interferon regulatory factors (IRF). Both mechanisms can account for the observed changes in maturation and cytokine secretion profile of dendritic cells upon their activation in the presence of SialoL.

P0178
A role for connexin signalling in innate immunity

S. Donnelly, A. Jan, J. Robertson, S. Lang & P. E. Martin
Life Sciences, Glasgow Caledonian University, Glasgow, UK

Purpose/Objective: Staphylococcal cell wall components peptidoglycan (PGN) and lipoteiochoic acid (LTA) elicit a potent pro-inflammatory response in diverse cell types, including endothelial cells and keratinoyctes.Such pro-inflammatory mediators are also reported to modulate Connexin (Cx) expression in diverse tissues. We explored the impact of PGN and LTA isolated from *S. epidermidis* and PGN isolated from *S.aureus* on Cx43, Cx26 and IL-6 expression and hemichannel activity in mouse and human endothelial cell lines (b.End5 and E. A.hy926 respectively) and in HaCat cells, a human keratinocyte cell line.
Materials and methods: Hemichannel activity was monitored following acute challenge (15min) with BCWC by ATP release assays in the presence or absence of the hemichannel blocker carbonoxolene (CBX)(100 uM). mRNA was harvested following 6, 18 and 24 h challenge with relevant BCWC and Real-time-PCR analysis determined Cx43, Cx26, IL-6 and TLR2 expression levels. IL-6 expression levels were also monitored by ELISA.
Results: In endothelial cells PGN and LTA (0.1 μg/ml) from *S. epidermidis* induced TLR2 expression and elicited an IL-6 and TNFα response. By contrast in HaCat cells PGN (at concentrations up to 10 μg/ml) isolated from *S. epidermidis* had little effect on IL-6 or Cx expression expression yet that sourced from *S. aureus* inducedIL-6 and Cx26 expression with no impact on Cx43 ($n = 3$, $P < 0.005$).Acute challenge (15 min) of endothelial cells with PGN or LTA induced hemichannel activity as determined by increased ATP release that was blocked by co-incubation with a range of hemichannel blockers including CBX, Gap26 and $LnCl_3$. By contrast in HaCat cells only PGN [10 μg/ml] derived from *S.aureus* induced a hemichannel response ($n = 3$; $P < 0.005$). Inhibition of acute hemichannel activity prevented the later induction of IL-6 and TLR2 mRNA but had no effect on the induction of Cx43 expression in b.End5 cells. By contrast in HaCat cells, Cx43 expression was not affected by PGN [10 ug/ml] isolated from *S.aureus* but an increase in Cx26 expression was observed.
Conclusions: Our results reveal that acute activation of Cx hemichannel signaling bypro-inflammatory mediators such as PGN and LTA isolated from*Staphylococcusspecies* plays a key a role in the initiation of an early inflammatory response and that their impact on Cx expression and function is highly tissue specific.

P0179
Adenine methylation in conserved GATC DNA sequences modulates macrophage and dendritic cell activation

M. Balzarolo,* A. Popovski,* A. de Jong,* J. P. Medema† & M. Wolkers*
*Sanquin, Hematopoiesis, Amsterdam, The Netherlands, †Academic Medical Center, Lexor-CEMM, Amsterdam, The Netherlands

Purpose/Objective: Pattern recognition is an important means for innate cells to sense microbial infections. Differences in the methylation status of microbial and mammalian DNA represent a key element to distinguish self from non-self. This is illustrated by unmethylated bacterial CpG sequences that trigger TLR9 and are currently employed as adjuvant for vaccines. In addition, several bacterial strain genomes contain conserved GATC motives in which adenine is methylated in position N6 (m6A). Whether these G(m6A) TC motives exert an immunomodulatory function and if so, which cells respond to these bacterial sequences is still unresolved. Here we aim to determine whether macrophages and dendritic cells (DCs) respond to bacterial G(m6A) TC sequences, and assess the functional outcome of this recognition.
Materials and methods: To this purpose, we transfected dsDNA sequences containing methylated or unmethylated GATC motives in murine macrophages and DCs, and compared their capacity to activate these cell types, influence cytokine production, and affect their functionality.
Results: We show that transfection of macrophages with methylated dsDNA results in higher expression of the activation markers CD69 and CD86 as compared to the unmethylated dsDNA, and led to higher production of IFNβ, as well as of other effector molecules. Similarly, methylated dsDNA induced higher CD86 expression in DCs. We are currently investigating by which mechanisms m6A motives induce such response, in particular whether antigen uptake, recognition and activation pathways are involved.

Conclusions: Activation with dsDNA sequences containing m6A motives results in increased expression of activation markers in macrophages and DCs. The functional consequences of these findings have yet to be determined. Our study will show whether G(m6A) TC motives are able to direct the immune response towards pathogens, and whether they could be employed as adjuvant to improve the efficiency of vaccines.

P0180
Crosstalk between the p38 and Akt pathways in macrophages

V. A. McGuire,* A. Gray,† S. Santos,* K. Lee,‡ M. Boothby,‡ M. Gaestel§ & J. S. C. Arthur*

**MRC Protein Phosphorylation Unit, University of Dundee, Dundee, UK, †Division of Molecular Physiology, University of Dundee, Dundee, UK, ‡School of Medicine, Vanderbilt University, Nashville, TN, USA, §Hannover Medical School, Institute of Biochemistry, Hannover, Germany*

Purpose/Objective: The AGC protein kinase Akt is activated downstream of PI3K signaling. Akt has well defined roles in cell survival and insulin signaling and recently has also been implicated in regulation of innate immunity. Akt is activated by phosphorylation on both Thr308 and Ser473. PDK1 phosphorylates Thr308 and although the identity of the Ser473-kinase has been harder to elucidate, the TORC2 complex (mTOR, rictor, mLST8, sin1 & protor) can phosphorylate Ser473 *in vivo*.

MK2 (MAPK-activated protein kinase 2) and MK3 are activated by p38α MAPK and play important roles in macrophages and dendritic cells. MK2 efficiently phosphorylates Akt *in vitro* on Ser473, and in some circumstances p38 inhibitors can block Akt activity in cells. While work on mTORC2 excludes a direct role for MK2 in Akt activation in most systems, the unexpected finding that in macrophages MK2 and 3 play a role in the TLR induced activation of RSK, another AGC kinase, led us to re-examine the possible role for MK2 in Akt activation in macrophages.

Materials and methods: Bone-marrow Derived Macrophages (BMDMs) were isolated from wild type, MK2/3 or rictor KO mice and differentiated *in vitro* before stimulation with 100 ng/ml LPS. Where indicated, cells were pre-incubated for 1 h with 5 μM p38 inhibitor SB203580, 1 μM mTOR inhibitor KU0063794 or 10 μM MK2 inhibitor PF3644022. Following stimulation, cells were either lysed then analysed by immunoblotting or lipids isolated and relative levels of PI(3, 4, 5) P3 measured using a TRFRET displacement assay.

Results: Akt is activated by phosphorylation on Thr308 and Ser473 in response to LPS in BMDMs, but this is blocked by the p38 inhibitor SB203580 or in MK2/3 DKO cells (Fig. 1A). The phosphorylation is unlikely to be direct as PI3K and mTOR (Fig. 1A) inhibitors can also block Akt activation in BMDMs. Furthermore, Ser473 was not phosphorylated in rictor knockout BMDMs (Fig. 1B).

Together this indicates that MK2/3 acts upstream of Akt. For activation, Akt must be first recruited to PIP3 in the membrane. We find that inhibition of MK2/3 activation blocks the accumulation of PIP3 following LPS stimulation (Table 1).

Table 1. Xxxxxx.

Treatment	PI(3, 4, 5)P3 fold stimulation (mean and SD $n = 6$)	PI(3, 4, 5)P3 fold stimulation (mean and SD $n = 4$)
Control	1.00	1.00
LPS 30′	5.50 ± 2.3	3.25 ± 1.2
LPS 30′ + SB203580	2.50 ± 1.1	1.30 ± 0.8
LPS 30′ + PF 003644022	2.73 ± 1.5	–

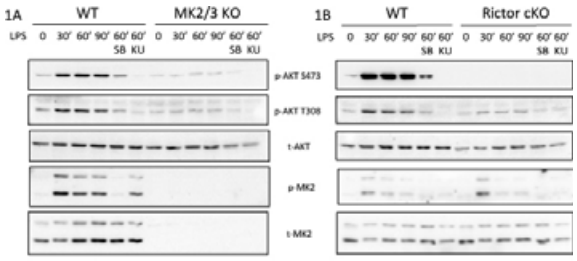

Figure 1

BMDMs were isolated from wild type, MK2/3 KO (A) or rictor KO (B) mice. Cells were stimulated with 100ng/ml for the indicated times in the presence or absence of 5μM p38 inhibitor SB203580 or 1μM mTOR inhibitor KU0063794. Cells were lysed and analysed by immunoblotting.

Conclusions: Our data reveals crosstalk between the p38/MK2 and Akt pathways in macrophages. MK2/3 do not appear to phosphorylate Akt directly, rather these kinases can modulate the localisation of Akt at the membrane, and hence its activation, by affecting PIP3 levels.

P0181
CYLD-deficiency protects against lethal infection with Listeria monocytogenes

N. Gopala krishna,* K. Wex,* R. Massoumi,† K. Borucki,‡ K. Schweitzer,§ N. Naumann§ & D. Schlüter*

**Medizinische Mikrobiologie, Institut für Medizinische Mikrobiologie, Magdeburg, Germany, †Department of Laboratory Medicine, Lund University, Malmö, Sweden, ‡Pathophysiology, Institute of Clinical Chemistry and Pathophysiology, Magdeburg, Germany, §Experimentelle Innere Medizin, Institut für Experimentelle Innere Medizin, Magdeburg, Germany*

Purpose/Objective: CYLD is a deubiquitylating enzyme which plays a pivotal inhibitory role in immune responses. CYLD downregulates NF-kB activity by the proteolysis of K63-linked ubiquitin from IKKγ, TRAF2/6 and also negatively regulates the MAPK pathway by de-ubiquitinating TAK1.To gain insight into the function of CYLD in infectious diseases we studied the role of CYLD in listeriosis.

Materials and methods: C57BL/6 $CYLD^{-/-}$ and wildtype (WT) mice were infected (i.v) with various doses of *Listeria monocytogenes*. Colony forming units in the liver and spleen were estimated by plating them on BHI agar. Leukocyte infiltration in the liver was analysed by flow cytometry. Cytokine levels in serum were measured by cytometric bead assays. Regulation of NF-kB and MAPK pathways were analysed by WB.

Results: Upon infection with non-lethal doses of *L. monocytogenes* both WT and $CYLD^{-/-}$ mice survived the infection. However, upon infection with a lethal dose of the bacterium all WT mice succumbed up to day 7 post infection, whereas $CYLD^{-/-}$ mice survived indicating that CYLD inhibits protective host responses. The bacterial load in the liver of $CYLD^{-/-}$ mice was significantly reduced illustrating that the improved survival of $CYLD^{-/-}$ mice was partially due to a more efficient control of *Listeria* in the liver. In addition, recruitment of leukocytes including granulocytes, macrophages and CD8T cells, to the liver was significantly increased in $CYLD^{-/-}$ mice. This was accompanied by increased production of the pro-inflammatory cytokines IL-6 and IFN-γ in the liver of $CYLD^{-/-}$ mice. Additional WB analysis showed an increased NF-kB and MAPK activity in $CYLD^{-/-}$ mice as indicated by an increased phosphorylation of p65 and p38MAPK.

Conclusions: Based on these data, we conclude that enhanced activation of the NF-kB and MAPK pathways in $CYLD^{-/-}$ mice resulted in enhanced recruitment of leukocytes to the infected liver, an increased production of protective cytokine, which limited the spread of *Listeria* and enhanced survival of $CYLD^{-/-}$ mice.

P0182

Endothelial cells present an innate resistance to glucocorticoid treatment

D. Viemann,* P. Koenen,† M. Wolf,‡ J. Roth‡ & K. Barczyk‡
Pediatric Pulmonology Allergy and Neonatology, Hannover Medical School, Hannover, Germany, †Operative Medicine, University of Witten-Herdecke, Cologne, Germany, ‡Immunology, University of Muenster, Muenster, Germany

Purpose/Objective: In contrast to other chronic inflammatory diseases glucocorticoids (GCs) alone do not maintain sufficient remission in primary vasculitis. Reasons for this therapeutic failure remain unclear. We therefore investigated the molecular effects GCs exert on endothelial cells (ECs) and elucidated molecular pathways behind.
Materials and methods: We used a comparative approach treating human micro- and macrovascular ECs as well as monocytes long-term and short-term with GCs or GCs and TNF-a. Gene expression changes were analysed applying microarray technology, sophisticated bioinformatic work up and quantitative RT-PCR. Glucocorticoid receptor (GR) translocation processes were traced by cell fractionation assays and immunfluorescence microscopy.
Results: In ECs GCs completely fail to inhibit the expression of immune response genes both after sole GC exposure and after GC treatment of a TNF-a-induced proinflammatory response. In contrast, we see an impressive down-regulation of proinflammatory genes in monocytes. We verify that the GR is comparably expressed in ECs and monocytes and demonstrate nice translocation of ligand-bound GR allowing genomic GC actions. Refined gene expression analysis shows that in ECs transactivation causing GC side effects on growth and metabolism takes place whereas transrepression-mediated anti-inflammatory effects like in monocytes are missing. Insufficient induction of SAP30, an important constituent of the Sin3A-HDAC complex, in ECs suggests impairment of transrepression due to corepressor absence.
Conclusions: The impressive unresponsiveness of ECs to anti-inflammatory GC effects is associated with deficiencies downstream of GR translocation not affecting transactivation but transrepression. Our findings provide first molecular clues to the poor benefit of GC treatment in patients with primary vasculitis.

P0183

Expression, purification and biological characterisation of a novel type I interferon, IFN epsilon

S. A. Stifter,* K. Fung,* J. Horvat,† P. Hansbro,† N. A. de Weerd* & P. J. Hertzog*
Centre for Innate Immunity and Infectious Diseases, Monash Institute of Medical Research, Melbourne, Australia, †Centre for Asthma & Respiratory Disease, University of Newcastle, Newcastle, Australia

Purpose/Objective: The interferons (IFNs) are a large family of functionally and structurally related cytokines eliciting antiviral, antiproliferative and immunoregulatory functions. Our group discovered a novel gene while annotating the type I interferon locus with sequence similarity to other known type I interferons and named it IFN epsilon (IFNε). Unlike other IFNs, IFNε is constitutively expressed in the female reproductive tract and is not induced by pathogens. Furthermore, an *Ifne1* null mouse generated in our laboratory demonstrates an increased susceptibility to genital tract chlamydia and herpes virus infections. Little else is known about this cytokine due to a lack of commercial reagents. The objective of this work was to produce recombinant murine IFNε in order to characterise its biological activities and function.
Materials and methods: Recombinant mIFNε was produced in a baculovirus expression system and purified by immunoaffinity chromatography. IFNε's biological activities were characterised in antiviral, antiproliferative and immunoregulatory assays. The cytokine's ability to signal via the canonical type I interferon receptor and JAK-STAT signalling pathways were also investigated. *In vivo* activity was evaluated in a mouse model of genital tract Chlamydia infection.
Results: Recombinant mIFNε produced from a baculovirus expression system was shown to be >95% pure with endotoxin levels <0.1 EU/μg. IFNε demonstrated classical biological activities associated with type I interferons although at much reduced levels when compared to IFNα and IFNβ. Signalling studies demonstrated that IFNε signals through the heterodimeric type I interferon receptor complex and induced interferon regulated genes via JAK-STATs. Mice treated with mIFNε prior to genital chlamydia infection demonstrated lower levels of bacterial burden 3 days post infection.
Conclusions: This work outlines the expression, purification and biological characterisation of the novel type I interferon, mIFNε. Our results show that IFNε signals via the canonical type I interferon receptor to protect against genital tract chlamydia infection. These findings demonstrate a distinct role for this novel cytokine in maintaining homeostasis of the female reproductive tract.

P0184

Functional dissection of the TLR3, 7, 8, 9 interactome

A. Fauster,* M. Rebsamen,* C. Baumann,† M. Bruckner,* J. Colinge,* K. Bennett* & G. Superti-Furga*
Ce-M-M-, Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria, †Boehringer Ingelheim RCV, Pharmacology, Vienna, Austria

Purpose/Objective: The endosomal Toll-like receptors (TLRs) 3, 7, 8 and 9 recognize the nucleic acids of invading pathogens. These receptors are able to sense structurally distinct ligands and subsequently elicit an immune response fine-tuned to the respective threat. A set of ancillary proteins, which complement and modulate the different TLR molecular machineries would best explain this functional diversity. We thus aim to identify such cofactors of the endosomal TLRs.
Materials and methods: A mass-spectrometry based proteomics approach, involving tandem affinity purification of tagged endosomal TLRs, was performed to identify interactor candidates. Selected target proteins were stably knocked down in RAW 264.7 macrophages. After validation of the knock-down by qRT-PCR (quantitative real time polymerase chain reaction), these cell lines were systematically screened for their response to TLR agonists, using different cytokines (IL-6, IFNbeta) as read-out for inflammation.
Results: A proteomics approach to find interactors of endosomal TLRs identified several target proteins. Selected candidates were stably knocked down in RAW macrophages to assess their loss-of-function phenotype under stimulation conditions. Increased cytokine production was observed upon knock-down of two candidates, suggesting their involvement in negative regulation of endosomal TLR signaling pathways. These two candidates are currently subjected to in-depth validation, including FACS-based phagocytosis assays, gain of function analysis as well as intracellular localization studies. Finally, doxycyclin-inducible expression of tagged versions of the candidates in RAW264.7 cells will be established to be used to perform pull-downs on the interactor candidates followed by mass-spectrometric analysis. This will extend our knowledge on their proteomic environment, and, by combination with the initial TLR pull-down data, allow construction of a detailed and functionally annotated map of the TLR interactome.
Conclusions: Proteomics analysis led to identification of several interactor candidates of the endosomal TLRs. A role for two of these candidates in negative regulation of endosomal TLR signaling pathways is currently being validated.

P0185

Global innate immune response of human primary macrophages exposed to (1, 3)-beta-glucans

L. Teirilä,* T. Öhman,† A. M. Lahesmaa-Korpinen,‡ V. Veckman,* S. Saijo,§ H. Wolff,* S. Hautaniemi,‡ T. A. Nyman† & S. Matikainen*
*Centre of Expertise for Health and Work Ability, Finnish Institute of Occupational Health, Helsinki, Finland, †Institute of Biotechnology, University of Helsinki, Helsinki, Finland, ‡Institute of Biomedicine and Genome-Scale Biology Research Program, University of Helsinki, Helsinki, Finland, §Department of Molecular Immunology, Chiba University, Chiba, Japan

Purpose/Objective: β-glucans and LPS are the immunostimulatory components of fungi and Gram-negative bacteria, respectively. β-glucans are known to activate the inflammasome and IL-1β secretion, however, the global innate immune response to β-glucan exposure has not been characterized. Here we have used a systems biology approach to study innate immune response activated by β-glucans and LPS in human primary macrophages.
Materials and methods: To characterize β-glucan induced secretomes in human macrophages the cells were stimulated with LPS, or β-glucans for 18 h, and the secreted proteins were analyzed by 4plex iTRAQ labelling combined with liquid chromatography-tandem mass spectrometry analysis. RNA microarray analysis was performed with Agilent technology to cells exposed to LPS and β-glucans for 6 h. Bioinformatic tools were utilised for data classification. Mouse bone marrow-derived dendritic cells from Dectin-1 deficient mouse and pharmacological inhibitors for SYK and Src tyrosine kinases were used in functional experiments. The PI3K inhibitor 3-methyladenine and small interfering RNAs of Beclin-1 were used for experiments to analyse the impact of autophagy in β-glucan induced secretome.
Results: We show that both β-glucan and LPS stimulation induced significant gene expression changes, but only β-glucans activated robust protein secretion through conventional and unconventional, vesicle-mediated protein secretion mechanisms, including exosome- and secretory lysosome-mediated release of proteins. The Dectin-1/Syk signaling pathway was essential for the release of IL-1b other unconventionally secreted proteins. β-glucan stimulation of human macrophages activated autophagy and our functional studies show that autophagy mediates unconventional protein secretion in β-glucan-stimulated human macrophages.
Conclusions: We provide the first comprehensive characterization of the secretome and associated intracellular signalling pathways involved in response to β-glucan exposure of macrophages. Our results demonstrate that activation of unconventional protein secretion was dependent on autophagy suggesting an important role for autophagy in innate immune response against fungal infections.

P0186

Heat stress facilitates innate anti-viral response through enhancing lipid raft-dependent induction of type I interferon

T. Chen,* M. Yang,* C. Wang,* X. Zhu,* S. Tang,† Z. Yu† & X. Cao*
*National Key Laboratory of Medical Immunology & Institute of Immunology, Second Military Medical University, Shanghai, China, †Institute of Immunology, Zhejiang University School of Medicine, Hangzhou, China

Purpose/Objective: Host is usually subjected to various environmental heat stresses. However, effects of heat stress on innate immunity and the underlying mechanisms have not been clearly elucidated. We investigate the effects and mechanisms of heat stress on anti-viral response.
Materials and methods: The RNA viruses vesicular stomatitis virus (VSV) and Sendi virus (SeV), and the DNA virus HSV-1, were prepared and intraperitoneally injected (5×10^6 PFU) into mice. For *in vivo* heat stress, mice were anaesthetized and suspended in a water bath at 42¡C for 30 min. For *in vitro* heat stress of macrophages, dendritic cells (DC) and MEFs, cells were heat treated at 42¡C for 30 min in an air incubator containing 5% CO2. Virus replication in the liver and spleen was examined by both qPCR and titration assays. Activation of TBK1-IRF3 was evaluated by reporter assays and ELISA assays of IFN-α/β. Lipid rafts were isolated by sucrose density gradient centrifugation.
Results: We find that heat stress pretreatment of mice or macrophages/DC cells can inhibit virus replication and promote the production of IFN-α/β. However, heat stress can not significantly affect the anti-viral effects in $IFNAR^{-/-}$ mice or $IFNAR^{-/-}$ DC/macrophages. By using macrophages as infection model, we find that heat stress can promote both Toll-like receptor (TLR) 2, 4, 7, 9-triggered TBK1/IRAK1-IRF3/7 activation and IFN-α/β production. Moreover, heat stress pretreatment can enhance RIG-I-induced TBK1-IRF3 activation and IFN-α/β production. Based on our previous studies showing heat stress can mobilize recruitment of molecules into lipid raft, we further tested the effects of heat stress on lipid raft localization of TLR-associated molecules. We find that methyl-beta-cyclodextrin (cholesterol deprivation agent) can abrogate the effects of heat stress on anti-viral response in macrophages. Correspondingly, heat stress can enhance the recruitment of TLR2/4/7/9- and RIG-I-associated signaling components into Triton X-100 insoluble lipid rafts.
Conclusions: Our study suggests that heat stress positively regulates TLR-dependent and TLR-independent TBK1-IRF3 signaling pathway for initiation of type I interferon production and anti-viral response via lipid raft-dependent recruitment of TLR- and RIG-I-assocated signaling complexes.

P0187

IL-3-induced TAK1 activation controls the Erk1/2- and JNK2-dependent proliferation in mast cells

S. Drube,* I. Meininger,* K. Reinecke,† T. Herdegen† & T. Kamradt*
*Immunologie, Universitätsklinikum Jena, Jena, Germany, †Institut für Experimentelle und Klinische Pharmakologie, Universitätsklinikum Schleswig-Holstein Campus Kiel, Kiel, Germany

Purpose/Objective: Stimulation of mast cells with IL-3 induces activation of Erk1/2, PKB/Akt, JNK1/2, p38 and finally leads to proliferation. Thereby the PI3Kδ/mTOR/p70S6K signalling pathway plays a predominant role.

Another important signalling pathway regulating mast cell effector functions is mediated by Myd88, Traf6 and TAK1. This signalling pathway typically leads to NFkB activation and finally to cytokine production. We investigated whether growth factors like IL-3 are also capable to activate mitogenic signalling pathways via TAK1.
Materials and methods: Cytokine release, proliferation and signaling pathways were assayed *in vitro* upon stimulation of bone marrow-derived mast cells (BMMCs) with IL-3. Several murine knockout strains and inhibitors were used to investigate the relevance of src-kinases, TAK1, the Erk- and the JNK-signalling pathway.
Results: Stimulation with IL-3 induced TAK1 activation mast cells (Kroeger et al., 2009). We found that the TAK1 inhibitor 5Z-7-oxozeaenol reduced the Erk1/2-, JNK1- and p70S6K- activation. Next we investigated whether Erk1/2 or JNK1/2 contributes to p70S6K activation and therefore to proliferation. The Erk1/2 inhibitor UO126 but not the JNK-inhibitor SP600125 reduced the IL-3-induced activation of p70S6K indicating that the IL-3-induced proliferation partly depends on TAK1 mediated Erk1/2 activation.

Interestingly, UO126, SP600125, but not 5Z-7-oxozeaenol blocked the IL-3-induced proliferation. This indicated that TAK1-inhibition induced a signaling pathway which compensates for the reduced activation of p70S6K, Erk1/2 and JNK1 after 5Z-7-oxozeaenol

treatment. Indeed we found that 5Z-7-oxozeaenol treatment increased the activation of JNK2.

Therefore we next analysed the role of JNK1 and JNK2 on the IL-3-induced signaling and proliferation. In *jnk1*$^{-/-}$ and *jnk2*$^{-/-}$ BMMCs the IL-3-induced signaling was not affected. Surprisingly, the IL-3-induced proliferation was reduced in *jnk2*$^{-/-}$- but not *jnk1*$^{-/-}$-BMMCs.

Conclusions: Our data show that the IL-3-induced proliferation is mediated by the TAK1-dependent Erk1/2- and the TAK1-independent JNK2-activation. Thereby activated TAK1 induces proliferation and simultaneously controls JNK2 activation to prevent uncontrolled mast cell proliferation.

P0188

Inflammasome activation in alveolar macrophages from healthy smokers

J. Ockinger, S. Kullberg, A. Eklund, J. Grunewald & J. Wahlström
Department of Medicine, Karolinska Institutet, Stockholm, Sweden

Purpose/Objective: Recent studies have shown that a smoking increases the risk for autoimmune diseases such as multiple sclerosis and rheumatoid arthritis. The mechanisms underlying the risk increase are not known, but we hypothesize that immunomodulation by tobacco smoke exposure could affect the systemic or organ specific immune response. Innate immunity, including inflammasome activation and TLR signaling are of particular interest since cytokines in these pathways are essential regulators of the immune system, including activation of the adaptive immune response.

Materials and methods: In order to investigate the innate immunity mechanisms related to smoking, samples were collected through bronchoalveolar lavage (BAL) from healthy smokers and non-smokers. mRNA expression of relevant genes and secretion of cytokines was measured in naïve and *in vitro* stimulated alveolar macrophages.

Results: Initial analyzes indicates that mRNA expression of the inflammasome component *NLRP3* as well as *pro-IL-1b* are upregulated in naïve macrophages from smokers, compared to non-smokers. In addition, cells from smokers show a tendency to increased IL-1§ secretion after *in vitro* stimulation with known NLRP3 inflammasome activators, compared to cells from non-smokers. In contrast, *TNF* expression is significantly downregulated in smokers, while other cytokines such as *IL-6* and *IL-8*, and the receptors *TLR2* and *4* are not differently expressed in healthy smokers and non-smokers.

Conclusions: Our results confirms that pro- and anti-inflammatory mechanisms are differentially regulated in alveolar macrophages from healthy smokers and non-smokers, and specifically indicate that tobacco smoke exposure might activate inflammasomes. Further research includes detailed studies of tobacco smoke induced signaling events and inflammasome activation, and its role in the regulation of systemic and lung-specific immune regulation.

P0189

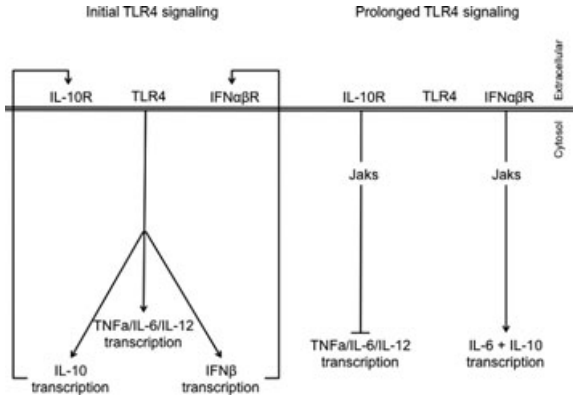
JAKs mediate the actions of Interleukin-10 and IFNbeta feedback loops downstream of TLR4 in macrophages

M. J. Pattison, K. F. MacKenzie & J. S. C. Arthur
MRC Protein Phosphorylation Unit, University of Dundee, Dundee, UK

Purpose/Objective: The action of multiple cytokines is mediated by Jak/STAT signaling and Jak inhibitors have attracted considerable interest as potential drugs for autoimmune disorders.In macrophages, the response to the TLR4 agonist LPS can be modified by opposing IFN and IL-10 mediated feedback loops.As both these cytokines signal via Jak1/Tyk2, we investigated the effect of Jak inhibition on macrophages.

Materials and methods: To analyze the effects of Jak1/Tyk2 signaling in macrophages, we made use of the Jak inhibitor, Ruxolitinib, in combination with bone marrow derived macrophages from wild type, IFNabR or IL-10 knockout mice.A combination of qPCR, ELISA and immunoblotting were used to profile macrophage function in response to the appropriate stimuli.

Results: IL-10 is an important anti-inflammatory cytokine produced by macrophages that can act in an autocrine manner to inhibit the secretion of pro-inflammatory cytokines.Accordingly, in response to LPS, secretion of TNF, IL-6 and IL-12 was markedly increased in IL-10 deficient macrophages compared to wild type cells.IL-10 stimulates Jak1/Tyk2, and treatment of wild type cells with Ruxolitinib was found to increase TNF and IL-12 in response to LPS to a similar level to that seen in IL-10 knockout cells.Ruxolitinib also increased IL-6 production, but not to the level seen in IL-10 knockout cells.This could be explained by either an inhibition of IL-10 signaling or IL-10 production.We therefore looked at the effect of Ruxolitinib on IL-10 production. Ruxolitinib had no effect on the initial production of IL-10 but was required for its sustained production.Further work using IFNab receptor knockout mice demonstrated that this was due to a requirement for an IFNb feedback loop to sustain IL-10 transcription in response to LPS. Furthermore, IFNβ can induce IL-10 transcription, which was blocked by Ruxolitinib. IFNβ also promoted IL-6 transcription and, in line with this, the IFNabR knockout reduced LPS-induced IL-6 production.Thus IL-6 is subject to competing Jak dependent control mechanisms; its production is repressed by IL-10 but promoted by IFNβ.



Conclusions: Together, these results show that Ruxolitinib can alter cytokine production in macrophages by blocking IL-10 and IFNβ autocrine loops. These data also shows that IFNβ is sufficient to induce IL-10 transcription and is required for its sustained production in response to LPS.

P0190

Lipopolysacccharide signaling in human pericytes: potential role in inflammation and immune response

I. Guijarro-Muñoz, M. Compte, A. Alvarez-Cienfuegos, L. Alvarez-Vallina & L. Sanz
Molecular Immunology Unit, Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain

Purpose/Objective: Activation of endothelium is a key event during the onset of inflammatory processes and implies the induction of chemokines, cytokines and adhesion molecules. Pericytes are embedded within the vascular basement membrane and play critical roles in vascular development and homeostasis; however, little is known about their role in inflammation. Our primary objective was thus to compare the response to lipopolysacccharide (LPS) in human endothelial cells and pericytes.

Materials and methods: To address this issue, we used cDNA microarrays-based analysis of gene expression of LPS-treated cells. We validated the microarray results using real time PCR. Supernatants were assayed for the production of secreted proteins with antibody arrays, and the expression of cell surface molecules was studied by flow cytometry. In addition, we explored the molecules implied in the signalling pathway, from the cell membrane to the nucleus.
Results: Incubation of human brain vascular pericytes with LPS for 4 h induced a significant increase in the transcription of 76 genes ($P < 0.05$), that were classified by functional annotation using gene ontology terms. Twenty-four terms in the list had a FDR value of <0.0001, including immune response, defense response and inflammatory response in the biological process category, and cytokine activity and chemokine activity in the molecular function category. LPS-treated pericytes released a plethora of cytokines and chemokines, as IL-6, IL-8, CXCL1 and CCL2; and upregulated cell surface expression of the adhesion molecules VCAM and ICAM. Furthermore, we assessed the expression of key elements of LPS signalling pathway (TLR-4, MD2, MyD88), as well as NF-KB translocation to the nucleus after LPS treatment.
Conclusions: LPS induces a robust modulation of gene expression in human pericytes that is similar to that induced in endothelial cells. These results indicate that pericytes contribute to the vascular cytokine and chemokine network and could play an important role in the inflammatory/innate immune response by influencing the site-specific recruitment of leukocyte subsets.

P0192
Src-family kinases and Syk are implicated in neutrophil extracellular traps formation

S. Nanì & G. Berton
Pathology and Diagnostics, University of Verona, Verona, Italy

Purpose/Objective: Upon activation, neutrophils release extracellular fibers or neutrophil extracellular traps (NETs), structures composed of chromatin and granule proteins that bind and kill pathogens. Accumulating evidence suggests that NETs can contribute to systemic and local pathologies such as sepsis, vasculitisand chronic lung pathologies like cystic fibrosis. Signal transduction mechanisms regulating NET formation are poorly understood. Given the important role of Src kinase family (SFKs) and Syk in inflammatory pathologies, we addressed whether these kinases regulated NET formation.
Materials and methods: NET formation was quantified by staining of extracellular DNA or visualized by fluorescence microscopy by standard procedures. As stimuli we used phorbol myristate acetate (PMA), beta-glucan (BG) and the *Pseudomonas aeruginosa* strain PAO1 (MOI 1).
Results: We found that beta-glucan, a ligand for the C-type lectin Dectin-1, is a strong inducer of NET formation. NET formation in response to beta-glucan requires both a SFK-dependent pathway and ROIs; in fact, in the presence of PP2 (inhibitor of SFKs) and DPI (an inhibitor of the NADPH oxidase) there is a reduction of about 50% in NET formation. Additionally, the new generation Syk inhibitor PRT-060318 reduces NET formation triggered by beta-glucan.

The most widely used activator of NET formation is the phorbol ester PMA that mimics the action of diacylglicerol an activator of protein kinase C (PKC). In presence of the Src family kinase inhibitor PP2 there is not a reduction of NET formation in response to PMA but there is a reduction in presence of DPI confirming previous studies.*P. aeruginosa* has been reported to induce NET formation. Notably, both PP2 and PRT-060318, effectively inhibited NET formation triggered by the strain PAO1 of *P. aeruginosa*.We also found that NET formation in response to beta-glucan and PAO-1 was defective in murine neutrophils deficient of the Src-family kinases Fgr and Hck.
Conclusions: These studies are instrumental to validate the use of Syk and SFKs inhibitors in pathologies, such as cystic fibrosis, COPD, sepsis and vasculitis, in which NET formation play an important role.

P0193
The Helicobacter pylori virulence factor VacA disrupts intracellular trafficking and blocks IFN-beta induced by *Lactobacillus acidophilus* in macrophages

G. Weiss,* S. Forster,† A. Irving,‡ H. Frøkiær,* R. Ferrero,† M. Kaparakis-Liaskos† & P. Hertzog†
**Basic Sciences and Environment Molecular Immunology, Copenhagen University, Copenhagen, Denmark, †Centre for Innate Immunity and Infectious Diseases, Monash Institute of Medical Research, Clayton, Vic., Australia, ‡Centre for Cancer Research, Monash Institute of Medical Research, Clayton, Vic., Australia*

Purpose/Objective: It is indicated that an impaired immune response contributes to failed eradication of *Helicobacter pylori* after standard antibiotic therapy. Lactobacilli have been suggested to exert a preventative and therapeutic effect on gastritis caused by *Helicobacter pylori* infection. We aimed to identify the cellular and molecular pathways activated upon stimulation of murine bone marrow derived macrophages (BMDM) with *Lactobacillus acidophilus, Helicobacter pylori*, and both strains in combination.
Materials and methods: BMDM were stimulated with *Lactobacillus acidophilus, Helicobacter pylori*, and both strains in combination. Samples were analysed by microarray analysis, RT-PCR, ELISA and confocal microscopy.
Results: Microarray analysis revealed that *H. pylori* induces a high expression of neutrophil recruiting chemokines (Cxcl3, Cxcl1, Cxcl2) and cytokines (IL-1b and IL-1a). In contrast, *L. acidophilus* activates a strong Th1 response characterized by a high expression of IL-12 and IFN-β and the T-cell recruiting chemokines Cxcl10 and Cxcl11. Unexpectedly, when both bacteria are added in combination, *H. pylori* completely blocks the expression of IFN-β and IL-12 induced by *L. acidophilus*. Other strongly down-regulated genes are *Rgs1/2*, *Fgd2*, and *Dock8*, all involved in Rho, Rac and Cdc42 GTPase signalling and key regulators of the actin cytoskeleton. Two genes are strongly induced: *P2rx2* and *Pdxp,* both involved in actin cytoskeleton alterations.

We tested two of the main virulence factors of *H. pylori*: Cag pathogenicity island (cagPAI) and VacA (Vacuolating cytotoxin). The inhibitory capacity of the CagPAI mutant is identical to the WT, however, the VacA mutant is unable to block IFN-β. Phagosomal maturation inhibitors completely block the induction of IFN-β. Confocal microscopy revealed that instead of a quick endosomal release into the cytoplasm, *L. acidophilus* gets trapped in the endosomal/lysosomal compartment in *H. pylori* infected macrophages.
Conclusions: Our data indicates that *H. pylori* disrupts intracellular trafficking of *L. acidophilus* and thereby blocks IFN-β signaling via the virulence factor VacA and GTPases involved in actin cytoskeleton alterations. As *H. pylori* prevents the release of *L. acidophilus* from the endosomal/lysosomal compartment into the cytoplasm, other factors, *e.g.* cytosolic DNA sensors, possibly trigger the release of IFN-β in macrophages stimulated with *L. acidophilus*. Finally, even though *L. acidophilus* does not modulate the immune response induced by *H.*

pylori, we were able to identify possible novel therapeutic targets for treatment and prevention of gastric infections caused by *H. pylori*.

P0194
The mitochondrial protein, Toag-1, interferes with MyD88 dependent Toll-like receptor signaling in dendritic cells

S. Vogel,* S. Schlickeiser,* I. Panov,* M. Schröder,† M. B. Lutz,‡ S. Lehnardt,§ K. Vogt,* G. Grütz* & B. Sawitzki*
**Institute of Medical Immunology, Charité Universitätsmedizin Berlin, Berlin, Germany, †Institute of Immunology, National University of Ireland Maynooth, Maynooth, Ireland, ‡Institute of Virology and Immunobiology, Julius-Maximilans-Universität Würzburg, Würzburg, Germany, §Department of Neurology Charité Medical School, Charité Universitätsmedizin Berlin, Berlin, Germany*

Purpose/Objective: We could recently show that Toag-1 is highly expressed in peripheral and graft infiltrating $CD4^+$ T cells and $CD11c^+$ cells DCs of tolerance developing recipients (Sawitzki *AJT* 2007) and the encoded protein is exclusively localized within mitochondria (Keeren *JI* 2009). Recently the importance of mitochondria in the regulation of host innate immune signaling, e.g. importance of TRAF6 translocation to mitochondria upon TLR1/2/4 ligand stimulation resulting in release of mROS, has been shown (Arnoult *EMBO* 2011). Here we investigated whether Toag-1 interferes with mitochondria-dependent events of TLR signaling in DCs and inhibits subsequent T cell priming.

Materials and methods: Bone marrow derived dendritic cells from C57BL/6 mice were transduced with an adenovirus encoding mouse Toag-1 or EGFP as a control. Upon stimulation with LPS, Pam3Cys or Poly(I:C) relative amounts of p-p38, MHCII, CD86, mitochondrial reactive oxygen species (mROS) and released cytokines were determined by FACS or Cytometric bead array. A transcriptional profiling was done by a mouse Toll-Like Receptor Signaling Pathway PCR Array. To determine their T cell priming capacities, stimulated DCs were co-cultured with eFluor450 labeled $CD4^+$ T cells from balb/c mice for 5 days.

Results: We observed an impaired LPS − and Pam3Cys-induced p38-MAPK activation upon Toag-1 overexpression in DCs. This was accompanied by a decreased release of inflammatory cytokines such as TNFa, IL-1a and IL-6, whereas upregulation of MHCII & expression of CD86 was not affected. Additionally we detected an abolished production of mROS. Using DCs from knock -out mice we could show that Toag-1 exclusively interferes with MyD88-dependent TLR signaling. Toag-1 overexpressing DCs display increased expression of SIGIRR, a negative regulator of Traf6-dependent signaling, but nearly completely abolished LPS-induced IL-2 expression. Subsequently, LPS and Pam3Cys stimulated Ad-Toag-1 transduced DCs failed to induce proliferation of and cytokine expression by allogeneic $CD4^+$ T cells.

Conclusions: Our data now show that Toag-1 regulates mitochondrial components of TLR signaling by preventing MyD88/ Traf6-dependent production of mROS and inflammatory cytokines but enhancing expression of negative regulators.

The role of triggering receptor expressed on myeloid cells (TREM)-1 and TREM-2 during influenza-induced inflammation

C. Lai, T. Bell, T. Fujimori & T. Hussell
Leukocyte Biology NHLI, Imperial College London, London, UK

Purpose/Objective: While Toll-like receptor (TLR) triggering by microbial products can lead to initiation of inflammation, the presence of other innate receptors is often required in order to amplify them. One such family of receptors is the triggering receptor expressed on myeloid cells (TREM) family. These membrane receptors are expressed on myeloid cells and associate with DNAX adaptor protein 12 (DAP12) in order to mediate inflammation. Different members of the family modulate inflammation in different ways. Upon association with TLRs, TREM-1 ligation induces signal transduction resulting in transcriptional activation of NFκB, thus amplifying the acute inflammatory response. Its role has been extensively described in bacterial-induced inflammation, such as sepsis, and a soluble form of TREM-1 (sTREM-1) is used as a diagnostic marker of both infectious and non-infectious inflammation. TREM-2, on the other hand, inhibits TLR responses and integrin-mediated migration, and is also involved in osteoclast differentiation and function.

Despite a clear role in infectious inflammation, to date, TREMs have only been studied in one type of viral infection, in which TREM-1 was found to be upregulated on neutrophils following filovirus infection. Exploration into the role of TREMs in other types of viral-induced inflammation is needed, in order to utilise knowledge of this recently discovered family of receptors for clinical benefit.

Materials and methods: We have utilised a murine model of influenza to investigate the expression of TREM-1 and TREM-2 on myeloid cell populations.

Results: Our studies have found increased surface expression of TREM-1 on myeloid cells during early time-points following influenza, while TREM-2 is associated with the resolution phase of inflammation. The role of TREM-1 and TREM-2 in the initiation and modulation of viral-induced inflammation in the lung will be discussed.

Conclusions: Expression of TREM-1 and TREM-2 is regulated during influenza-induced inflammation. Elucidating TLR amplifiers and regulators could provide novel drug targets for the treatment of inflammatory lung disease that carries a reduced risk of pathogen outgrowth.

TLR2 and MyD88 mediated signaling is essential for induction of inflammatory response against Brucella but not for replication of the bacterium inside human macrophages

O. Dimitrakopoulos, K. Liopeta, G. Dimitracopoulos & F. Paliogianni

Microbiology, University of Patras Medical School, Patras, Greece

Purpose/Objective: Innate immune recognition constitutes an efficient mechanism against *Brucella*. However it is not clear how signals from different TLRs are orchestrated in leading to effective clearance of infection, especially in the human system. Our aim was to elucidate the involvement of TLR pathway members in the inflammatory response against *Brucella* and their effect on the outcome of *Brucella* infection in human macrophages.

Materials and methods: 293 cells, stable transfected with TLR2 or TLR4, were transiently transfected with NF-κB, AP-1 or CREB reporter driving the expression of luciferase gene for 16 h before stimulation. Differentiated THP-1 cells were transiently transfected with TLR2 or MyD88 siRNA for 48 h before stimulation with viable *Brucella melitensis* bacteria, at a multiplicity of infection (MOI) of 20. Luciferase activity was assayed with Dual-Luciferase Reporter System and cytokines in cell culture supernatants were measured by ELISA, 16 h after infection. Intracellular survival of *B. melitensis* was assessed with gentamycin protection assays, followed by lysis of THP-1 cells 0, 24, 48 and 72 h post infection.

Results: Viable *B. melitensis* bacteria activated NF-κB via TLR2 by eightfold but not via TLR4, in 293 cells. AP-1 or CREB activation was detected neither in TLR2 nor in TLR4 transfected 293 cells. Silencing of TLR2 and MyD88 genes resulted in the reduction of IL-6, TNF-α and IL-10 production in response to live *B. melitensis* bacteria by 50–55%, compared to control siRNA treated cells, whilst it had no effect on IL-1β production. Survival of *B. melitensis* in TLR2 and MyD88 silenced cells remained identical with the survival inside control cells, even 72 h post infection.

Conclusions: These results provide evidence that *Brucella* induces a TLR2-MyD88 dependent inflammatory response through NF-κB activation which in turn initiates transcription of pro- (TNF-α, IL-6) and anti- (IL-10) inflammatory cytokines. However, *Brucella's* survival inside human macrophages is independent of this response and of signals originated from TLR2 and MyD88. Synergy between intracellular innate immune receptors and TLRs to control *Brucella* infection in human system remains to be defined.

Poster Session: Responding — Leukocyte Cell Biology

P0197

Exploring neutrophil behaviour in a zebrafish model of inflammation through the generation of novel parameters using MatLab algorithms

K. M. Henry,* S. A. Renshaw* & C. C. Reyes-Aldasoro†
*Centre for Developmental and Biomedical Genetics, University of Sheffield, Sheffield, UK, †Biomedical Engineering School of Engineering and Informatics, University of Sussex, Sussex, UK

Purpose/Objective: Tracking of immune cells is key to understanding their behaviour during inflammation. Current software available for tracking of immune cells is limited. The aim of this study was to develop a MatLab package of segmentation and tracking algorithms to apply in the tracking of neutrophils, fluorescently labelled in our zebrafish model. The development of algorithms in MatLab allows us to explore parameters not available in other software packages such as directionality of neutrophil movement and neutrophil behaviour inside and outside of a wound region.
Materials and methods: Tail fin transection was performed on Tg(mpx:GFP) zebrafish (3 dpf) which were imaged on a spinning disk confocal from 1 h post injury (hpi) to 7 hpi. Images were exported from Volocity™ and analysed using MatLab m-files written for the tracking of immune cells. This is a fully automated analysis, after the user defines the initial thresholds based on fluorescent intensity of the images.
Results: Neutrophils from injured embryos had a lower meandering ratio and a greater speed than neutrophils tracked in uninjured embryos (meandering ratio 0.24 ± 0.03 versus 0.42 ± 0.05, $P = 0.003$; speed 4.03 ± 0.32 versus 1.31 ± 0.21 pixels/frame, $P < 0.0001$, $n = 3$), however there was no significant difference in total distance travelled (166.9 ± 17.4 versus 210.1 ± 30.28 pixels, $P > 0.05$). In injured embryos with a defined wound region, the oriented velocity towards the wound was 0.31 ± 0.24 pixels/frame. Once within the wound region, the oriented velocity of neutrophil tracks was -0.39 ± 0.32 pixels/frame; indicating that while the neutrophils travel at a similar speed, they are now travelling away from the wound. The 'in wound ratio' was 0.91 ± 0.04, indicating that once neutrophils enter the wound region they tend to stay, in the timeframe studied. The 'leave wound ratio' was 0.37 ± 0.03, a measure of the rate at which neutrophils move away from the site of injury once they have entered the wound region.
Conclusions: Using these algorithms, we can analyse the behaviour of immune cells in a more detailed way. In addition to previously available parameters such as meandering ratio and speed, more complex parameters such as velocity towards or away from a wound region and a measurement of how neutrophils behave while in a wound region are available. Combining this novel tracking technology with established assays in our laboratory will enable the further dissection of neutrophil fate following an inflammatory stimulus.

P0198

HIF-1 transcription complex is essential for translational control of myeloid cell functions

V. Sumbayev, B. F. Gibbs, I. Yasinska & G. S. Lall
Medway School of Pharmacy, University of Kent, Chatham Maritime, UK

Purpose/Objective: Myeloid hematopoietic cells are key effectors of host innate immune defence and are also majorly involved in autoimmune and hypersensitivity reactions. Upon malignant transformation myeloid cells also cause different types of acute myeloid leukaemia, which affect high numbers of people of different age groups worldwide. Normal and pathological responses of myeloid hematopoietic cells require adaptation to a signalling stress controlled by the hypoxia-inducible factor 1 (HIF-1) transcription complex. HIF-1 is known to trigger expression of genes responsible for glycolysis, angiogenesis and cell adhesion. However, since its functions in the biological responses of myeloid cell are not well characterised our aims were to elucidate the mechanisms of HIF-1-mediated regulation of myeloid cell functions.
Materials and methods: THP-1 human myeloid cells, LAD2 mast cells and purified primary human basophils were used to perform mechanistic studies. Western blot, ELISA, quantitative real-time PCR and biochemical assays were employed to conduct the study. The obtained results were validated using *in vivo* mouse models.
Results: Here we have shown for the very first time that in myeloid cells HIF-1 controls activation of mammalian target of rapamycin (mTOR) a key regulator of ribosomal translation of the proteins responsible for cell survival, proliferation and aging. HIF-1 was found responsible for control of the AMP/AMP-kinase branch of the signalling pathways regulating mTOR pro-translational activity. Moreover, we also demonstrated that mTOR is critically involved in HIF-1 activation through a biosynthetic mechanism.
Conclusions: The cross-talk of HIF-1 and mTOR pathways is responsible for the regulation of stress-adaptation mechanisms and translational control of myeloid cell functions.

P0199

Hsp70 is involved in different immune processes

M. Streltsova, A. Boyko, A. Klinkova, N. Troyanova, O. Shustova, E. Kovalenko & A. Sapozhnikov
Immunology, Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russia

Purpose/Objective: HSP70 possess diverse functions that are essential for different intracellular processes and for protection of cells from adverse factors of microenvironment. HSP70 are intracellular proteins but there are evidences of cell surface and extracellular localization of HSP70. The functions of surface and extracellular HSP70 are still not clear. However it was shown that surface and extracellular HSP70 could activate different immunocompetent cells. These data indicate involvement of HSP70 in immune processes and pose the ground for study effects of these proteins in immune system.
Materials and methods: We carried out investigation of involvement of HSP70 in immune processes using different models and approaches.
Results: Our results showed that HSP70 was presented in lymphoid cell populations in intracellular, surface and extracellular forms. All these pools of HSP70 play essential role in lymphocyte populations. We revealed that intracellular HSP70 was involved in execution of programmed cell death and these proteins were translocated to the surface of apoptotic cells. Cytotoxic immune cells recognize and eliminate target cells bearing surface HSP70. It was also found that activated lymphoid cells produced extracellular HSP70. Different type of lymphocytes can bind and internalize exogenous HSP70. It is important that this internalization resulted in increased resistance of the cells to apoptosis. Another noteworthy property of extracellular HSP70 is their pronounced affinity to the surface of apoptotic cells and cells with denaturated membrane proteins. Along with effects mentioned above we revealed significant suppressing action of exogenous HSP70 on generation of reactive oxygen species (ROS) by phagocytes.
Conclusions: These results suggest an ability of HSP70 to restrain ROS production during inflammation with the purpose of prevention of the tissue from destruction. Further to the described data we discovered a distinct influence of stress hormones on HSP70 expression in immune cells that display an involvement of these proteins in neuroendocrine immunoregulation.

Inhibition of IL-27 attenuates atherosclerosis

O. Ramos, S. C. de Jager, P. J. van Santbrink, M. ter Borg, R. van der Sluis & J. Kuiper
Biopharmaceutics, Leiden Amsterdam Center for Drug Research/Leiden University, Leiden, The Netherlands

Purpose/Objective: Interleukin 27 binds to cytokine receptor WSX-1 to activate cells resulting in both pro- and anti inflammatory responses. In this study IL-27 was blocked *in vivo* to study the role in atherosclerosis.
Materials and methods: 239T cells were transfected with a lentivirus encoding the extracellular domain of WSX-1 with a human IgG tag or an empty virus. The medium was incubated with IL-27 prior to addition to activated splenocytes. Cytokine release was measured to confirm IL-27 blockade. LDLR $^{-/-}$ were injected i.m. with a sWSX-1 or an empty virus.A hIgG ELISA was performed to measure the release of sWSX-1. Mice with IgG levels higher than the control mice who received an empty virus were considered to be responders. The non-responders did not show an increased hIgG level in response to the treatment. Two weeks after the injection the mice were put on a high fat diet for 2 or 6 weeks to induce atherosclerosis. Lesion development, macrophage content and collagen content were determined in the aortic arch. FACS analysis was performed on blood, heart lymph node and the spleen to determine leukocyte activation. Splenocytes were also activated with αCD3 and αCD28 to determine cytokine production.
Results: *In vitro* the IL-27-mediated IFNγ and IL-10 secretion in spleen cells was reduced by the soluble receptor. *In vivo* blockade of IL-27 via the soluble receptor resulted in increased CD163 and IL-10 positive macrophages in the spleen after 2 weeks high fat diet. Neutralization of IL-27 via the soluble receptor resulted in a 31% reduction weeks in aortic lesion size after 6 weeks. The lesion size negatively correlated with the concentration of the soluble receptor in the serum of the responders.The collagen content was not affected, while there was a trend toward increased macrophage content. FACS analysis showed that blockade of IL-27 increased the circulating T helper cell population after 6 weeks high fat diet. Simultanously, the percentage of circulating regulatory T cells increased upon neutralization of IL-27. Surprisingly, no alterations were detected in the Th1 and Th17 populations. Furthermore, CCR2 expression on monocytes was reduced while CD163 expression increased.
Conclusions: Taken together these results indicate that blockade of interleukin 27 reduces lesion formation by inducing a less inflammatory immune response by inducing regulatory T cells and shifting monocyte differentiation towards anti inflammatory M2 macrophages.

P0202
Macrophage-delivered signals drive inflammation resolution in an *in vivo* zebrafish model

C. A. Loynes,*C. Gray,†T. Chico†& S. A. Renshaw*
**Infection and Immunity, University of Sheffield, Sheffield, UK,* †*Cardiovascular Science, University of Sheffield, Sheffield, UK*

Purpose/Objective: The inflammatory response is critical for maintaining tissue homeostasis. Neutrophils are the primary cell to respond to tissue injury or infection but can cause irreversible damage to surrounding tissues if they are not successfully removed. Neutrophils may leave inflammatory sites by death by apoptosis and subsequent uptake by macrophages or by migration away. Soluble mediators have been shown to be released from macrophages following ingestion of apoptotic cells *in vitro*, and these include prostaglandin E2 (PGE2). We therefore hypothesised that such mediators might be released *in vivo* and might drive neutrophil removal to aid successful resolution of inflammation.

Using zebrafish tail transection as a model of neutrophilic inflammation, we aimed to investigate the roles of macrophages on neutrophils during inflammation and to identify soluble mediators that can influence the outcome of inflammation resolution.
Materials and methods: Transgenic zebrafish allow leukocyte-specific ablation using Metronidazole to assess the role of macrophages during tail transection induced inflammation. Inhibitors and soluble mediators were added exogenously to dissect the molecular mechanisms involved. Neutrophil numbers, apoptosis and reverse migration of neutrophils were visualised *in vivo*.
Results: Tail transection in control larvae causes a peak number of neutrophils at 6 h post injury (hpi), which are fully resolved by 24hpi. Ablation of macrophages during inflammation causes resolution to fail, with significantly more neutrophils remaining at the site of tail transection 24 hpi. Neutrophil number at the site of injury in macrophage-depleted larvae is 14.41 ± 1.30 compared to 7.44 ± 1.14 in control larvae ($P < 0.001$). There is no significant difference in the number of apoptotic neutrophils however, at the site of injury.

PGE2 drives inflammation resolution by 12hpi in control larvae in a dose dependent manner.When PGE2 is added to macrophage-depleted larvae, neutrophil numbers are significantly reduced by 12hpi and maintained at 24hpi, with a mean of 8.894 ± 0.55 compared to macrophage-depleted larvae mean of 13.81 ± 0.70 ($P < 0.001$).
Conclusions: These data suggest PGE2 can drive inflammation resolution *in vivo*, and that macrophages produce soluble mediators that affect inflammation resolution, with PGE2 being a candidate compound suitable for further investigation.

P0203
Mechanisms of TGFß1 and IL-4 induced TREM-2 expression in monocytes

J. Bradley,* F. Squirrell,* D. Sexton† & M. O'Connell*
**Pharmacy, The University of East Anglia, Norwich, UK,* †*Pharmacy, Biomedical Research Centre, Norwich, UK*

Purpose/Objective: Triggering receptor expressed on myeloid cells (TREM)-2 suppresses the inflammatory response by reducing proinflammatory cytokines such as TNF-α and IL-6. TREM-2 expression is increased in chronic inflammatory conditions such as chronic obstructive pulmonary disease (COPD) and multiple sclerosis. Interestingly, most pro-inflammatory stimuli reduce TREM-2 expression. Therefore, the aim of this study was to identify inflammatory mediators that upregulate TREM-2 expression in human monocytes and investigate the mechanisms involved.
Materials and methods: Primary human monocytes or the human monocytic THP-1 cell line were utilised in this study. Human monocytes were isolated from peripheral blood of healthy volunteers using a Ficoll Paque Plus density gradient, followed by adherence. TREM-2 protein expression was measured by western blot analysis and immunofluorescence. TREM-2 mRNA expression was analysed by quantitative RT-PCR.
Results: Stimulation of THP-1 cells with either TGFβ1 or interleukin-4 (IL-4) increased TREM-2 protein expression. TGFβ1 and IL-4 also increased TREM-2 mRNA expression, six and twofold respectively. These results were also observed in primary human monocytes. TGFβ1-induced TREM-2 mRNA expression was suppressed by pre-incubation with the p38 inhibitor, SB203580. In contrast, inhibitors of PKC (bisindoylmaleamide), extracellular-signal-regulated kinase 1/2 (PD98059), phosphoinositide-3-kinase (LY294002) and the proteosome/nuclear factor kappa-B (MG132) had no significant effect on TGFβ1-induced TREM-2 mRNA expression.
Conclusions: The anti-inflammatory cytokines, TGFβ1 and IL-4 are involved in the resolution of inflammation and are upregulated in inflammatory conditions. TGFβ1 and IL-4 increased TREM-2 expression in monocytes. For TGFβ1, this was partially inhibited by p38

inhibition, suggesting that although p38 is involved, it is not the only mechanism. Current studies are analysing the role of SMADs in TGFβ1 induced TREM-2 expression and the mechanism of IL-4 induced TREM-2 upregulation. In conclusion, TGFβ1 and IL-4 may play a role in the increase in TREM-2 expression seen in chronic inflammatory conditions. These results support existing evidence for the role of TREM-2 in the resolution of inflammation.

Metal ions influence onto cytokines production by T lymphocytes in patients undergoing implantation therapy in dental medicine

S. Podzimek, E. Oganessian, M. Tomka, J. Bartova & J. Prochazkova
Institute of Clinical and Experimental Dental Medicine, 1st Faculty of Medicine and GUH Charles University, Prague, Czech Republic

Purpose/Objective: The purpose of the study was to establish cytokines production under metal ions influence by T lymphocytes of patients in which individually the most appropriate material for implantation therapy and followed prosthetic treatment was choosen.
Materials and methods: Levels of twenty cytokines, typical for inflammatory reaction, were established in T lymphocyte cultures influenced by titanium and mercury ions obtained from 15 patients before implantation therapy (I), after implantation therapy and before prosthetic therapy (II) and after implantation and prosthetic therapy (III) using Quantibody human custom array.
Results: In non-stimulated culture significantly increased levels of IL-10, IL-11 and TNF-alpha between examinations II and III and significantly increased levels of ICAM-1, IL-10, IL-11, IL-15, TNF-alpha and TNF- beta between examinations I and III were found. After stimulation of lymphocytes by titanium significantly increased levels of IL-2, IL-10, IL-11, IL-13, IL-15 and MIP-1b between examinations I and III were found. In general, significantly increased concentrations of inflammatory reaction cytokines after stimulation by titanium as well as in the course of implantation therapy process were found.
Conclusions: This study confirmed the influence of metal ions onto levels of inflammatory reaction cytokines produced by lymphocytes of patients undergoing implantation therapy. The establishment of individually the most appropriate material for implantation therapy and followed prosthetic treatment should become common procedure.
Acknowledgement: The study was supported by research projects SVV 2012 nr. 264501 and PRVOUK-P28/LF1/6 of Ministry of Education, Youth and Sports, Czech Republic and by project NT 13087-3 of the Internal Grant Agency, Ministry of Health, Czech Republic.

Metal ions influence onto lymphocyte proliferation in patients undergoing implantation therapy in dental medicine

P. Sommerova, S. Podzimek, E. Oganessian, M. Tomka, J. Bartova & J. Prochazkova
Institute of Clinical and Experimental Dental Medicine 1st Faculty of Medicine and GUH, Charles University, Prague, Czech Republic

Purpose/Objective: Purpose of the study: The purpose of the study was to prove the importance of metal intolerance diagnostics in patients undergoing implantation therapy in dentistry by determination of individually the most appropriate material for implantation therapy and followed prosthetic treatment.
Materials and methods: Materials and methods: Thirty-eight patients fullfilled the entrance criteria for implantation therapy, in these patients the test for metal intolerance (to Hg, Ti, Zr, Cr, Co) was performed three times [before implantation therapy (i), after implantation therapy and before prosthetic therapy (ii) and after implantation and prosthetic therapy (iii)] to choose the most appropriate material for implantation therapy and followed prosthetic treatment.
Results: Results: Based on results of metal intolerance test I to titanium, the patients were divided into two groups: Group A (24 patients with titanium implants-tolerating Ti) and Group B (14 patients with zirconia implants-with Ti intolerance). In Group A patients, prosthetic treatment was done by metaloceramics (Group A1-14 patients-tolerating Cr and Co) and by zirconia (Group A2-10 patients-with Cr and/or Co intolerance) based on metal intolerance test II. At least half a year after prosthetic treatment control metal intolerance test III was performed. In patients with Hg intolerance and/or galvanic currents in their oral cavity, amalgam fillings were replaced by non-metallic ones. Control metal intolerance test III showed the improvement of lymphocyte reaction in patients previously non-tolerating tested metals.
Conclusions: Conclusions: This study confirmed the importance of metal intolerance diagnostics in patients undergoing implantation therapy in dentistry. The establishment of individually the most appropriate material for implantation therapy and followed prosthetic treatment should become common procedure. Acknowledgement:

The study was supported by research projects SVV 2012 nr. 264501 and PRVOUK-P28/LF1/6 ofMinistry of Education, Youth and Sports, Czech Republic and by project NT 13087-3 of the Internal Grant Agency, Ministry of Health, Czech Republic.

Neuropilin-1 interferes with $CD4^+$ T cell responses

M. Hutzler & W. Hansen
Medical Microbiology, University Hospital Essen, Essen, Germany

Purpose/Objective: Naturally occurring $CD4^+$ $CD25^+$ $FoxP3^+$ regulatory T cells (Tregs) represent promising targets for the therapy of autoimmune diseases and allergy as well as cancer and certain infectious diseases. Our group identified the neuronal surface receptor Neuropilin-1 (Nrp1) to be highly expressed on murine Tregs, correlating with the expression of Foxp3 and *in vitro* suppressive function, thus representing a suitable surface marker for the identification of regulatory T cells. To characterize the role of Nrp1 in $CD4^+$ T cells we generated a transgenic mouse line overexpressing Nrp1 under control of the CD4 promoter (CD4-Nrp1).
Materials and methods: Lymphocyte distribution and frequencies as well as their Nrp1 expression were analyzed in wildtype (WT) and CD4-Nrp1 transgenic mice by flow cytometry. $CD4^+$ $CD25^-$ T cells were FACS-sorted, stimulated *in vitro* and their gene expression profile was assessed by Agilent gene chip analysis. The proliferative capacity of $CD4^+$ $CD25^-$ T cells from wildtype and transgenic mice was measured as loss of CFSE dye by FACS upon *in vitro* stimulation. In the contact hypersensitivity model, mice were sensitized with DNFB and ear-challenged on day 5. Ear swelling was evaluated as difference between challenged and unchallenged ear after 36 h.
Results: In CD4-Nrp1 transgenic mice we detected a significant increase in $CD4^+$ $Nrp1^+$ T cells, in particular in $CD4^+$ $CD25^-Nrp1^+$ T cells while the distribution of $CD4^+$ and $CD8^+$ T cells and $CD4^+$ $FoxP3^+$ Tregs in lymphoid tissues did not alter from wild type mice. $CD4^+$ $CD25^-$ T cells from CD4-Nrp1 transgenic mice exhibited lower proliferative capacity, expressed decreased levels of T cell activation markers and produced less proinflammatory cytokines than wild type cells upon stimulation *in vitro*. Microarray analyses of stimulated $CD4^+$ $CD25^-$ T cells from transgenic and wild type mice revealed differences in the gene expression profile particularly of molecules involved in T cell activation. *In vivo* studies using different models showed that Nrp1 expression on $CD4^+$ T cells also interferes with immune responses in this more complex situation.
Conclusions: Consequently, we hypothesize that Neuropilin-1 plays a role in the regulation of $CD4^+$ T cell responses.

Neuroregulator RET is critical to haematopoietic stem cell survival and function

D. Fonseca-Pereira,* S. Arroz-Madeira,* M. Campos,* I. Barbosa,* R. Dominges,* A. R. M. Almeida,* H. Ribeiro,* A. Potocnik† & H. Veiga-Fernandes*

**Immunobiology Unit, Instituto de Medicina Molecular, Lisbon, Portugal, †Division of Molecular Immunology, MRC National Institute for Medical Research, London, UK*

Purpose/Objective: Haematopoiesis is a developmental cascade that generates all blood cell lineages in physiological and transplantation conditions.This process relies on Haematopoietic Stem Cells (HSCs) capable to differentiate and to self renew.HSCs localise in microenvironmental niches that are thought to regulate their proliferation, survival and differentiation.However, the molecular mechanisms regulating HSC fate and homeostasis remain largely unknown.Here we show that the neurotrophic factor receptor RET is critical to HSC survival and function.
Materials and methods: This hypothesis was adressed taking advantage of cellular, molecular and genetic approaches both *in vitro* and *in vivo*, mainly multiparametric flow cytometer analysis and serial transplantation assays.
Results: We found that RET signalling molecules are expressed by HSCs and *Ret* ablation leads to reduced HSC numbers. Despite normal differentiation potential, RET null HSCs exhibit loss of *in vivo* stress response and reconstitution potential, being rapidly exhausted.RET deficient HSCs were unfit due to reduced *Bcl2* and *Bcl2l1*, downstream of impaired p38/MAP kinase and CREB activation.Accordingly, enforced expression of RET down-stream targets, *Bcl2 or Bcl2l1,* was sufficient to restore the *in vivo* activity of *Ret* null progenitors.Finally, activation of RET results in improved HSC survival and *in vivo* transplantation efficiency.
Conclusions: Thus, our work shows that RET is an essential cell-autonomous regulator of HSCs function, revealing neurotrophic factors as critical components of the HSC microenvironment.

P0209

New insights into the pro-inflammatory activities of Ang1 on neutrophils; induction of MIP-1ß synthesis and release

M. Sirois, E. Dumas, K. Martel & P. E. Neagoe

Research Centre, Montreal Heart Institute, Montreal, QC, Canada

Purpose/Objective: We reported the expression of angiopoietin receptor Tie2 on human neutrophils and the capacity of both angiopoietins (Ang1 and Ang2) to induce CD11b/CD18 activation and neutrophil migration. We also observed differential effects between Ang1 and Ang2 on neutrophils. Namely, Ang1, but not Ang2, does induce interleukin-8 (IL-8) synthesis and release, which prolongs neutrophil viability. Herein, we addressed whether Ang1 and/or Ang2 could modulate the synthesis and release of other inflammatory cytokines.
Materials and methods: Human neutrophils were isolated from venous blood of healthy volunteers.
Results: We observed by ELISA that Ang1, but not Ang2, mediates macrophage inflammatory protein-1 beta (MIP-1β; CCL4) synthesis and release by the neutrophils. Basal synthesis and release of MIP-1β was undetectable from 0 to 6 h post-isolation, whereas at 24-h, the basal synthesis and release was approximately 95 and 35 pg/million neutrophils, respectively. Treatment with Ang1 (up to 10 nM) and IL-8 (positive control; 25 nM) increased neutrophil MIP-1β synthesis by 310 and 307% and its release by 388 and 413% respectively. Neutrophils pretreatment with blocking anti-Tie2 antibodies did not inhibit the capacity of Ang1 to induce MIP-1β synthesis and release, suggesting that this effect of Ang1 is Tie2-independent and could rather be mediated upon integrins interactions. Pretreatment with p38 or p42/44MAPK inhibitors (SB203580 and U0126, respectively) abrogated Ang1 effects on MIP-1β synthesis and release. In addition, pretreatment with NF-κB inhibitors (Bay7085, Bay7082 and IKK inhibitor VII) also abrogated the capacity of Ang1 to induce MIP-1β synthesis and release. To assess the capacity of Ang1 to promote MIP-1β DNA to mRNA transcription and protein synthesis, neutrophils were pretreated with a transcription inhibitor (actinomycin D), and a protein synthesis inhibitor (cycloheximide). We observed that Ang1-induced MIP-1β synthesis and release was completely blocked by both inhibitors, suggesting that Ang1-induced MIP-1β synthesis and release is dependent on its DNA transcription and mRNA translation.
Conclusions: Our study is the first one to report Ang1 capacity to induce MIP-1β synthesis and release from the neutrophils, and that these effects are mediated through the activation of p38MAPK, p42/44MAPK and NF-κB signaling pathways.

Normal dendritic cell mobilization to lymph nodes under conditions of severe lymphatic hypoplasia

A. M. Platt,* C. Martel,† J. M. Rutkowski,‡ E. L. Kuan,§ M. A. Swartz‡ & G. J. Randolph†

**University of Glasgow, Infection Immunity and Inflammation, Glasgow, UK, †Department of Pathology & Immunology, Washington University in St. Louis, St. Louis, MO, USA, ‡EPFL, Bioengineering, Lausanne, Switzerland, §Mount Sinai School of Medicine, Immunology, New York, NY, USA*

Purpose/Objective: To address the requirement for lymphatic capillaries in the mobilization of dendritic cells (DCs) from skin to lymph nodes.
Materials and methods: We utilized mice bearing one allele of a functionally inactivated VEGFR3 where skin lymphatic capillaries are reported absent.
Results: Unexpectedly, DC mobilization from the back skin to draining lymph nodes was similar in magnitude and kinetics to control mice. By contrast, DC migration from body extremities, such as the ear and forepaws, was ablated. An evaluation in different regions of skin revealed rare patches of lymphatic capillaries only in body trunk areas where migration was intact. These regions had a local density of ~40% of control animals but were separated by vast regions of skin lacking lymphatic capillaries, such that there was a ~90% reduction in overall lymphatic density. Residual lymphatic capillaries expressed higher levels of CCL21 and collecting vessels of *Chy* mice had higher smooth muscle coverage, changes that likely aid in compensating for scarce lymphatic capillary density.
Conclusions: These studies identify anatomic differences in the impact of a mutant copy of VEGFR3 on lymphatic patterning and reveal that with regard to the regulation of DC migration, lymphatic capillaries are able to compensate for a marked loss in density to maintain normal mobilization of DCs from skin.

P0211

Packed red blood cells suppress myeloid dendritic cell and monocyte inflammatory responses in a whole blood model of transfusion

M. M. Dean,* L. D. Samson,* A. M. Christensen† & R. L. Flower*

**Australian Red Cross Blood Service, Research and Development, Brisbane, Qld, Australia, †Biomedical Sciences, Queensland University of Technology, Brisbane, Qld, Australia*

Purpose/Objective: The basis for poor outcomes in some patients post transfusion remains largely unknown. Despite leukodepletion, there is still evidence of immunomodulatory effects of transfusion that require further study.In addition, there is evidence that the age of

blood components transfused significantly affects patient outcomes. Myeloid dendritic cell (DC) and monocyte immune function were studied utilising an *in vitro* whole blood model of transfusion.

Materials and methods: Freshly collected ('recipient') whole blood was cultured with ABO compatible leukodepleted PRBC at 25% blood-replacement-volume (6hrs). PRBC were assayed at [Day (D) 2, 14, 28 and 42 (date-of expiry)]. In parallel, LPS or Zymosan (Zy) were added to mimic infection.Recipients were maintained for the duration of the time course (2 recipients, 4 PRBC units, $n = 8$).Recipient DC and monocyte intracellular cytokines and chemokines (IL-6, IL-10, IL-12, TNF-α, IL-1α, IL-8, IP-10, MIP-1α, MIP-1β, MCP-1) were measured using flow cytometry.Changes in immune response were calculated by comparison to a parallel no transfusion control (Wilcoxin matched pairs). Influence of storage age was calculated using ANOVA.

Results: Significant suppression of DC and monocyte inflammatory responses were evident.DC and monocyte production of IL-1α was reduced following exposure to PRBC regardless of storage age ($P < 0.05$ at all time points). Storage independent PRBC mediated suppression of DC and monocyte IL-1α was also evident in cultures co-stimulated with Zy. In cultures co-stimulated with either LPS or Zy, significant suppression of DC and monocyte TNF-α and IL-6 was also evident. PRBC storage attenuated monocyte TNF-α production when co-cultured with LPS ($P < 0.01$ ANOVA). DC and monocyte production of MIP-1α was significantly reduced following exposure to PRBC (DC: $P < 0.05$ at D2, 28, 42; Monocyte $P < 0.05$ all time points). In cultures co-stimulated with LPS and zymosan, a similar suppression of MIP-1α production was also evident, and production of both DC and monocyte MIP-1β and IP-10 were also significantly reduced.

Conclusions: The complexity of the transfusion context was reflected in the whole blood approach utilised. Significant suppression of these key DC and monocyte immune responses may contribute to patient outcomes, such as increased risk of infection and longer hospital stay, following blood transfusion.

P0212
Production modi of IL-22

K. Wolk,* K. Warszawska,† K. Witte,† K. Brett,† E. Witte,† G. Alber,‡ W. Sterry,§ H. D. Volk¶ & R. Sabat*

**Interdisciplinary Group of Molecular Immunopathology – Dermatology/Medical Immunology Psoriasis Research and Treatment Center – Department of Dermatology and Allergy, University Hospital Charité, Berlin, Germany, †Interdisciplinary Group of Molecular Immunopathology – Dermatology/Medical Immunology, University Hospital Charité, Berlin, Germany, ‡College of Veterinary Medicine, Institute of Immunology, University of Leipzig, Leipzig, Germany, §Department of Dermatology and Allergy, University Hospital Charité, Berlin, Germany, ¶Institute of Medical Immunology, University Hospital Charité, Berlin, Germany*

Purpose/Objective: Psoriasis is a common disease and is generally regarded as a model disease for other chronic immune-mediated disorders like rheumatoid arthritis and Crohn's disease. The latest results from other and our lab strongly suggest that IL-22 plays a crucial role in the induction of the epidermal alterations in diseased skin of psoriasis patients. Currently, it is assumed that Th17-cells are the main producers of this cytokine in humans. By this study, we aimed to further investigate the production modes of IL-22.

Materials and methods: IL-22 production wasinvestigated in different human Th-subsets. Furthermore, we used SCID/beige, Rag1-, IL-2Rgamma-, CD1d-, IL-12p35-, and IL-23p19-deficient mice and psoriasis patient samples to confirm the *in vitro* results.

Results: First, we demonstrated that IL-22 can be produced both by T-cells following T-cell receptor (TCR) stimulation and by NKT-cells after activation with inflammatory cytokines with comparable levels. Interestingly, type-I interferons were able to potently inhibit these productions. Among different human Th-cell subsets, Th22- and Th1-cells produced high amounts of IL-22, whereas the secretion by Th17-cells was very low. The relevance of Th1-cells as an important source of IL-22 in psoriasis lesions was substantiated by significant positive correlation between levels of IL-22 and IFN-gamma, but not of IL-22 and IL-17A in samples of diseased skin from psoriasis patients. The presence of TNF-alpha, but not IL-6, was most critical for the generation of IL-22-producing Th22-cells. For IL-22 production after inflammatory cytokine stimulation IL-23, but not IL-12 played an important role. In line with this observation we found strong significant positive correlation between IL-22 and IL-23p19 levels in samples of diseased skin from psoriasis patients.

Conclusions: Taken together, our study suggests that in the psoriatic lesions both an antigen-specific activation via TCR and stimulation with inflammatory cytokines induced high IL-22 production and can explain the efficacy of anti-TNF-alpha- and anti-p40-therapy in psoriasis.

P0213
Reduced frequency of regulatory T cells in competitive athletes

T. Rogosch,* S. Kerzel,* S. Markert,* R. F. Maier,* A. Hattesohl,† R. Koczulla† & M. Zemlin*

**Department of Pediatrics, Philipps-University, Marburg, Germany, †Department of Internal Medicine Division for Pulmonary Diseases, Philipps-University, Marburg, Germany*

Purpose/Objective: The objective of our study was to evaluate whether the frequency of B and T lymphocytes and of natural killer cells in peripheral blood is influenced by moderate exercise in competitive athletes and in non-athletes, respectively.

Materials and methods: Blood samples from 11 competitive athletes and six non-athletes were obtained before, directly after, and 1 h after moderate exercise. Peripheral blood mononuclear cells (PBMCs) were isolated by density centrifugation and analysed by four-colour flow cytometry.

Results: Whereas the frequency distribution of B lymphocyte subpopulations ($CD19^+$ cells, class-switched/non class-switched memory cells, plasmablasts) was maintained in both groups, we found considerable differences in the T cell subpopulations:

While T cell subpopulations in the athletes group did not change compared to pre-exercise baseline, we found a significant induction of cytotoxic T cells (Tc; $CD3^+$ $CD8^+$; $P < 0.05$, compared to pre-exercise baseline), activated Tc ($CD3^+$ $CD8^+$ $CD69^+$; $P < 0.05$), and natural killer T cells (NKT; $CD3^+$ $CD56^+$; $P < 0.05$) in the non-athletes group directly after exercise, which returned to baseline within 1 h. In contrast, numbers of T helper cells (Th; $CD3^+$ $CD4^+$; $P < 0.01$) and regulatory T cells (Treg; $CD3^+$ $CD4^+$ $CD25^+$ CD127-; $P < 0.05$) were reduced 1 h after exercise in non-athletes.

Interestingly, even at baseline level Treg numbers in athletes were significantly reduced compared to non-athletes ($P < 0.001$).

The frequency of natural killer cells (NK; CD3-$CD16^+$ $CD56^+$ $Nkp46^+$; $P < 0.01$) increased in athletes and non-athletes after exercise. However, the increase in NK numbers was significantly alleviated in athletes compared to non-athletes ($P < 0.01$).

Conclusions: We found significant temporary changes in the frequency of Tc, Th, Treg, NKT, and NK cells in PBMCs from non-athletes, whereas cell frequencies in athletes, except for NK cells, did not change. Reduced Treg numbers in athletes imply a putative role of Treg cells in the immune regulation during chronic exercise and might contribute to the increased susceptibility to infections in competitive athletes.

P0215

Stimulation of dopamine receptor D3 expressed on $CD4^+$ T-cells favours Th1 immunity

R. Pacheco, F. Contreras, C. Prado, H. González, D. Elgueta & D. Franz
Biomedicine, Fundación Ciencia para la Vida, Santiago, Chile

Purpose/Objective: Since inappropriate $CD4^+$ T-cell differentiation may lead to infection susceptibility, tumor progression or autoimmunity, this process must be tightly regulated. Lately, neurotransmitters have emerged as immune modulators as they may influence the function of immune system cells. Dopamine (DA) is a neurotransmitter that may trigger signals through five DA receptors (DARs) which often are coupled to modulation of adenylate cyclase activity. Considering that DAR D3 (D3R) is the highest affinity DAR and that selective D3R agonists favour secretion of IFN-γ by human T-cells *in vitro*, we aimed to determine the relevance of D3R expressed on $CD4^+$ T-cells as a modulator of adaptive immunity.
Materials and methods: We used a model of autoimmune colitis in which $CD45RB^{HIGH}$ $CD4^+$ T-cells from wild type (WT) or D3R knockout (D3RKO) mice were transferred into RAG1 knockout recipient mice. Disease severity was evaluated as weight loss. Th1, Th17 and Tregs cells infiltrated into lamina propia were analyzed by flow cytometry. Expression of D3R, IFN-γ and T-bet transcripts were analyzed by qPCR. *In vitro* T-cell activation was determined by IL-2 secretion and CFSE-assay. Differentiation toward Th1, Th17 and Tregs phenotypes was analyzed by intracellular staining of IFN-γ, IL-17 and Foxp3 in the $CD4^+$ or $CD4^+$ $CD25^+$ population respectively.
Results: Results show expression of D3R on both naïve and activated $CD4^+$ T-cells. Expression data was supported by signaling assays, as treatment with a selective D3R agonist reduced cAMP levels and ERK1/2 phosphorylation in WT but not in D3RKO $CD4^+$ T-cells. *In vitro* experiments show that polyclonally-stimulated T-cell activation was significantly impaired when $CD4^+$ T-cells lack D3R. In addition, *in vitro* polarization assays showed that the frequency of Th1, but not of Th17 cells, was notably reduced in absence of D3R. *In vivo* experiments show that D3RKO $CD4^+$ T-cells were unable to induce weight loss in recipient mice. In line with these results, a reduced proportion of Th1 cells was found in the colons of mice when D3RKO $CD4^+$ T-cells were transferred.
Conclusions: These findings reveal a novel modulatory mechanism of $CD4^+$ T-cell function, in which D3R-mediated signaling contributes significantly to efficient T-cell activation, to Th1 differentiation and to the progression of a $CD4^+$ T-cell-mediated autoimmune response *in vivo*.

P0216

Stimulation of Juvenile systemic lupus erythematosus blood cells induces IL-17 production

L. Ballantine, J. Ong, A. Midgley, L. Watson & M. W. Beresford
Institute of Translational Medicine, University of Liverpool, Liverpool, UK

Purpose/Objective: Th17 cells are a subset of $CD4^+$ cells known to produce the cytokine IL-17A. Th17 cells will differentiate from naïve T cells in the presence of IL-1β, IL-23 and IL-6 under the control of the transcription factor RORC. The pathogenesis of adult-onset systemic lupus erythematosus (SLE) has been linked to Th17 cells due to increased serum IL-17A [1]. There have been few investigations into the presence and role of Th17 cells within the more severe, juvenile-onset SLE (JSLE). The objective of this study was to investigate the mRNA and protein level of IL-17A and associated protein in JSLE patients and whether stimulation of JSLE peripheral blood mononuclear cells (PBMCs) induces IL-17 protein production.
Materials and methods: JSLE ($n = 5$) and control ($n = 5$) PBMCs were stimulated with CD3/CD28 activation beads at a 2:1 ratio for 2 days then cell-free supernatantsanalysed by IL-17 ELISA. Unstimulated PBMC RNA was extracted from JSLE ($n = 12$) and control ($n = 12$) patients. RT-PCR quantified levels of IL-17A, IL-23, IL-23R and RORC mRNA relative to RPL13A housekeeping gene. $CD4^+$ T cells were isolated from JSLE ($n = 16$) and control ($n = 10$) patients for IL-17A mRNA measurement. Plasma from JSLE ($n = 19$) and control ($n = 18$) were analysed for IL-17A levels by ELISA. The level of IL-17A in $CD4^+$ cells from JSLE ($n = 4$) and control ($n = 4$) was determined by Western blot.
Results: JSLE CD3/CD28 activated PBMCs produced higher levels of IL-17A protein compared to control PBMCs (383.9 pg/ml ±147.9 versus 55.2 pg/ml ±27.5). IL-17A and IL-23 mRNA expression was significantly higher in JSLE PBMCs compared to controls [IL-17A: 0.30 (±0.08) versus 0.07 (±0.02) $P = 0.02$; IL-23: 0.41 (±0.11) versus 0.34 (±0.25), $P = 0.04$]. RORC and IL-23R mRNA expression was also raised in JSLE compared to controls, although not statistically [IL-23R: 0.43 (±0.16) versus 0.16 (±0.07), $P = 0.19$; RORC: 0.52(±0.16) versus 0.3(±0.13), $P = 0.22$]. JSLE $CD4^+$ cellsexpressed higher levels of IL-17A mRNA compared to control $CD4^+$ cells (0.85 ± 0.14 versus 0.5 ± 0.13, $P = 0.06$). IL-17A was significantly higher in JSLE plasma compared to control (21.5 ± 5.2 pg/ml versus 7.2 ± 2.5 $P = 0.02$). An IL-17A band was detected in JSLE CD4 by western blot.
Conclusions: Th17 cells may be playing a pathogenic role in JSLE as JSLE PBMCs are able to secrete IL-17A upon stimulation and IL-17A is detected at significantly higher levels in JSLE plasma. The higher level of IL-17A associated proteins and transcription factor mRNA and IL-17A protein in JSLE patients indicates the presence of the pro-inflammatory environment required for Th17 differentiation.

P0217

The role of CCR7 in cross-priming

E. Mettke, V. Semmling & C. Kurts
Institutes of molecular Medicine and experimental Immunology, University Clinics Bonn, Bonn, Germany

Purpose/Objective: The effective priming of T cell responses after encounter with various pathogens is important for pathogen clearance and the subsequent T cell memory induction. The contact of T cells and antigen-presenting cells (APCs), which is required for effective T cell priming, is a result of highly coordinated migration processes. CCR7 and its ligands are centrally involved in mediating interactions of naïve T cells with antigen-presenting dendritic cells (DCs) within secondary lymphoid organs (SLOs) during steady-state lymphocyte recirculation. In contrast, a role for CCR4 and CCR5 has been described under inflammatory conditions when mature DCs acquire the potential to immunogenically activate $CD8^+$ T cells: if DCs are activated by $CD4^+$ T_H cells in the presence of TLR-ligands like CpG, they start producing CCR5-ligands that selectively attract CCR5-expressing $CD8^+$ T cells for cross-priming (classical DC licensing). DCs can also get activated by NKT cells if glycolipid antigens like α-galactosylceramide (aGC) are present. In this case, CCL17 is produced by DCs, attracting CCR4-expressing $CD8^+$ T cells for cross-priming (NKT cell-mediated DC licensing). Here, we investigated the role of CCR7 relative to CCR5 and CCR4 in cross-priming under inflammatory conditions.
Materials and methods: We induced classical or NKT cell-mediated cross-priming, but excluded an effect of CCR7 by using $CCR7^{-/-}$ mice in an *in vivo* cytotoxicity assay.
Results: Despite the induction of CCR4 or CCR5 ligands, CCR7 and its ligands were not dispensable, as cytotoxicity in $CCR7^{-/-}$ mice was highly diminished. To account for the disrupted microarchitecture of SLOs in $CCR7^{-/-}$ mice, we transferred $CCR7^{-/-}$ OT-I (ovalbumin (OVA)-specific T cell receptor transgenic $CD8^+$ T cells) into WT mice.

After subsequent priming of recipient mice with OVA and CpG and/or aGC, levels of cytotoxicity were highly diminished, suggesting that CCR5 or CCR4 expression on T cells cannot compensate for CCR7 expression. Current efforts are aimed at clarifying whether $CCR7^{-/-}$ OT-I T cells cannot enter the white pulp or if CCR7 is needed within the white pulp.

Conclusions: CCR7 is necessary also under inflammatory conditions *in vivo* and cannot be replaced by upregulation of other chemokine receptors.

P0218
The Role of SPHKs and SIPRs in rheumatoid arthritis

A. Elmesmari,* P. Pushparaj,† J. Reilly,* S. Kerr,* M. Kurowska-Stolarska* & I. McInnes*

**Immunology, Institute of Infection Immunity and Inflammation, Glasgow, UK, †Center of Excellence in Genomic Medicine Research, King Abdulaziz University, Jeddah, Saudi Arabia*

Purpose/Objective: Sphingosine kinase (SPHKs), SphK1 and SphK2, have been identified to phosphorylate sphingosine into sphingosine-1-phosphate (S1P). They are involved in a wide variety of cellular responses. S1P acts via S1P Receptors, $S1PR_1$, $S1PR_2$, $S1PR_3$, $S1PR_4$ and $S1PR_5$, all of which can be bound and activated specifically by S1P. A defect either in S1P signalling or S1PRs has been associated with many pathologies. Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by high levels of proinflammatory cytokine production. Elevated SPHK1, S1P, and $S1P_1$ have been reported in RA synovium. S1P signalling via $S1P_1$ promotes synoviocyte proliferation, increases COX-2 expression and prostaglandin E_2 production. This study comprehensively evaluated expression of SPHK1/2 and S1PRs in RA patients compare to healthy controls (HC) and osteoarthritis (OA) in peripheral blood (PB) and synovial tissues, respectively.

Materials and methods: mRNA and protein expression of SPHK1/2 and SIPRs were examined in neutrophils, monocytes and T lymphocytes of peripheral blood of 10 HC and RA patients, who met the diagnostic criteria of 2010 ARC / EULAR by QPCR and FACS, respectively. Competitive ELISA assessed SIP in serum of RA patients with remission and relapse and HC. We also performed SPHK 1/2 and SIPRs immunohistochemistry in synovial tissue from 4 RA/ OA patients.

Results: S1P was three times high in RA than those observed in HC, also was statistically higher in RA patient with relapse than remission. Intracellular expression of hSPHK1 in RA patients, with opposed to HC, was up regulated 1.4-folds in monocytes and T- lymphocytes with significance expression in CD4T cells. $hS1P_1$ and $hS1P_3$ exhibited a similar expression were up-regulated in neutrophils, while, $hS1P_5$ was statistical high in T cells. In contrast, $hS1P_4$ was down regulated in all sorted cells particularly in CD4T cells. As opposed to OA synovial tissue, RA synovial tissues were strongly positive for hSPHK1 and $hS1P_{1,\ 3}$ expressions. Quantitative analysis showed, SPHK1 and $hS1P_3$ are expressed in lining, sub lining and vascular endothelial layer, while $hS1P_1$ expressed mainly in lining and sub lining layers of the RA synovial tissue compared with OA.

Conclusions: These results suggest that SPHKs/S1P and its S1PRs might play a role in RA pathogenesis. The clinical significance of S1P as a biomarker for disease activity deserves further attention.

P0219
Tunneling nanotubes as a novel mechanism of intercellular communication between immune cells

C. Schiller,* J. Semmlinger,* K. N. Diakopoulos,* S. Spranger,† D. J. Schendel,† U. H. Weidle‡ & E. H. Weiss*

**Department of Biology II, Ludwig-Maximilians-Universität, Martinsried, Germany, †Institute of Molecular Immunology, Helmholtz Zentrum München, München, Germany, ‡Roche Diagnostics, Division Pharma, Penzberg, Germany*

Purpose/Objective: The efficiency of the immune response relies on carefully orchestrated intercellular communication. Recently, tunneling nanotubes (TNT) have emerged as a novel mechanism of cell-cell communication. These long membrane protrusions can establish cytoplasmic continuity between distant cells and enable the exchange of cellular components. TNT have been found to connect a wide range of immune cells like B cells, T cells, macrophages, mast cells, NK cells and dendritic cells. This has prompted the assumption that TNT mediate intercellular communication between immune cells. In the present study we have aimed to elucidate the molecular basis for TNT formation and to investigate whether TNT enable exchange of cellular components between dendritic cells (DC).

Materials and methods: TNT formation and function was studied in HeLa, HEK-293T and U-937 transfectants, immature and mature DC. TNT were visualized by confocal microscopy of live and fixed cells, TNT functionality was assessed by transfer of stained vesicles/organelles. Interacting proteins were identified by coimmunoprecipitation, mass spectrometry and western blot analysis. Plasma membrane recruitment of interacting proteins was assayed by performing either immunocytochemistry or FRAP experiments.

Results: We report that the transmembrane MHC class III protein LST1 induces the formation of TNT. LST1-induced nanotubes were functional and enabled vesicle transfer between cells. While LST1 overexpression clearly enhanced both TNT formation and nanotube length, depletion of LST1 inhibited endogenous TNT formation and significantly reduced vesicle transfer. We identified several LST1-interacting proteins, and confirmed six binding partners, which contribute to nanotube development. A systematic analysis of these interactions allows us to propose a mechanistic model for nanotube formation.

Conclusions: We propose that LST1 recruits key effector molecules of actin reorganization to the plasma membrane and promotes the assembly of the molecular machinery required for membrane protrusions. Recent insights into the regulation of TNT formation during dendritic cell maturation and nanotube-mediated protein transfer between these cells will be discussed.

P0220

Use of the human eosinophilic cell line EoL-1 to investigate the molecular mechanisms regulating cyclin-dependent kinase inhibitor drug-induced apoptosis

A. L. Alessandri,* L. Hoodless,* C. D. Lucas,* J. F. Lyons,† C. Haslett,* R. Duffin* & A. G. Rossi*

**MRC Centre for Inflammation Research, The Queen's Medical Research Institute University of Edinburgh Medical School, Edinburgh, UK, †Astex Therapeutics, Cambridge, UK*

Purpose/Objective: Eosinophils are important in host defence against parasitic infection but also contribute to the pathogenesis of allergic diseases such as asthma and allergic rhinitis. Cyclin-dependent kinase inhibitor (CDKi) drugs induce eosinophil apoptosis and promote the resolution of eosinophil-dominant inflammation (Duffin et al., FEBS Lett. 2009; 583:2540−6; Alessandri et al., PLoS One, 2011;6;e25683). However study of the molecular mechanisms regulating eosinophil function and apoptosis is often difficult partly because of their scarcity in peripheral blood of normal healthy volunteers and their relative intractability to standard molecular biological techniques. Therefore having readily available cells such as the eosinophilic leukemia cell line, EoL-1, as a human eosinophil surrogate cell is useful for the study of granulocyte function. Here we investigated the effect and mechanism of action of CDKi on EoL-1 cell apoptosis.

Materials and methods: EoL-1 cells were treated with the CDKi drugs AT7519, DRB or flavopiridol and apoptosis assessed morphologically using light microscopy and by flow-cytometric detection of annexin-V/propidium iodide staining. Furthermore, we examined the effect of the CDKi drugs on the expression of the key granulocyte survival protein Mcl-1 and the cleavage of caspase-3 using western blotting techniques.

Results: AT7519, DRB and flavopiridol induced apoptosis in EoL-1 cells in a concentration- and time-dependent manner and caused marked Mcl-l down-regulation. The CDKi drug-induced apoptosis was caspase-dependent since rapid caspase-3 cleavage was observed and apoptosis was abrogated by the pan-caspase inhibitor Q-VD-OPh.

Conclusions: CDKi drugs promote caspase-dependent EoL-1 cell apoptosis via down-regulation of Mcl-1. These findings indicate that EoL-1 cells provide a good model system to study the effects of CDKi drugs and suggest that they could be used to investigate new biologically active CDKi drugs.

12/15-lipoxygenase mediates GC-induced anti-inflammatory mechanisms in monocytes

Y. Kusche,* L. Klotz,† H. Wiendl,† J. Roth* & K. Barczyk*
**Institute of Immunology, University Hospital Muenster, Muenster, Germany, †Department of Neurology-Inflammatory Disorders of the Nervous System and Neurooncology, University Hospital Muenster, Muenster, Germany*

Purpose/Objective: Glucocorticoids (GC) are drugs of choice for the treatment of many chronic inflammatory diseases. Our previous studies have shown that GC treatment does not simply suppress monocyte functions but induces a distinct anti-inflammatory phenotype in these cells. Also the treatment of LPS-stimulated monocytes with GC leads to re-programming of the cells towards a specific population involved in resolution of inflammation. Microarray analysis has shown up-regulated expression of anti-inflammatory and pro-resolution 12/15-lipoxygenase (12/15-LOX) in GC- and LPS/GC-treated monocytes. The aim of our studies was to determine lipoxygenase-dependent effects in GC-treated monocytes.
Materials and methods: Bone marrow-derived monocytes were isolated from wild type (wt) C57BL/6 and 12/15-LOX$^{-/-}$ mice and stimulated with GC and/or LPS. Gene expression was analyzed using quantitative RT-PCR. Protein expression was examined by Western Blot, Flow Cytometry and CBA technology. Functional assays were performed to analyze monocyte migration, chemotaxis, phagocytosis, killing and oxidative burst.
Results: GC induced reduction of adhesion to the plastic surface in wt as well as 12/15-LOX$^{-/-}$ cells. However, this effect was less pronounced in cells lacking 12/15-LOX. Migration was enhanced in GC- and LPS/GC-treated monocytes isolated either from wt or 12/15-LOX$^{-/-}$ mice. In contrast GC induced resistance to apoptosis was much more pronounced in wt as in 12/15-LOX$^{-/-}$ cells. GC-treated monocytes from wt but not from 12/15-LOX$^{-/-}$ mice show reduced production of ROS. Phagocytosis of carboxylated-modified latex-beads is increased in GC-treated monocytes. However, this effect was much weaker in GC-treated monocytes isolated from 12/15-LOX$^{-/-}$ mice. In contrast, phagocytosis of latex beads mimicking foreign particles was not significantly altered in monocytes isolated from wt and 12/15-LOX$^{-/-}$ mice.
Conclusions: GC- and LPS/GC-treatment induced anti-inflammatory and pro-resolving monocytes show increased expression of 12/15-LOX. Our results indicate that inhibition of ROS production as well as apoptotic processes, migration and adhesion by GC-treated monocytes are at least partially mediated by 12/15-LOX.

Specific targeting of the 12/15-LOX pathway may be a promising strategy to block undesirable inflammation with fewer side effects.

P0222
A role for syntaxin 3 in dendritic cell secretion

L. Collins, J. DeCourcey & C. E. Loscher
Biotechology, Dublin City University, Dublin, Ireland

Purpose/Objective: Dendritic cells (DC) act as a link between innate and adaptive immunity with the ability to drive a range of T helper cell subsets. The DCs responsible for this differ primarily in the cytokines they secrete. Soluble-*N*-ethylmaleimide-sensitive-factor accessory-protein receptor (SNARE) family members are proteins that drive membrane fusion and have been shown to play a key role in cytokine release. Little is known about the specific mechanisms involved in cytokine secretion from DCs, therefore we examined the expression of these proteins in DCs.
Materials and methods: We first examined the cytokine and chemokine secretion in DCs following stimulation with a range of Toll-Like Receptor (TLR) ligands by ELISA. SNARE mRNA expression, following this stimulation with the panel, was then analysed using RT-qPCR. Subcellular location of candidate SNAREs for cytokine/chemokine secretion was also analysed using confocal microscopy.
Results: Stimulation with a panel of TLR ligands in DCs resulted in differential cytokine and chemokine secretion. We then examined the expression of SNARE proteins and demonstrated that Syntaxin 3 but not SNAP 23 or Vamp 8 was upregulated in TLR4-stimulated DCs. Expression of Syntaxin 3 mRNA was also up-regulated in TLR7-stimulated but not in TLR2-stimulated DCs. Further analysis using confocal microscopy revealed that in TLR4 and TLR7-stimulated DCs Syntaxin 3 translocated from the cytoplasmic region into the plasma membrane. This was not seen in TLR2-stimulated cells.
Conclusions: Our data shows for the first time the differential expression of SNARE proteins in DCs following activation of TLRs and suggests a role for Syntaxin 3 in secretion of immune mediators. Given the importance of cytokine secretion by DCs in the pathogenesis of inflammatory disease, SNARE proteins may represent therapeutic targets in such diseases.

P0223
Activated platelets upregulate monocyte IL-10 production *in vitro*

S. Gudbrandsdottir,* H. C. Hasselbalch,† L. de la Motte‡ & C. H. Nielsen§
**Department of InfectiousDiseases and Rheumatology, Institut for Inflammtions Research, Copenhagen Univeristy Hospital Rigshospitalet, Copenhagen, Denmark, †Department of Hematology, Copenhagen Univeristy Hospital ROSKILDE, Roskilde, Denmark, ‡Department of Vascular Surgery, Copenhagen Univeristy Hospital Rigshospitalet, Copenhagen, Denmark, §Department of InfectiousDiseases and Rheumatology, Institute for Inflammation Research, Copenhagen Univeristy Hospital Rigshospitalet, Copenhagen, Denmark*

Purpose/Objective: Platelets accumulate at sites of inflammation and modulate adaptive immune responses, e.g. CD4$^+$ T-cell proliferation, *in vitro*. Little is known about the effects of platelets on the function of innate immune cells.

We aimed to investigate the effect of activated platelets on monocyte IL-10 and TNF-α production.
Materials and methods: Mononuclear cells (MNCs) from healthy donors were stimulated with the self-antigen thyroglobulin (TG) or the foreign antigen lipopolysaccharide (LPS) and cultured in the absence or presence of activated autologous platelets. To assess the potential roles of CD40L and platelet factor 4 (PF4) in immunomodulation by platelets, neutralizing antibodies to CD40L or the PF4-receptor CXCR3 were included in some experiments. Supernatants were analysed for IL-10 and TNF-α after 18 h, and monocytes were analysed flow-cytometrically for IL-10 secretion after 18 h. Platelet/monocyte aggregates were detected as CD14/CD61-double positive events.
Results: Addition of activated platelets to MNCs stimulated with LPS or TG resulted in an increased production of IL-10 and decreased production of TNF-α. Blockade of CD40L slightly inhibited this effect ($P < 0.05$), while blockade of CXCR3 had no effect. Two subsets of monocytes secreting high and low amounts of IL-10, respectively, were observed. The presence of activated platelets increased the proportion of the high-secreting subset following stimulation with TG ($P < 0.001$), and increased the amount of IL-10 produced per cell within the low-secreting subset ($P < 0.01$). Platelet/monocyte aggregates were found irrespective of whether platelets had been added

in vitro, but their proportion was increased after addition of activated platelets to cultures stimulated with TG (3.9 versus 8.0%, $P < 0.01$). Of note, platelet-bearing monocytes showed significantly higher IL-10 secretion than monocytes without adherent plateles ($P < 0.05$).
Conclusions: The data suggest that activated platelets exert an immunoregulatory function by enhancing IL-10 production by monocytes. This effect was dependent on direct platelet-monocyte contact, slightly dependent on CD40L and independent of PF4/CXCR3 interaction.

Activating APCs for immunological tolerance

R. Spörri,* W. Kratky,* C. Reis e Sousa† & A. Oxenius*
**Institute of Microbiology, ETH Zurich, Zurich, Switzerland, †Immunobiology Laboratory, Cancer Research UK, London, UK*

Purpose/Objective: Successful priming of adaptive immune responses is crucially dependent on innate activation signals that convert resting antigen-presenting cells (APCs) into immunogenic ones. APCs expressing the relevant pattern recognition receptors can be directly activated by pathogen-associated molecular patterns (PAMPs) to become competent to prime T-cell responses. Alternatively, it has been suggested that APCs could be activated indirectly by proinflammatory mediators synthesized by PAMP-exposed cells. However, data obtained with $CD4^+$ T cells suggest that inflammatory signals often cannot substitute for direct pattern recognition in APC activation for the priming of T helper responses.
Materials and methods: To test whether the same is true for $CD8^+$ T cells, we studied cytotoxic T lymphocyte development in mixed chimeric mice where coexisting APCs can either present a model antigen or directly recognize a given PAMP, but not both. To examine T cell antigen encounter on indirectly-activated APCs in unmanipulated mice, we targeted antigen to DNGR-1/CLEC9A$^+$ (TLR7-) APCs and co-administered a TLR7 agonist.
Results: We show that indirectly-activated APCs promote antigen-specific proliferation of naïve $CD8^+$ T cells but fail to support their survival and effector differentiation. Indirectly-activated APCs exceed immature ones in silencing of T cells.
Conclusions: Thus, inflammation cannot substitute for direct pattern recognition in T-cell priming and instead may facilitate tolerance. These findings have important practical implications for vaccine design, indicating that adjuvants must be judiciously chosen to trigger the relevant pattern recognition receptors in APCs. Conversely, the findings open up new avenues for the prevention of autoimmunity by 'vaccination' in the context of non-cognate adjuvants.

Activation of the Rar-related orphan receptor a by H5N1 leads to subsequent NF-kB inhibition and suppression of inflammatory responses in monocytes

J. Friesenhagen,* D. Viemann,* Y. Boergeling,† M. Schmolke,† C. O. Spiekermann,‡ S. Kirschnek,§ S. Ludwig† & J. Roth‡
**Experimental Neonatology, Hannover Medical School, Hannover, Germany, †Institute of Molecular Virology, University of Muenster, Muenster, Germany, ‡Institute of Immunology, University of Muenster, Muenster, Germany, §Medical Microbiology, University of Freiburg, Freiburg, Germany*

Purpose/Objective: Infections of the human host by highly pathogenic avian influenza viruses (HPAIV) are characterized by development of a cytokine storm and systemic spreading of infection. We assumed monocytes as main producers of cytokines to be involved in the emergence of a cytokine burst.
Materials and methods: Human blood-derived monocytes infected with A/Thailand/1 (KAN-1)/2004 (H5N1) or low pathogenic human influenza virus A/PR8/34 (H1N1) were analyzed in a genome-wide microarray analysis. Results were confirmed by quantitative Real-time PCR experiments and Western Blot. ROR$\alpha^{sg/J}$ mice from Jackson Laboratories were bred in order to receive ROR$\alpha^{-/-}$ fetuses. Embryonic liver stem cells from ROR$\alpha^{-/-}$ fetuses and corresponding Wt fetuses were used to establish an immortalized ER-Hoxb8 monocytic cell line.
Results: Surprisingly, genome-wide microarray analysis showed a strongly reduced inflammatory response of human blood-derived monocytes infected with HPAIV H5N1 compared to monocytes infected with low pathogenic human H1N1. Transcription factor profiling revealed overexpression of the Rar-related orphan receptor alpha (RORα), a nuclear receptor known to suppress NF-κB signalling. Western Blot analysis confirmed a stronger activation and nuclear translocation of RORα in case of H5N1 infection compared to H1N1 infection in human blood-derived monocytes. In line with this, translocation of the NF-κB subunit p65 was clearly reduced during H5N1 infection. Infection of ER-Hoxb8 knockout and Wt monocytes enabled us to prove coherence between RORα activation and NF-κB inhibition. Additionally, we could show a biological relevance of RORα activation during H5N1 infection as we observed a significantly stronger inflammatory and antiviral response in RORα knockout monocytes compared to corresponding Wt cells.
Conclusions: In summary, we present a novel mechanism by which H5N1 escapes the first immune reponse. This mechanism contributes to the high pathogenicity of H5N1 by enabling the virus to spread systemically.

P0226
Agrin, key player for the erythroid development

C. Mazzon,* A. Anselmo,* C. Soldani,* J. Cibella,* G. D'amico,† C. Buracchi,* A. Biondi,† S. Burden,‡ A. Sarukhan* & A. Viola*
**Immunology and Inflammation, Istituto Clinico Humanitas, Rozzano (Milan), Italy, †Clinical Medicine and Prevention, Centro Ricerca "M. Tettamanti" Clinica Pediatrica Università degli Studi di Milano Bicocca, Monza, Italy, ‡Molecular Neurobiology Program, Skirball Institute of Biomolecular Medicine, New York, NY, USA*

Purpose/Objective: Erythroblastic islands (EI) are specialized niches in which erythroid precursors proliferate, differentiate and enucleate. They are composed of a central macrophage surrounded by erythroblasts at various stages of differentiation. Several roles have been proposed for macrophages at the erythroblastic niches, acting as a 'nurse' cell providing erythropoietin, inhibition of apoptosis, and engulfment of nuclei extruded by mature red cells.

We have previously demonstrated that agrin – a critical regulator of neuromuscular synapses-is a novel, non-redundant player at the hematopoietic stem cell niche. In addition we have recently demonstrated agrin requirement for survival and maturation of monocytic cells. On the basis of the observed defects we asked whether another well-defined hematopoietic niche – the erythroblastic island – was impaired.
Materials and methods: Agrin expression was evaluated by FACS and confocal analysis.

Murine MSCs were isolated from the bone marrow of C57Bl/6 female mice.

Clusters composed of splenic macrophages and erythroblasts were isolated as already described (Iavarone A. et al, Nature 2004).
Results: Here we show that agrin controls multiple steps of erytrocyte maturation. Agrin-deficient mice had bone marrow and splenic red pulp failure and showed decreased frequency and number of Myeloid Erythroid Progenitor (MEP) with an impairment of erythrocytes and monocytic development. This defect is partially rescued by the

addition of agrin-producing mesenchimal stem cells, thus suggesting a critical role of this proteoglycan in the cross-talk between mesenchymal and erythroblastic island cellular components.
Conclusions: Agrin-deficient mice are indeed characterized by impaired erythropoiesis, which may be due to the inability of agrin-deficient macrophages to support formation of erythroblastic islands. However, our results from reconstituted criss-cross islands supported a dual role of agrin in this cell-cell interaction. Interestingly in wild type recipient mice reconstituted with agrin-deficient bone marrow cells plus agrin-expressing MSC erythropoiesis was partially restored, even though both erythroblasts and myeloid cells lack agrin.

P0227

Analysis of differential gene expression in IFNß$^+$ versus IFNß- plasmacytoid dendritic cells *ex vivo* reveals different functional subsets

J. Bauer, R. Dress, P. Dresing & S. Scheu
Institute of Medical Microbiology and Hospital Hygiene, Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany

Purpose/Objective: Type I interferons (IFN) consist of multiple IFNαs and one single IFNβ and are crucial mediators of protective immune responses predominantly against viral infections. Initial binding of IFNβ to the type I IFN receptor (IFNAR) induces a positive auto- and paracrine feedback loop leading to the expression of IFN-stimulated genes. Our previous studies using a bicistronic IFNβ/YFP reporter-knockin mouse model (IFN$\beta^{mob/mob}$) revealed that IFNβ expression is restricted to a minor population of plasmacytoid dendritic cells (pDCs) after *in vivo* TLR9 stimulation with CpG. Here, we wanted to determine whether IFNβ-producing pDCs harbor a specialized gene expression profile.
Materials and methods: CpG1668 was injected into IFN$\beta^{mob/mob}$ or IFNAR$^{-/-}$xIFN$\beta^{mob/mob}$ mice. Microarray and qRT-PCR expression analyses on *ex vivo* isolated splenic IFNβ/YFP$^+$ versusIFNβ/YFP$^-$ pDCs were performed and accompanied by immunofluorescent microscopy.
Results: *In vivo*, pDCs are the major source of IFNβ in the spleen after TLR9 stimulation with CpG. Notably, IFNβ-producing pDCs comprised only 10% of all pDCs. These IFNβ/YFP$^+$ pDCs displayed a different localization within the spleen as compared to pDCs not producing IFNβ. A microarray based transcriptome analysis of *ex vivo* isolated IFNβ-producing versus non-producing pDCs revealed that more than 1500 genes were differentially expressed between these two populations. Selected genes were submitted to qRT-PCR analyses and found to be differentially expressed between IFNβ-producing and non-producing pDCs also in IFNAR$^{-/-}$ mice.
Conclusions: IFNβ expression defines a subpopulation of splenic pDCs, which is unique not only with regard to the expression of IFNβ and its response genes, but also differs from pDCs not producing IFNβ in the expression of other immune-relevant genes. Intriguingly, signaling via the IFNAR plays no essential role in the expression of selected genes involved in T and NK cell activation and migration. Taken together, the differential expression of genes involved in immune modulation contradicts the current hypothesis of IFNβ induction being a stochastic event and provides a molecular mechanism for e.g. the selective recruitment of IFNβ-producing pDCs into the T cell zone and the induction of inflammatory immune responses mediated by these specialized pDCs.

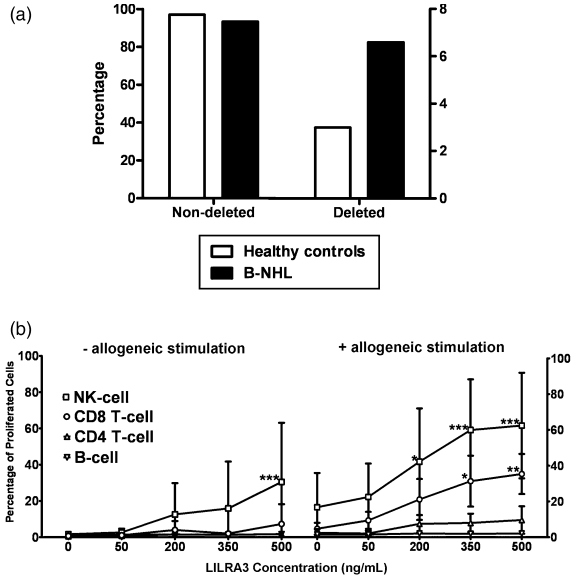
Association of the LILRA3 (ILT6) deletion with B-NHL and functional characterization as an activator of the cytotoxic immune response

H. Z. Low,* S. Reuter,† M. Topperwien,‡ N. Dankenbrink,‡ T. Matthias,§ R. E. Schmidt‡ & T. Witte‡
**Clinic for Immunology and Rheumatology, Hannover Medical School, Hannover, Germany, †AESKU. KIPP Institute, Wendelsheim, Germany, ‡Clinic for Immunology and Rheumatology, Hannover Medical School, Hannover, Germany, §AESKU Diagnostics, Wendelsheim, Germany*

Purpose/Objective: B-non Hodgkin's lymphoma (B-NHL) is a malignant disorder which is predisposed in the impairment of the immune response. LILRA3 is the only member of the leukocyte receptor complex that exists as a solely soluble form, but is not functionally characterized. Deletion of LILRA3 has been associated with multiple sclerosis and Sjögren's syndrome, thus we are interested in studying whether the deletion of LILRA3 is also a risk factor for B-NHL and what function LILRA3 has in the immune response.
Materials and methods: For LILRA3 genotyping, we performed PCR on genomic DNA from 196 B-NHL patients and 798 healthy controls. For functional studies, recombinant LILRA3 was produced in a baculovirus system and PBMCs were obtained in heparinized tubes from blood bank donors. LILRA3 was conjugated to a fluorochrome to identify it binding subsets in PBMCs by flow cytometry. Using ^{3}H-thymidine assay, we determined whether LILRA3 induces proliferation in a mixed lymphocyte reactions (MLR), and resolved the specific proliferating populations using CFSE. A transwell MLR was performed to determine whether cell contact and/or soluble factors were crucial to the LILRA3-induced proliferation. We used cytometric bead array (CBA) as well as surface staining for HLA-DR, HLA-ABC, CD80 and CD86 on monocytes and B-cells to characterize the LILRA3-induced response on a molecular level.
Results: The homozygous LILRA3 deletion genotype is significantly overrepresented among B-NHL patients compared to healthy controls (Fig. 1A) ($P = 0.0325$; OR 2.273). Among the various PBMC subpopulations, LILRA3 bound specifically to monocytes, to a lesser extent to B-cells, but not to T- or NK-cells. LILRA3 greatly enhanced proliferation in an MLR, especially in CD8$^+$ T-cells and NK-cells (Fig. 1B). CD8$^+$ T-cells required cell contact to monocytes and allogeneic feeder cells to proliferate, whereas NK-cells required soluble factors produced by monocytes. Incubation of PBMCs with LILRA3 upreg-



ulated CD80 and HLA-ABC on monocytes, CD86 and HLA-DR on B-cells, as well as IL-6, IL-8, IL-1β in the supernatant.
Conclusions: LILRA3 deletion is associated with B-NHL. It is an activator of the immune response, via the activation of antigen presenting cells, which then induce the proliferation cytotoxic responder cells. This has interesting implications for viral immunity, since B-NHL is well known to be predisposed among HIV patients.

Autocrine BMP production regulates PD-L1 and PD-L2 expression in human monocyte-derived dendritic cells

V. M. Garcia,* J. Valencia,* L. Hidalgo,* A. G. Zapata,† C. Hernández-López,* A. Vicente,* R. Sacedón* & A. Varas*
**Cell Biology, Faculty of Medicine Complutense University, Madrid, Spain, †Cell Biology, Faculty of Biology Complutense University, Madrid, Spain*

Purpose/Objective: Bone Morphogenetic Proteins (BMPs) are multifunctional secreted growth factors implicated in the regulation of differentiation, proliferation and cell death in numerous systems including the immune system. Previously, we described that the BMP signalling pathway is functional in monocyte-derived dendritic cells (MoDCs) which were found to express both the specific receptors and the Smad proteins required for the signal transduction. In the present study we investigated whether MoDCs are capable of producing BMP-4 and the role of this autocrine production during the maturation process.
Materials and methods: Immature DCs were generated from peripheral blood monocytes and maturation was induced by a proinflammatory cocktail. BMP signalling over the maturation was analysed by FACS and ELISA. The canonical signalling pathway during the maturation was inhibited by the addition of Dorsomorphin and the phenotypic and functional characteristics of the resulting mature DCs were determined by FACS, ELISA and q-PCR.
Results: We found that BMP-4 production by DCs was increased over the maturation process as well as the BMP signal transduction. When DCs were matured in the presence of Dorsomorphin the expression of the maturation markers PD-L1 and PD-L2 was especially reduced while cytokine production was not affected. As a result, these mature DCs presented an augmented ability to stimulate both T cells and NK cells. Eventually, the inhibition of BMP signalling during the maturation caused a reduced expression of IRF1, a transcription factor that positively regulates the expression of PD-L1 and PD-L2.
Conclusions: The present study demonstrates that the BMP signalling pathway regulates PD-L1 and PD-L2 expression in MoDCs during the maturation process through the IRF1 transcription factor. These findings also point out that the manipulation of BMP signalling might considerably improve the immunogenicity of MoDCs used in immunotherapy.

P0233
Cross species reactivity of Interleukin 34 (IL-34)

D. J. Gow, V. Garceau, D. Sester & D. A. Hume
Developmental Biology, The Roslin Institute & R(D) SVS, Edinburgh, UK

Purpose/Objective: A second functional ligand for the CSF-1R, interleukin 34 (IL-34), has been identified in humans and mice. Together, CSF-1 and IL-34 are regulators of differentiation, proliferation, and survival of cells of the mononuclear phagocyte lineage. As yet, no distinct biological role of IL-34 has been discovered and no viable knockout mouse line has been reported. It has previously been reported that human IL-34 is considerably less active than the mouse protein in stimulating CSF-1R mediated mouse macrophage proliferation, a finding we have confirmed. We investigated the cross species reactivity of human and mouse IL-34 on the porcine CSF-1R by generation of a stable Ba/F3 cell line expressing full length functional porcine CSF-1R (pCSF-1R).
Materials and methods: An MTT bioassay using the Ba/F3 cells expressing pCSF-1R was optimised and performed with either rhIL-34 or rmIL-34.2 $\times$ 10^4 cells/well of a 96 well plate were plated and rmIL-34 or rhIL-34 was added. Cells were incubated for 48 h at 37°C. MTT solution (0.5 mg/ml) was added directly to each well and incubated at 37°C for 3 h prior to solubilisation overnight. Plates were read at 570 nm with reference wavelength of 405 nm.
Results: Both recombinant IL-34 proteins were almost equally active on the pCSF-1R expressing cells.We also compared the efficacy of human CSF-1 and IL-34 on the porcine CSF-1R, demonstrating similar activity. For both mouse and human IL-34 to be biologically active on the porcine CSF-1R, but no cross species reactivity, there must be a significant difference between mouse and human IL-34. Non-conserved contact amino acids between human and mouse IL-34 that may explain this, most notably, Asn187 (Lys mouse), which together with Leu186, Trp188 and Gln 189 makes up the α4 region required for biological activity. The change to Lys alters the charge from neutral to positive, and may produce a steric effect that influences the binding of IL-34 to CSF-1R, possibly by hindrance or repulsion.
Conclusions: This finding suggests that the pig could be an intermediate species in which to test therapeutic applications of recombinant IL-34 and combined with the successful expression of the porcine CSF-1R provides the tools for evaluation of IL-34 in pig and rodent preclinical models.

Dendritic cell trafficking is altered during hypertrophy-induced cardiac remodeling

C. Weisheit,* A. Faron,* O. Koepke,* S. Schulz,* S. Muenster,* A. Tittel† & C. Kurts†
**Department for Anesthesiology and Operative Intensive Care, Anesthesiology, Bonn, Germany, †Institutes of Molecular Medicine and Experimental Immunology, Immunology, Bonn, Germany*

Purpose/Objective: Heart failure continues to present a substantial healthcare burden, despite recent treatment advances. The key pathophysiological process that ultimately leads to chronic heart failure is cardiac remodeling in response to chronic myocardial injury as for example arterial hypertension. Cells of the innate immune system could already be identified as important players in the induction of inflammation and tissue remodeling. Here, we investigated the role of dendritic cells (DC) on cardiac remodeling in a murine model of left ventricular hypertrophy.
Materials and methods: To induce cardiac remodeling, 12–14 week old female C57Bl6/N mice were subjected to transverse aortic constriction (TAC) and the relationship between DC subsets and left ventricular hypertrophy was studied. Innate immune cells were characterized and quantified by FACS analysis in the cardiac tissue of the left ventricle, the draining lymph nodes and the spleen to follow cellular migration and trafficking processes. DC migration was examined 3, 6 and 21 days after TAC intervention.
Results: At all three time points we observed a significant increase in the heart-weight/body-weight index in the mice after TAC compared to control animals. The percentage of $CD45^+$ cells in the tissue of the left ventricle increased from 8 to 14% at day 21 after TAC. The percentage of DCs in the myocardial tissue was significantly elevated at day 6 after surgical intervention. DC activation, as measured by CD86 expression, rose significantly at day 21. At the same time the percentage of DCs in the spleen was increased compared to days 3 and 6 after TAC and control mice.
Conclusion: Our current findings show an increased number of activated DCs in the myocardial tissue during cardiac remodelling

process. The altered number of DCs is caused by altered cell trafficking after myocardial injury. The functional relevance of DCs in the heart, as well as their migration, proliferation and cytokine pattern is currently under observation.

Detection of cytokines in human cell lines stimulated with metal ions

Z. Venclikova,* J. Bartova* & J. Belacek†
**Institute of Clinical and Experimental Dental Medicine GUH and 1st Faculty of Medicine, Charles University, Prague, Czech Republic, †Institute of Biophysics and Informatics GUH and 1st Faculty of Medicine, Charles University, Prague, Czech Republic*

Purpose/Objective: Human mucosal surface represents a vast area in which the external and internal environments come into contact. An important role in this contact is played by epithelial cells and the chemicals they produce. We therefore concentrated on studying the production of cytokines in cells stimulated with metal ions that are parts of dental alloys and whose corrosion products affect not only the oral cavity mucosa but, after ingestion, also the mucosal epithelium of the gastrointestinal tract.
Materials and methods: The study was performed on the macrophage cell line THP1 and two lines of human intestinal epithelial cells cultivated with Hg and Ni salts and also with other allergens such as Ti, Pd, Co and Cr. The cytokines were determined by the Ray Bio® Human Inflammation Antibody Array III, which permits the determination of 40 cytokines.
Results: The intestinal epithelial cell lines DLD 1 and HT 29 were found to respond differently to stimulation with metal ions. Cultivation with ions affected epithelial lines to various degrees of production of pro- as well as anti-inflammatory factors, growth factors and chemokines. Cultivation of the THP1 macrophage cell line with metal ions brought about a higher production of cytokines than that found with the epithelial cell lines; e. g. stimulation with chromium ions caused a significantly higher production of the pro-inflammatory factor Rantes. Nickel ions significantly increased the production of pro-inflammatory cytokine IL-6, chromium enhanced the production of IL-8. Cobalt activated the pro-inflammatory TNF beta.
Conclusions: The findings in the macrophage cell line THP1 were in keeping with the clinical experience implying the observation of high proliferative activity of mononuclear cells in patients diagnosed for undesirable response to dental alloys.

This project was supported by IGA of MH CR No. NT/12206-4.

Effects of interleukin-33 on phagocytosis and nitric oxide synthesis in macrophages

H. Aksoy, E. U. Bagriacik & V. Bulut
Immunology, Gazi University, Ankara, Turkey

Purpose/Objective: This study is aimed to enlighten effects of IL-33 on NO synthesis and the phagocytosis in macrophage 774.1 cell line.
Materials and methods: J774.1 cell line macrophages were used in this study. Cells were divided into several groups. In order to induce cells, low dose LPS (10 ng/ml), high dose LPS (1 μg/ml), IFN-γ (40 U/ml)$^+$ LPS (10 ng/ml), IL-33 in a variety of concentrations were applied.

In our study, NO production was measured by Griess reaction. Phagocytosis tests were done by using fluorometry. Kruskall-Wallis and Student's t statistical tests were applied by using SPSS.15.0 v. software.
Results: IL-33 was added into J774.1 cell cultures stimulated by IFN-γ plus LPS or high dose LPS alone and unstimulated. Then, nitrite levels were measured by Griess reaction. We observed that IL-33 in a variety of concentrations did not lead to NO production in J774.1 cell line. IL-33 also did not alter NO levels inJ774.1 cells stimulated by IFN-γ plus low dose LPS or high dose LPS alone in a dose dependent manner and in time-point experiments.

When added IL-33 into cultures, it caused to increasement in phagocytosis response of macrophages compared to negative controls ($P < 0.01$). Phagocytosis responses were found to be865% and 792% in response to IL-33 (20 ng/ml, 100 ng/ml, respectively). In cells stimulated by IFN-γ plus LPS, phagocytosis response was found to be 489%.
Conclusions: Macrophages are critical effectors and regulators of inflammation and the innate immune response. Although IL-33 did not lead to elevation in NO levels in macrophages, J774.1 cell line, it caused to a remarkable eightfold increase in phagocytosis response. In comparison with cells stimulated by IFN-γ and LPS, this phagocytosis response was twofold higher in cells induced by IL-33. It is a paradigm of macrophages that IFN-γ plus LPS induction leads to fully activation of macrophages. However, in our study we show that IL-33 is more potent effector for phagocytosis. Further experiments have been going on in order to elicit mechanisms for the effect of IL-33.

P0239

Efferocytosis by alveolar macrophages inhibit phagocytosis of *Streptococcus pneumoniae* by PG2/cAMP

T. Picolo-Souza, A. C. G. Salina, T. R. Toledo & A. I. Medeiros
Universidade Estadual Paulista 'Júlio de Mesquita Filho' – UNESP, Biological Science, Araraquara/São Paulo, Brazil

Purpose/Objective: Alveolar macrophages (AMs) are the first line of defense against microbial pathogens in the lung. The uptake of ACs by macrophages suppresses immune responses by releasing anti-inflammatory mediators such as TGF-β and PGE_2. The Scavenger receptor AI/II (SR-AI/II) and macrophage receptor with collagenous structure (MARCO) are the major receptors involved in the *Streptococcus pneumoniae* phagocytosis. However, the role of PGE_2 produced in response to efferocytosis in the phagocytosis of *Streptococcus pneumoniae* by alveolar macrophages is unclear.
Materials and methods: To induce early apoptosis, Jurkat cell were treated for 5 h with 8 μg/ml camptothecin (CPT). AMs were pre-incubated for 30 min pharmacological inhibitor and then incubated with AC (3:1) for 1 h, followed by FITC-labeled S. pneumoniae.
Results: We found that the pre-incubation for 1 h with AC (3:1) inhibited the ingestion of different *S. pneumoniae*-to-cell ratios by rat AMs (AMs:Sp 1:100 = ~ 43%, $^*P < 0.05$ versus AM^+Sp). The inhibition of *S. pneumoniae* phagocytosis by efferocytosis was partially reverted when endogenous PGE_2 production was inhibited with COX inhibitor indomethacin (AMs:Sp – 1:100 = ~ 25%, #, $P < 0.05$ versus AM^+Sp) and by adenylate cyclase inhibitor (AMs:Sp – 1:100 = ~ 17%, versus AM^+Sp). The suppressor effect of efferocytosis by AMs on *S. pneumoniae* phagocytosis was compared with exogenous PGE2 and Forskolin (1:100 = 41%, #, $P < 0.05$ versus AM^+Sp). Moreover, we investigated whether efferocytosis by AMs are able to inhibit the S. pneumoniae phagocytosis by scavenger receptor AI/II (SR-AI/II) and/or macrophage receptor with collagenous structure (MARCO). The inhibition of *S. pneumoniae* phagocytosis by efferocytosis was more pronounced when SR-AI/II were blocked CASR antagonist, fucoidan.
Conclusions: Conclusion: In the present study, we demonstrated that efferocytosis by AMs through of PGE2/adenylate cyclase/cAMP pathway inhibit S. pneumoniae phagocytosis and MARCO is the most important scavenger receptor involved in this suppressive effects mediated by efferocytosis.

Efferocytosis-induced macrophage regulatory phenotype is dependent on PAFR and CD36, lipid raft integrity and COX2-dependent IL-10 production

M. Ferracini, F. J. O. Rios & S. Jancar
Immunology, Institute of Biomedical Sciences, University of Sao Paulo, São Paulo, Brazil

Purpose/Objective: We have previously shown that PAFR interacts with scavenger receptors and that phagocytosis of apoptotic cells requires both receptors. Here, we investigated whether interaction of PAFR with scavenger receptor CD36 affects macrophage phenotype.
Materials and methods: Bone marrow-derived macrophages (BMDM) from C57BL/6 mice were treated with WEB2086 (50 μM), CD36 blocking antibody (1 μg/ml), piceatannol (50 μM), β-cyclodextrin (1 mM), nimesulide (30 μM), GW9662 (20 μM) or cytochalasin D, (5 μM), 30 min before incubation with apoptotic thymocytes (annexin V^+ after 5 Gy irradiation). After 18 h, BMDM were stimulated or not with LPS (10 ng/ml) for 24 h.
Results: BMDM that ingested apoptotic cells expressed PAFR, mannose receptor, arginase-1 and IL-12 and IL-10. The PAFR antagonist WEB2086 reduced both cytokines but preferentially IL-10 (55%). Inhibition of COX-2 by nimesulide had similar effect on IL-10 production (56% of inhibition). In LPS-stimulated BMDM, although the levels of IL-10 and IL-12 were increased, WEB2086 and nimesulide reduced only IL-10 production. Furthermore, IL-10 levels were also reduced by blocking CD36, by disrupting lipid rafts with β-cyclodextrin and by inhibiting phagocytosis with cytochalasin D. Inhibitors of Syk (piceatannol) and PPARγ (GW9662) also reduced IL-10.
Conclusions: These results suggest that, for apoptotic cells to induce a regulatory phenotype ($IL\text{-}10^{high}$ and $IL\text{-}12^{low}$), it requires ingestion, engagement of PAFR and CD36 and lipid rafts integrity. The IL-10 is dependent on COX-2, Syk and PPARγ activation.
Financial support: FAPESP and CNPq.

Escherichia coli heat-labile enterotoxin affects stability of mouse embryo by inducing Th1 cytokine production and activating inflammasome

F. Zhong,* D. M. Han,* X. Y. Li,* X. J. Li,† C. A. Neng,† H. H. Chen‡ & W. Y. Li‡
Veterinary Medicine, Agricultural University of Hebei, Baoding, China, †Environmental and Chemical Engineering, Yanshan University, Qinhuangdao, China, ‡Veterinary Medicine, Agricultural University of Hebei, Baoding, China

Purpose/Objective: To analyze the effects of recombinant *Escherichia coli (E. coli)* heat-labile enterotoxin (LT) on mouse embryo stability, cytokine production and inflammasome activation.
Materials and methods: The recombinant LT was prepared with *E. coli* expression system. The pregnant mice was treated *in vivo*with LT to investigate the effects of LT on embryo stability and cytokine production. The macrophages were treated*in vitro* with LT to investigate the effects of LT on inflammasome activation.
Results: The results showed LT could significantly decreased mouse embryo survival rate. The Th1 cytokine (IFN-γ, IL-2) levels in the mouse uterus were significantly increased, the Th2 cytokines (IL-4, IL-10) were not significantly changed, which indicate that LT can shift Th1/Th2 immune balance to Th1 immune response, which is considered as a contributor to embryo instability. The results also showed that LT could enhance IL-1β production in the mouse uterus, which suggests that LT can activate inflammasome which promotes pro-IL-1β maturation and secretion from monocyte/macrophage, resulting in inflammatory reaction in the uterine tissue. To verify LT activity for inflammasome activation, we stimulated LPS-primed mouse macrophage (B6 cells) *in vitro* with LT and its different subunits (LT-A and LT-B), respectively. The results showed that both LT and LT-A subunit could enhance IL-1β secretion, and LT showed more powerful enhancement than that of LT-A subunit in IL-1β secretion, however, LT-B subunit did not enhance IL-1β secretion. These results demonstrated that LT-A subunit plays a critical role in activating inflammasome.
Conclusions: These results indicate that LT affects embryo stability is mainly related to its dysregulation on immune response of pregnant mice.

P0242

Evaluation of the potency of CD137-activated macrophages in inhibiting tumor cell growth

W. L. Pang & H. Schwarz
Department of Physiology and Immunology Programme, National University of Singapore, Singapore, Singapore

Purpose/Objective: Macrophages are hematopoietic cells which play a pivotal role in immune defense. Macrophages can phagocytose pathogens and even entire cells. Also, by releasing toxic compounds including reactive oxygen intermediates or by expressing apoptosis-inducing cytokines such as tumor necrosis factor (TNF) or TRAIL, macrophages can kill bacteria and tumor cells.

Macrophages express the ligand for CD137 on their cell surface which induces their activation, via reverse signaling. In this study, we aim to investigate whether CD137 ligand signaling can enhance the ability of macrophages to interfere with the growth and /or viability of cancer cells.
Materials and methods:

1. Peripheral human monocytes were cultured for up to 10 days. Macrophage colony-stimulating factor (M-CSF) was added to differentiate the monocytes into macrophages.
2. The macrophages were treated with recombinant immobilized CD137-Fc protein overnight before being co-cultured with MCF-7, a human breast cancer cell line, or with HeLa, a human cervical cancer cell line.
3. Proliferation of cancer cells was quantified by ^{3}H-thymidine incorporation and CFSE dilution.
4. The cell cycle of the cancer cells was analysed by flow cytometry after 7-AAD staining.
5. Levels of TNF, M-CSF and interleukin-6 (IL-6) were measured by ELISA.

Results: Macrophages that had been pre-treated with immobilized CD137-Fc protein significantly reduced the proliferation of MCF-7 and HeLa cells, and caused a higher percentage of MCF-7 and HeLa cells with a reduced DNA content, which would be consistent with an increased incidence of apoptosis. Also, higher levels of TNF, M-CSF and IL-6 were present in the supernatants of these macrophage tumor cell co-cultures.
Conclusions: Our study shows that activation of macrophages by recombinant CD137 protein which induces reverse CD137 ligand signaling enables macrophages to suppress proliferation of cancer cells *in vitro*. Future studies will evaluate whether CD137 protein might be able to enhance the cytolytic activity of macrophages.

P0243

Expression pattern of sirtuins in innate immune cells and influence of Sirtuin 1/2 inhibition on innate immune responses to Toll-like receptor ligands and to infection

E. Ciarlo, J. Lugrin, G. Grandmaison, D. Le Roy & T. Roger
Infectious Diseases Service, CHUV — University of Lausanne, Lausanne, Switzerland

Purpose/Objective: The family of histone deacetylases comprises 18 members in mammals, among which seven sirtuins (SIRT1-7). Sirtuins

are NADP-dependent enzymes that have been involved in the control of cell metabolism, proliferation and survival. The expression pattern of sirtuins and their influence on host response to microbial infection remain largely unknown. The aim of the study was to analyze the expression of SIRT1-7 and to address the effects of SIRT1/2 inhibition on innate immune responses *in vitro* and *in vivo*..

Materials and methods: *in vitro*: Bone marrow (BM), BM-derived macrophages (BMDMs) and dendritic cells (BMDCs) and RAW 264.7 and J774.1 macrophage cell lines were stimulated for 0, 2, 6 and 18 h with LPS, Pam_3CSK_4 and CpG ODN. SIRT1-7 mRNA was quantified by real time-PCR. TNF was measured by ELISA. *In vivo*: BALB/c mice were challenged with LPS (350 μg i.p.) with or without a SIRT1/2 inhibitor. Blood and organs were collected after 0, 1, 4, 8 and 24 h to quantify SIRT1-7 and TNF. Mortality was assessed daily.

Results: Bone marrow, macrophages and DCs express, in order of abundance, SIRT2 > > SIRT1, SIRT3 and SIRT6 > SIRT4, SIRT5 and SIRT7. Microbial products decrease the expression of all sirtuins except SIRT6 in a time dependent manner in BMDMs (0−24 h). SIRT2 is the most expressed sirtuin also in the liver, kidney (together with SIRT3) and spleen. Upon LPS challenge, SIRT1, SIRT3, SIRT4 and SIRT7 mRNA levels decrease in the liver (from 4 h to 24 h), whereas SIRT1-7 mRNA levels decrease within 1 h in both kidney and spleen. Pharmacological inhibition of SIRT1/2 decreases TNF production by macrophages stimulated with LPS, Pam_3CSK_4 and CpG ODN ($n = 6$; $P < 0.001$). In agreement, prophylactic treatment with a SIRT1/2 inhibitor decreases TNF production ($n = 8$; $P = 0.04$) and increases survival ($n = 13$, $P = 0.03$) of mice challenged with LPS.

Conclusions: Sirtuins are expressed in innate immune cells. Inhibition of SIRT1/2 activity decreases cytokine production by macrophages and protects from endotoxemia, suggesting that sirtuin inhibitors may represent novel adjunctive therapy for treating inflammatory disorders such as sepsis.

Supported by the Swiss National Science Foundation.

Fc receptor-induced differentiation of Ly6Chi monocytes to Ly6Cint patrolling-like monocytes

J. Montgomery, L. M. MacLellan, J. Doonan, F. Herrington & C. S. Goodyear

Medical Veterinary and Life Sciences, Institute of Infection Immunity and Inflammation, Glasgow, UK

Purpose/Objective: *Purpose/objective.* Monocytes can be sub-divided into two subsets that are defined by their Ly6C and CX_3CR1 expression. $Ly6C^{hi}$ CX_3CR1^{int} are said to be the pro-inflammatory subset that are released from the bone marrow in a CCR2 dependent manor. $Ly6C^{int}$ CX_3CR1^{hi} monocytes can be seen patrolling along blood vessels and some say these cells give rise to a more anti-inflammatory macrophage or dendritic cell. Though there is much debate over the origins and function of the two monocyte subsets. Studies by our group have shown that staphylococcus protein A (SpA) interacts with IgG *in vivo* to form small immune complex (SIC) that drive anti-inflammatory pathways. Theses complexes interact in an FcgRI-dependent fashion *in vivo* with both monocytes and macrophages. They have been shown to skew macrophage to an anti-inflammatory phenotype. The profound effect of SIC on macrophage phenotype made us question how SIC interaction with monocyte subsets and alter their phenotype.

Materials and methods: C57BL/6 mice were treated with either 500 mg of SpA or ovalbumin. In adoptive transfer studies, $Ly6C^{hi}$ monocytes from the bone marrow of CX_3CR1-GFP mice were sorted and 2×10^6 cells were adoptively transferred into recipient C57BL/6 prior to treatment. Twenty-four hours later blood, bone marrow and spleen were harvested and examined by flow cytometry.

Results: Treatment with SpA showed a significant decrease in the proportion of $Ly6C^{hi}$ monocytes and a significant increase in the proportion of $Ly6C^{int}$ monocytes in the blood in relation to the control group, no changes were seen in other tissues. Suggesting an either an altered differentiation of $Ly6C^{hi}$ into $Ly6C^{int}$, or an increase mobilization of $Ly6C^{int}$. To investigate the form hypothesis, GFP-$Ly6C^{hi}$ monocytes were adoptively transfer into C57BL/6. In SpA treated mice there was a significant shift in the profile of blood $LyC6^{hi}$ GFP^+ monocytes to a $Ly6C^{int}$ phenotype. This change was also associated with an up-regulation of CX_3CR1 and a down-regulation of GR-1 and CD64. This phenotype was also seen in the spleen and bone marrow though far less GFP cells had trafficked to these sites.

Conclusions: SIC via an Fc receptor-mediated interaction induces the differentiation/maturation of blood $Ly6C^{hi}$ monocytes into $Ly6C^{int}$ monocytes. This increase in the $LyC6^{int}$ population has the potential to modify the responsiveness of the immune system it inflammatory challenges.

Gene Expression Analysis of Pig Macrophages Reveals Similarities to Humans

R. Kapetanovic,* L. Fairbairn,* D. P. Sester,† A. L. Archibald* & D. A. Hume*

**The Roslin Institute and R(D) SVS, University of Edinburgh, Easter Bush, UK, †Innate Immunity Laboratory, School of Chemistry and Molecular Biosciences, University of Queensland, Brisbane, Qld, Australia*

Purpose/Objective: The laboratory mouse is an imperfect model in which to study human innate immunity. The larger size of the pig, and closer evolutionary distance to humans, offer several advantages. In particular, it is more straightforward to access large numbers of lung macrophages. In this study, we compared the gene expression profiles of macrophages from different breeds and compartments; alveolar (AM), bone-marrow-derived, monocyte subsets and monocyte-derived macrophages.

Materials and methods: We isolated a large number of mononuclear cells from the lung, bone-marrow and blood of 25 pigs from five breeds. Phagocytosis, TNF production and the expression of macrophage markers were characterised. We used a newly-generated and annotated pig expression array to characterise gene expression and the response to lipopolysaccharide.

Results: Isolated macrophage populations from pigs resemble those of humans. All type of macrophages expresses CD16, the LPS co-receptor CD14, CD172a. CD163 expression defined a subset of monocytes, and was expressed inversely with CD14. It was retained on alveolar macrophages (AM). Alveolar macrophages had a specific gene expression profile that included high levels of many C type lectins. Like peripheral blood monocytes, AM comprised two two subpopulations that differed in adherence, LPS response, phagocytosis and expression of CD163. $CD14^{++}$ monocytes resembled $CD14^{++}$ human monocytes in the expression profile. Human and pig macrophages also shared expression of LPS-inducible genes (STAT4, IDO, CCL20, Cyp27B1) that are not induced in mouse macrophages, and failed to induce iNOS. Pig breeds showed no great differences in response to LPS. The few genes differentially expressed included cytochrome CYP3A29, the metalloproteinase MMP1, STEAP4 and the N-Myc interactor NMI.

Conclusions: We have isolated and characterised the gene expression profiles of pig macrophages in multiple differentiation and activation states. The data support the use of the pig as a model of innate immunity that more closely resembles humans, and is economically important in its own right.

P0247

High-resolution transcriptome of human macrophages

M. Beyer, M. R. Mallmann, J. Xue, A. Staratschek-Jox, D. Vorholt, W. Krebs, D. Sommer, A. Nino-Castro, S. V. Schmidt & J. L. Schultze

Genomics & Immunoregulation, Life & Medical Sciences Institut (LIMES), Bonn, Germany

Purpose/Objective: Macrophages are dynamic cells integrating signals from their microenvironment to develop specific functional responses. Microarray-based transcriptional profiling has established transcriptional reprogramming as an important mechanism for signal integration and cell function of macrophages yet current knowledge on transcriptional regulation is far from complete. RNA sequencing (RNA-seq) is ideally suited to fill this need but also to discover novel marker genes, an area of great need particularly in human macrophage biology.

Materials and methods: Applying RNA-seq, we provide a high-resolution transcriptome profile of human macrophages under classical (M1-like) and alternative (M2-like) polarization conditions and demonstrate a dynamic range exceeding observations obtained by previous technologies, resulting in a more comprehensive understanding of the transcriptome of human macrophages.

Results: In addition, we were able to detect differential promoter usage, alternative transcription start sites, and different coding sequences for 57 gene loci in human macrophages. Moreover, this approach led to the identification of novel M1-associated (CD120b, TLR2, SLAMF7) as well as M2-associated (CD1a, CD1b, CD93, CD226) cell surface markers.

Conclusions: Taken together, these data support that high-resolution transcriptome profiling of human macrophages by RNA-seq leads to a better understanding of macrophage function and will form the basis for a better characterization of macrophages in human health and disease.

Human CD1a$^+$ dendritic cells mediate potent anti-viral immune responses via RIG-I and MDA5 signalling

E. Rajnavolgyi,* A. Szabo,* K. Bene,* A. Lanyi,* B. Rethi,† B. Dezso‡ & P. Gogolak*

**Immunology, Univesity of Debrecen, Debrecen, Hungary, †Karolinska Institute, MTC, Stockholm, Sweden, ‡Pathology, Univesity of Debrecen, Debrecen, Hungary*

Purpose/Objective: Cytosolic RIG-I-like helicases (RLH) are pattern recognition receptors involved in type I interferon production and antiviral immunity. The heterogeneous population of dendritic cells (DCs) act as professional antigen presenting cells in both lymphoid and non-lymphoid tissues to coordinate innate and adaptive immunity. This study focuses to the comparative analysis of the expression, functional activities and signalling cascades associated to RLH in *in vitro* generated and previously characterized CD1a$^+$ and CD1a$^-$ human monocyte-derived dendritic cell (moDC) subsets.

Materials and methods: Human moDCs were differentiated from blood-derived monocytes. CD1a$^-$ and CD1a$^+$ DCs were sorted by FACS DiVa. Relative mRNA expressions were analyzed by real-time Q-PCR. Protein expressions were measured by Western blot, the levels of secreted cytokines were detected by ELISA. Small interfering RNA (siRNA) was introduced by electroporation.

Results: Our results revealed that the expression of RLH genes and proteins as well as the activity of the coupled signalling pathways were significantly higher in the CD1a$^+$ subset than in its developmentally related but phenotypically and functionally distinct CD1a$^-$ counterpart. Specific activation of RLH in moDCs by polyI:C or influenza virus induced the secretion of IFNβ via IRF3, and pro-inflammatory cytokine responses through TLR3. Ligand-induced RLH-mediated signalling in CD1a$^+$ moDCs was shown to be indispensable for both priming naïve CD8$^+$ T lymphocytes and inducing potent influenza virus-specific cellular immune responses as demonstrated by RIG-I/MDA5 silencing that abrogated these functions. We also provide evidence that this migratory moDC subset can be detected in human tonsil and reactive lymph nodes.

Conclusions: We demonstrated the DC subset-specific activation of RLH and identified CD1a$^+$ moDCs as potent antigen presenting and highly inflammatory cells due to their specialized functional activities Targeting the differentiation and RLH ligand-specific activation of the CD1a$^+$ DC subpopulation may offer new tools for improving the efficacy of anti-viral vaccines.

Human monocytes express functional trail receptors and are susceptible to trail-induced apoptosis

C. Belgiovine, M. Liguori, G. Germano, C. Buracchi, A. Mantovani & P. Allavena

Immunology and Inflammation, Istituto Clinico Humanitas, Milano, Italy

Purpose/Objective: In several tumor types, the presence of Tumor-Associated Macrophages (TAM) correlates with poor clinical outcome and resistance to conventional treatment.TAM promote disease progression by supporting cancer cell survival, proliferation and invasion. Furthermore, TAM and related myeloid cells (Tie2$^+$ monocytes and MDSC) trigger neo-angiogenesis and suppress adaptive immune responses. Targeting of tumor macrophages is considered a promising therapeutic strategy to be combined with other conventional anti-tumor treatments. It is known that in tumor cells the activation of the apoptotic pathway via death receptors represents a good therapeutic strategy. For this purpose we decided to study the expression of death receptors and ligands and their functional activity in leukocyte population.

Materials and methods: We checked expression of death receptors in whole human blood by FACS analysis. We treated human monocytes with a recombinant trail protein and we checked its functionality by Annexin V$^+$ apoptosis and caspase 8 expression by citofluorimeter analysis.

Results: We show in this study that blood monocytes express the death receptors for theTumor necrosis factor-Related Apoptosis Inducing Ligand (TRAIL), a cytokine known to induce apoptosis in a wide variety of transformed cell lines but not normal cells. R1 (TNFRSF10A) and R2 (TNFRSF10B) are significantly expressed by monocytes while the non-signaling decoy receptor R3 (TNFRSF10C) is virtually absent. In marked contrast, lymphocytes and neutrophils express high levels of R3 and not of R1 and R2, implying that monocytes are selectively susceptible to this killing mechanism. Recombinant TRAIL protein induced death of human monocytes *in vitro* via caspase 8 activation and Annexin V$^+$ apoptosis, which was specificallyinhibitedby blocking anti-TRAIL receptor antibodies.

Conclusions: Along the current concept that modulation of the host micro-environment, of macrophages in particular, may result in enhanced response to anti-cancer therapies, we propose thatmonocytes/macrophages can be targeted by TRAIL.

Human scavenger protein Spalpha regulates key macrophage lipid homeostasis events that lead to atherosclerosis development

N. Amézaga,* L. Sanjurjo,* J. Julve,† T. León,‡ B. Pérez-Cabezas,§ P. Bastos-Amador,§ F. Blanco-Vaca,† F. Borràs,§ A. Valledor‡ & M. R. Sarrias*

*Innate Immunity Group Gastroenterology Department, Health Sciences Research Institute Germans Trias i Pujol (IGTP), Badalona, Spain, †IIB Sant Pau, Servei de Bioquímica Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ‡Nuclear Receptor Group Department of Physiology and Immunology, School of Biology, University of Barcelona, Barcelona, Spain, §Department of Cell Biology Physiology and Immunology, Health Sciences Research Institute Germans Trias i Pujol (IGTP), Universitat Autònoma de Barcelona Research, Badalona, Spain

Purpose/Objective: Macrophage Secreted Protein α (Spα/CD5L) belongs to the Scavenger Receptor Cysteine Rich Superfamily (SRCR-SF). In the mouse, its expression is under control of the Nuclear Receptor (NR) transcription factors LXR and RXR. Murine Spα is considered a pro-atherogenic factor by protecting macrophages from the apoptotic effects of oxidized lipids. To date, the sole information available on its human counterpart (hSpα) is that it is detected in human atherosclerosis lesions. The objective of this study was to assess the contribution of hSpα to the macrophage events that lead to atherosclerosis.
Materials and methods: THP1 cells stably expressing hSpα and human macrophages differentiated from healthy donor peripheral blood monocytes treated with recombinant hSpα have been studied.
Results: Our results show that, as in mice, hSpα plays an antiapoptotic effect to modified LDL (mLDL) in macrophages. Furthermore, hSpα increased foam cell formation as assessed by Oil-Red-O staining and total and esterified cholesterol content quantification by thin layer chromatography. Flow cytometry studies showed that hSpα increases fluorescently labelled mLDL uptake by macrophages. This could be explained by an increase on the mRNA levels of the canonical mLDL uptake receptors CD36 and SRA. Also, hSpα did not affect cholesterol efflux during 3H-labelled cholesterol reverse transport to plasma. Real time PCR and western blot analyses revealed no differences between human and mice in terms of regulation by OxLDL and LXR/RXR synthetic agonists. Yet, hSpα protein synthesis and secretion are tightly regulated.
Conclusions: Taken together our data suggest that hSpα retains the antiapoptotic role and that its expression is under control of the NR. We further demonstrate that hSpα contributes to additional key aspects of the role of macrophages in lipid homeostasis, such as foam cell formation due to an imbalance between cholesterol uptake and efflux. Our findings provide valuable information for its potential therapeutic intervention for the treatment of atherosclerosis.

P0251

IFN-a inhibits the type I immune response of human monocytes

R. A. de Paus,* A. van Wengen,* I. Schmidt,* M. Visser,† E. M. E. Verdegaal,† J. T. van Dissel* & E. van de Vosse*

*Infectious Diseases, Leiden University Medical Center, Leiden, The Netherlands, †Clinical Oncology, Leiden University Medical Center, Leiden, The Netherlands

Purpose/Objective: Both IFN-α and IFN-γ display immunomodulatory effects. IFN-γ is the main mediator of Th1 responses essential in the control of infections by intracellular bacteria, such as non-tuberculous Mycobacteria, while IFN-α plays a role in viral infections. Virulent Mycobacterium tuberculosis strains may induce IFN-α and thereby interfere with an effective Th1 response against this bacterium. Herein we investigate how IFN-α modulates type I immune responses by monocytes.
Materials and methods: Human blood $CD14^+$ monocytes were isolated and stimulated overnight with various concentrations of IFN-α and IFN-γ in the presence or absence of LPS. The IFN-γ induced expression of CD54 and CD64 was measured by FACS and the production of type I cytokines by Elisa. Next, we investigated the mechanism by which IFN-α inhibits the type I immune responses. We examined the influence of IFN-α on the expression of the IFN-γ receptor and on the IFN-γ-induced signal transduction, by FACS and Western blot. To investigate a role for protein arginine methyltransferase-1 (PRMT-1) in the inhibition of IFN-α we used a competitive PRMT inhibitor.
Results: IFN-α reduced the IFN-γ-enhanced CD54 and CD64 expression up to threefold. The LPS-induced IL-12p40 production was fivefold reduced by IFN-α. The IL-12p40, TNF and IL-1β production induced by the combination of IFN-γ and LPS were seven-, four- and threefold reduced by IFN-α, respectively.

To study the effects of IFN-α on IFN-γ signalling we determined the kinetics of STAT1 and STAT2 phosphorylation and found that IFN-α interferes directly with the IFN-γ-induced STAT1 phosphorylation. The cell surface expression of IFN-γR1 was gradually reduced after 2 h of stimulation with IFN-α to <25% it's starting value. In addition, we revealed a role for PRMT1, which is associated with the IFN-α receptor, in the inhibitory effects of IFN-α.
Conclusions: In conclusion, IFN-α strongly inhibits type I immune response of monocytes via diverse modes of action.

P0252

IL-15-dependent $NKp46^+$ innate lymphoid cells control intestinal inflammation via CCL3-CCR1-dependent recruitment of inflammatory monocytes

J. Schulthess,* B. Meresse,* E. Ramiro-Puig,* N. Montcuquet,* S. Darche,† B. Begue,* F. Ruemmele,* C. Combadiere,‡ J. P. Di Santo,† D. Buzoni-Gatel§ & N. Cerf-Bensussan*

*INSERM U989, Universite Paris Descartes, Paris, France, †Institut Pasteur, Unite Immunite Innee-INSERM U668, Paris, France, ‡Universite Pierre et Marie Curie, INSERM-UMR-S 945, Paris, France, §INRA, U1282, Nouzilly, France

Purpose/Objective: Interleukin 15 (IL-15) is a pleiotropic cytokine with a large range of functions at the interface between innate and adaptive immunity. Its contribution during intestinal inflammation was investigated by using a model of acute ileitis induced by oral administration of *Toxoplasma gondii* (*T. gondii*) in C57BL/6 wild type (WT) mice.
Materials and methods: The role of IL-15 was assessed by studying the severity of ileitis WT and $IL\text{-}15^{-/-}$ mice.
Results: Ileitis was markedly attenuated in $IL\text{-}15^{-/-}$ mice but the parasite load was not modified, indicating that IL-15 enhanced the severity of intestinal inflammation induced by *T. gondii*. The pro-inflammatory effect of IL-15 did not depend on IEL activation. In contrast, IL-15 promoted the recruitment of $CCR1^+$ inflammatory monocytes (IM) into the inflamed gut. IMs produced high levels of inflammatory cytokines which lead to epithelial damage. $CCR1^+$ IMs were attracted by CCL3, produced by a subset of intestinal $NKp46^+$ innate lymphoid cells. A non-hematopoietic source of IL-15 controlled the development and function of these intestinal $NKp46^+$ cells in response to inflammatory cytokines, and notably to IL-18 during ileitis induced by *T. gondii* infection.
Conclusions: Together these data delineate a novel function for a IL-15-dependent subset of intestinal $NKp46^+$ cells as an important source of CCL3, promoting the recruitment of $CCR1^+$ inflammatory monocytes. Preliminary evidence suggests that this pathway may also operate in Crohn disease.

P0253

Immobilized immune complexes recruit CD16-positive human blood dendritic cells

T. Döbel, A. Lonsdorf, A. Hänsel, A. Enk & A. Schäkel
Dermatology, Heidelberg University Hospital, Heidelberg, Germany

Purpose/Objective: The deposition of immune complexes (ICs) in the skin is a critical pathogenic event in the promotion of autoimmune inflammatory responses. Fc receptor-mediated interaction of these ICs with the machinery of dendritic cells (DCs) contributes to IC-triggered inflammation and tissue damage. Among human blood DCs we previously identified the CD1c- $CD11c^+$ slanDCs, identifiable by expression of the carbohydrate modification 6-sulfo LacNAc. SlanDCs stand out by their high level expression of the low affinity Fc gamma receptor III (CD16) and exert powerful proinflammatory effects by serving as a major and early source of IL-12 and TNF-alpha.
Materials and methods: We produced small soluble and fluorescent ICs and flow cytometrically measured the binding of these ICs to human blood DCs and monocytes. Furthermore, we applied a flow chamber adhesion assay and time-lapse video microscopy to measure the arrest function of blood leukocytes to immobilized immune complexes under conditions of physiological shear stress.
Results: We show that marked expression of CD16 equips slanDCs with an outstanding capacity to capture small soluble ICs. We then demonstrate that ICs alone are highly efficient in mediating the firm arrest of slanDCs under conditions of physiological shear stress. In stark contrast, other human blood DCs (plasmacytoid DCs and $CD1c^+$ DCs) or T cells completely failed to adhere immobilized ICs. By selectively blocking the FcγRs on slanDCs, we clearly show that their shear-resistant adherence to immobilized ICs critically depends on CD16, while CD32 (FcγRII) expression is irrelevant. The existence of this CD16/IC-mediated DC recruitment at the endothelial interface is furthermore supported by data showing enhanced arrest of slanDCs on monolayers of human dermal microvascular endothelial cells that were pre-incubated with anti-endothelial cell IgG antibodies.
Conclusions: Taken together, we have shown that CD16 expressed by slanDCs mediates 1) highly efficient capture of soluble ICs and 2) efficient shear-stress-resistant adhesion of circulating slanDCs to immobilized ICs. These data provide evidence for a novel conduit of rapid FcR-dependent recruitment of DCs in IC-mediated tissue inflammation.

P0254

Immune response to diphtheria toxin-mediated depletion complicates the use of the CD11c-DTRtg model for studies of bacterial gastrointestinal infections

L. Westermark, A. Fahlgren & M. Fällman
Molecular Biology, Umeå University, Umeå, Sweden

Purpose/Objective: Dendritic cells (DCs) play an important role in the immune defense against pathogens, as they alert the immune system to invaders, and are responsible for the activation and control of both innate and adaptive immune responses. In this study, we aimed to investigate the role of DCs during early *Y. pseudotuberculosis* infection by the use of a mouse DC-depletion model.
Materials and methods: The CD11c-DTR^{tg} model has been extensively used to study the role of DCs during steady-state and infection conditions. The CD11c-DTR^{tg} mice express a primate DTx receptor (DTR) under the control of the CD11c promoter (Itgax), which allows for conditional knock-out of $CD11c^{high}$ cells, including most DC populations, by injection of DTx. *Yersinia* infection was monitored by IVIS and the immune response in the mice was evaluated by immunohistochemistry, flow cytometry and a multiplex cytokine assay.
Results: Infecting DC-depleted mice orally with *Y. pseudotuberculosis* results in a markedly reduced level of infection compared with infection of non-depleted mice, suggesting an important role for DCs in establishment of the infection. However, investigations of the immune status in uninfected mice after DTx-treatment revealed that this lower bacterial colonization is due to a DTx-mediated immune response leading to recruitment of PMNs in Peyer's patches and increased levels of keratinocyte-derived cytokine in blood.
Conclusions: DTx-mediated depletion leads to an immune response that efficiently reduces the initial colonization of *Y. pseudotuberculosis* in Peyer«s patches. It is possible that the recruited PMNs eliminate the majority of the infecting bacteria or that the induced inflammatory response in the Peyer's patches causes restriction of bacterial entry.

P0255

Impact of Sirtuin 2 knockout on innate immune responses

E. Ciarlo,* J. Lugrin,*I. dos Santos Pinheiro,* D. Le Roy,* N. Moulan,† H. Yamamoto,† H. Acha-Orbea,‡ T. Calandra,* J. Auwerx† & T. Roger*
**Infectious Diseases Service, CHUV – University of Lausanne, Lausanne, Switzerland, †Laboratory for Integrative and Systems Physiology, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ‡Department of Biochemistry, University of Lausanne, Lausanne, Switzerland*

Purpose/Objective: Histone deacetylases (HDACs) deacetylate histones and transcriptional regulators thereby affecting numerous biological functions. Seven mammalian sirtuins (SIRT1-7) constitute the NAD-dependent class III subfamily of HDACs. Sirtuins are the center of great interest due to their regulatory role in the control of metabolism, ageing and age-related diseases. Up to now, little is known about the influence of sirtuins on immune responses, and nothing about the role of SIRT2. The aim of the study was to analyze the influence of SIRT2 knockout on immune cell development and innate immune responses *in vitro* and *in vivo*.
Materials and methods: SIRT2 germline knockout were produced on a C57BL/6J background. The cellularity of thymus and spleen was assessed by flow cytometry ($n = 3$). Bone marrow derived macrophages (BMDMs) and dendritic cells (BMDCs) and splenocytes were stimulated with LPS, Pam_3CSK_4 lipopeptide, CpG ODN, *E. coli*, *S. aureus*, TSST-1, SEB, anti-$CD3^+$ CD28 and concanavalin A ($n = 3–8$). TNF, IL-2, IL-6, IL-12p40 and IFNγ production, SIRT1–7 and CD40 expression, and proliferation were quantified by real time-PCR, ELISA, flow cytometry and H^3-thymidine incorporation. Mice ($n = 6–16$) were challenged with LPS, TNF/D-galactosamine, *E. coli* and *K. pneumonia* titrated to cause either mild or severe infections or shock. Blood was collected to quantify cytokines and bacteria. Mortality was checked regularly.
Results: SIRT2 is the most expressed sirtuin in macrophages and myeloid DCs. To test whether SIRT2 impacts on innate immune responses, we generated SIRT2 germline knockout mice. $SIRT2^{-/-}$ mice born at the expected Mendelian ratio and develop normally. The proportions and absolute numbers of DN1-4, DP and SP thymocytes, and of T-cells (DN and SP, naïve and memory), B-cells (immature and mature), DCs (cDCs and pDCs) and granulocytes in the spleen are similar in $SIRT2^{+/+}$ and $SIRT2^{-/-}$ mice. $SIRT2^{+/+}$ and $SIRT2^{-/-}$ BMDMs, BMDCs and splenocytes produce cytokines (RNA and protein), upregulate CD40, and proliferate to the same extent. $SIRT2^{+/+}$ and $SIRT2^{-/-}$ mice respond similarly (cytokine blood levels, bacterial counts and mortality) to non-severe and lethal endotoxemia, *E. coli* peritonitis, *K. pneumonia* pneumonia and TNF-induced shock.
Conclusions: SIRT2 knockout has no dramatic impact on the development of immune cells and on innate immune responses *in vitro* and *in vivo*. Considering that SIRT2 may participate to control metabolic homeostasis, we are currently assessing the impact of SIRT2 deficiency on innate immune responses under metabolic stress.

P0256

in vitro differentiation of negatively isolated primary monocyte: an adequate model system to study infections of human macrophages by Listeria monocytogenes

C. Neu, A. Sedlag & C. U. Riedel
Institute of Microbiology and Biotechnology, AG Riedel, Ulm, Germany

Purpose/Objective: Macrophages are an important defence mechanism against intracellular pathogens such as *Listeria monocytogenes* (*Lm*). Depending on their surface marker expression and immunological function, macrophages have pro-inflammatory or anti-inflammatory characteristics. Most studies to date on *Lm* infections of macrophages have been conducted in cell lines or murine bone-marrow-derived macrophages. Several differences have been reported between murine and human macrophages. In the present study we thus evaluate different methods to generate macrophages from primary human monocytes to investigated *Lm* infections.
Materials and methods: *In vitro* these two subpopulations can be derived from $CD14^+$ monocytes isolated from human blood by cultivation in the presence of either granulocyte macrophage colony-stimulating factor (GM-CSF) or macrophage colony-stimulating factor (M-CSF) to generate inflammatory GM-CSF monocyte derived macrophages (GM-MDM) and anti-inflammatory M-CSF monocyte derived macrophages (M-MDM). We used both negative as well as positive selection to isolate $CD14^+$ monocytes from human blood samples. For comparison PMA-derived THP-1 macrophages were used. Cells were subsequently incubated with either GM-CSF or M-CSF and analyzed for surface expression of the macrophage differentiation markers CD163 and CD206.
Results: While PMA-stimulated THP-1 macrophages were negative for these two markers, GM-MDM stained high for CD206 and M-MDM were positive for CD163 following both positive and negative isolation methods. However, when analyzed for phagocytosis of *Lm,* a striking difference was observed between macrophages derived from monocytes isolated by the two methods. After positive selection both GM-MDM and M-MDM were highly phagocytic towards the pathogen. By contrast, when isolated by negative selection only M-MDM displayed high phagocytosis. Moreover, high non-specific phagocytosis of latex beads by M-MDM was observed irrespective of the method used for isolation of monocytes. High phagocytic activity in GM-MDM from negatively selected monocytes could be induced by addition of the CD14-antibody (short term and 7 days) used for positive selection.
Conclusions: Collectively the results suggest that positive selection using a CD14-antibody alters the phagocytic behavior of GM-MDM towards *Lm*. Human macrophages derived from primary monocytes by negative selection are proposed as the most suitable model to study *Lm* infection of macrophages.

P0257

Increased inflammation modifies RA monocyte susceptibility to TRAIL-induced apoptosis

U. Meusch, M. Rossol, M. Klingner, C. Baerwald & U. Wagner
Department for Internal Medicine Dermatology and Neurology Section Rheumatology, University of Leipzig, Leipzig, Germany

Purpose/Objective: The autoimmune disease rheumatoid arthritis (RA) is characterized by the production of proinflammatory monocytic cytokines like TNF alpha and IL-1 beta. Neutralization of TNF alpha with anti-TNF antibodies is a critical therapeutic approach, which has a strong influence on disease activity in RA patients. In a previous study we already have shown that monocytes from patients with rheumatoid arthritis are less sensitve and sometimes resistant against TRAIL-induced apoptosis. In the following study, the influence of disease activity of RA patients on TRAIL-induced apoptosis of monocytes should be analyzed. Furthermore the importance of an anti-TNF therapy in this context will be studied.
Materials and methods: Monocytes of 24 RA patients were assessed for TRAIL induced apoptosis and cytokine production before (BL) and after 4, 12 and 24 weeks of anti-TNF treatment. Therefore monocytes were isolated from the peripheral blood of RA patients were incubated with 100 ng/ml TRAIL for 16 h. Subsequently TRAIL induced apoptosis was measured via annexinV/PI staining. Production of IL-8 was analyzed by ELISA. Expression levels of all TRAIL receptors and mTRAIL were detected by flow cytometry. Evaluation of disease activity by using DAS 28, ESR and CRP takes place at every time point of the treatment periode.
Results: The analysis of TRAIL induced apoptosis of RA monocytes before anti-TNF therapy show that monocytes from patients with a high disease activity undergo TRAIL induced apoptosis while monocytes from patients with low disease activity are did not. During the study a decreasing disease activity in patients under threapy was observed. Simultaneously the TRAIL induced apoptosis decreases in positve correlation with the disease activity. Furthermore, it was shown that RA monocytesproduce increased amounts of IL-8 production after TRAIL stimulation. This production was significantly inhibited during anti-TNF therapy. The disease activity of the monocyte donors has no effect on the spontaneous IL-8 production andon the TRAIL induced IL-8 production. Of all the donors monocyte cell surface expression of all TRAIL receptors and of mTRAIL was determined to BL and at different time points during therapy. It was shown that anti-TNF treatment leads to inhibition of TRAIL R1 and R3 expression.
Conclusions: anti-TNF therapy inhibits inflammation induced amplification of proinflammatory effects of TRAIL in RA monocytes.

P0258

Induction of peroxisome proliferator-activated receptor (PPAR) -g in macrophages by human amniotic membrane

M. Hennig,* S. Wasmuth,* H. Baehler,* M. Busch,* K. P. Steuhl,† S. Thanos,‡ A. Heiligenhaus* & D. Bauer*
Ophtha-Lab, Department of Ophthalmology at St. Franziskus Hospital, Muenster, Germany, †Department of Ophthalmology, University of Duisburg-Essen, Essen, Germany, ‡Institut of Experimental Ophthalmology, University of Muenster School of Medicine, Muenster,* **Germany

Purpose/Objective: To study the observed immune suppressive functions of amniotic membrane (AM) on macrophages.
Materials and methods: Apoptosis of macrophages was studied by flow cytometric analysis by using the annexin V/7-AAD system. Cytokines were measured by ELISA and the expression of nuclear factor (NF)-κB and PPAR-γ by western blot. The activity of arginase was determined by bioassay. The expression of costimulatory molecules and PPAR-κ was measured by flow cytometric observation. Accumulation of lipids in the cytoplasma was observed by Oil red O staining or Sudan black B.
Results: After coculture with AM macrophages show a decreased NF-κB expression, cytokine secretion (TNF-α, IL-6, IL-10, IL-12), expression of costimulatory molecules (CD80, CD86, CD40), phagocytosis, proliferation, and viability. The expression of CD206, CD204, CD163, and CD68, lipid accumulation in the cytoplasma, PPAR-γ expression and arginase activity was increased.
Conclusions: We conclude that the action mechanisms of AM is associated with an activation of the PPAR-γ pathway and engagement of the lipid metabolism in macrophages, resulting in a modulation of classically activated macrophages into alternative activated macrophages or macrophage cell death upon activation.

P0259

Inhibition of inflammasome activation in human macrophages by highly pathogenic avian influenza viruses caused by missing M2 protein expression

J. Friesenhagen,* Y. Boergeling,† E. Hrincius,† S. Ludwig,† J. Roth‡ & D. Viemann*
Experimental Neonatology, Hannover Medical School, Hannover, Germany, †Institute of Molecular Virology, University of Muenster, Muenster, Germany, ‡Institute of Immunology, University of Muenster, Muenster, Germany

Purpose/Objective: Purpose/Objective: Infections of the human host by highly pathogenic avian influenza viruses (HPAIV) are characterized by development of a cytokine storm and systemic spreading of infection. Macrophages as part of the first barrier of defense against systemic infections are important producers of cytokines and therefore most likely to be involved in the emergence of a cytokine storm.
Materials and methods: Materials and methods: We analyzed human blood-derived macrophages infected with low pathogenic human A/PR8/34 (H1N1) and HPAIVs A/FPV/Bratislava/79 (H7N7) and A/Thailand/1 (KAN-1)/2004 (H5N1) in a genome-wide microarray study and confirmed results in quantitative Real-time PCR experiments. Immunofluorescent staining and Western Blot were used for analysis of viral protein expression.
Results: Results: We found a surprisingly low inflammatory and antiviral response of macrophages infected with HPAIV in contrast to those infected with human H1N1. Immunofluorescence and Western Blot analyses revealed that virus replication and expression of viral proteins in the host cell take place with one exception. Viral protein M2 is not expressed in macrophages in case of HPAIV infection. As M2 serves as second signal for inflammasome activation in macrophages, we found a significant reduction of IL-1β protein expression.
Conclusions: Conclusions: Missing M2 expression therefore leads to subsequent suppression of an important part of the inflammatory and antiviral response and thus enables HPAIV to bypass effective immune responses of one of the most important cell types of the innate immune system. Consequently, systemic spreading of HPAIV infection is facilitated.

Intestinal CD8a$^+$ dendritic cells constitutively migrate from the intestinal lamina propria to the mesenteric lymph node

S. Houston, V. Cerovic, A. Aumeunier, A. M. Mowat & S. W. F. Milling
Immunology, Institute of Infection Immunity and Inflammation, Glasgow, UK

Purpose/Objective: Dendritic cells (DCs) are central to the initiation of all adaptive intestinal immune responses. They transport antigen from the periphery to the mesenteric lymph nodes (MLNs) where they prime naïve T cells. Previous work has focused on a CD103$^+$ CD11b$^+$ tolerogenic subset of DCs migrating from the intestinal Lamina Propria (LP) to the MLN; however, we have recently identified four distinct subsets of migratory DCs including a subset of CD103$^+$ CD8α^+. In order to deepen our understanding of these subsets of migratory intestinal DCs, we sought to determine their anatomical origins. Specifically, to determine if these DCs originate from the LP or from organised lymphoid tissues in the intestine.
Materials and methods: We used two mouse models which lack specific secondary lymphoid tissues in the intestine. RORγt$^{-/-}$ mice lack Peyer's patches (PPs) and isolated lymphoid follicles (ILFs), while progeny of mice treated with Lymphotoxin-β Receptor Fusion Protein (LT-β-R-Ig) lack only PPs. In order to examine migratory DCs, we developed a technique for thoracic duct cannulation (TDC) preceded by mesenteric lymphadenectomy (MLNx), allowing the isolation of all intestinal lymph-borne DCs (LDCs). By collecting migrating lymph DCs from mice lacking specific intestinal lymphoid tissues, the anatomical origins of these DCs can be elucidated.
Results: The absence of PPs and ILFs in RORγt$^{-/-}$ mice was confirmed by immunohistochemistry on Swiss rolls made from sections of small intestine. Imaging was also performed on live intestinal tissue of LT-β-R-Ig progeny, confirming that PPs were missing in these animals. All four intestinal lymph DC subsets were present in LT-β-R-Ig progeny in comparable proportions to WT mice. However, intestinal lymph and LP from RORγt$^{-/-}$ animals contained similar proportions of only three of the four DC subsets found in WT mice; the CD103$^-$CD11b$^-$ DC subset is missing from RORγt$^{-/-}$ mice.
Conclusions: The techniques of MLNx followed by TDC allow the isolation of bona fide migratory DCs. Three subsets of LDCs, including a CD103$^+$ CD8α^+ DC subset; migrate into intestinal lymph from the LP, while CD103$^-$CD11b$^-$ DCs appear to originate from ILFs in the small intestine. Determining the anatomical origins of LDCs provides exciting new avenues for the treatment of inflammatory bowel disease and the development of oral vaccines by enabling subsets of DCs to be targeted in the intestine.

Investigating human monocyte subsets in periodontitis – potential targets for immunomodulatory treatment

S. Björnfot,* O. Hammarfjord,* A. Gustafsson† & M. Svensson*
Medicine, Karolinska Institutet, Stockholm, Sweden, †Dental Medicine, Karolinska Institutet, Stockholm, Sweden

Purpose/Objective: In Periodontitis (PD), patients suffer from chronic inflammation that causes destruction of tooth supportive tissues. Evidence suggests that the persistent inflammation in PD occurs due to abnormal host innate immune responses to oral micro flora. We hypothesize that defective functional properties of the monocytes, contributes significantly to unrestrained bacteria-induced responses in PD. Monocytes are divided into three subsets, the CD14$^+$ CD16-, CD14$^+$ CD16$^+$ and CD14lowCD16$^+$ subset, with different pro- and anti-inflammatory functions. We aim to address if the composition of the subsets and their ability to migrate into tissue based on chemokine receptor expression, is altered in PD patients. In parallel we aim to develop a human 3D model of the oral mucosa with implanted monocytes, to further study their functionality at the site of inflammation.
Materials and methods: Peripheral blood was obtained from patients with PD and control individuals. Blood cell numbers and C-reactive protein (CRP) levels were analyzed. Percentages of the monocyte subsets as well as chemokine receptor expression were analyzed with multicolor flow cytometry and RT-qPCR. For the model, primary oral fibroblasts were cultured in a collagen based matrix with monocytes and the oral keratinocytes cell line OKF6-TERT2 seeded on top.
Results: The number of monocytes is significantly increased in PD patients compared to controls. In addition, PD is associated with an altered monocyte subset composition, including a decrease of the CD14lowCD16$^+$ subset. We also observed an increase in the CRP levels in PD. Finally, PD is associated with an increase of the chemokine receptor 7 (CCR7), on all monocyte subsets.
Conclusions: PD is associated with increased number of monocytes and changes in the percentages of the monocyte subsets with an altered chemokine receptor expression, potentially changing their migratory behaviour and contributing to disease progression.

Lack of PPARgamma in myeloid cells confers resistance to listeria monocytogenes infection

Z. Abdullah,* S. Geiger,* A. Nino-Castro,† J. Böttcher,‡ K. Riethausen,‡ F. A. Schildberg,‡ T. Chakraborty,§ J. L. Schultze,† P. A. Knolle‡ & L. Klotz¶

Molecular Medicin, Institutes of Molecular Medicine and Experimental Immunology, Bonn, Germany, †LIMES, Genomics and Immunregulation, Bonn, Germany, ‡Molecular Medicin, Institutes of Molecular Medicine and Experimental Immunology, Bonn, Germany, §Medical Faculty, Institutes of Medical Microbiology, Giessen, Germany, ¶Inflammatory Disorders of the Nervous system and Neuro-oncology, Clinic of Neurology, Bonn, Germany

Purpose/Objective: The peroxisomal proliferator-activated receptor gamma (PPARg) is a nuclear receptor that controls inflammation and immunity. Innate immune defense against bacterial infection appears to be compromised by PPARg. The relevance of PPARg in myeloid cells, that organize anti-bacterial immunity, for the outcome of immune responses against intracellular bacteria such as *Listeria monocytogenes in vivo* is unknown. In this work we address the question whether PPARg with its potent regulatory activity on innate immune functions in myeloid cells plays a regulatory role during infection with *L. monocytogenes* and whether PPARg restricts innate immunity in myeloid cells against *Listeria* infection.

Materials and methods: To investigate whether PPARg in myeloid cells influences innate immunity against bacterial infection we have generated a transgenic mice with myeloid-cell specific ablation of PPARg (LysMCre × $PPARg^{flox/flox}$) andused *Listeria monocytogenes* as a model for intracellular baceterial infection.

Results: Our data have shown that loss of PPARg in myeloid cells results in enhanced innate immune defense against *Listeria monocytogenes* infection both, *in vitro* and *in vivo*. This increased resistance against infection was characterized by augmented levels of bactericidal factors and inflammatory cytokines: ROS, NO, IFNgγ TNFα IL-6 and IL-12. Moreover, myeloid cell-specific loss of PPARg enhanced chemokine and adhesion molecule expression leading to improved recruitment of inflammatory $Ly6C^{hi}$ monocytes to sites of infection. Importantly, increased resistance against *Listeria* infection in the absence of PPARg was not accompanied by enhanced immunopathology.

Conclusions: Our results elucidate a yet unknown regulatory network in myeloid cells that is governed by PPARg and restrains both listeriocidal activity and recruitment of inflammatory monocytes during *Listeria* infection, which may contribute to bacterial immune escape. Pharmacological interference with PPARg activity in myeloid cells might represent a novel strategy to overcome intracellular bacterial infection.

P0263

Langerhans' cell migration and lymph node dendritic cell accumulation in response to chemical allergens: roles of tumour necrosis factor-a

L. H. Eaton, A. Metryka, I. Kimber & R. J. Dearman
Faculty of Life Sciences, University of Manchester, Manchester, UK

Purpose/Objective: Langerhans' cells (LC), the dendritic cells (DC) of the epidermis, once activated, migrate to the draining lymph nodes, where they orchestrate and regulate immune responses. We have shown previously that tumour necrosis factor (TNF)-α is required for DC accumulation in the skin draining lymph nodes after topical exposure of BALB/c strain mice to the chemical contact allergen oxazolone. TNF-α induces changes in LC, including the down-regulation of E-cadherin, which allows dissociation from neighbouring keratinocytes in the epidermis, in addition to up-regulation of matrix metalloproteinases. There are two receptors for TNF-α; TNF-R1 and TNF-R2, of which LC express only the latter. Another group has demonstrated that TNF-R2 (but not TNF-R1), is required for the accumulation of fluorescein isothiocyanate (FITC) bearing cells in the draining lymph node after topical application of the chemical allergen FITC. The aim of these experiments was to characterise the requirement for TNF-α for LC migration and DC accumulation in response to the chemical allergens dinitrochlorobenzene (DNCB) and FITC.

Materials and methods: Wild type (C57/BL6), and $TNF\text{-}R2^{-/-}$ strain mice received topical application of either DNCB or FITC, to the dorsum of both ears. After 4 or 24 h treatment with DNCB, the epidermis was isolated and stained for LC using FITC-conjugated MHC Class II antibody and analysed for LC frequency by fluorescence microscopy. Twenty-four hours after application of DNCB or FITC, auricular lymph nodes were excised and DC frequency assessed by CD11c expression, analysed by flow cytometry.

Results: 4 h after topical application of DNCB, LC migration was induced from the epidermis in both wild type and $TNF\text{-}R2^{-/-}$ strain mice. Furthermore, 24 h application of DNCB not only induced loss of LC from the epidermis, but also caused a marked increase in the number of DC in the skin draining lymph node of $TNF\text{-}R2^{-/-}$ strain mice. In contrast, FITC increased the frequency of DC in the draining lymph node of wild type, but not $TNF\text{-}R2^{-/-}$ strain mice.

Conclusions: These data suggest that, unlike FITC, DNCB-induced migration of LC from the epidermis and subsequent arrival of DC in the lymph node is not dependent on signalling through TNF-R2.

P0264

Langerhans' cells have a type 2 phenotype with regards to their Toll-like receptor ligand response and chemokine expression pattern

L. H. Eaton, K. T. Mellody, I. Kimber & R. J. Dearman
Faculty of Life Sciences, University of Manchester, Manchester, UK

Purpose/Objective: Langerhans' cells (LC) are the dendritic cell (DC) population of the epidermis and express toll like receptors (TLR) that are capable of recognising pathogen-associated molecular patterns. Upon activation, LC migrate to the lymph nodes where they initiate an immune response. Both DC and LC can secrete chemokines, of which some are associated with a type 1 or a type 2 immune response.

Materials and methods: Single cell suspensions were created from the epidermis of BALB/c strain mice. Unfractionated, LC-enriched (94% pure) and LC-depleted (predominantly keratinocyte) fractions were analysed for chemokine expression (type 1- [CXCL9 and CXCL10] and type 2- [CCL17 and CCL22] associated) by RT-PCR. Chemokine secretion by XS106 cells (an LC-like cell line derived from murine epidermis) was analysed by ELISA. TLR ligands were used to stimulate XS106 cells and surface expression of membrane markers (MHC class II, CD80, CD86 and CD40) and chemokine production was analysed by flow cytometry and ELISA, respectively. Migration of LC following intradermal injection of BALB/c strain mice with various TLR ligands was assessed in epidermal sheets by immunofluorescence staining for MHC class II.

Results: The LC-enriched and LC-depleted fractions mainly expressed type 2-associated CCL22 and type 1-associated CXCL10, respectively. XS106 cells expressed constitutively higher levels of type 2 chemokines compared with type 1 chemokines. Furthermore, XS106 cells responded differently to TLR simulation with respect to chemokine production, which was considerably lower after stimulation with type 1 TLR ligands (CpG and R-848), compared with type 2 TLR ligands (peptidoglycan [PGN] and flagellin), and was still biased towards type 2 chemokines CCL17 and CCL22. Additionally, XS106 cells up-regulated membrane marker expression after treatment with PGN and flagellin, but not CpG or R-848. However, all of the TLR ligands investigated stimulated the *in vivo* migration of LC.

Conclusions: These data suggest that keratinocytes and LC in the epidermis have preferential roles in promoting type 1 and type 2

immune responses, respectively. Therefore, the migration of LC *in vivo* after encounter with CpG or R-848 may be secondary to interaction of the TLR ligands with keratinocytes.

P0265

Linkage-specific loss of sialic acid from the aged erythrocyte as a signal for tolerogenic immune clearance

H. Cao,* W. Pickford,* L. Cairns,* P. R. Crocker,† M. Vickers* & R. N. Barker*

**Division of Applied Medicine, University of Aberdeen Institute of Medical Sciences, Aberdeen, UK, †Division of Cell Signalling and Immunology, University of Dundee, Dundee, UK*

Purpose/Objective: The typical lifespan of the human erythrocyte is 120 days. Erythrocytes are produced, and when aged, cleared at a very high rate of 2.4 million cells per second.Despite this rapid rate of uptake mediated by macrophages, the process of removal of aged erythrocytes is immunologically silent.We set out to investigate the link between how age-related changes to surface markers on the erythrocyte contribute to efficient recognition and tolerogenic clearance by phagocytes.

Materials and methods: Since erythrocytes increase in density as they age, we used a Percoll based gradients to isolate fractions of circulating erythrocytes from healthy human donors.The most dense fraction contained0.5% of all erythrocytes, which we estimate corresponds to ages between 119~120 days.

Results: Employing binding assays using a panel of lectins, including MAL-II and SNA, we show that α2, 3-linked sialic acids are well maintained during the aging process of erythrocytes while α2, 6-linked sialic acids are selectively lost in the last days of life.In contrast to natural aging, we saw complete loss of all sialic acids when aged erythrocytes were damaged, for example by osmotic shock, suggesting that this might provide a different, more immunogenic signal to phagocytes.

Conclusions: This linkage selective loss of sialic acids implies erythrocytes are subjected to specific enzymatic activity at the end of the aging process and this could contribute to their recognition by macrophages and dendritic cells, as well as the tolerogenicity of the uptake process.Loss of α2, 6-linked sialic acids would be predicted to reveal the underlying galactose sugar residue on surface glycans.This exposure can trigger phagocytosis through galactose binding receptors onmacrophages and dendritic cells, such as Galectin-1, Galectin-3 and MGL. Conversely, selective maintenance of α2, 3-linked sialic acids on erythrocytes can potentially engage inhibitory receptors on phagocytes such as members of the siglec family, siglec-5, CD33, siglec-11, which can all down-regulate phagocyte activation and thereby contribute to tolerogenicity of the uptake process.

These results lead us to hypothesise that a selective loss of α2, 6-linked sialic acids contributes to an important set of signals on aged erythrocytes that allow physiological recognition and tolerogenic uptake by phagocytes.

P0266

LPS stimulation inhibits viral infection of human macrophages with two distinct mechanisms

M. Vissers,* K. Short,† P. W. M. Hermans,* D. Diavatopoulos* & G. Ferwerda*

**Laboratory of Pediatric Infectious Diseases, Nijmegen Institute for Infection Inflammation and Immunity, Nijmegen, The Netherlands, †Department of Microbiology and Immunology, The University of Melbourne, Melbourne, Vic., Australia*

Purpose/Objective: It is well known that respiratory viral infections enable commensal bacteria in the nasopharynx to disseminate to other sites in the body and cause disease. However, this is not a uni-directional interaction and the presence of specific bacterial species in the nasopharynx may also affect viral pathogenesis. At present, it remains unclear if bacteria are able to exacerbate viral infections or if bacteria possibly serve to limit viral infections. We use influenza A virus (IAV) and respiratory syncytial virus (RSV) to examine how bacterial ligands in the nasopharynx can affect the pathogenesis of subsequent viral infections.

Materials and methods: Human monocyte derived macrophages were cultured from buffy coats and stimulated with bacterial ligands after which they were infected with GFP-IAV and GFP-RSV. Flow cytometry was used to determine percentage infection and phenotyping of the macrophages.

Results: Human epithelial cells (A549) stimulated by a panel of different bacterial ligands did not display any significant alteration in susceptibility to RSV or IAV. However, pre-stimulation of human monocyte derived macrophages with lipopolysaccharide (LPS) reduced the infection rate of both RSV and IAV with 80%. In contrast, bacterial ligands derived from Gram positive bacteria [lipoteichoic acid (LTA) and muramyl dipeptide (MDP)] did not inhibit viral infection. The protective effect was not due to pro-inflammatory cytokines or apoptosis of the macrophages. LPS protects against viral infection in two distinct mechanisms. It inhibited the entry of RSV early in the infection, whereas, in contrast, it triggered a long-term, non-specific, type I IFN response to prevent IAV infection.

Conclusions: Taken together, these data demonstrate the bi-directional nature of viral-bacterial interactions, and that the composition of an individual's nasopharyngeal flora may help determine their susceptibility to viral infections.

P0268

Maturation of distinct DC subsets is characterized by a profound and convergent genetic reprogramming

Y. Alexandre, T. P. Vu Manh, T. Baranek, K. Crozat & M. Dalod

CIML, Dalod Team, Marseille, France

Purpose/Objective: Dendritic cells (DC) express many innate immune recognition receptors able to sense a variety of microbial, danger or cytokine signals. The integration of these signals drives DC maturation and functional polarization during infection or tumorigenesis. Maturation is often assessed through the measurement of a few parameters, e.g. redistribution of MHC class II molecules from endosomes to plasma membrane, up-regulation of co-stimulation molecules and production of pro-inflammatory cytokines. Yet, DC maturation is much more complex and has been proposed to fundamentally differ between plasmacytoid DC (pDC) and conventional DC (cDC). To gain novel insights into this biological process, the gene expression reprogramming occurring in DC subsets upon activation was examined.

Materials and methods: Spleen DC subsets were isolated from untreated or murine cytomegalovirus (MCMV)-infected mice. Their gene expression was examined using microarrays. Gene chips data for other conditions of DC activation were generated in-house or retrieved from public repositories. Bioinformatics meta-analyses were performed. The expression pattern of selected genes was confirmed using custom-designed PCR-Arrays.

Results: In hierarchical clustering analysis, the 3 spleen DC subsets isolated from infected mice regrouped together, apart from their quiescent counterparts. This reflected that MCMV infection induced profound and convergent changes in the gene expression programs of all DC subsets *in vivo*. Indeed, while activated DC kept the transcriptional signature characteristic of their subset, they commonly induced and repressed several hundred of genes. Many genes followed the same pattern of regulation, whether the stimuli used were viruses or purified ligands for different Toll-like receptors, whether DC were

isolated *ex vivo* or derived *in vitro*, and whether the species studied were mouse or human.

Conclusions: This study allowed the identification of a core gene expression program associated with DC maturation irrespective of subsets, stimuli and species. DC maturation was associated with a remodeling of the gene expression program as profound and complex in cDC or monocyte-derived DC than in pDC. Maturation did not involve a true cell-fate conversion in any case since each activated DC subset kept a transcriptional blueprint of its specific ontogeny.

P0269

Mechanism of glucocorticoids action on monocytes during inflammation: reprogramming towards anti-inflammatory phenotype

K. Barczyk,* Y. Kusche,* J. M. Ehrchen† & J. Roth*

**Institute of Immunology, University Hospital of Muenster, Muenster, Germany, †Department of Dermatology, University Hospital of Muenster, Muenster, Germany*

Purpose/Objective: We have previously demonstrated that the treatment of monocytes with GC does not suppress monocyte functions, but rather induces specific differentiation of cells with anti-inflammatory phenotype. Nevertheless the mechanism of GC action on monocytes during inflammation is currently not well defined. The aim of our studies was to investigate the effects of GC on pro-inflammatory monocytes.

Materials and methods: GC-, LPS- and GC-LPS-induced gene expression patterns in monocytes were analysed by microarray technology. The results were confirmed by quantitative RT-PCR. Protein expression and activation was analysed by Western Blot and Flow Cytometry. Monocyte functions essential for innate immunity migration, chemotaxis, phagocytosis, killing, oxidative burst were assessed.

Results: As expected, treatment of LPS-stimulated monocytes with GC resulted in inhibited expression of many of pro-inflammatory factors. Nevertheless, many of them have not been described to be regulated by GC in monocytes or any other cell type so far. Surprisingly, we have found that GC-LPS treatment of monocytes additionally led to synergistical up-regulation of many genes, which were not induced by GC or LPS alone. Moreover, we also observed additive effects of GC and LPS on expression of many anti-inflammatory genes which was much more pronounced compared to monocytes stimulated with GC alone. Analysis of the specific function of monocytes has shown that GC-LPS treatment inhibited specifically monocyte adherence, but enhanced spontaneous migration, chemotaxis, phagocytosis and killing of pathogens, and engulfment of apoptotic cells as well as the ability to produce anti-inflammatory lipid mediators.

Conclusions: Our results demonstrate that GC do not simply suppress LPS-mediated activation of monocytes, but rather induce their reprogramming toward a specific anti-inflammatory phenotype involved in resolution of inflammation.

P0271

Monocyte-derived tumour necrosis factor stimulated gene-6 (TSG-6) alters bone mass via effects on osteoblasts and osteoclasts

S. Afrough,* D. Mahoney,† A. Sabokbar† & N. Horwood*

**Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, Kennedy Institute, Oxford, UK, †Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, Botnar Research Centre, Oxford, UK*

Purpose/Objective: Osteoporosis and rheumatoid arthritis (RA) are associated with a disregulation of homeostatic bone turnover leading to bone loss and an increased risk of fracture. As inflammatory bone disease is costly to treat, and osteoporosis an increasing problem in an ageing population, there is an increasing need to develop anabolics for the promotion of localised bone formation.

Materials and methods: Skeletal health is likely dependent on the interaction of mesenchymal stem cells (MSCs) with those of the immune system. Using alkaline phosphatase levels and bone nodule formation assays, we have recently demonstrated that cell-cell interactions between monocytes and MSCs is necessary to drive the latter to differentiate into bone forming osteoblasts. To gain an insight into these monocyte-derived osteogenic factors, illumina whole genome microarray analysis was carried out after cellular contact. Of these, Tumour necrosis factor Stimulated Gene-6 (TSG-6) mRNA was found to be significantly up-regulated.

Results: TSG-6 is an ~ 30 KDa protein expressed in bone marrow under healthy physiological conditions, but has been found to accumulate in the synovial fluid of patients with inflammatory diseases such as RA. TSG-6 has been shown to have potent inhibitory effects on RANKL-mediated osteoclastogenesis, as well as BMP2-dependent alkaline phosphatase deposition, suggesting it is a bone homeostasis protein protecting against bone erosion and excess mineralisation respectively. These *in vitro* studies are unlikely to wholly reflect the role of this protein in the MSC niche, which is a source of many of the cellular precursors of bone remodelling and in which the interaction of all cell types with a protein determines its' function.

Conclusions: To further investigate the role of TSG-6 in bone homeostasis we are investigating i) the bone histomorphometry of WT and TSG-$6^{-/-}$ mice during ageing, ii) the effect of TSG-6 in *ex vivo* cultures and iii) the effect of inhibitors of known ligands of TSG-6 on *in vitro* assays.

P0272

Monocytes promote osteogenic differentiation of mesenchymal stem cells via PGE2 and Oncostatin M

V. Nicolaidou,* S. Afrough,* M. Wong,* A. N. Redpath,* A. Ersek,* D. F. Baban,† L. Williams,‡ A. Cope§ & N. Horwood*

**Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, Kennedy Institute of Rheumatology, Oxford, UK, †Nuffield Department of Clinical Medicine, The Wellcome Trust Centre for Human Genetics, Oxford, UK, ‡Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, Kennedy Institute, Oxford, UK, §Academic Department of Rheumatology, Centre for Molecular and Cellular Biology of Inflammation Division of Immunology, London, UK*

Purpose/Objective: Bone loss is a characteristic of chronic inflammatory and degenerative diseases such as rheumatoid arthritis and osteoporosis. A major challenge is how to replace bone once it is lost leading to the need for novel bone anabolic agents. The immune system regulates bone as demonstrated by the differentiation and activity of osteoclasts by immune cells and cytokines. However, less is known about the regulation of osteoblasts (OB).

Materials and methods: Mesenchymal stem cells (MSC) are multipotent progenitors that can be induced in culture to form OBs. Alkaline phosphatase (ALP) expression was assessed at 7 days and bone nodule formation at 28 days from MSC cultured in the normal and osteogenic media, in the presence or absence of human peripheral blood mononuclear cells.Cytokine levels were measured by ELISA and Luminex, microarray analysis used Illumina whole human genome chips.

Results: Monocytes/Mϕs potently induced MSC differentiation to OBs evidenced by increased ALP and mineralisation. The monocyte-mediated osteogenic effect was mediated by cell contact as well as monocyte-derived soluble factors.This was not due to BMPs or TGFβ production or cytokines such as IL-6, TNF and IL-10 that were found to be up-regulated following monocyte:MSC contact. Monocyte:MSC co-cultures also resulted in the up-regulation of PGE_2 whilst inhibition

of PGE_2 production by COX2 inhibitor NS-398 resulted in the abrogation of monocyte-induced osteogenesis. However, PGE_2 failed to directly induce osteogenic differentiation in MSC cultures indicating that it acts indirectly to induce the production of other factors by monocytes. Gene profiling microarray of monocytes identified Oncostatin M (OSM) as a mediator of monocyte-induced osteogenesis. The activation of STAT3 signalling by OSM in MSCs enhanced osteogenic differentiation; similar results were obtained using STAT3 constitutively active adenoviral overexpression.
Conclusions: This study establishes a role for monocyte/Mϕs as critical regulators of osteogenic differentiation via OSM production and the induction of STAT3 signalling in MSC. OSM, and other factors, induced by the contact between monocytes and MSC may be valuable new anabolic factors for use in osteoporosis and in localised bone remodelling during fracture and arthritis.

P0273

Mononuclear phagocytes produce VEGF that promotes neovascularization in laser-induced choroidal neovascularization

T. A. Urzynicok,* A. F. Alex,† D. R. Engel,* C. Kurts* & N. Eter†
**Institutes of Molecular Medicine and Experimental Immunology, University Clinic of Bonn, Bonn, Germany, †Department of Ophthalmology, University of Münster, Münster, Germany*

Purpose/Objective: Age-related macular degeneration (AMD) is the most prevalent cause of blindness in the elderly, and its exudative subtype critically depends on local production of vascular endothelial growth factor (VEGF). In tumour models, mononuclear phagocytes (MPh) produce VEGF. MPh including dendritic cells, macrophages and microglia cells, express CX3CR1. MPh precursors, such as monocytes, can be recruited to sites of inflammation by CCR2. Here we studied VEGF production by MPh in a laser-induced murine model of choroidal neovascularisation (CNV) that mimics CNV in exudative AMD, and the impact of CCR2 on such production.
Materials and methods: CCR2-competent and -deficient CX3CR1-reporter mice expressing GFP in Mph were used to visualize these cells by 3 fluorescence-based techniques. CNV was induced by rupturing Bruch«s membrane beneath the retina by laser. 3 and 6 days later, eyes were enucleated and single cells from retina and choroid were stained for cellular subsets and for intracellular VEGF-production by flow cytometry. Neovascular areas were measured in choroidal and retinal flatmounts by isolectin staining. Scanning-Laser-Ophthalmoscopy (SLO) was used to reveal Mph in living animals.
Results: VEGF-positive phagocytes increased 3 days post laser, with microglia being dominant in the retina (twofold) and macrophages in the choroid (>25-fold). On day 6, VEGF-expressing microglia numbers remained increased, whereas macrophages had already declined. This temporary increase in macrophage numbers was abrogated in the absence of CCR2, whereas microglia was CCR2-independent. Consistent with flow-cytometry, microscopy and *in vivo SLO* revealed that Mph accumulated in CNV areas. This area was reduced in CCR2-deficient mice on day 14, but not later.
Conclusions: We describe an intracellular staining method for VEGF-production, a non-invasive *in vivo* imaging method for MPh in the eye, and identify Mph as relevant producers of VEGF in CNV. Infiltrating CCR2-dependent Mph only temporarily increase CNV, arguing against CCR2 inhibition as a successful solitary strategy to prevent AMD.

P0274

Nanomolar extracellular ATP promotes TLR4 signaling in dendritic cells to induce Th1 polarization through type I interferon

T. Chen,* M. Yang,* X. Zhu,* C. Wang,* S. Tang,† Z. Yu,† L. Shi‡ & X. Cao*
**National Key Laboratory of Medical Immunology & Institute of Immunology, Second Military Medical University, Shanghai, China, †Institute of Immunology, Zhejiang University School of Medicine, Hangzhou, China, ‡Department of Immunology, Hangzhou Normal University, Hangzhou, China*

Purpose/Objective: Dendritic cells (DC) can recognize both exogenous pathogen-associated molecules and endogenous dander signals. However, whether these stimuli can cooperate in functional regulation of DC has not been extensively investigated.
Materials and methods: Bone marrow-derived DC were treated with LPS (1 ng/ml) or recombinant HSP70 (1 μg/ml) in combination with different concentrations of extracellular ATP (1, 100, 100 and 1 mM). Then cytokine levels and DC phenotype were examined by ELISA and FACS, respectively. The activation of signaling pathways (MAPK, NF-κB and IRF3) were examined by either ELISA or Western blot. Finally, the effects of the *in vitro* induced DC on T cell proliferation and polarization were examined.
Results: We find that nanomolar extracellular ATP, released under nonfatal heat-stressed conditions, can synergize with Toll-like receptor (TLR)4 agonists, lipopolysaccharide (LPS) and heat shock protein (HSP)70, in promoting maturation and Th1-polarizing functions of DC. We demonstrate that nanomolar ATP promotes TLR4-triggered maturation of mouse bone marrow-derived DC and human monocyte-derived DC for Th1 response, in contrast to micromolar ATP-induced Th2-polarizing function of DC. In the presence of nanomolar ATP, TLR4-triggered interleukin (IL)-12p70 and type I interferon production as well as TRIF-dependent TBK1-IRF3 activation of DC are enhanced. In DC derived from $TLR4^{-/-}$, $IRF3^{-/-}$ or $IFNAR^{-/-}$ but not $MyD88^{-/-}$ mice, ATP fails to promote TLR4-induced type I interferon production, and subsequently IL-12p70 production or Th1-polarizing functions of DC. Additionally, we find that ATP-induced enhancement of TLR4 signaling relies on purinergic 2 (P2)Y receptor (P2YR)-mediated activation of phospholipase C-novel protein kinase C-Src tyrosine kinase signaling pathway.
Conclusions: Our study suggests that nanomolar extracellular ATP can cooperate with LPS or HSP70 in modulating DC functions for Th1 polarization potentially through TLR4-triggered type I interferon production. Our study thus possibly provides an explanation for efficient clearance of pathogens and induction of Th1 immune response under non-fatal infectious or injury conditions.

NK-DC interaction is controlled by an activin A-dependent negative feedback pathway

P. Seeger,* D. Bosisio,* S. Parolini,* R. Badolato,† A. Santoni‡ & S. Sozzani*
**Dipartimento di Scienze Biomediche e Biotecnologie, Università degli Studi di Brescia, Brescia, Italy, †Dipartimento di Materno Infantile e Tecnologie Biomediche, Università degli Studi di Brescia, Brescia, Italy, ‡Dipartimento di Medicina Sperimentale, Università di Roma 'La Sapienza', Roma, Italy*

Purpose/Objective: Crosstalk of natural killer (NK) cells with dendritic cells (DC) leads to reciprocal activation. Although some of the mechanisms involved in this interaction have been described, the characterization of the molecules involved deserves further attention.
Materials and methods: A PCR array-based gene expression screen, focused on common cytokines, was performed on human monocyte-derived DC cocultured with allogenic NK cells, pre-activated with IL-

15. The array led to the identification of activin A in NK-DC co-cultures. In order to determine the functional role of endogenously produced activin A during NK-DC interaction we analyzed DC maturation (CD83 and CD86 expression) and the release of cytokines (i.e. IL-1β, IL-6, IL-8, IFN-γ, TNF-α and GM-CSF) using follistatin, a natural inhibitory protein of activin A.
Results: Among a set of 84 cytokines investigated, activin A is the second highest induced cytokine in NK-DC co-cultures, with IL-8 being the most upregulated gene. Activin A is a member of the TGF-b superfamily that was previously shown to possess both pro- and anti-inflammatory activities and to control certain DC and NK cell functions. In NK-DC co-culture experiments, the induction of activin A required cell contact and was dependent on the presence of pro-inflammatory cytokines (i.e. IL-1β, IFN-γ, TNF-α and GM-CSF) and cell death. Conversely, the expression of activin A was negatively controlled by HLA-specific inhibitory receptors. In co-culture experiments, inhibition of acitivn A by follistatin resulted in the upregulation of pro-inflammatory cytokine release (i.e. IL-6, IL-8, TNF-α) and in the increased NK cell-induced DC maturation, as evaluated by CD83 and CD86 expression.
Conclusions: In conclusion, our study suggests that the production of activin A during NK-DC interaction represents a relevant negative feedback mechanism to prevent excessive immune activation.

P0276
NR4A1 mediates anti-inflammatory effects of apoptotic cells

N. Ipseiz, S. Uderhardt, C. Scholtysek, G. Schett & G. Krönke
Friedrich-Alexander-University Erlangen-Nuremberg, Med 3, Erlangen, Germany

Purpose/Objective: The nuclear receptor NR4A1 has been implicated as negative feedback regulator of NF kappa B signalling and as key regulator during the differentiation of Ly6C-low resident monocytes. Apoptotic cells are known to exert anti-inflammatory effects on macrophages but the underlying mechanisms are still poorly understood. Here we studied a potential role of NR4A1 as mediator of the macrophage response to apoptotic cells.
Materials and methods: We analysed the effect of apoptotic thymocytes on wild type and NR4A1$^{-/-}$ peritoneal resident macrophages, and determined the consequences on intracellular signalling, gene expression and cytokine profile. Moreover, we examined the consequences of the lack of NR4A1 during maintenance of self tolerance by using the pristine-induced model of murine sytemic lupus erythematosus.
Results: Expression of NR4A1 was rapidly and highly induced in resident macrophages after incubation with apoptotic thymocytes. NR4A1$^{-/-}$ resident macrophages showed an exacerbated pro-inflammatory profile as well as an increased activity of NF-κB. Moreover, the anti-inflammatory effects of apoptotic cells were reduced in NR4A1$^{-/-}$ macrophages. In the pristine model of murine lupus, NR4A1$^{-/-}$ mice displayed increased levels of autoantibodies such as ds-DNA antibodies.
Conclusions: Tacking together, this data show for the first time that NR4A1 is an important mediator of the anti-inflammatory effects of apoptotic cells in tissue resident macrophages and thereby contributes to the maintenance of self-tolerance.

P0277
Osteoactivin is produced by tumor-conditioned monocytes/macrophages

M. Liguori, C. Belgiovine, N. Polentarutti, G. Solinas, A. Mantovani & P. Allavena
Istituto Clinico Humanitas, Cell immunology and Inflammation, Milano, Italy

Purpose/Objective: Tumor-associated macrophages (TAM) are key orchestrators of the tumor microenvironment directly affecting neoplastic cell growth, neoangiogenesis, and extracellular matrix remodeling. In a gene profiling analysis of human monocytes co-cultured with M-CSF-expressing tumor cells, we identified a number of up-regulated genes. One of the most expressed gene was Human Glycoprotein non-metastatic melanomal protein B (GPNMB) also called Osteoactivin or Mouse Dendritic cell-associated Heparan Sulfate Proteoglycan-Integrin Ligand (DC-HIL). Osteoactivin is a transmembrane molecule with diverse biological functions spanning from cell adhesion and migration, to immune-suppression and tissue repair. This study investigates the modulation of Osteoactivin and its functional role inmonocytes/macrophages and TAM.
Materials and methods: Monocytes and macrophages were tested for expression and modulation of Osteoactivin after treatment with different stimuli in RT-PCR, flow cytometry and ELISA. *In vivo* mouse models of tissue injury and tumor growth in mice bearing a spontaneous mutation of Osteoactivin (DBA2J strain).
Results: In macrophage/tumor cell co-cultures the protein Osteoactivin was mainly produced by macrophages and not by tumor cells. Among the different stimuli tested, the strongest up-regulation was observed with M-CSF, Corticosteroids and TGFb. In contrast GM-CSF, IL-1 or TNF were poor stimulators. Osteoactivin expression by *in vitro* polarized macrophages was higher in IL-4-stimulated M2 macrophages and further increased in hypoxic conditions. Prolonged *in vitro* culture of monocytes/macrophages induced cleavage of Osteoactivin from cell membranes (not before 4 days). Osteoactivin had no effect on myeloid cell differentiation or tumor cell proliferation, but did enhance monocyte adhesion via its integrin binding domain. MutantOsteoactivin mice (*DBA/2J*) andmice reconstituted with the wild type gene (*DBA/2J-Gpnmb*$^{+}$) are currently being studied in mouse tumor and tissue injury models.
Conclusions: Osteoactivin is an interesting moleculeproduced by tumor-conditioned and M2-polarizedmacrophages and modulated by M-CSF, corticosteroids and hypoxia. Its role in the injured tissues or tumor-micro-environment is as yet not clarified.

P0278
Paired immunoglobulin-like receptor B (PIR-B) negatively regulates pulmonary fibrosis by suppressing IL-4-induced macrophage activation

D. Karo-Atar,* I. Moskovitz,* O. Eickelberg,† M. Konigshoff† & A. Munitz*
**Human Microbiology and Clinical Immunology, Tel-Aviv University, Tel-Aviv, Israel, †Comprehensive Pneumology Center, Institute of Lung Biology and Disease Helmholtz Zentrum, Munich, Germany*

Purpose/Objective: Macrophages are pleotropic cells, which possess fundamental roles in innate and adaptive immunity. Recent data highlight that a central IL-4: macrophage axis exists in fibrotic settings since IL-4-activated macrophages (i.e. M2 macrophages) express numerous pro-fibrogenic mediators and can promote tissue repair and remodeling. Paired immunoglobulin-like receptor B (PIR-B) is a prototype inhibitory receptor capable to counter-regulate macrophage activation. However, the expression and function of PIR-B in the regulation of M2 macrophage responses and pulmonary fibrosis is unknown.

Materials and methods: Wild type (WT) and *Pirb*$^{-/-}$ mice were intratrachealy-challenged with bleomycin (BLM) or recombinant IL-4. PIR-B expression in the lungs of WT mice was assessed (qPCR, flow cytometry). Bronchoalveolar lavage following BLM or IL-4 administration was assessed for differential cell counts as well as cytokine and chemokine expression (ELISA). Bone marrow (BM)-derived WT and *Pirb*$^{-/-}$ macrophages were stimulated with IL-4 and assessed for various M2-associated molecules.
Results: PIR-B was upregulated in several lung myeloid cell subsets (CD45^{+} /CD11c^{high}/Gr-1^{high} and CD45 /CD11c^{high}/Gr-1^{int}) following BLM administration. BLM-treated *Pirb*$^{-/-}$ mice evidenced significantly increased lung fibrosis in comparison with BLM-treated WT mice (e.g. increased lung histopathology, collagen content and α-smooth muscle actin expression). Increased disease severity was accompanied with increased lung levels of resistin-like molecule α (Relm-α), matrix metalloproteinase 12 (MMP-12), tissue inhibitor of metalloproteinase 1 (TIMP1) and osteopontin (OPN). Notably, flow cytometric analysis revealed increased Relm-α^{+} and MMP-12^{+} alveolar macrophages in BLM-treated *Pirb*$^{-/-}$- mice. Consistently, administration of IL-4 to WT and *Pirb*$^{-/-}$ mice resulted in increased total lung Relm-α expression and Relm-α^{+}/MMP-12^{+} alveolar macrophages in *Pirb*$^{-/-}$ mice. Furthermore, IL-4-activated BM-derived *Pirb*$^{-/-}$ macrophages displayed increased Relm-α, MMP12 and TIMP-1 induction in comparison with wild type cells. Finally, PIR-B human orthologues (e.g. ILT-5/CD85a) were readily detected in lung biopsies obtained from idiopathic pulmonary fibrosis patients (IPF).
Conclusions: Our results establish a key role for PIR-B in pulmonary fibrosis by negatively regulating IL-4-induced macrophage activation and suggest a possible role for PIR-B human orthologues in IPF.

P0279
PHD inhibition induces M2 macrophage polarisation and has differential effects on lung fibrosis

A. Alzber,* S. Moncur,* J. Stewart,* M. K. Whyte,† S. R. Walmsley,† S. E. M. Howie* & N. Hirani*
**MRC Centre for Inflammation Research, University of Edinburgh, Edinburgh, UK, †Academic Unit of Respiratory Medicine, University of Sheffield, Sheffield, UK*

Purpose/Objective: Pulmonary fibrosis is a common consequence of lung inflammation, leading to organ dysfunction and hypoxia. Prolyl hydroxylases (PHDs) are the main oxygen sensors and regulators of hypoxia inducible factors (HIFs) in cells and thus key enzymes involved in hypoxic signalling. Several studies have shown that manipulation of hypoxic or HIF signalling in tissues and specifically macrophages can promote tissue healing. However, macrophages are also recognised to contribute to fibrosis.
Materials and methods: We aimed to investigate the effect of PHD inhibition in bleomycin induced murine lung injury and its effect on macrophage polarisation. We hypothesised that PHD inhibition may induce alternatively activated (M2) macrophages that may have pro-resolution or pro-fibrotic potential dependent upon their temporal expression. For this purpose, we used the bleomycin model which exhibits two phases, an early inflammatory phase followed by a late fibrotic phase.
Results: Pharmacological PHD inhibition was achieved using DMOG and FG0041. DMOG was administered in both the early and the late phase of the bleomycin model. End points included lung collagen content and measures of lung inflammation. Administration of DMOG during the early, inflammatory phase of the model significantly reduced lung fibrosis. In contrast, late phase administration enhanced lung fibrosis. DMOG given in the early phase does not reduce lung inflammation or inhibit collagen synthesis, but there was evidence of enhanced M2 macrophage polarisation. *In vitro*, both DMOG and FG0041 enhanced M2 macrophage activation. Genetic manipulation using LysM/Cre HIF2A KO mice showed that M2 macrophage enhancement by PHD inhibition is HIF2A independent.
Conclusions: We have demonstrated that PHD inhibition induces M2 macrophage activation independent of HIF2A. This may be a potential therapeutic strategy in lung fibrosis.

P0280
Phenotype and localization of a novel subpopulation of IFNß producing plasmacytoid dendritic cells *in vivo*

R. Dress, J. Bauer, P. Dresing & S. Scheu
Institute for Medical Microbiology and Hospital Hygiene, Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany

Purpose/Objective: During the initial response to viral infections type I interferons (IFN) are crucial mediators of subsequent protective immune mechanisms. It is well established that plasmacytoid dendritic cells (pDCs) are potent producers of type I IFN. Recently we could show that IFNβ is produced mainly by pDCs after TLR9 stimulation with CpG *in vivo* using an IFNβ/YFP reporter-knockin mouse model (IFN$\beta^{mob/mob}$). These IFNβ producing pDCs are located in the spleen within the T cell zone of the white pulp, whereas according to published data pDCs are located within the marginal zone. We suggest that these pDCs define a unique subpopulation and due to the increasing variety of pDC surface-markers we performed a comprehensive study on phenotype and localization of these up to now ill-defined IFN producing pDCs.
Materials and methods: C57BL/6, IFN$\beta^{mob/mob}$, IFNAR$^{-/-}$ or IFNAR$^{-/-}$xIFN$\beta^{mob/mob}$ mice were i.v. injected with CpG 1668 complexed to DOTAP or left untreated and organs were harvested after 6 h. For FACS analysis cells were stained for CD3ε, CD19, CD11c, mPDCA-1, B220, SiglecH, CCR9 and CD9. For histology spleen sections were fixed with acetone or paraformaldehyde followed by a staining for B220, CD11c, mPDCA-1, SiglecH or YFP and visualized by fluorescence microscopy.
Results: Our FACS data indicate that only a minor fraction of pDCs that are CD11c^{int}B220^{+} mPDCA-1^{+} SiglecH^{+}CCR9^{+} CD9^{-} produce IFNβ early (6 h) after TLR9 stimulation. Extending our previous histological findings YFP/IFNβ^{+} cells are co-positive for pDC markers and can be found at the interface of the T and B cell areas of the spleen whereas staining with different pDC markers like mPDCA-1 or SiglecH shows the vast majority of pDCs in the areas around the marginal zone.
Conclusions: Thus we assume that IFNβ producing cells constitute a unique subpopulation within the classical CCR9^{+} B220^{+} pDCs. IFNβ producing pDCs show a unique localization within the spleen *in vivo*. This is complemented by a microarray based transcriptome analysis where we found more than 1500 genes differentially expressed between IFNβ-producing and non-producing pDCs after TLR9 stimulation. Further analyses of this pDC subpopulation at additional time points after stimulation and the impact of the IFN type I receptor mediated feedback loop are currently under way.

P0282
Porphyromonas gingivalis LPS induces cytokine secretion in macrophages without costimulatory marker expression

J. Holden, N. M. O'Brien-Simpson & E. C. Reynolds
Melbourne Dental School, The University of Melbourne Oral Health CRC, Melbourne, Vic., Australia

Purpose/Objective: Ligation of Toll-like receptors (TLRs) on macrophages by bacterial pathogen-associated molecular patterns (PAMPs) such as lipopolysaccharide (LPS) leads to macrophage maturation, pathogen phagocytosis, antigen presentation and recruitment of immune effector cells. Macrophages primed with interferon gamma (IFN-γ) and exposed to PAMPs mature into classically acti-

vated macrophages (M1 macrophages). M1 macrophages synthesise high levels of microbicidal compounds and costimulatory molecules and are involved in pathogen clearance. *Porphyromonas gingivalis* is a key pathogen associated with chronic periodontitis. Mono-phosphorylated tetra-acylated or penta-acylated LPS from *P. gingivalis* has been shown to induce variable immune responses in mammalian cells when compared to other gram negative pathogens. However the effect of priming macrophages with cytokines prior to TLR ligation has yet to be investigated.

Objective: To investigate the effect of *P. gingivalis* LPS on the maturation and function of M1 macrophages.

Materials and methods: Mouse bone marrow-derived macrophages were primed with IFN-γ then exposed to *Escherichia coli* LPS, the synthetic lipoprotein PAM3Cys or *P. gingivalis* LPS. Macrophage maturation was then monitored by analysis of costimulatory markers and the production of nitric oxide and various inflammatory cytokines.

Results: Macrophage primed with IFN-γ and activated with 10 ng/ml of *E. coli* LPS or PAM3Cys resulted in a significant upregulation of costimulatory molecules and the production of nitric oxide and inflammatory cytokines, indicating classical activation. However activation of macrophages with *P. gingivalis* LPS did not, even at concentrations 100-fold higher. Despite the lack of costimulatory marker expression, M1 macrophages stimulated with 10 μg/ml *P. gingivalis* LPS produced significant levels of the cytokines TNF-α, IL-6, IL-1β and IL-12.

Conclusions: Our results demonstrated that M1 macrophages activated with *P. gingivalis* LPS were unable to fully differentiate into a classically activated macrophages, even at high concentrations of LPS. These results suggest that the impaired ability of macrophages to recruit cells of the adaptive immune system and kill bacteria may contribute to the inability to clear *P. gingivalis* during chronic periodontitis.

P0283
Presence of CCR7-independent transport of skin antigens from the dermis

M. Yoshino,* K. Okuyama,* A. Murata,* M. Tomura,† Y. Shimoda,* M. Hikosaka* & S. I. Hayashi*

**Division of Immunology School of Life Science, Tottori University Faculty of Medicine, Yonago, Japan, †Center for Innovation in Immunoregulative Technology and Therapeutics, Kyoto University Graduate School of Medicine, Kyoto, Japan*

Purpose/Objective: The transport of peripheral self-antigens (self-Ags) to regional lymph nodes (LNs) is thought to play a critical role in the maintenance of peripheral tolerance. Dendritic cells (DCs) play a major role in the capture and transport self-Ags. It has been reported that a chemokine receptor CCR7 dominantly regulates the migration of skin DCs to regional LNs in a steady state. However, CCR7-knockout (*Ccr7*$^{-/-}$) mice do not show any skin autoimmune disorders. To determine whether the transport of skin self-Ags is actually impaired under CCR7-deficient conditions, we examined *Ccr7*$^{-/-}$ mice.

Materials and methods: The transport of skin self-Ags to regional LNs in *Ccr7*$^{-/-}$ mice was examined using epidermis- or dermis-hyperpigmented transgenic mice.

Results: While the transport of epidermal self-Ags was considerably disturbed in 7-week-old *Ccr7*$^{-/-}$ mice, the transport was clearly observed in 30-week-old *Ccr7*$^{-/-}$ mice. In these aged mice, the accumulation of epidermal self-Ags in the dermis was also observed. Next we investigated the transport of dermal self-Ags in 7-week-old *Ccr7*$^{-/-}$ mice, and found the transport of dermal self-Ags to regional LNs. Immunohistochemistry and cell sorting indicated the involvement of CD11c^{+} cells in this transport, while CD205^{+} cells, CD207^{+} cells and $\gamma\delta$ T cells might not significantly contribute to it.

Conclusions: Skin self-Ags were transported under CCR7-deficient conditions. This CCR7-independent system is present in the dermis, and DC-lineage cells other than CD207^{+} dermal DCs or CD205^{+} Langerhans cell-descendants should contribute to this transport. The dermal system might support the continuous transport of both epidermal and dermal self-Ags even under CCR7-deficient conditions.

P0284
Protective role of antioxidant systems in human monocytic cell lines during differentiation and stimulation with a TLR2 ligand

I. Sachrajda, M. Gorzkiewicz & L. Pulaski

Laboratory of Transcriptional Regulation, Institute of Medical Biology of PAS, Lodz, Poland

Purpose/Objective: Monocytes and macrophages recognize and kill pathogens during many processes resulting in production of a number of oxygen-containing compounds. The aim of this study was to investigate changes in antioxidant defense status of this cell lineage during differentiation and exposition to pathogen associated molecular patterns. THP-1 and Mono Mac 6 (MM6), human monocytic cell lines, can serve as an appropriate model to test susceptibility of undifferentiated and differentiated (macrophage like) cells to oxidative conditions.

Materials and methods: Cell lines were differentiated for 72 h: THP-1 with PMA, MM6 with Vitamin D3 and TGF-β. For TLR2 activation, cells were stimulated with Pam3CSK4. Gene expression levels were assessed by real time PCR. Activity of redox protective enzymes and glutathione content were measured biochemically. Susceptibility of cells to H_2O_2 was tested using a resazurin-based assay.

Results: Glutathione level was comparable in THP-1 and MM6 and this concentration increased in THP-1 as a result of differentiation. The basal level of antioxidant enzymatic activity in MM6 was higher than in THP-1, but in THP-1 most of it increased upon differentiation up to the level seen in MM6. Similar results were seen with expression level of genes encoding main antioxidant enzymes: in MM6, the basal level of expression of these genes was higher; differentiation and TLR2 stimulation caused gene activation apart from the thioredoxin system in MM6, which was not up-regulated.

Pretreatment of THP-1 with Pam3CSK4 as well as differentiation caused these cells to become more resistant to H_2O_2-mediated cell death. On the other hand, low susceptibility to H_2O_2 was characteristic for MM6 and this high resistance was not further modulated either upon Pam3CSK4 treatment or upon differentiation.

Conclusions: In summary, MM6 cells have a high level of crucial antioxidant enzymes conferring a strong resistance to H_2O_2 in the basal state and this resistance is largely unmodified upon differentiation or stimulation. THP-1 cells are more susceptible to oxidative stress, but TLR2 stimulation or differentiation both result in significant induction of redox protecting enzymes, especially thioredoxin reductase. Thus, THP-1 cells are probably well-suited for studies on the role of the thioredoxin system in oxidative stress response in macrophages.

P0285
Proteinase activated receptor-2 (PAR-2) modulation of human macrophage subset differentiation and effector function

A. Crilly,* R. Steven,* J. C. Lockhart,* W. R. Ferrell† & I. B. McInnes†

**Centre for Musculoskeletal Science, University of the West of Scotland, Glasgow, UK, †Institute of Infection Immunity and Inflammation, Glasgow University, Glasgow, UK*

Purpose/Objective: Proteinase activated receptor-2 (PAR-2) is a G protein coupled receptor expressed by a variety of cell types, including

macrophages. Activated by specific serine proteases, an emerging role for PAR-2 in immune regulation has been recognized. Despite advances in the understanding of PAR-2 biology, its role in human macrophage subset development and effector function remains relatively unexplored. The aim of this study was to elucidate the role of PAR-2 in GM-CSF and M-CSF derived macrophages.

Materials and methods: $CD14^+$ monocytes purified from human peripheral blood were cultured for 6 days with GM-CSF or M-CSF. Matured cells were activated with a PAR-2 activating peptide (SLIG) and regulation of PAR-2 expression assessed by FACS while TNFα and IL-10 levels were measured by ELISA.

In differentiation experiments, monocytes were matured with GM-CSF or M-CSF ± SLIG for 6 days followed by LPS stimulation for 48 h and supernatants collected for cytokine analysis.Cell area was measured using Zeiss Axiovision LE software to assess morphological changes.

Results: Both GM-CSF and M-CSF derived macrophages expressed PAR-2 which was up regulated by SLIG. GM-CSF cells activated with SLIG made significantly more TNFα than M-CSF cells [9740 ± 152 pg/ml versus 3487 ± 309 pg/ml, $P < 0.001$], and significantly less IL-10 [27 ± 3 pg/ml versus 769 ± 73 pg/ml, $P < 0.001$].

Macrophage subsets polarized in the presence of SLIG had an altered morphology, with a significant reduction in cell area ($P < 0.05$). GM-CSF cells matured with SLIG produced significantly less TNFα when LPS challenged compared to control cells (6043 ± 793 pg/ml versus 9230 ± 765 pg/ml, $P < 0.05$), with no significant change in IL-10. In contrast, M-CSF cells matured with SLIG produced significantly more TNFα compared to control cells (5730 ± 187 pg/ml versus 3390 ± 748 pg/ml, $P < 0.05$) with reduced IL-10 secretion (11 ± 3 pg/ml versus 2062 ± 472 pg/ml, $P < 0.01$).

Conclusions: PAR-2 activation in macrophage subsets up regulates PAR-2 expression and drives the release of signature cytokines. Activation of PAR-2 during macrophage differentiation appears to skew cell phenotype, as assessed by cytokine profiles. This may be relevant in macrophage driven disease where protease rich environments may influence macrophage effector function.

Regulatory activity of DC-10 IS stringently dependent on the levels of hla-g expression

G. Amodio,* K. Fleischhauer,† M. G. Roncarolo* & S. Gregori*
**Department of Regenerative Medicine Stem Cells and Gene Therapy, San Raffaele Telethon Institute for Gene Therapy, Milano, Italy,*
†Division of Regenerative Medicine and Stem Cell Therapy, Unit of Molecular and Functional Immunogenetics (UMFI), Milano, Italy

Purpose/Objective: DC-10 are a subset of human tolerogenic DC which efficiently prime T cells to become adaptive IL-10-producing type 1 regulatory (Tr1) cells. DC-10 secrete high levels of IL-10 and strongly express the tolerogenic molecules Immunoglobulin-Like-Transcript (ILT)4 and HLA-G, which are critically involved in the differentiation of Tr1 cells *in* vitro. Although all these three players, ILT4, HLA-G and IL-10 are important for DC-10 regulatory activity, it still remains to define their relative contribution in promoting tolerance *via* Tr1-cell induction. To dissect the role of HLA-G in tolerance associated with DC-10, we took the advantage that polymorphisms at 3' untraslated region (UTR) of the HLA-G gene locus might influence its expression.

Materials and methods: Healthy donors have been typed for polymorphisms at the 3' UTR of HLA-G locus and classified according to the presence of 14bp Insertion/Deletion (Ins/Del) and C/G in position$^+$3142 as following: DelC/DelC, InsG/InsG, DelG/X, and DelC/InsG. DC-10 were differentiated from 3'UTR HLA-G typed donors, by culturing $CD14^+$ monocytes in the presence of IL-4, GM-CSF and IL-10 for 7 days, and then were phenotypically and functionally characterized.

Results: Results demonstrated that DC-10 derived from DelC/DelC or DelG/X monocytes express significantly higher percentage of HLA-G as compared to DC-10 derived from InsG/InsG monocytes. DC-10 independently from 3'UTR polymorphisms poorly stimulate allogeneic T cells. Interestingly, DC-10 expressing high levels of HLA-G induced alloantigen-specific anergic T cells, whereas T cells stimulated with DC-10 expressing low levels of HLA-G display significant proliferation. This effect is independent from both ILT4 and IL-10, since DC-10 from different 3'UTR HLA-G typed donors expressed comparable levels of ILT4 and secrete similar amounts of IL-10.

Conclusions: In conclusion our findings demonstrate that the expression of HLA-G on DC-10 is critically required for promoting anergy in T cells and Tr1 cells. These results represent the first step forward to understand how DC-10 promote/restore tolerance *in vivo* and provide us with new tools for tailoring protocols for *in vitro* generation of antigen-specific Tr1 cells suitable for cell therapy *via* tolerogenic DC-10.

P0287

Role of UNC93B1, a chaperone molecule, in the MHC class I cross presentation pathway

S. Maschalidi,* P. Vargas,† F. Sepulveda,‡ J. Mintern,§ J. Villadangos,§ B. Ryffel,¶ A. M. Lennon-Duménil† & B. Manoury**
**INSERM U1013, Hôpital necker, Paris, France, †INSERM U932, Institut Curie, Paris, France, ‡INSERM U768, Hôpital Necker, Paris, France, §WEHI, Immunology, Melbourne, Australia, ¶UMR6218, University of Orléans, Orléans, France, **INSERM U1013, Hôpital Necker, Paris, France*

Purpose/Objective: Several studies have suggested that intracellular TLRs can be targeted directly from the endoplasmic reticulum (ER), where they reside, to endosomes in which they signal. Mouse and human genetics have identified UNC93B1, which encodes for a highly conserved 12-membrane spanning molecule residing in the ER, as a key regulator in the transport of intracellular TLRs (7, 8 and 9). The 3d mutation (UNC93B1 mutation) results in a phenotype where no signalling occurs via the intracellular TLRs 3, 7 and 9 and also diminishes presentation of exogenous antigen. However, the mechanism that lies beneath and the exact role that UNC93B1 displays on antigen presentation remain to be fully elucidated.

Materials and methods: All our experiments *in vitro* were performed in primary dendritic cells (GM-CSF derived and $CD8^+$ cDCs purified from the spleen). We used a panel of many different tecnics *in vitro* (siRNA, transfection, confocal microscopy, ELISA) and *in vivo* (i.v antigen injection and T cell proliferation using CFSE dilution).

Results: Firstly, we show that MHC I cross presentation of exogenous antigen is drastically impaired in UNC93B1-mutated $CD8^+$ and inflammatory dendritic cells *in vitro* as well as in UNC93B1 mutated mice (3d mice) *in vivo*. Phagosomes are the dedicated compartments for antigen cross presentation. Our data show that the fusion with late endosomal compartments during phagosomal maturation is increased in UNC93B1-mutated DCs suggesting that ER-phagosome interaction may be altered. Moreover, UNC93B1 mutation in dendritic cells remarkably reduced antigen degradation and export of processed antigens into the cytoplasm. Notably, UNC93B1 deficiency impairs endosomal/phagosomal acidification and decreases the proteolytic activity in phagosomes. Altogether, these data strongly suggest an 'abnormal' phagosomal environment in UNC93B1-mutated DCs leading to severely reduced MHC class I cross-presentation. Finally, immunoprecipitation and immunofluorescence assays reveal new binding partners for UNC93B1 that display a critical role on antigen presentation.

Conclusions: Our findings provide new insights into the mechanism employed by UNC93B1, a chaperone molecule, to hijack the MHC I cross presentation pathway.

P0289

SOCS3 promotes M1 macrophage activation and function through effects on nucler factor kappaB activity

H. Wilson, C. S. Whyte, C. E. Kluge & R. N. Barker
Division of Applied Medicine, University of Aberdeen Institute of Medical Sciences, Aberdeen, UK

Purpose/Objective: Macrophages respond to their microenvironment and develop polarised functions critical for orchestrating an appropriate inflammatory response. M1-activated macrophages eliminate pathogens, but can cause host tissue damage, while M2-activated macrophages promote regulation and repair. M1-macrophage activation is strongly associated with SOCS3 expression but the functional consequences of this, especially *in vivo*, are not clear. The aims were to determine the phenotype and function of SOCS3-expressing macrophages in immune-mediated glomerulonephritis, and address mechanisms by which SOCS3 controls macrophage pro-inflammatory potential.
Materials and methods: Triple immunohistochemistry determined the number of CD68 positive macrophages co-expressing SOCS proteins and the M1-activation marker iNOS in kidney sections of animals with experimental nephritis; severity of nephritis was assessed by albuminuria. SOCS3 was knocked down in bone marrow derived macrophages by specific siRNA and NFκB-p65 activity determined by EMSA based ELISA. Western blotting defined IκB-α degradation and PI3K activation.
Results: Macrophages infiltrating inflamed glomeruli show up-regulation of SOCS3 that co-localises with iNOS. The correlation between the number of SOCS3 (but not SOCS1) expressing glomerular macrophages and severity of nephritis was highly significant supporting their pro-inflammatory role in *vivo*. siRNA mediated knockdown of SOCS3 in macrophages adoptively transferred and conditioned in the inflamed peritoneum demonstrate its importance in driving production of pro-inflammatory mediators IL-6 and nitric oxide, and curtailing expression of anti-inflammatory IL-10 and SOCS1. The SOCS3 induced pro-inflammatory effects were due, at least in part, to its role in controlling NFκB nuclear activity. Surprisingly, SOCS3 also limits the activity of PI3K that is thought to regulate NFκB activation and using PI3K inhibitors we reveal that this may provide a novel mechanism by which SOCS3 controls macrophage pro-inflammatory properties.
Conclusions: These data demonstrate the importance of SOCS3 in directing and maintaining macrophage activation to a pro-inflammatory phenotype and emphasise that decreasing macrophage SOCS3 expression has potential as a therapeutic manoeuvre to limit autoimmune and inflammatory diseases.

P0290

Subsets of alternatively activated human macrophages show differential capacity to produce reactive oxygen species

M. D. Kraaij,* K. M. Koekkoek,* S. W. van der Kooij,* K. A. Gelderman† & C. van Kooten*
**Nephrology, Leiden University Medical Center, Leiden, The Netherlands, †Pathology, VU University Medical Center, Amsterdam, The Netherlands*

Purpose/Objective: We recently showed that ROS production by type 2 macrophages (Mph2) is involved in immunosuppressive properties and in the induction of regulatory T cells. Mph display a high plasticity depending on the cytokine milieu, and various Mph2 subsets with different functional characteristics have been described. In the current study we investigated ROS producing capacity of well defined human Mph subsets and studied the contribution of ROS in the APC-T cell interaction.
Materials and methods: Monocytes were differentiated into macrophages with M-CSF (Mph2), IL-4 (Mph2a), or IL-10 (Mph2c). The ROS producing capacity of these Mph was tested by flow cytometry using DHR123, and expression of the NADPH oxidase (NOX2) complex was analyzed at mRNA and protein level. T cell stimulatory capacity of the Mph was investigated by allogeneic MLR. The effect of DPI, an inhibitor of the NOX2 complex, was investigated both in MLR as well as directly on Mph regarding MHC and CD86 expression, and cytokine production.
Results: Upon PMA stimulation, Mph2 and Mph2c showed a high ROS producing capacity, whereas only low ROS production was observed in Mph2a. Mph2a expresses lower mRNA and protein levels of NOX2 protein $gp91^{phox}$ compared to Mph2 and Mph2c, whereas no differences were observed for $p47^{phox}$. Mph2 and Mph2c displayed a reduced T cell stimulatory capacity compared to Mph2a. However, we were not able to restore the T cell stimulatory capacity by the use of the NOX2 inhibitor DPI. In contrast, DPI even decreased the T cell proliferation in a MLR in concentrations that did not affect CD3/CD28-activated T cells. When tested directly on Mph2 subsets, levels of HLA-DR and CD86 levels were not affected by DPI. However, DPI specifically decreased the LPS-induced and CD40L-induced IL-10 and IL-12p40 production of all Mph2 subsets.
Conclusions: The ROS producing capacity is not the same for different anti-inflammatory Mph subsets; Mph2 and Mph2c have a higher ROS producing capacity compared to Mph2a, possibly related to a reduced $gp91^{phox}$ expression of the latter. The difference in T cell stimulatory capacity between Mph2 subsets is not directly linked with this differential ROS producing capacity. In contrast, DPI inhibited T cell stimulation and cytokine production by all Mph2 subsets, indicating a ROS-dependent mechanism of T cell activation.

P0291

Suppressors of cytokine signaling 2 and 3 diametrically control macrophage polarisation

S. Spence, A. Fitzsimons, C. R. Boyd, J. Kessler, D. Fitzgerald, J. Elliott, J. Gabhann, A. Kissenpfennig & J. Johnston, et al
Centre for Infection and Immunity, Queens University Belfast, Belfast, UK

Purpose/Objective: Suppressors of cytokine signalling (SOCS) are important regulators of LPS and cytokine responses but their role in the control and regulation macrophage polarisation is unknown.
Materials and methods: We investigated the role of SOCS proteins using *in vivo* knockout mouse models of endotoxic shock, polymicrobial sepsis (Caecal ligation and puncture) and adoptive transfer. *In vitro* and *ex.vivo* we underscored the mechanistic actions of these proteins using techniques such as Q-PCR, Chromatin Immunoprecipitation, ELISA, Western blot and Flow cytometry.
Results: Myeloid restricted SOCS3 deletion ($SOCS3^{LysMcre}$) resulted in profound resistance to endotoxic shock, whereas on the other hand $SOCS2^{-/-}$ mice were highly susceptible. We observed a striking bias towards M2-like macrophages in $SOCS3^{LysMcre}$ mice, whereas in $SOCS2^{-/-}$ the M1-like population was enriched. Through adoptive transfer experiments we show that these antipodal responses to endotoxic shock and to polymicrobial sepsis were both transferable and entirely macrophage-dependent. Critically this dichotomous response was associated with enhanced Treg recruitment by the $SOCS3^{-/-}$ cells, but in the presence of $SOCS2^{-/-}$ macrophages $Foxp3^{+}$ T cells were completely absent at the inflammatory site. The altered polarisation coincided with enhanced IFNg-induced STAT1 in $SOCS2^{-/-}$ macrophages and enhanced IL-4/IL-13 induced STAT6 phosphorylation in $SOCS3^{-/-}$ cells.

Conclusions: Therefore SOCS are essential controllers of macrophage polarisation and thereby regulate the inflammatory response.

P0292

Tetraspanin CD82 plays a vital role in antigen presentation and processing in dendritic cells, and influences migration in opposition to CD37

E. Jones,* J. Wee,* J. Nguyen,† J. V. Ramos,‡ P. K. Ho,* J. Villadangos,§ G. J. Hämmerling,¶ M. Hickey† & M. D. Wright*
**Immunology, Monash University, Melbourne, Vic., Australia, †Centre for Inflammatory Diseases, Monash University, Clayton, Vic., Australia, ‡Microbiology and Immunology, University of Melbourne, Melbourne, Vic., Australia, §Microbiology and Immunology, University of Melbourne, Melbourne, Vic., Australia, ¶Molecular Immunology, German Cancer Research Center, Heidelberg, Germany*

Purpose/Objective: Tetraspanins are a superfamily of membrane molecules which form microdomains to organise the cell surface. CD82 is a broadly expressed molecule best characterized as a metastasis suppressor gene, and is the closest phylogenic relative of the tetraspanin CD37. CD82 is strongly linked to homotypic and heterotypic cell-cell adhesion and CD37 is known to negatively regulate MHC/peptide presentation. Here we examine the affect of CD82 ablation using a new knockout mouse model.
Materials and methods: CD37KO DCs are hyperstimulatory to T cells *in vitro*, and this effect is due to an increase in MHC-peptide presentation, as measured by interaction of peptide pulse DCs with hybridoma cells. We use this cellular assay and others based on the OT1/OT2 antigen model to examine CD82KO DCs. We also look at the affect of *in vitro* differing DC morphology on DC migration both *in vitro* and *in vivo* using intravital microscopy and inflammatory models.
Results: CD82 ablation causes a significant decease in the ability of dendritic cells to stimulate T cell proliferation *in vitro*. We show that this is not due to uptake, surface expression, costimulation or MHC-peptide presentation, but due to a decrease of conjugate formation between DCs and T cells, possibly linked to a failure of formation of dendrites in mature DCs. We show that CD82 and CD37 appear to act in opposition in migration of DCs, with CD82 loss increasing migration potential, while loss of CD37 inhibits this process.
Conclusions: Our data indicates that CD82 and CD37 act in different mechanisms in antigen presentation and act in opposition in migration. CD82 acts on the physical interaction between DCs and T cells, and may act upon the same mechanism to influence DC migration *in vivo*. Our results have implications in the role of CD82 and its involvement in cellular migration, as seen in metastasized cancer.

P0293

The $CD14^{++}/CD16^{+}$ monocyte subset promotes the expansion of Th17 cells in rheumatoid arthritis

N. Raulien, S. Kraus, M. Pierer, C. Baerwald, U. Wagner & M. Rossol
Department of Internal Medicine/Rheumatology, University Leipzig, Leipzig, Germany

Purpose/Objective: Monocytes can be subdivided by their expression of CD14 and CD16. The 'classic' monocyte subset expresses high levels of CD14 and no CD16 ($CD14^{++}/CD16^{-}$), the 'non-classical' monocytes express low levels of CD14 and CD16 ($CD14^{+}/CD16^{+}$) and the third subset, described as pro-inflammatory, is classified by their high expression of CD14 and CD16 ($CD14^{++}/CD16^{+}$). Aim of this study was to analyze the monocyte subpopulations in patients with rheumatoid arthritis (RA) and to characterize the $CD14^{++}/CD16^{+}$ monocyte subpopulation.
Materials and methods: Human PBMCs were isolated by density gradient centrifugation. Monocytes were enriched by depletion of other cells using antibody-coupled microbeads. Subsequently, monocyte subpopulations were sorted according to their CD14 and CD16 expression by flow cytometry and cocultured with $CD4^{+}$ T cells in the presence of LPS for 5 days. After 12 days Th17 cells were detected by flow cytometry. Cytokines were measured in the supernatant by ELISA.
Results: The analysis of the monocyte subpopulations in patients with RA compared to healthy controls shows a higher frequency of $CD14^{++}/CD16^{+}$ monocytes in patients with RA (median 10.1%, $n = 60$ versus median 5.4%, $n = 30$, $P < 0.0001$).

$CD14^{++}/CD16^{+}$ monocytes produce more pro-inflammatory cytokines (IL-1β, IL-1α and TNF) compared to $CD14^{+}/CD16^{+}$ and $CD14^{++}$/CD16- subsets. The co-culture of LPS-activated monocyte subsets with $CD4^{+}$ T cells led to the expansion of Th17 cells. In the presence of $CD14^{++}/CD16^{+}$ monocytes, more Th17 cells were expanded than in co-cultures with the two other monocyte subpopulations. Additionally, more IL-23 and IL-1β was detected in co-cultures of $CD14^{++}/CD16^{+}$ monocytes with $CD4^{+}$ T cells in comparison to the other monocyte subpopulations.

ex vivo analysis of the blood from RA patients and healthy donors indicate an increase of Th17 cells in patients with RA. This increased frequency correlates strongly with the higher frequency of $CD14^{++}/CD16^{+}$ monocytes ($r = 0.767$, $P = 0.0036$), implicating a role of this subpopulation in Th17 differentiation *in vivo*.
Conclusions: In summary these findings indicate an important role of the $CD14^{++}/CD16^{+}$ monocyte subpopulation in generating a pro-inflammatory milieu to promote the differentiation of Th17 cells in RA patients.

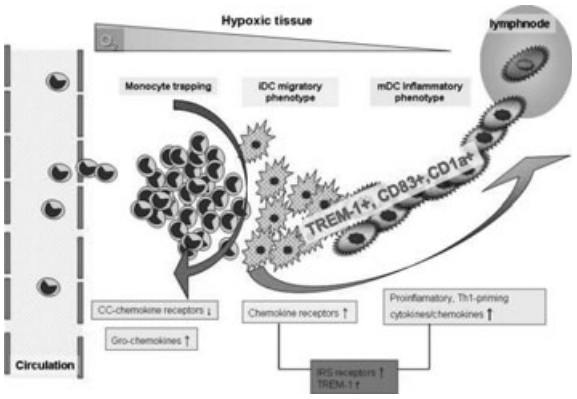
P0294

The hypoxic environment induces a migratory or a proinflammatory phenotype in DCs depending on their maturation stage. Identification of TREM-1 as a common hypoxia marker

F. Raggi,* F. Blengio,* D. Pierobon,† C. Vanni,* P. Cappello,† M. Giovarelli,† L. Varesio* & M. C. Bosco*
**Laboratory of Molecular Biology, G. Gaslini Institute, Genova, Italy, †Department of Medicine and Experimental Oncology, CERMS/University of Torino, Torino, Italy*

Purpose/Objective: DCs are central to the orchestration of innate/adaptive immunity and maintainance of self-tolerance. DC functions are acquired during a complex differentiation and maturation process tightly regulated by signals present in the microenvironment, and deregulated DC responses may result in amplification of inflammation, loss of tolerance, or establishment of immune escape mechanisms. Pathological conditions are characterized by low partial oxygen pressure (pO_2, hypoxia). Understanding DC biology in low O_2 environment may open new therapeutic opportunities for inflammation and cancer.
Materials and methods: We defined the hypoxic transcriptome of immature (i) and mature (m) DCs generated from human monocytes under chronic hypoxic conditions (5 days, 1% O_2).
Results: We present data showing that chronic hypoxia differentially reprograms DCs depending on their maturation stage. Specifically, hypoxia promotes the onset of a migratory phenotype in iDCs through the upregulation of chemokine receptors and an inflammatory state in mDCs by increasing production of proinflammatory, Th1-priming chemokines/cytokines. Interestingly, hypoxia induces profound changes in the expression of a significant cluster of genes coding for immunoregulatory receptors in both cell subsets. Among them, we identified the triggering receptor expressed on myeloid cells (TREM)-1, a member of the Ig receptor family and a strong amplifier of inflammation, as a hypoxia-inducible gene in both iDCs and mDCs *in vitro* and confirmed TREM-1 expression *in vivo* in DCs infiltrating the

inflamed hypoxic joints of Juvenile Idiopathic Arthritis patients. TREM-1 inducibility by hypoxia was reversed by cell reoxygenation and mediated by HIF-1a. TREM-1 engagement elicited DAP12-linked signaling resulting in the production of proinflammatory cytokines/chemokines and upregulation of T cell costimulatory molecules and chemokine homing receptors.



Conclusions: These findings indicate that reduced O_2 availability critically contributes to the persistence and amplification of inflammation by regulating iDC migration and mDC capacity to promote leukocyte trafficking in diseased tissues and identify TREM-1 as a novel marker of hypoxic DCs endowed with pro-inflammatory properties. The potential implications of DC reprogramming by hypoxia for disease progression will be discussed.

P0295

The LILRB1 inhibitory receptor specific for HLA class I molecules regulates macrophage activation in response to tumour cells

D. Baía,* A. Muntasell† & M. López-Botet*

**Department of Experimental and Health Sciences, Universitat Pompeu Fabra, Barcelona, Spain, †Immunology, IMIM Hospital del Mar Research Institute, Barcelona, Spain*

Purpose/Objective: The loss of HLA class I (HLA-I) expression by tumour cells impairs T cell-mediated recognition but promotes the response of NK cells, which are controlled by inhibitory receptors specific for HLA-I. We addressed whether macrophage (MØ) inhibitory receptors specific for HLA-I (LILRB1 and LILRB2) regulate as well their interaction with tumour cells.

Materials and methods: Monocyte-derived M1 and M2 MØ, differentiated respectively with GM-CSF and M-CSF, were co-cultured with HLA class I (HLA-I) deficient tumour cell lines (721.221, K562) transfected with different HLA-I molecules. MØ activation was monitored analysing cytokine secretion (IL-6, IL-8, TNFa and IL-10) and surface expression of co-stimulatory molecules (CD80, CD86).

Results: Both M1 and M2 MØ expressed surface LILRB1, whereas LILRB2 expression was only detected in M2. Interaction with HLA-I-deficient cell lines triggered cytokine secretion and enhanced CD80 surface expression in both MØ cell types. The response was inhibited upon co-culture with target cells transfected with HLA-G or HLA-B27, but not with HLA-Cw15 or *Cw35alleles, thus suggesting that HLA-I molecules interacting with LILRB1 repressed macrophage activation. Altering target cell HLA-I conformation by acid pH treatment, which prevented LILRB1 binding, restored M2 MØ cytokine secretion. Similar results were obtained by antagonizing the interaction with HLA-I with soluble LILRB1-Fc, but not with LILRB2-Fc.

Conclusions: These data support that LILRB1 plays a dominant role in the HLA-I dependent regulation of MØ activation, and that an altered expression of HLA-I in tumours may promote cytokine production by infiltrating MØ.

P0296

The PI3K/PTEN pathway governs alternative activation and Arginase I expression in macrophages

G. Schabbauer,* E. Sahin,* V. Saferding† & S. Blüml†

**Instiute for Physiology, Medical University of Vienna, Vienna, Austria, †Division of Rheumatology, Medical University of Vienna, Vienna, Austria*

Purpose/Objective: Innate immune responses are tightly regulated in order to quickly respond accordingly to invading pathogens. Signaling pathways such as the IKK/NFkB pathway and the MAP kinase pathways are activated in response to pathogens or tissue damage resulting in the expression of a plethora of cytokines and chemokines. We could previously show that the macrophage specific PTEN deficiency limits the excess production of pro-inflammatory mediators and protects from host tissue damage. The aim of our study was to investigate potential mechanisms contributing to the anti-inflammatory phenotype observed in PTEN deficient macrophages.

Materials and methods: In addition to the pre-existing $PTEN^{fl/fl}$ LysM cre mice, we newly generated $PTEN^{fl/fl}$ Arginase $I^{fl/fl}$ LysM cre mice. Furthermore we had access to a potent Arginase inhibitor, N-hydroxy-nor-L-Arginine, and recombinant human pegylated Arginase I. Macrophages were either isolated as thioglycollate elicited macrophages or differentiated to macrophages from bone marrow with M-CSF or conditioned L929 medium. Pure LPS or CpG DNA (ODN 1668) were used to activate macrophages *in vitro*.

Results: In the present study we could provide evidence for differential gene expression in response to TLR agonists suggesting that the PI3K and PTEN are important molecules for M1/M2 macrophage polarization. One of the most potently upregulated genes in PTEN deficient macrophages we identfied was the urea cycle enzyme Arginase I. Arginase I is a signature molecule for alternatively activated macrophages and exhibits important immunological properties.Pharmacologic inhibition as well as cell type specific ablation of the Arginase I gene in macrophages abrogated the protective phenotype observed in PTEN deficient cells. Furthermore we found that vast amounts of Arginase I were secreted by PTEN gene ablated macrophages. Extracellular Arginase I via secondary metabolites could influence not only macrophage activation but also T-cell functions. Using recombinant Arginase I our data suggest that secreted Arginase I confers immune-modulatory effects on macrophages by the reduction of pro-inflammatory cytokines.

Conclusions: Taken together we have ample evidence that PI3K/PTEN govern macrophage polarization and enhanced Arginase I expression contributes to the down-regulation of pro-inflammatory cytokines in PTEN deficient macrophages.

P0297

The role of folate receptor ß-positive macrophages in diseased tissue

A. Ohradanova-Repic,* C. Machacek,* E. Steinhuber,* G. J. Zlabinger,† E. Petrova‡ & H. Stockinger*

**Molecular Immunology Unit, Institute for Hygiene and Applied Immunology Center for Pathophysiology Infectiology and Immunology, Medical University of Vienna, Vienna, Austria, †Institute of Immunology Center for Pathophysiology Infectiology and Immunology, Medical University of Vienna Vienna Austria, Vienna, Austria, ‡EXBIO Praha, Vestec, Czech Republic*

Purpose/Objective: Macrophages display remarkable plasticity that allows them to efficiently respond to environmental signals and change

their phenotype. In chronic inflammatory diseases, such as rheumatoid arthritis (RA), upregulation of several proinflammatory cytokines is responsible for classical (M1) macrophage activation that significantly contribute to the pathology of the disease. Folate receptor β (FRβ) was described as a marker of activated macrophages in RA-affected synovia. However, FRβ expression was also detected in tumour-associated M2 macrophages that show immunoregulatory and tissue repair phenotype.

Materials and methods: To learn which macrophage subset expresses FRβ and to clarify the function of these cells, we differentiated macrophages from human peripheral blood monocytes. We determined their phenotypic characteristics and phagocytic capacity by flow cytometry, measured released cytokines and tested their stimulatory capability by coculture with T cells.

Results: Macrophages differentiated with GM-CSF failed to express FRβ. On the other hand, differentiation using M-CSF produced macrophages highly positive for FRβ. The subsequent activation of the latter by various stimuli showed minor effect on FRβ expression, but revealed existence of functionally different subtypes.

Conclusions: By gaining the possibility to generate *in vitro* macrophages that resemble those in diseased tissues we can comprehensively study their biology and find ways for their elimination or reprogramming.

P0298

The role of protein kinase D enzymes in the innate immune system

L. Robertson & S. Matthews
Immunology, University of Dundee Medical Research Institute, Dundee, UK

Purpose/Objective: Protein kinase D (PKD) is a novel family of serine/threonine kinases that belong to the calcium/calmodulin-dependent kinase superfamily. Recent research has implicated these enzymes in a vast array of important cellular signaling pathways and downstream functions including cell proliferation, survival, motility and more. Interestingly, a recent role for PKD enzymes has been established in the adaptive immune system whereby murine PKD2 was shown to be essential for normal peripheral T cell function *in vitro* and normal humoral immune responses *in vivo*.PKD enzymes also have a role in regulating innate immune responses in murine/human myeloid lineage cells in Toll-like receptor signaling.

Although the activation and regulation of PKD isoforms is well characterized, little is known about the true physiological roles of these enzymes with regard to myeloid cell development and function.

Materials and methods: Using novel and specific PKD inhibitors in combination with genetically altered PKD mutant mice we are interested in the role of PKD isoforms in macrophage and dendritic cell development, activation responses and effector functions.

Results: Our preliminary data suggests that both PKD1 and PKD2 isoforms are involved the development and effector functions of macrophage and dendritic cells. Using flow cytometry to assess specific myeloid cell populations in the hematopoietic compartment of mice expressing catalytically inactive PKD1 and/or PKD2 alleles we see increased frequencies of conventional DCs and decreased frequencies of macrophages and neutrophils in the spleens of these mutant mice. We also observed that bone marrow-derived dendritic cells produced from PKD2-catalytically inactive mice express higher levels of co-stimulatory molecules such as CD80 and CD86 in response to TLR4 stimulation.Interleukin-6 production by TLR4-stimulated PKD2-catalytically inactive bone marrow-derived macrophages and dendritic cells is also considerably higher than that produced by wild-type cells.

Conclusions: Overall these results suggest that mammalian PKD enzymes may be involved in regulating the innate immune response(s) of myeloid cells.

P0300

The role of vascular-adhesion-protein 1 (VAP-1) in mediating monocyte migration across inflamed hepatic sinusoidal endothelium

H. Zimmermann, C. J. Weston, S. M. Curbishley, T. Bruns, J. Thomas, Z. Stamataki & D. H. Adams
School of Immunity and Infection, Centre foir Liver Research, University of Birmingham, Birmingham, UK

Purpose/Objective: Monocyte progeny cells drive liver fibrosis. The $CD14^{+}$ $CD16^{++}$ monocyte subset is believed to be pro-inflammatory whereas $CD14^{++}CD16^{-}$ monocytes maybe reparative. The molecular basis of monocyte transmigration across hepatic sinusoidal endothelial cells (HSEC) into the liver is poorly understood. VAP-1 is an atypical adhesion molecule and an ectoenzyme with monoamine oxidase activity that is involved in the recruitment of hepatic lymphocytes. We now report that VAP-1 and its ectoenzyme activity differentially regulate the recruitment of pro-inflammatory monocytes across HSEC.

Materials and methods: Human HSEC were isolated from explanted livers. After TNF-α/IFN-γ stimulation HSEC were treated with VAP-1 antibody or enzyme inhibitors. Peripheral monocytes were enriched using density gradient. Monocyte subsets were obtained via FACS-sorting. Monocytic transendothelial migration was analyzed in a flow assay. Transwell assays were used to study phenotypic changes in transmigrated monocytes. Surface marker expression was studied by FACS and imaging the route of monocyte transmigration across HSEC (transcellular versus paracellular) was performed by confocal microscopy.

Results: Inflamed HSEC displayed enhanced adhesion molecule expression (ICAM-1, VCAM-1, VAP-1, CD31). Confocal microscopy revealed an increase of monocytes taking the transcellular route through inflamed HSEC, indicating the translocation of adhesion molecules to transcellular pores. Anti-VAP-1 antibody or enzyme inhibitor both reduced monocyte transmigration under flow but did not alter monocyte phenotype. VCAM-1 blockade had a similar but redundant impact and PTx and ICAM-1-inhibtion further impacted transmigration. Blocking VAP-1 led to a profound reduction in $CD14^{+}$ $CD16^{++}$ transmigration but also affected $CD14^{++}CD16^{+}$ cells whereas $CD14^{++}$CD16- cells were not affected. Monocyte subsets differentially expressed the potential VAP-1 ligands SIGLEC-9/-10. Under static conditions the effect of VAP-1 was significantly blunted suggesting that flow is a prerequisite for its biological function.

Conclusions: Endothelial VAP-1 differentially modulates monocyte recruitment under flow in a time-dependent fashion favouring transmigration of a proinflammatory monocyte subset, but other adhesion molecules and chemokine-mediated signals significantly contribute to monocyte transmigration across inflamed HSEC. The critical role of VAP-1 ectoenzyme function implies that small molecule enzyme inhibitors maybe effective in combating liver inflammation and subsequent fibrosis.

P0301

The tetraspanin CD37 promotes dendritic cell migration

M. C. Demaria,* K. H. Gartlan,* J. Wee,* M. J. Hickey† & M. D. Wright*
**Immunology, Monash University, Melbourne, Vic., Australia, †Centre for Inflammatory Diseases, Monash University, Melbourne, Vic., Australia*

Purpose/Objective: Tetraspanins are a family of integral membrane proteins that function by forming tetraspanin-enriched microdomains (TEMs), thus organizing the cell surface. TEM formation allows tetraspanins to function in critical processes including cell adhesion and migration. Immune system aberrations are observed in tetraspanin

deficient mice. T cells and dendritic cells (DC) derived from $CD37^{-/-}$ mice display hyperproliferative and hyperstimulatory phenotypes, respectively. However, interestingly these mice are unable to generate an effective T cell response *in vivo*, following antigenic challenge, including irradiated B16OVA (an ovalbumin expressing tumor cell line). We aim to determine that a defective migratory capability of $CD37^{-/-}$ DCs underlies this poor response.

Materials and methods: The i*n vivo* antigen presenting capability of WT and $CD37^{-/-}$ mice was determined by the adoptive transfer of CFSE-labelled WT OT-I T cells and subsequent challenge of these mice with irradiated B16OVA. T cell proliferation was then determined by flow cytometric analysis. Dermal DC migration following inflammation was visualized by two-photon confocal microscopy of $CD37^{-/-}$CD11c-YFP mice. Finally, integrin expression on WT and $CD37^{-/-}$ BMDC was determined by flow cytometric analysis.

Results: Antigen presenting capability within $CD37^{-/-}$ mice is poor, as demonstrated by the inadequate ability of these mice to efficiently prime WT OT-I T cells *in vivo*. Dermal DC are unable to effectively migrate in a directional manner following induction of inflammation. Finally, expression of a range of integrins is normal on $CD37^{-/-}$ BMDC.

Conclusions: $CD37^{-/-}$ DC poorly prime WT OT-I T cells *in vivo*, consistent with a defect in the migratory capability of these cells. This is supported by the observation that $CD37^{-/-}$ dermal DC do not migrate directionally in an inflamed state. This inability to migrate is not dependant on poor expression levels of integrins. As tetraspanins can regulate integrin outside-in signalling and cytoskeletal rearrangement, we are currently investigating any possible roles for CD37 in these processes.

P0302

Triggering of B7h by the inducible costimulator modulates maturation and migration of monocyte-derived dendritic cells

E. Boggio,* S. Occhipinti,† C. Dianzani,‡ N. Clemente,* C. L. Gigliotti,* R. Minelli,‡ M. Giovarelli,† A. Chiocchetti* & U. Dianzani*

**Interdisciplinary Research Center of Autoimmune Diseases (IRCAD) and Department of Health Sciences, 'A. Avogadro' University of Eastern Piedmont, Novara, Italy, †Department Medicine and Experimental Oncology, University of Turin, Torino, Italy, ‡Department of Science and Pharmaceutical Technology Oncology, University of Turin, Torino, Italy*

Purpose/Objective: B7h, expressed by several cell types, binds Inducible co-stimulator (ICOS) expressed by activated T cells. This work investigated the effect of B7h triggering by ICOS on human monocyte-derived dendritic cells (DC).

Materials and methods: Monocytes were induced to differentiate to immature DC (iDC) by a 5-day culture with GM-CSF and IL-4. They were then induced to mature for 2 days with LPS in the absence (mDC) and the presence (mDC^{ICOS}) of ICOS-Fc, a recombinant form of ICOS fused to the human or mouse IgG1 Fc; the mutant ^{F119S}ICOS-Fc, which doesn't bind B7h, and CTLA-4-Fc were used as controls. Supernatants were then collected for cytokine analysis by ELISA. In the antigen presentation assay, keyhole limpet hemocyanin (KLH) was added to DC with during the maturation step in the presence of the different ICOS-constructs; these DC were then cocultured with autologous T cells, and IFN-gamma production from $CD4^+$ and $CD8^+$ T cells was assessed by ELISpot. In the adhesion assay, endothelial cells (EC) were treated or not with the different ICOS-Fc constructs and incubated with iDC or mDC; adherent cells were then counted by the Image Pro Plus Software. In the migration assay, iDC or mDC were plated onto the Boyden chamber in the presence of appropriate chemoattractants and the different ICOS constructs. Cells on the bottom of the filter were stained with crystal-violet and counted.

Results: Results showed that mDC^{ICOS} produced higher amounts of IL-23 and IL-10, and lower amounts of TNF-α and IL-6 than mDC. Moreover upon pulsing with KLH, mDC^{ICOS} were better stimulators of IFN-gamma production in $CD8^+$ T cells than mDC, whereas no difference was found in $CD4^+$ T cells. Finally, ICOS-Fc inhibited adhesion of both iDC and mDC to EC, and their migratory activity.

Conclusions: These data suggests that 'reverse' signaling mediated by B7h modulates DC maturation by influencing cytokine secretion and potentiating antigen cross-presentation. Moreover, it modulates DC adhesiveness and migration and might thus influence their recruitment into tissues.

P0303

Wnt5a plays an essential role during human monocyte-derived dendritic cell maturation and function

J. Valencia, C. Hernández-López, V. G. Martínez, L. Hidalgo, A. G. Zapata, A. Vicente, A. Varas & R. Sacedón

Faculty of Medicine, Complutense University of Madrid, Cell Biology, Madrid, Spain

Purpose/Objective: Recent evidences reveal an immunomodulatory role for Wnt5a. *In vivo* Wnt5a levels increase under numerous pro-inflammatory situations; being detected in human inflammatory diseases and raise in the sera from patients with sepsis. Our previous results demonstrate that Wnt5a interfere in dendritic cell (DC) differentiation from human monocytes (MoDCs) leading to unconventional DCs with tolerogenic features. In the present work we analyse the role of Wnt5a during DC maturation and function.

Materials and methods: Immature DCs were obtained from human $CD14^+$ monocytes and stimulated by LPS treatment. Changes during DC maturation in the pattern of expression of non canonical Wnts and their receptors were determined by PCRq. The effect in DC phenotype and function of an increase in Wnt5a signaling, previous or simultaneous to LPS response was analysed. The production of Wnt5a by DC was silenced with specific pre-designed siRNAs to analyze the impact of Wnt5a drop during DC maturation and function.

Results: Wnt5a is the main non canonical Wnt protein expressed by MoDCs and LPS signaling stimulated its production. Nevertheless, Wnt5a alone was not able to induce DC phenotypic maturation or cytokine secretion but improved their endocytic capability. Moreover, in response to LPS pre-treated Wnt5a-DCs secreted higher levels of IL-12 but lower of IL-10 and MLR assays showed lower production of IL-10 by naïve T cells primed with pre-treated Wnt5a-DCs. The addition of Wnt5a during DC LPS-maturation increased also IL-12 secretion and reduced that of IL-10 but its impact on DC allostimulatory capabilities was irrelevant suggesting a main role for autocrine Wnt5a. Accordingly, Wnt5a-silenced DCs showed a reduced viability and failed to produce pro-Th1 cytokines while the secretion of IL-10 was increased. Consequently, these Wnt5a-silenced DCs showed a reduced capacity to induce Th1 responses promoting IL-10 secretion by CD4 T cells. This situation was rescued by the addition of Wnt5a.

Conclusions: Although our previous results demonstrate that the increment Wnt5a signaling on monocytes interfere with their differentiation into DCs, the data presented herein indicate a positive and necessary function for Wnt5a on immature and mature DCs suggesting a timing-dependent dual role for Wnt5a on human monocyte derived DCs.

Zinc oxide nanoparticles and monocytes: impact of size, charge and solubility on activation status

M. Prach,* V. Stone† & L. Proudfoot‡

*Centre for Nano Safety School of Life Sport and Social Science, Edinburgh Napier University, Edinburgh, UK, †Centre for Nanosafety School of Life Science, Heriot-Watt University, Edinburgh, UK, ‡Centre for Nano Safety School of Life Sport and Social Science, Edinburgh Napier University, Edinburgh, UK

Purpose/Objective: The abundance of products containing ZnO nanoparticles (ZnO NPs) available to the consumer poses an important question of safety. Therefore our objectives were firstly to assess ZnO NP induced cytotoxicity with respect to size, charge and solubility on the monocytic cell line THP-1. Secondly, to determine how these factors at sub lethal concentrations influence the activation of these cells.

Materials and methods: We have used three manufactured ZnO NP dispersions (average diameter 70 nm: anionic, cationic and non ionic) and compared their effects on THP-1 cells with bulk ZnO (<44 μm mesh) and equimolar $ZnSO_4$. Three different cytotoxicity/viability assays were evaluated: release of lactate dehydrogenase (LDH), WST-1 conversion to formazan and nuclear binding of 7-Amino-actinomycin D (7-AAD). THP-1 cells were exposed for 24 h to a dose range of 6.25−300 $\mu g/10^6$ cells. Dissolution of ZnO NPs was assessed in the presence or absence of 10% foetal bovine serum (FBS) using flame atomic absorption spectroscopy (AAS) and centrifugal filtration. The immunomodulatory effect of the NPs was assessed by cytokine ELISA and surface marker expression by flow cytometry.

Results: ZnO NPs are more toxic than the bulk form and a positive charge enhances cytotoxicity of the NP despite their relatively high dissolution. Centrifugal filtration (cut off of 5kDa) and Zn element analysis by AAS confirmed that in the absence of cells $ZnSO_4$, bulk and NP ZnO to 10% FBS resulted in a strong association of the Zn^{2+} ions with protein. Following 24h exposure of THP-1 cells at sublethal concentrations of these Zn particles there was no effect on immunological markers of inflammation such as HLA-DR and CD14. There was a modest increase in the adhesion molecule CD11b. There was no induction of the classical pro-inflammatory cytokine TNFα and also no effect on LPS-stimulated TNFα production.

Conclusions: These results suggest that ZnO NP despite their toxicity do not induce a classical pro-inflammatory effect on THP-1 cells.

Poster Session: Sensing – NLRs, IL1 & Inflammasomes

Activation of inflammatory pathways by apoptotic inducers

H. Ball & D. Brough
Department of Life Sciences, University of Manchester, Manchester, UK

Purpose/Objective: Inflammation and cell death play key roles in numerous conditions including stroke and Alzheimer's disease. Although both processes act through caspases, they are conventionally considered to be distinct pathways. Recent studies, however, have highlighted interactions between the two, such as the regulation of NLRP3 activation by oxidised mitochondrial DNA and by the anti-apoptotic protein Bcl-2, plus the ability of the AIM2/ASC complex to initiate a caspase-8-dependant apoptosis in the absence of caspase-1. The purpose of this work was to investigate interactions between the apoptotic and IL-1β processing pathways by investigating cell death and IL-1β release induced by DAMPs and apoptosis inducers.
Materials and methods: Bone marrow-derived macrophage cell lines (WT and NLRP3 KO) were treated with either DAMPs or one of a range of apoptosis inducers for 1 to 24 h, with or without a 4 h LPS pre-treatment. Caspase involvement was determined with the use of either specific or broad-spectrum inhibitors. Cell death was measured using the LDH assay, and IL-1β release quantified by ELISA. IL-1β was characterised as pro- or mature by Western blot.
Results: Treatment with DAMPs such as ATP, sphingosine or monosodium urate crystals resulted in cell death that was not affected by LPS priming. Mature IL-1β was released from LPS-primed cells treated not only with known DAMPs such as ATP or sphingosine, but also with the apoptotic inducers staurosporine or TPEN. A significantly lower level of IL-1β release was seen for other apoptosis inducers, which caused significant levels of cell death.
Conclusions: Induction of apoptosis can result in the processing of IL-1β, i.e. initiation of inflammatory pathways. As this effect was not equal across apoptosis inducers, it cannot be considered as a general apoptotic event, but is rather related to a specific action of some of these toxins. These differences could be used to identify new mechanisms driving inflammation.

Activation of the inflammasome by fungal immunomodulatory proteins LZ-8 and GMI

C. Y. Lu & C. J. Chen
Biochemical Science and Technology, National Taiwan University, Taipei, Taiwan

Purpose/Objective: IL-1β is a key proinflammatory cytokine regulating both innate and adaptive immune responses, and its production is controlled by the inflammasome. Inflammasomes are multiprotein platforms responsible for caspase-1 activation and subsequent processing and secretion of mature IL-1β. Here we studied the stimulatory effect of fungal immunomodulatory proteins (FIPs) LZ-8 and GMI on inflammasome activation and IL-1β production in murine macrophages.
Materials and methods: Murine peritoneal resident macrophages or bone marrow-derived macrophages were treated with recombinant LZ-8 and GMI proteins in the presence or absence of LPS, and the production of caspase-1 and mature IL-1β were evaluated. C57BL/6 and IL-1R$^{-/-}$ mice were treated with LZ-8 before *Listeria monocytogenes* challenge to assess the protective function of LZ-8 against bacterial infection in animals.
Results: FIP stimulation resulted in caspase-1 activation and robust IL-1β production in LPS-primed macrophages. FIP-induced IL-1β production was inhibited in the presence of high extracellular KCl or inhibitors targeting the membrane pores P2X7 and pannexin-1, indicating that FIP-induced inflammasome activation requires potassium efflux through ion channels. In addition, inhibition of reactive oxygen species (ROS) production also reduced FIP-induced IL-1β production, indicating that ROS generation is also involved in the process. Intraperitoneal administration of LZ-8 in mice elicited a robust influx of neutrophils which was attenuated in IL-1R$^{-/-}$ mice, and this immune response could protect mice against subsequent *L. monocytogenes* infection.
Conclusions: Our findings provide evidence that FIPs can activate the inflammasome formation and IL-1β secretion, leading to a protective immune response against bacterial infection.

P0307
Analysis of inflammasome related molecules in the response to H5N1 Avian Influenza

F. Sarah,* S. Burggraaf,* W. G. Kimpoton† & A. G. B. Bean‡
**Australian Animal Health Laboratories, Commonwealth Scientific and Industrial Research Organization, Geelong, Australia,* †*Faculty of Veterinary Sciences, The University of Melbourne, Parkville, Australia,* ‡*Australian Animal Health Laboratories, Commonwealth Scientific and Industrial Organization, Geelong, Australia*

Purpose/Objective: Highly pathogenic avian influenza (HPAI) infection is extremely acute and associated with severe mortality in both humans and poultry. The rapid onset of disease suggests that virus-host interactions, such as the immune response to virus, might contribute to the severity. With this in mind, it is critical to understand the host-pathogen interactions in order to develop novel approaches to managing infection. Pro-inflammatory cytokines, such as interleukin (IL)-1β and IL18, are crucial to an anti-viral response, however, the control of the expression of these molecules is vital, as exacerbated levels can lead to deleterious outcomes. In mammals these cytokines are regulated by a complex cytoplasmic protein scaffold known as the Nalp3 inflammasome. Currently, the mechanisms for Nalp3 activation are largely unknown, however, it appears Nalp3 and the associated cleavage enzyme caspase 1 (ICE) are important regulators. To elucidate the role of the inflammasome in the chicken response to H5N1 HPAI, we identified and characterized chicken Nalp3, ICE, IL1β and IL18 and investigated their role during infection.
Materials and methods: Through qRT-PCR, siRNA gene knockdown and ELISA analysis, the chicken Nalp3 inflammasome has been identified and its role in the response to H5N1 HPAI analysed.
Results: ChickenIL-1β, IL-18, Nalp3 and ICE are upregulated during H5N1 infection, particularly Nalp3 and ICE. In correlation with this was an observed increased in IL-1β, IL-18 and IFN-γ protein secretion, measured in chicken sera.
Conclusions: Together, these data indicate a strong Nalp3 inflammasome response; following HPAI infection in the chicken.This work provides an insight into strategies that target the immune system for improving resistance to avian influenza.

P0308
Apis mellifera (honey bee) venom activates the AIM2 inflammasome in primary keratinocytes – a first step to allergic sensitisation?

Y. Dombrowski, M. Peric, S. Koglin, N. Kaymakanov, V. Schmezer, T. Ruzicka & J. Schauber
Department of Dermatology and Allergy, Ludwig-Maximilian-University Munich School of Medicine, München, Germany

Purpose/Objective: Following allergen exposure, cytokines and other pro-inflammatory signals play an important role in the immunological cascade leading to allergic sensitisation. Inflammasomes sense exoge-

nous and endogenous danger signals and trigger IL-1β and IL-18 activation which in turn shape Th2 responses. Honey bee venom (BV) allergies are very common however, the local inflammatory cascade leading to initiation of allergic sensitisation towards BV is poorly understood. In this study the local inflammatory cascades in the skin after exposure to BV were investigated.

Materials and methods: In human skin and in cultured primary keratinocytes the mechanisms of inflammasome activation upon BV exposure were analysed by ELISA, Western Blot, flow cytometry, siRNA techniques and immunofluorescence.

Results: In an *ex vivo* bee sting model BV induced IL-1β release suggesting activation of an inflammasome. Indeed, in cultured primary keratinocytes the BV component melittin triggered IL-1β and IL-18 release via the AIM2 inflammasome whereas the NLRP3 inflammasome remained unaffected. AIM2 is a cytosolic DNA receptor and mitochondrial as well as genomic DNA was detected in the cytosol of melittin treated keratinocytes as triggers of inflammasome activation. As a mechanism, melittin specifically mediated destruction of mitochondrial membranes leading to leakage of mitochondrial DNA into the cytosolic compartment which subsequently activated AIM2.

Conclusions: These data suggest that upon BV exposure keratinocytes are involved in a primary immune response by activation of the AIM2 inflammasome triggered by endogenous DNA resulting in a subsequent IL-1β and IL-18 release. As IL-1β and IL-18 are critically involved in Th2 and IgE mediated immune reactions these results could add to the understanding of the role of the local tissue microenvironment to subsequent allergic responses in predisposed individuals.

P0309
ATP-induced inflammasome activation in LPS-primed bovine monocytes is independent of the purinergic receptor P2X7

J. Hussen, A. Düvel, M. Koy & H. J. Schuberth
Immunology, Institute of Immunology, Hannover, Germany

Purpose/Objective: Inflammasome-mediated release of IL-1§ from ATP-stimulated human and murine monocytes requires the expression of the the ATP-gated ion channel subtype P2X7 receptor. We investigated the role of the purinergic receptor P2X7 for inflammasome activation in bovine monocytes.

Materials and methods: ATP-induced inflammasome assembly in bovine monocytes was analyzed by flow cytometric evaluation of caspase-1 activation and the measurement of IL-1b release with ELISA after LPS^+ATP-stimulation. To evaluate the function of the cell surface pore-forming ATP receptors in bovine MNC, agonist-induced ethidium bromide (EB) uptake in MNC was assessed using time-resolved flow cytometry. To investigate the role of Ca^{2+} influx for ATP-induced inflammasome activation, bovine MNC were Fluo-4-loaded and a continuous measurement of cytosolic calcium was measured by flow cytometry. Cells were loaded with the dye DHR-123 to analyze the generation of reactive oxygen species (ROS) by flow cytometry.

Results: The release of IL-1b was minimal when MNC were stimulated with LPS alone but sixfold higher in the presence of ATP. Inhibition of caspase-1 activation with a pan-caspase-inhibitor completely blocked IL-1b release. ATP, BzATP and 2-MeSATP induced pore formation and uptake of EB in bovine lymphocytes but not in monocytes or B cells. A human P2X7 receptor antagonist inhibited the EB uptake of ATP stimulated $CD4^+$ T cells but not the IL-1b release from bovine MNC. All ATP isomers induced ROS generation in bovine lymphocytes with BzATP being the most effective one. In monocytes only PMA but none of the three ATP isomers was able to induce ROS. In addition, ATP and 2-MeSATP but not the high affinity P2X7 agonist BzATP induced calcium influx in bovine monocytes. Inhibition of K^+ efflux by high extracellular K^+ concentrations completely blocked the LPS^+ATP-induced release of IL-1b from bovine MNC.

Conclusions: P2X7 mediated pore formation was observed in subsets of bovine T lymphocytes ($CD4^+ > CD8^+$) but not in monocytes or in B cells. The data indicate that neither ROS generation nor Ca^{2+} influx play a role in the ATP-induced release of IL-1b from bovine monocytes, which is independent of the purinergic receptor P2X7.

P0310
Deubiquitinating enzymes: new players in IL-1beta release

G. Lopez-Castejon,* N. Luheshi,* E. Swanton,† S. High,† R. Whitehead,‡ S. Flitsch‡ & D. Brough*
**AV Hill Building – Faculty of Life Sciences, University of Manchester, Manchester, UK, †Micahel Smith Building – Faculty of Life Sciences, University of Manchester, Manchester, UK, ‡School of Chemistry – Faculty of Life Sciences, University of Manchester, Manchester, UK*

Purpose/Objective: Ubiquitination is a post-tranlational modification essential for maintaining cellular homeostasis. The classical role of ubiquitin is to target proteins for degradation by the proteasome. Ubiquitin molecules are recycled by the cell prior to protein degradation by deubiquitinating enzymes (DUB).DUBs present specificity towards different ubiquitin chain topologies and are important regulators of key cellular processes such as cellular trafficking, gene transcription and cellular signalling.

IL-1beta is a potent proinflammatory cytokine that is synthesised as a precursor molecule upon pathogen or danger associated molecular pattern (PAMP and DAMP) stimulation. Once synthesised this cytokine has to be processed by caspase-1 in order to become active and secreted. This activation occurs in the cytosol within a molecular complex called the inflammasome. The NLRP3 inflammasome is the best studied so far and its assembly can be triggered by a wide variety of stimuli.However the signalling pathways by which these stimuli lead to the assembly of the inflammasome complex are not completely understood.

The aim of this study was to investigate the role of DUBs in inflammasome activation.

Materials and methods: For this study we pre-treated murine peritoneal macrophages and the human cell line THP-1 with different DUB inhibitors and study the effect of this compounds in the ATP and nigericine induced processing and release of IL-1beta by western blot and ELISA.

Results: Here we report that DUBs play a crucial role in inflammasome activation. We have found that inhibition of DUBs with the inhibitors eeyarestatin I, b-AP15 and WP1130 block the processing and release of IL-1beta in macrophagesinduced by the NLRP3 inflammasome activators ATP, nigericin and monosodium urate crystals (MSU). These inhibitors do not block activity of recombinant caspase-1 *per se* but impair the formation of the ASC pyroptosome suggesting that DUBs act upstream caspase-1 activation. This is a proteasome independent process since inhibition of the proteasome with the clinically used Bortezomib does not impair this process.

Conclusions: All these data suggests that deubiquitination plays an essential role in inflammasome assembly and IL-1beta release indicating a new function for DUB activity in the innate immune response.

P0311
Ethanol inhibits NLRP3 and AIM2 inflammasome activation

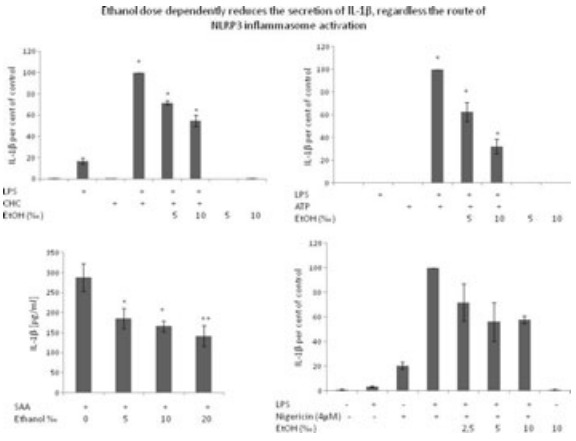
K. Nurmi, K. Rajamäki, P. T. Kovanen & K. K. Eklund
Cardiovascular Research, Wihuri Research Institute, Helsinki, Finland

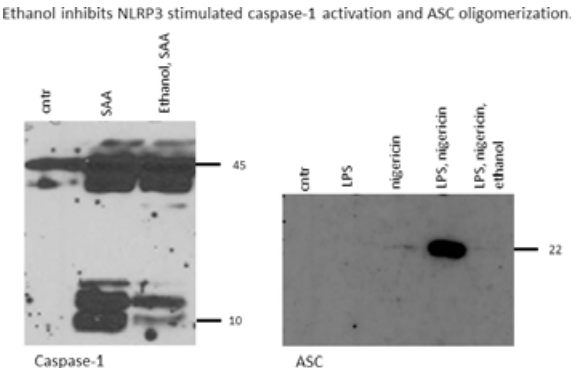
Purpose/Objective: Local macrophage driven inflammation and the secretion of proinflammatory cytokines is recognized as a major driving force in the pathogenesis of atherosclerosis. Acute ethanol exposure has been shown to reduce the release of proinflammatory cytokines. We examined whether ethanol would modulate the activa-

tion of NLRP3 and AIM2 inflammasomes and subsequent secretion of IL-1β in cultured human macrophages.

Materials and methods: Primary human macrophages and THP-1 cell line cells were used. NLRP3 inflammasome was activated by cholesterol crystals, ATP, Serum amyloid A (SAA) and nigericin. AIM2 inflammasome was activated with Poly (dA:dT). The secretion of IL-1β was measured by ELISA and Western blot assays. Activation of caspase-1 and ASC was studied by Western blotting. The lysosomal rupture and release of cathepsin B was imaged by fluorescent staining. Cholesterol crystal esterification was judged by TLC. mRNA expressions were analyzed by quantitative real time PCR.

Results: Ethanol decreased dose-dependently the production of mature IL-1β induced by the activators of NLRP3 and AIM2 inflammasomes. Ethanol reduced the NLRP3 inflammasome activation induced by chemically diverse inducers, ATP, cholesterol crystals, serum amyloid A and nigericin. Decreased secretion of IL-1β paralleled the reduction of the activation of caspase-1, an enzyme which cleaves the proIL-1β into the mature form. Ethanol also attenuated the secretion induced by synthetic double stranded DNA, an activator of AIM2 inflammasome. Ethanol attenuated the disruption of lysosomal integrity and the leakage of lysosomal protease cathepsin B. Ethanol also reduced ASC oligomerization. Ethanol had no significant effect on the expression of NLRP3 or proIL-1β mRNA in LPS-primed macrophages, suggesting that ethanol inhibits the inflammasome activation instead of synthesis of proIL-1β. In contrast, acetaldehyde, a highly reactive metabolite of ethanol, had no effect on the ATP-induced IL-1β secretion.





Conclusions: Provided that ethanol also inhibits macrophage inflammasome activation *in vivo* the present findings provide a plausible mechanistic explanation for the association between moderate alcohol consumption and reduced incidence of cardiovascular diseases.

P0312

Identification of novel NOD2-regulated proteins using phosphoproteomics

T. A. M. Steevels,* P. Allan,* R. Fischer,† B. Kessler† & A. Simmons†

**Nuffield Department of Medicine, University of Oxford, Oxford, UK, †Centre for Cellular and Molecular Physiology, University of Oxford, Oxford, UK*

Purpose/Objective: NOD2 is an intracellular pattern recognition receptor (PRR) that recognizes muramyl dipeptide (MDP). Variants in the NOD2 ligand recognition domain have been found to be associated with a significant percentage of Western Crohn's disease, but the mechanisms leading to disease are so far unknown. Our objective was to define the molecular mechanism of NOD2 signalling by performing a phosphoproteomic analysis of the NOD2 signalling cascade. Cell activation was enhanced by stimulating cells with both MDP and TLR2 ligand PAM3cys, which strongly synergizes with MDP.

Materials and methods: Human monocyte-derived dendritic cells from five different donors were left untreated or stimulated with MDP, PAM3cys or both. Eluates were subjected to tryptic digest before mass spectrometry analysis by LC-MS/MS and Q-TOF. Identified phosphoproteins that showed a > 1.5-fold increase or <0.67-fold decrease relative to control sample were considered significantly regulated. The regulation of the individual proteins was validated by examining phospho-enriched samples on Western blot.

Results: Different treatments resulted in distinct patterns of regulated proteins. As expected, stimulation with both MDP and PAM3cys resulted in an increased number of regulated proteins compared to MDP alone. We found several significantly regulated proteins previously described to be involved in NOD2 signalling. Identified regulated proteins were, among others, associated with NFκB activation, autophagy induction, endosomal transport, proteasomal degradation and MHC presentation. The MDP-induced regulation of l-plastin, heat shock protein beta1, zyxin and NCF1 has been confirmed by Western blot.

Conclusions: The phosphoproteomic analysis of the NOD2 signalling cascade is validated by the retrieval of proteins previously described in NOD2 signalling. Identified regulated proteins are associated with a wide range of immunological functions. We have thus far been able to identify and confirm l-plastin, heat shock protein beta1, zyxin and NCF1 as proteins involved in NOD2 signalling. Currently the functional role of each protein identified is being assessed in terms of bacterial handling, antigen presentation and cytokine production.

P0314

Intestinal manipulation during surgery causes sterile inflammation and post-operative ileus via mast cell protease activity — dependent IL-1receptor signalling

W. de Jonge,* S. A. Snoek,* S. van Bree,* F. A. Hilbers,* B. Stoffels† & S. Wehner†

**Gastroenterology, Academic Medical Center, Amsterdam, The Netherlands, †Department of Surgery, University of Bonn Medical School, Bonn, Germany*

Purpose/Objective: Intestinal manipulation (IM) of the bowel surgery commonly causes a transient post-surgical cessation of gut motility, i.e. postoperative ileus (POI). We have previously shown that POI is mediated by activation of mast cells. We studied the role of mast cells and IL1signaling routes as causal factors for POI.

Materials and methods: WT C57Bl/6 mice, TLR$^{-/-}$, MyD88 $^{-/-}$, and mast cell deficient Kit/wsh mutants were used. In a mouse model for POI, mice underwent laparotomy (L) or manipulation of the small bowel (IM). After surgery, intestinal transit and inflammation was assessed.

Results: Surgical manipulation (IM) led to a neutrophil infiltrate in the intestinal muscle layer in WT mice (L: 21 ± 10; IM: 219 ± 24 cells/mm^2), associated with a significantly enhanced production of cytokines IL1 alpha, IL1 beta, CCL-2, IL-6 and KC in the muscle layer. This inflammatory infiltrate after IM was significantly attenuated in mast cell deficient Kit/wsh mice.

Muscular inflammation in POI was dependent on MyD88 signaling, as neutrophil recruitment (IM-WT: 219 ± 24 versus IM-MyD88$^{-/-}$:80 ± 18 cells/mm^2) as well as production of CCL2, and IL-6 was significantly reduced in MyD88$^{-/-}$ undergoing IM. MyD88 is crucial in TLR and IL-1R signaling. However, TLR 2, 4, 2/4, and 9 $^{-/-}$ mice displayed no change in IM-induced neutrophil infiltrate after IM. In contrast, treatment with the IL-1R antagonist (Anakinra) significantly reduced muscularis IL-6 and CCL2 production and neutrophil recruitment, and ameliorated intestinal transit. Interestingly, IM-induced POI was unaffected in mice deficient in inflammasome proteins NALP3 or ASC1, indicating that Il1beta is cleaved by inflammasome independent pathways. Further, we show that active IL-1beta production was significantly inhibited in mast cell deficient mice intestinal muscularis. *In vitro*, conditioned medium from a peritoneal mast cell culture elicited Il1beta release in bone marrow dendritic cells. In conjunction, treatment of mice with mast cell proteinase inhibitor chysmostatin inhibited colonic IM-induced CCL2 and IL-6 production significantly.

Conclusions: IM during abdominal surgery induces mast cell activation, and an inflammatory infiltrate via an IL1R dependent pathway. Our data further suggest that POI arises via mast cell proteinase activity that cleaves and activates IL-1 in the manipulated small intestinal muscularis.

P0315
Lactate induces caspase-1-independent release of interleukin-1 beta

M. Edye, D. Brough & S. M. Allan
Faculty of Life Sciences, University of Manchester, Manchester, UK

Purpose/Objective: Lactic acidosis is a clinical consequence and contributor to many major diseases. Inflammation, and in particular the pro-inflammatory cytokine interleukin-1 beta (IL-1b), contributes to the development and exacerbation of multiple diseases; including epilepsy, Alzheimer's disease and stroke. IL-1b is synthesised as an inactive precursor which is subsequently cleaved to a 17 kDa active form by caspase-1. To cleave IL-1b, caspase-1 also requires prior activation. This occurs through association with a large protein complex termed the 'inflammasome'. To determine whether acidosis affects IL-1b processing, we examined the effect of lactate on IL-1b release from glia.

Materials and methods: Mixed glial cultures were grown from wild type and NLRP3 knock-out mice. Pro- and mature IL-1b release was measured following addition of 25–55 mM lactate with, or without, pre-treatment with the caspase-1 inhibitor, YVAD-CHO (Calbiochem).

Results: 25 mM lactate induced the release of IL-1b from mouse glial cultures. IL-1b release was not significantly altered by pre-treatment with YVAD-CHO. Lactate-mediated IL-1b release also occurred in NLRP3 knock-out cultures. The lactate-induced IL-1b release is distinct from the caspase-1 dependent process since the mature IL-1b present in treated supernatants is 20 kDa as opposed to 17 kDa.

Conclusions: Lactate induced IL-1b release from glial cells and this release was independent of the classical NLRP3 inflammasome/caspase-1 pathway. Further investigation of this caspase-1-independent IL-1b pathway may in future provide novel targets for the treatment of inflammatory disease.

This work was supported by BBSRC CASE Award with Pfizer.

P0317
NLRC$_4$ mediates protection in bacterially triggered intestinal inflammation

S. E. Nordlander,* D. Baban† & K. J. Maloy*
**Sir William Dunn School of Pathology, University of Oxford, Oxford, UK, †The Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, UK*

Purpose/Objective: Pattern recognition receptors (PRRs) enable mammals to discriminate self from non-self through the recognition of microbial signatures, such as bacterial flagellin. Flagellin is detected by the PRR NLRC4, which drives the activation and release of potent pro-inflammatory mediators. We aimed to characterize the role of NLRC4 in bacterially-triggered intestinal inflammation.

Materials and methods: We used a model based on the intestinal pathogen *Citrobacter rodentium*, a close relative of enteropathogenic *E. coli,* that induces acute intestinal pathology and diarrhea in mice.

Results: Following oral infection with *C. rodentium*, NLRC4$^{-/-}$ mice developed more severe weight loss, increased bacterial colonization levels and exacerbated intestinal inflammation compared to WT mice. Experiments using bone marrow chimeras revealed that the protective effects of NLRC4 were mediated by non-hematopoietic cells.

Conclusions: In conclusion, NLRC4 signalling in non-hematopoietic cells provided protection from bacterially-induced intestinal inflammation, possibly by limiting bacterial colonization. Further studies are needed to elucidate the molecular mechanisms responsible for protection.

P0318
NLRP3 inflammasome activation by prion protein fibrils

I. Hafner-Bratkovic,* M. Bencina,* K. A. Fitzgerald,† D. Golenbock† & R. Jerala*
**Department of Biotechnology, National Institute of Chemistry, Ljubljana, Slovenia, †Division of Infectious Diseases and Immunology, University of Massachusetts Medical School, Worcester, MA, USA*

Purpose/Objective: Transmissible spongiform encephalopathies (prion diseases) are characterized by accumulation of abnormal form of prion protein, spongiform change, gliosis and progressive neuronal cell loss; however, the underlying cause of neurodegeneration is not known. Previous studies have indicated the role of innate immunity, particularly of NLRP3 inflammasome in other amyloid diseases Alzheimer's disease and type II diabetes. Production of proinflammatory cytokine IL-1β has also been observed in brain in several types of prion disease and IL-1R deficiency significantly prolonged the onset of the disease. The aim of our study was to investigate whether prion protein deposits can instigate NLRP3 inflammasome.

Materials and methods: We prepared several types of assemblies of prion protein and biophysically characterized them. Cytokine release from fibril-activated microglia and macrophages from wild-type mice and from mice deficient in NLRP3, ASC and caspase-1 was assessed by ELISA. Confocal microscopy and flow cytometry were used to determine caspase-1 activation, lysosome destabilization and neurotoxicity in co-cultured microglia and neurons.

Results: We show that prion protein fibrils, converted from α- to predominantly β-type conformation, trigger cleavage of pro-IL-1β, which requires the inflammasome components NLRP3, ASC and caspase-1, whereas the native monomeric form of prion protein does not induce activation of IL-1β. Several of the previously proposed NLRP3 inflammasome activation pathways may contribute to prion fibril-induced inflammasome activation, since it can be blocked by inhibition of K^+ efflux and inhibition of phagocytosis. Proteinase K-resistant prion protein fibrils induce release of neurotoxic species by microglial cells and can thus contribute to neuronal cell death.

Conclusions: We demonstrated that prion protein fibrils, but not oligomers or monomers, via activation of NLRP3 contribute to neuronal cell death. Our results and previous studies on IL-1R-deficient mice suggest the IL-1 signaling pathway as the perspective target for the therapy of prion disease.

P0319
NLRP3 inflammasome activity is negatively controlled by miR-223

F. Bauernfeind, A. Rieger & V. Hornung
Institute for Clinical Chemistry and Pharmacology, University Hospital Bonn, Bonn, Germany

Purpose/Objective: Inflammasomes are multiprotein signaling platforms that form upon sensing microbes or endogenous danger associated molecular patterns to activate caspase-1. Activated caspase-1 leads to the secretion of proinflammatory cytokines and the initiation of a special type of cell death, known as pyroptosis. Especially the NLRP3 inflammasome appears to be a general sensor of cell stress. In contrast to other inflammasome proteins, NLRP3 is expressed under limiting conditions in resting cells and an additional priming signal is critically required to boost its expression. This induction of NLRP3 protein expression is licensed by PRR signaling which allows respective NLRP3 activators to trigger caspase-1 cleavage. In general, NLRP3 inflammasome activation is tightly regulated at several steps including the transcriptional control of its expression. Based on the observation that the upregulation of NLRP3 mRNA following a pro-inflammatory signal is rather short-lived we speculated that NLRP3 expression could also be subject to miRNA-dependent posttranscriptional regulation.
Materials and methods: To systematically address this hypothesis, we performed genome-wide screening using a miRNA precursor library to identify microRNAs that regulate NLRP3 expression. These data were correlated with miRNA expression arrays. Screening results were verified in primary cells by loss of function and gain of function experiments.
Results: We identified the myeloid specific miRNA miR-223 as critical regulator of NLRP3 inflammasome activity. miR-223 suppresses NLRP3 expression through a conserved binding site within the 3' UTR of NLRP3. This translates into reduced NLRP3 inflammasome activity.
Conclusions: While miR-223 itself is not regulated by proinflammatory signals, its expression varies among different myeloid cell types. Thereby, given the tight transcriptional control of NLRP3 message itself, miR-223 functions as an important rheostat controlling NLRP3 inflammasome activity.

P0321
Pattern recognition receptor modulation of murine cutaneous wound healing.

H. Williams,* L. Campbell,* R. A. Crompton,* A. McBain,† S. Cruickshank* & M. J. Hardman*
**Faculty of Life Sciences, University of Manchester, Manchester, UK, †School of Pharmacy and Pharmaceutical Sciences, University of Manchester, Manchester, UK*

Purpose/Objective: Chronic wounds including pressure sores, venous leg ulcers and diabetic foot ulcers occur in one in twenty of the elderly population greatly affecting quality of life. They cause pain, distress and disability for patients, and pose a continuing challenge to global health care professionals, with estimated annual treatment costs exceeding £3 billion in the UK alone. Emerging data suggest wound colonization with bacterial species including Staphylococcus, Pseudomonas and Enterbacter and ultimately the formation of a biofilm is a key confounding factor in the aetiology of chronic wound ontogenesis and the prolonged pro-inflammatory non-healing phenotype. Despite recent advances in the profiling of microflora in infected wounds, the mechanisms whereby the host responds to (or in cases of pathology fails to respond to) colonising bacteria remain unclear. Over a wide range of epithelia host pattern recognition receptors (PRRs) play a key role in this environmental surveillance through their ability to recognise and respond to a diverse range of pathogen associated molecular patterns (PAMPs). Surprisingly, little is known about host-microflora interaction during skin wound repair. The aim of this study was to explore host modulation of skin microflora in PRR null mice and preclinical delayed healing murine models.
Materials and methods: The bacterial skin flora of normal and wounded skin from each model was profiled by eubacterial 16S PCR-DGGE, in conjunction with DNA sequencing.
Results: We reveal an important interplay between the cutaneous microbiota, the innate immune system and specific skin PRRs. Further, we identify key miroflora changes in delayed healing mouse models.
Conclusions: Our findings support the hypothesis that specific genetic or functional changes in the skin predispose to colonization with potentially pathogenic bacteria, and subsequent detrimental effects on wound repair.

P0322
Priming through TLR4 but not TNFRs enhances inflammasome activation in human neutrophils

Y. Tingle, S. Sethu, J. Hamdam, L. Abbas Al-Huseini, N. Alhumeed, D. Williams & J. Sathish
Molecular and Clinical Pharmacology, University of Liverpool, Liverpool, UK

Purpose/Objective: Objective: ATP is essential source of energy forcellular homeostasis.However, as a DAMP (damage associated molecular pattern) from injured or dying cells and tissues, ATP hasdeleterious effects on cells, including a variety of immune cells resulting in unwanted immune responses leading to the progression of tissue damage.ATP induced innate immune responses are mediated through NLRP3 inflammasome activation. However, the role of this process in neutrophils is not well explored. In the current study we investigate the effect of neutrophil priming in ATP induced inflammasome activation.
Materials and methods: Method: Primary neutrophils were isolated from whole peripheral human blood.TNF-alpha and TLR4 agonist (LPS) were used as priming agents prior to ATP exposure. IL-1beta level was measured by ELISA as an indicator of inflammasome activation andIL-8 level was measured as non-inflammasome mediated response.
Results: Results: LPS priming significantly increased ATP-inducedIL-1beta secretion by human neutrophils whereas TNF-alpha priming did not produce similar effects. Furthermore, IL-8 secretion induced by either TLR4 or TNFR stimuli was not influenced by inflammasome activation.
Conclusions:
Conclusion: Activation of TLR4 is a potent priming factor for inflammasome activation resulting in increased IL-1beta production whereas TNFR priming has little or no effect in human neutrophils.

P0323
The bacterial virulence factor TcpC activates the Nalp3 inflammasome by direct interaction

A. M. Waldhuber, C. Cirl, S. Duerr & T. Miethke
Department of Medicine, Institute for Medical Microbiology Immunology and Hygiene TU Munich, München, Germany

Purpose/Objective: Toll-like receptors (TLRs) play essential roles in the activation of innate immune responses against microbial infections. They are characterized by an extracellular leucine-rich repeat and an

intracellular Toll/interleukin 1 receptor (TIR) domain. The TIR domain is crucial for TLR signaling by recruiting TIR containing adaptor proteins to the cytoplasmic domain of TLRs.

We recently described TIR domain containing proteins (Tcps) in the uropathogenic *Escherichia coli* strain CFT073 (TcpC) and in *Brucella melitensis* (TcpB) as a new class of virulence factors. Despite its inhibitory effect on TLR pathways TcpC is able to induce interleukin-1 beta (IL-1β) secretion suggesting a possible role of the inflammasome.
Materials and methods: The main focus of this work was to investigate the interaction between TcpC with components of the inflammasome. We therefore co-expressed TcpC in 293T cells together with various inflammasome associated proteins and performed immunoprecipitation experiments and confocal microscopy. Subsequent experiments using wild-type, ASC or Nalp3- deficient bone marrow derived macrophages (BMMs) infected with CFT073 addressed whether these inflammasome components are important for IL-1 β secretion.
Results: Indeed we observed an interaction or colocalization of a truncated form of TcpC with Nalp3 and Caspase-1. Support for a direct interaction of recombinant TIR-TcpC and Nalp3 was shown by an endogenous pull-down assay with lysates prepared of BMMs.

Infection experiments of BMMs with CFT073 revealed that TcpC-dependent induction of IL-1β secretion was strictly dependent on Nalp3 and ASC.
Conclusions: In summary our recent findings show, that TcpC inhibits TLRs but also activates the inflammasome.

The NLRP3 inflammasome in stable COPD

M. Juan-Otero,* R. Faner,† P. Sobradillo,‡ A. Noguera,§ C. Gómez,¶ N. González, N. Ballester E Soler,†† Y. Arostegui JI Yagüe,‡‡ R. Rodriguez-Rosín§§ & A. Agustí¶¶**
**Immunology Service, Hospital Clínic, Barcelona, Spain, †Hospital Clínic & FISIB, CibeRES, Barcelona-Mallorca, Spain, ‡Pulmonary Service, CIBERES & Hospital Txagorritxu, Vitoria-Mallorca, Spain, §CIBERES & Hospital Universitari Son Espases, CibeRES, Mallorca, Spain, ¶Hospital Universitari Son Espases, CibeRES, Mallorca, Spain, **Pulmonary Service, CIBERES & Hospital Clinic, Barcelona-Mallorca, Spain, ††Pulmonary Service, Hospital Clinic, Barcelona, Spain, ‡‡Immunology Service, Hospital Clinic, Barcelona, Spain, §§Pulmonary Service, CIBERES & Hospital Clínic & IDIBAPS, Barcelona, Spain, ¶¶Pulmonary Service, FISIB & CIBERES & Hospital Clínic & IDIBAPS, Barcelona-Mallorca, Spain*

Purpose/objective (introduction and objectives): The NLRP3 inflammasome is a multi-protein cytoplasmic sensor that governs the inflammatory response. Auto-inflammatory diseases are characterized by inflammasome abnormalities that result in excessive inflammation.

We hypothesized that the enhanced inflammatory response that characterizes chronic obstructive pulmonary disease (COPD) can have an auto-inflammatory component.

To test this hypothesis, we compared the expression, activity, functionality and transcriptional profile of the NLRP3 inflammasome in lung tissue samples and peripheral blood samples obtained from COPD patients, smokers (Sm) with normal spirometry and non-smoker (NSm) controls. Besides, we studied *in vitro* its functional response in isolated peripheral blood mononuclear cells (PBMCs).
Materials and methods: Immunohistochemistry techniques were used to assess the expression of caspase-1 in lung tissue, and Western blot, ELISA and/or real time PCR to quantify markers of inflammasome activation and related inflammatory mediators in lung tissue homogenates, serum and PBMCs *in vitro*.
Results:

1 Caspase-1, a core component of the NLRP3 inflammasome, was widely expressed in lung tissue.
2 Sm and COPD patients (including former Sm) had higher pulmonary protein levels of several makers of inflammasome activation, such as IL-1b, IL-1RA and IL-18. Besides, transcription of NLRP3 was increased in COPD patients, and mRNA levels of NLRP3 and IL-1b correlated negatively with the severity of airflow limitation.
3 Differences between groups were attenuated in serum, but serum caspase-1 levels were significantly related with those determined in lung tissue.
4 The *in vitro* functional response of the inflammasome in COPD was normal.

Conclusions: These results show that theNRLP3 inflammasome participates in the inflammatory response of COPD, exclude an auto-inflammatory component of COPD and support the use of serum caspase-1 levels as a systemic surrogate biomarker of inflammasome activation in the lung parenchyma.

P0325
The role of the NOD-like receptor NLRC3 in the innate immune system

L. Bremer, S. Lipinski, S. Schreiber & P. Rosenstiel
Cellbiology, Institute of Clinical Molecular Biology, Kiel, Germany

Purpose/Objective: The innate immune system enables eukaryotes to detect potential pathogenic elicitors in the host microbiome. It relies on several pattern recognition receptors (PRRs) to identify pathogen associated molecular patterns (PAMPs). One of the most prominent non-clonal, germline encoded but yet not fully characterized PRR group are the NOD-like receptors (NLR). In humans more than 20 NLRs have been identified and molecular evidence suggests that NLRs evolved to high pathogen specificity. NLRs occur in the closed boundaries of cells, upon detection of PAMPs they tend to oligomerize and form high molecular weight complexes. Those structures are an essential hub for further downstream signaling resulting in an inflammatory answer of the respective cell. Here, we aimed to analyze the expression pattern of NLRC3, a hitherto rarely characterized NOD-like receptor.
Materials and methods: In order to study the intracellular localization of NLRC3, we used immortalized HEK-293 and HeLa cells to overexpress NLRC3 and to conduct fluorescence staining. A tissue panel of human or murine origin was used to determine basal NLRC3 expression by real-time TaqMan PCR. Several stimulation regimes were applied. Western blotting using an antibody to NLRC3 was performed to confirm presence of NRLC3 in selected cell lines and tissues.
Results: We found NLRC3 to be strongly expressed in the cytosol of unstimulated epithelial HEK-293 cells and primary tissues. Especially immune related tissues like liver and spleen contain a high NLRC3 yield. Human peripheral blood mononuclear cells and murine bone marrow derived macrophages were found to be ideal models for stimulation experiments and expression analysis. Additionally we were able to show a close connection between the autoimmune disease Wegener's Granulomatosis and altered NLRC3 expression. In nasal mucosa biopsies from patients with Wegener's Granulomatosis the protein level of NLRC3 was significantly decreased compared to non-diseased individuals.
Conclusions: We identified epithelial and immune cells to constitutively express NLRC3. A disturbed NLRC3 expression pattern was shown in the nasal mucosa of Wegener's Granulomatosis patients, connecting NLRC3 to autoimmune diseases. Based on these findings, further studies will be employed to characterize NLRC3 function. Revealing the molecular function of NLRC3 will improve the understanding of the innate immune system.

Zinc-depletion activates processing and secretion of IL-1ß by inflammasome-dependent and independent mechanisms

D. Brough,* H. Summersgill,* N. Luheshi,* C. B. Lawrence,* J. Pahle† & P. Mendes†

**Faculty of Life Sciences, University of Manchester, Manchester, UK, †Computer Science and Manchester Centre for Integrative Systems Biology, University of Manchester, Manchester, UK*

Purpose/Objective: Inflammation exacerbates the pathology of non-communicable disease. A key driver of this damaging inflammatory process is the pro-inflammatory cytokine interleukin-1beta (IL-1beta). IL-1beta is produced as an inactive precursor (pro-IL-1beta) that is cleaved by a protease called caspase-1 following its activation by the inflammasome complex. Multiple inflammasomes are known to exist but the best characterised, and the one implicated in sterile disease, is formed by the pattern recognition receptor NLRP3, the adaptor protein ASC and caspase-1. Zinc deficiency is a common cause or consequence of inflammatory disease and is prevalent in the aged population. The purpose of this study was to examine whether zinc depletion acted as an inflammatory stimulus to macrophages to induce the processing and release of IL-1beta via assembly of the NLRP3 inflammasome.

Materials and methods: Peritoneal macrophages were prepared from wild type (WT), NLRP3 and ASC knockout (KO) mice and cultured overnight. Cultures were then primed with bacterial endotoxin (lipopolysaccharide, LPS, 1 μg/ml) for 2 h before a 4 h treatment the zinc chelators TPEN or DTPA.

Results: Our data show that zinc depletion of LPS-primed macrophages induced the release of processed IL-1beta. Pharmacological studies using a cathepsin B inhibitor (Ca074), glyburide and a caspase-1 inhibitor (YVAD) suggested that zinc-depletion-induced IL-1beta processing was dependent on the NLRP3 inflammasome. However, studies in the knockout cells suggest that this is only partially true with multiple mechanisms of IL-1beta processing engaged.

Conclusions: These data suggest that zinc depletion can activate the processing of IL-1beta via multiple pathways. Zinc deficiency is a major contributor to inflammatory diseases of ageing and it is possible that the mechanisms we report here contribute to this effect.

P0328

A naturally occurring carrier substance coupled to immunostimulatory RNA serves as a potent adjuvant delivery system

H. L. Obermann, A. Kaufmann & S. Bauer
Institute for Immunology, Philipps University, Marburg, Germany

Purpose/Objective: Vaccination is indispensable to prevent infectious diseases and therefore the development of safe and potent vaccine adjuvants becomes highly important. Here we investigate the specific activation of the innate immune system via TLR7 by coupling a TLR ligand to a natural carrier.
Materials and methods: Human PBMCs and murine Flt3L*induced mixed cultures of myeloid and plasmacytoid DCs of wt and TLR7$^{-/-}$ mice were used to analyze cytokine induction. These cells were incubated with immunostimulatory RNA coupled to the natural carrier versus complexation of the TLR7 ligand with the transfection reagent DOTAP. Supernatants were harvested after 20h and cytokine induction was analyzed by ELISA.

Murine Flt3L-induced cultures were incubated with fluorescent-stained RNA coupled to the natural carrier or complexed with DOTAP. Cellular uptake was analyzed by FACS and fluorescent microscopy.
Results: We could show that the TLR ligand coupled to the natural carrier is a potent inducer of IFNα and proinflammatory cytokines such as TNFα and IL-6. Interestingly, the TLR ligand coupled to the natural carrier leads to an increased IFNα secretion in comparison to complexation to the conventional transfection reagent DOTAP. Furthermore we were able to demonstrate that activation of the immune cells is strictly dependent on TLR7.

Coupling of the carrier to a non-stimulatory RNA did not lead to any cytokine induction which is an important aspect to prevent side-effects triggered by the carrier.

Cellular uptake of the TLR ligand coupled to the carrier was demonstrated by FACS-analysis and fluorescent microscopy.
Conclusions: In this study we developed a very potent adjuvant delivery system for TLR7. Our *in vitro* experiments showed an effective activation of immune cells stimulated with a TLR ligand coupled to the carrier. Thus, DOTAP induced side-effects could be abrogated by using this natural carrier. With focus on avoiding undesired side-effects like cell toxicity the use of a natural adjuvant delivery substance would be a major advantage for boosting immune responses initiated by vaccination.

P0329

Activated T cells detect intracellular single- and double-stranded DNA but fail to activate type I IFN responses – implication for restriction of HIV replication

S. H. Rahbek,* R. K. Berg,† S. R. Paludan,* M. R. Jacobsen* & T. H. Mogensen†
**Institute of Biomedicine, Health Science, Århus C, Denmark, †Infectious Diseases, Health Science, Århus C, Denmark*

Purpose/Objective: During HIV replication the virus genome is both in RNA and DNA form. It is however unknown how or if they activate the innate immune reactions in T-cells. There are numerous classes of PRRs involved in recognition of viral specific components. This work is primary concentrated on cytosolic DNA receptors in T-cells. Interferon-inducible 16 (IFI16) has been described as an intracellular DNA sensor, that co-localize with the endogenous cytoplasmic DNA.
Materials and methods: PBMCs were isolated from buffy coats and stimulated with IL-2 and PHA. In this study we investigate which cytosolic DNA sensors, that recognize dsDNA in IL-2/PHA activated T-cells. These T-cells were transfected with labled ssDNA, dsDNA or ssRNA using the transfection agent Lipofectamine 2000. After 1 h of incubation, the cells were fixed and antibody stained for CD3, IFI16 and STING, which were visualized and quantified by confocal microscopy. After 6 h of incubation the mRNA level of IFN-β and CXCL-10 were measured by qPCR. Moreover the CXCL-10 protein level were measured by ELISA after 24 h of incubation.
Results: Transfected cytosolic DNA failed to stimulate anti-HIV activity in activated T cells. Flow-analysis confirmed efficient transfection. Confocal imaging showed that IFI16 relocated and co localized with transfected dsDNA and ssDNA, and not ssRNA. After DNA sensing in activated T-cells there was no activation of IFN responses.
Conclusions: We conclude that IL-2/PHA activated T-cells recognize cytosolic DNA, but fails to induce IFN responses. This data may provide insight into why T-cells are permissive to HIV infection.

P0331

Comparing the effects of human beta defensin 3 and LL-37 on Toll-like receptor signaling

F. Semple,* S. L. Cox,* S. Webb,* D. J. Davidson† & J. R. Dorin*
**Medical Research Council Human Genetics Unit, Institute of Genetics and Molecular Medicine, Edinburgh, UK, †Queen's Medical Research Institute, MRC/University of Edinburgh Centre for Inflammation Research, Edinburgh, UK*

Purpose/Objective: Beta-defensins are key players in innate and adaptive immunity and recently human beta defensin-3 (hBD3) has been shown to limit production of pro-inflammatory cytokines in TLR4-stimulated macrophages. The MyD88 and TRIF pathways are both inhibited by hBD3, however the direct targets are yet to be identified. The human cathelicidin LL-37 has been shown to both augment and mitigate signaling by various Toll-like receptors and may drive autoimmune disease, such as psoriasis, by converting self-DNA into an effective activator of TLR9 in pDCs. This study compares the effects of hBD3 and LL-37 on stimulation of Toll-like receptors 2, 3, 7 and 9.
Materials and methods: Primary macrophages and pDCs were treated with with the TLR2, 3, 4, 7 or 9 agonists, Pam3CSK4, poly I:C, LPS, R848 and CpG respectively, in the presence or absence of hBD3 or LL-37. Cytokine levels in cell culture supernatants were measured by ELISA.
Results: We show that although both hBD3 and LL-37 suppress and increase particular TLR signaling pathways, they also demonstrate distinct effects. hBD3 and LL-37 suppress LPS-induced TNF alpha, IL-6 and RANTES, however neither have an effect on cytokine induction by TLR2 or TLR7. In addition, hBD3 and LL-37 exacerbate the proinflammatory effect of the TLR3 agonist pI:C. In contrast, IFN alpha induction by CpG is amplified by the presence of LL-37 but inhibited by the presence of hBD3. Furthermore, hBD3 abolishes this LL-37-enhanced TLR9 activation in pDCs.
Conclusions: We have shown that hBD3 interacts with TLR signaling pathways to both suppress and augment cytokine and interferon production. hBD3 is part of a cluster of highly copy number variable genes and individuals may have variable expression levels, the effects of which may have implications for autoimmune disease. In addition the enhanced effects of hBD3 and LL-37 on pI:C should be considered in the development of nucleic adjuvants in vaccines.

P0332

Expression of melatonin receptors in the cells of immune system

V. Cernysiov,* R. Bozaite,† M. Mauricas,† I. Girkontaite† & V. Cernysiov†

Faculty of Natural Science, Vilnius University, Vilnius, Lithuania, † Department of Immunology, State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania

Purpose/Objective: Melatonin is a hormone that regulates many physiological circadian rhythms. It regulates and controls biological clock, stimulates the immune system and protects the central nervous system. The disrupted synthesis of melatonin leads to pathological process, including cancer, autoimmune diseases; i.e. diseases caused by the disorder of the immune system.

Melatonin acts via four types of receptors: MT1, MT2, MT3 and nuclear receptors (ROR*a*, RZRβ, and RORγ). The knowledge about the expression of melatonin receptors on the cells of the immune system is insufficient. The data about detail expression of those receptors could contribute to understand the mechanisms of the immunomoduliatory action of melatonin.

Materials and methods: We analysed the expression of melatonin receptors in the murine organs (spleen, bone marrow, thymus, lymph nodes) and cells (macrophages, dendritic cells, granulocytes) of immune system. The analysis was performed using rtPCR.

Results:

The main research findings include: mRNA of MT1 melatonin receptor was found mainly in the thymus. A weak expression of MT1 was detected in the granulocytes. MT1 was not detected in the bone marrow, lymph nodes, spleen, macrophages and dendritic cells.

MT2 mRNA was found in the thymus only. It was not detected in the bone marrow, lymph nodes, spleen, granulocytes, macrophages and dendritic cells.

RORg mRNA was detected in the thymus and granulocytes. Also, we amplified very small amounts of RORg mRNA in the lymph nodes and bone morrow cells. However, this receptor was not detected in spleen, macrophages and dendritic cells.

MT3 mRNA was found in all tested organs (spleen, bone marrow, thymus, lymph nodes) and cells (macrophages, dendritic cells, granulocytes).

RORa mRNA was found in all tested organs (spleen, bone marrow, thymus, lymph nodes), in the macrophages and dendritic cells. However, this receptor was not detected in granulocytes.

RORb mRNA was not detected in all tested organs and cells.

Conclusions: During research work was investigated the expression of melatonin receptors in the murine organs (spleen, bone marrow, thymus, lymph node) and cells (macrophages, dendritic cells, granulocytes) of immune system.

P0333

Extracellular toll like receptor regulator RP105/CD180 ameliorates atherosclerosis via its role on B cells

S. C. de Jager,* J. C. Karper,† I. Bot,* M. R. de Vries,† C. J. Binder,‡ J. Kuiper* & P. H. Quax†

Biopharmaceutics, Leiden Amsterdam Center for Drug Research/Leiden University, Leiden, The Netherlands, †Surgery, Leiden University Medical Center, Leiden, The Netherlands, ‡Laboratory Medicine, Medical University of Vienna, Vienna, Austria

Purpose/Objective: RP105 is a structural homolog of TLR4 and an important regulator of TLR4 signaling. RP105 enhances B-cells activation while it dampens the TLR4 response on myeloid cells. B-cells are known to be important in autoimmune disease and increase atherosclerosis independently of antibody production or presence of other leukocytes. RP105 is also linked to autoimmune disease however a role for RP105 in atherosclerosis still remains unknown.

Materials and methods: Male LDLR$^{-/-}$ mice were irradiated and subsequently received bone marrow from either RP105$^{-/-}$ or wild type control mice. After 6 weeks of recovery the mice were fed a hypercholesterolemic diet for 9 weeks and sacrificed for further analysis.

Results: Plaque burden in the proximal aorta was significantly attenuated ($230 \pm 26 \times 10^3$ μm^2 versus $131 \pm 15 \times 10^3$ μm^2 $P = 0.004$) in the RP105$^{-/-}$ chimeras. No difference in activation of Dendritic Cells, Macrophages, or T cells was found whereas B cell activation was significantly reduced in the RP105$^{-/-}$ chimeras as depicted by the percentage of cell surface bound IgM and CD86 expression on CD19$^+$ B cells. Expression of pro-inflammatory cytokines was significantly decreased in the spleen of RP105$^{-/-}$ chimeras. IgM against oxLDL or MDA-LDL were not altered while IgG levels against oxLDL and MDA-LDL were significantly lowered in the RP105$^{-/-}$ chimeras. *In vitro* B cells from RP105$^{-/-}$ mice showed reduced activation and proliferation upon LPS stimulation but not upon αCD40 stimulation and a decrease in IL6 production. Furthermore *ex vivo* stimulation showed that splenocytes from RP105$^{-/-}$ chimeras showed less proliferation upon oxLDL or LPS incubation. Although we could not find a difference in systemic T-cells activation, we did find a significant reduction in both intimal and perivascular T lymphocyte and macrophage accumulation.

Conclusions: Our study is the first to show a TLR mediated role for B cells in atherosclerosis via the effects of RP105 in an antibody and cytokine dependant manner.

P0334

Functional and biological characterization of SSc5D, a novel molecule of the scavenger receptor cysteine−rich family

C. Bessa Pereira, R. F. Santos, C. M. Gonçalves & A. M. Carmo

Institute for Molecular and Cell Biology and Abel Salazar Institute for Biomedical Sciences, University of Porto, Group of Cell Activation and Gene Expression, Porto, Portugal

Purpose/Objective: SSc5D is a member of the Scavenger Receptor Cysteine-Rich (SRCR) superfamily. This group of proteins is characterized by the presence of one or more SRCR domains, which are thought to mediate protein-protein interactions within the immune system, or to serve as pathogen pattern recognition motifs. SSc5D consists of two structurally distinct parts − a N-terminal domain containing five SRCR domains, and a C-terminal domain made up of a high number of repetitive and extensively O-glycosylated sequences similar to mucins. The overall function of the SRCR family is still poorly understood; therefore unraveling the biological and functional properties of SSc5D may help to clarify the role of this group of highly conserved proteins.

Materials and methods: SSc5D cell expression at the mRNA and protein levels was analyzed in different cells and cell lines, and tissue-expression analysis was accessed by immunohistochemical staining of normal and pathological sections of uterus, placenta, spleen, kidney, etc. To evaluate the binding of SSc5D to different types of cell, including different pathogens, the two distinct domains of SSc5D* the SRCR containing domain, and the mucin-like domain − were independently produced.

Results: SSc5D is highly-expressed in PBMCs, in particular in CD4$^+$ T lymphocytes and in the monocytic lineage cells. Nevertheless, it is also detected in other cell-types from different tissues, although presenting different molecular weights. This suggests that post-transcriptional or -translational modifications may be cell-specific. Confirming our previous results from Northern blotting analysis, a high expression of SSc5D in placenta was detected by immunohistochemical staining of sections, where we observed the localization of SSc5D in syncytiotrophoblast cells, which can suggest a possible role in fetal immunity.

Conclusions: SSc5D is expressed in different types of cells and tissues and its peculiar characteristics suggest a role as a novel immune receptor. Ours and other's results suggest that SSc5D may be produced by a variety of different cells and provide a molecular bridge for the interaction of immune cells with pathogens in different tissues.
Acknowledgments: This work is supported by FEDER-COMPETE, and by FCT (PTDC/SAU-MII/100588/2008 and PEst-C/SAU/LA0002/2011)

P0335

Functional significance of evolutionary divergence in Toll-like receptor-regulated gene expression in human versus mouse

M. J. Sweet,* K. Schroder,* K. M. Irvine,* M. Taylor,† N. J. Bokil,* S. Broomfield,* M. A. Schembri,‡ K. J. Stacey‡ & D. A. Hume§
**Institute for Molecular Bioscience, University of Queensland, Brisbane, Qld, Australia, †Medical Research Council Human Genetics Unit, Western General Hospital, Edinburgh, UK, ‡School of Chemistry and Microbial Sciences, University of Queensland, Brisbane, Qld, Australia, §Roslin Institute and Royal (Dick) School of Veterinary Studies, University of Edinburgh, Edinburgh, UK*

Purpose/Objective: Host immune response genes must co-evolve with rapidly evolving pathogens. Thus, species-differences in immune genes are likely to be particularly important in host defence. Differences in the way that orthologous genes are expressed are thought to be particularly critical for phenotypic differences between species. This study defined the extent of divergence in TLR4-regulated gene expression between primary human and mouse macrophages, the underlying mechanisms responsible for this divergence, and the functional significance of 'human-specific' TLR4-target genes in host defence.
Materials and methods: A custom expression profiling platform was developed to compare TLR4 regulated expression of orthologous genes in human versus mouse. Species-specific gene regulation was confirmed across a panel of human and mouse macrophage cell types at the mRNA and protein level. Promoters of TLR4 target genes (identified on a genome wide-scale) were interrogated to identify mechanisms of regulatory divergence. Functional analysis of human-specific TLR4 target genes was performed in primary human macrophages responding to Gram-negative bacterial pathogens.
Results: Although there was a pattern of conservation in TLR4-regulated gene expression between human and mouse, approximately 7.5% of TLR4 target genes showed striking divergence in regulation between these species across an LPS time course. Features of divergently regulated gene promoters include TATA box enrichment, CpG island depletion and, paradoxically, enhanced sequence conservation. Divergence in anti-microbial effector genes was common. Functional analysis of 'human-specific' TLR4 target genes identified a role for a novel zinc transporter in human macrophage anti-microbial responses, since knock-down of this gene in primary human macrophages impaired clearance of intracellular *E. coli*, whilst exogenous zinc enhanced killing of *E. coli*. However, this transporter has been hijacked by *Salmonella typhimurium* to permit intracellular survival of this pathogen.
Conclusions: Striking divergence in the regulation of innate immune genes is common. Highly conserved, complex promoters control the expression of these genes. This complexity likely increases their susceptibility to evolutionary change. Many 'human-specific' TLR4 target genes are likely to have important, unexplored roles in host defence.

P0336

Gene expression induced by Toll-like receptors in macrophages requires the transcription factor NFAT5

M. Buxadé,* G. Lunazzi,* J. Minguillón,* S. Iborra,† R. Berga-Bolaños,* M. del Val,‡ J. Aramburu* & C. López-Rodríguez*
**Department of Experimental and Health Sciences, Universitat Pompeu Fabra, Barcelona, Spain, †Centro Nacional de Microbiología, Instituto de Salud Carlos III, Madrid, Spain, ‡Centro de Biología Molecular Severo Ochoa, CSIC/Universidad Autónoma de Madrid, Madrid, Spain*

Purpose/Objective: Toll-like receptors engage networks of transcriptional regulators to induce genes essential for antimicrobial immunity. The map of transcription factors downstream TLRs is not fully understood and our work identifies NFAT5 as a novel regulator of mammalian anti-pathogen responses downstream TLRs.
Materials and methods: We used bone marrow derived macrophages (BMDMs) and peritoneal macrophages from WT and NFAT5$^{-/-}$ mice stimulated with LPS from *E. coli*. Gene expression and regulation of transcription was assessed by western blot, RT-qPCR, cDNA microarray analysis and Chromatin Immunoprecipitation assays. Luciferase reporter assays and siRNA technology was also used to further study gene expression regulation. As *in vivo* models, we have used LPS injection and *Leishmania major* infection.
Results: We show that upon treatment of macrophages with TLR agonists, NFAT5 is induced and recruited to the regulatory regions of pro-inflammatory genes. Accordingly, NFAT5-deficent bone marrow derived macrophages (BMDMs) show a selective defect in the expression of pro-inflammatory and antimicrobial genes such as *Nos2*, *Il6* and *Tnf*. Moreover, we show that NFAT5 exhibits two modes of association with its target genes, as it is constitutively bound to *Tnf* and other genes, while its recruitment to *Nos2* or *Il6* requires TLR activation. Further analysis revealed that TLR-induced recruitment of NFAT5 to *Nos2* is dependent on IKKβ activity, *de novo* protein synthesis and sensitive to histone deacetytases. cDNA microarray analysis allowed us to determine to what extent NFAT5 contributes to the inflammatory gene expression program. Consistent with our *in vitro* studies, peritoneal macrophages from NFAT5$^{-/-}$ mice challenged *in vivo* with LPS displayed reduced expression of several pro-inflammatory and anti-microbial genes compared to their wild type littermates. Moreover, experiments of infection of mice with *Leishmania major*, demonstrated that NFAT5 is a key factor in the control of *L. major* replication and dissemination.
Conclusions: These findings unravel new aspects on the mechanisms regulating the cellular response to microbial products and provide important new insights into the regulation of inflammatory diseases. Altogether this work identifies NFAT5 as a novel regulator of mammalian anti-pathogen responses.

P0337

Genetic screens in evolutionary divergent wild-derived mice reveal novel regulators of the balance between inflammation and cell death

A. Poltorak & S. Schworer
Department of Pathology, Tufts University, Boston, MA, USA

Purpose/Objective: Using evolutionary divergent wild-derived mice, we identified several molecular differences between 'wild-derived' inbred strains of mice (such as MSM and MOLF/Ei) and classical inbred strains (such as C57BL6) at the IRAK2 locus, which lead to potent acute phase innate immune responses in wild-derived mice. In addition, we identified a novel anti-inflammatory function of IRAK1bp1. Here we report a novel role for CYLD in maintaining the balance pro-inflammatory signaling and cell-death.
Materials and methods: Peritoneal macrophages from B6 and MOLF were stimulated with LPS or IMQ$^{+/-}$ zVAD$^{+/-}$Nec-1 and assayed for

viability.Each mouse from the panel of backcross (B6 × B6 × MOLF) mice was genotyped using microsatellite markers.QTXb analyzed d the correlation between genotype and phenotype at each marker.Likelihood of odds (LOD) score measures the likelihood that phenotype is linked to genotype at a given locus.LOD>3 is significant.C. Genotype of N2 mice at D8Mit163 (within the peak of highest linkage).Viability phenotype at D8Mit163 is associated with more viability following IMQ^{+}zVAD stimulation.

Results: During ell death through RIP1-mediated regulated necrosis is emerging as an important mechanism through which cells respond to certain viral pathogens. To determine novel regulatory mechanisms of this signaling pathway, we studied cellular responses to Toll-like receptor (TLR) agonists in evolutionarily divergent wild-derived mice (MOLF/Ei) in a forward genetic screen of TLR-induced necrosis. In contrast to C57BL/6 macrophages, which are susceptible to TLR-induced necrosis, MOLF macrophages are resistant to death induced through this pathway. Using an N2 panel and forward genetic analysis, we found a locus on chromosome 8 that confers resistance to TLR-induced necrosis. Through gene expression analysis, allelic bias studies, and siRNA knockdown in peritoneal macrophages, we concluded that a genetic difference in CYLD confers the differential susceptibility to TLR-induced necrosis between B6 and MOLF macrophages.This difference was revealed through analysis of the regulation of CYLD mRNA species following TLR stimulation.The molecular basis for in greater survival of MOLF cells appears to be down-regulation of full-length CYLD mRNA following activation.

Conclusions: Through our use of wild-derived mice in forward genetic analysis, we were able to uncover a novel regulatory mechanism CYLD in a physiologic setting.

P0338

Hepatic regulation of pro-inflammatory stimuli through communication of liver sinusoidal endothelial cells and hepatocytes

F. A. Schildberg & P. A. Knolle
Institutes of molecular Medicine and experimental Immunology, University of Bonn, Bonn, Germany

Purpose/Objective: In the liver, hepatocytes are in close contact with liver sinusoidal endothelial cells (LSECs). These LSECs separate hepatocytes from leukocytes passing through the liver sinusoid. Although LSECs are known to be fenestrated and not interconnected by tight- junctions, they have been shown to form a functional barrier between hepatocytes and circulating leukocytes. LSECs and hepatocytes therefore fulfill different, yet complimentary functions: hepatocyte exert mainly metabolic functions whereas LSECs possess extraordinary scavenger functions. Distinct and mutually exclusive expression of different receptors and regulating molecules forms the molecular basis for cooperative and instructive interaction between these two cell populations. Ideally, the interaction of hepatocytes and LSECs is aimed at optimal functional adaptation.

Materials and methods: Presence of defined proinflammatory pathogen–associated molecular patterns (PAMP) is sensed through germ–line encoded pattern recognition receptors (PRRs), the majority of which are Toll–like Receptors (TLRs).

Results: We have been able to define the molecular basis for PAMP–recognition on LSECs. Here, we show new insights of the communication between hepatocytes and LSECs, which are crucial for the regulation of biological functions in hepatocytes by signalling of distinct TLRs and the expression of proinflammatory cytokines in LSECs.

Conclusions: Thus, we define the molecular basis how LSECs integrate and present microenvironmental signals to hepatocytes, thereby extrapolating signalling processes from the level of sinusoidal compartment into the whole organ.

P0339

Identification of a novel IFN-inducible short isoform of RIG-I that acts as feedback negative regulator

K. Eisenächer,* H. Sarioglu,† S. Hauck† & A. Krug*
**Medical Department, Technische Universität München Klinikum rechts der Isar, 2., München, Germany, †Helmholtz Zentrum München, Research Unit for Protein Science-Core Facility Proteomics, Neuherberg, Germany*

Purpose/Objective: Innate immune signaling in response to viral infection is triggered by differential activation of the cytosolic retinoic acid-inducible gene I (RIG-I)-like receptors (RLRs). Activation of these receptors leads to the induction of type I interferon (IFN I) and proinflammatory cytokines. RIG-I is the prototypic member of the RLR family. Therefore, the mechanisms of RIG-I activation and its modulation to prevent uncontrolled IFN I production were extensively studied. In line with this, we identified a novel isoform of human RIG-I that acts as inhibitor of its own pathway.

Materials and methods: RIG-I isoform expression was monitored by western blot. Identification of the newly identified RIG-I variant (RIG-I SF) was assessed by immunoprecipitation and mass spectrometry analysis. To illuminate the function of RIG-I SF, the corresponding sequence was cloned and luciferase reporter assay, ELISA and site-directed mutagenesis were applied. Proteasome and caspase-specific inhibitors were tested to investigate the generation of the novel RIG-I variant.

Results: Detection of endogenous RIG-I in WCLs of human cells after IFN I stimulation revealed a yet unknown short 95 kDa isoform of RIG-I. RIG-I SF is expressed in a time and dose-dependent manner in response to IFN I treatment, pppRNA transfection and virus infection, with a delayed kinetics compared to RIG-I splice variant. Mass spectrometry analysis indicated that RIG-I SF might comprise amino acids L155 to K925 of RIG-I. Overexpression of RIG-I SF leads to a dose-dependent inhibition of the RIG-I-mediated IFN response. This inhibitory capacity was absent when RIG-I SF bearing point mutations in the pppRNA-binding site was analyzed. Analysis of WCLs of cells pretreated with proteasome or caspase inhibitors indicated the involvement of the proteasome in the generation of RIG-I SF.

Conclusions: We identified a new IFN inducible isoform of RIG-I, which is structurally different from RIG-I splice variant and generated by proteasomal cleavage. RIG-I SF acts as negative regulator of its own pathway and seems to exert its regulatory function by competitive binding of the RNA ligand. We hypothesize that RIG-I SF is involved in controlling the activation of endogenous RIG-I in infected cells, thereby balancing the innate immune response.

P0340

IgG opsonization of bacteria promotes T helper 17 responses via synergy between Toll-like receptors and Fc gamma receptor IIa in human dendritic cells

J. den Dunnen,* L. T. C. Vogelpoel,* T. Wypych,* F. J. M. Muller,* L. de Boer,† T. W. Kuijpers,‡ S. A. J. Zaat,† M. L. Kapsenberg* & E. C. de Jong*
**Department of Cell Biology and Histology, Academic Medical Center, Amsterdam, The Netherlands, †Department of Medical Microbiology, Academic Medical Center, Amsterdam, The Netherlands, ‡Department of Pediatric Hematology, Academic Medical Center, Amsterdam, The Netherlands*

Purpose/Objective: Dendritic cells (DCs) are essential in inducing adaptive immunity against bacteria by expressing cytokines that skew towards protective T helper 17 (Th17) cells. Although it is widely recognized that induction of these cytokines by DCs involves activation of multiple receptors, it is still incompletely characterized which combination of receptors drives Th17 cell responses upon exposure to

bacteria. In the present study we have taken into account that in most conditions DCs will engage bacteria opsonized by cross-reactive IgG, resulting in simultaneous stimulation of Fc gamma receptors (FcγRs) and bacterial sensors. Therefore, the objective of this study was to determine how IgG opsonization of bacteria affects T helper cell polarization and subsequently to unravel the underlying mechanisms.
Materials and methods: Human monocyte-derived DCs were stimulated with IgG-opsonized bacteria or specific Toll-like receptor (TLR) ligands and complexed IgG. Cytokines were measured both at mRNA and protein level, and caspase-1 activation using a FLICA-assay. Th17 induction was assessed by measuring IL-17 production after DC-T cell co-culturing.
Results: IgG opsonization of bacteria strongly promoted Th17 responses by DCs, which was FcγRIIa-dependent and coincided with enhanced production of selected cytokines by DCs, including Th17-promoting IL-1β and IL-23. Notably, FcγRIIa stimulation on DCs did not induce cytokine production when stimulated individually, but selectively amplified cytokine responses through synergy with TLR2, 4 or 5. Importantly, this synergy is mediated at two different levels. First, TLR-FcγRIIa co-stimulation strongly increased transcription of pro-IL-1β and IL-23p19. Second, FcγRIIa triggering induced activation of caspase-1, which cleaves pro-IL-1β into its bioactive form and thereby enhanced IL-1β secretion.
Conclusions: Here we identified IgG opsonization of bacteria as a new mechanism by which the immune system promotes Th17 responses. IgG opsonization promotes Th17 induction by DCs, which fully depends on synergy between TLRs and FcγRIIa. Since most tissues just below the epithelial barriers contain abundant amounts of DCs and interstitial IgGs, this may be a universally relevant natural mechanism to counteract bacterial infections in numerous sites in the human body.

P0341
Modulation of the inflammatory response in gestation associated tissues by IL-4

A. Bryant, R. H. Jones, G. D. Healy, G. Morgan, I. M. Sheldon & C. A. Thornton
Institute of Life Science College of Medicine, Swansea University, Swansea, UK

Purpose/Objective: Preterm birth (PTB) is the leading cause of perinatal morbidity and mortality in the Western world. Local and systemic inflammation is a feature of preterm labour and delivery. Inflammatory mediators such as IL-1β and MIP-1α are produced by the three main gestation-associated tissues (amnion, choriodecidua and placenta) in response to pathogen-associated molecular patterns (PAMPs).The cytokines interleukin (IL)-4, IL-10 and IL-13 are anti-inflammatory and might have potential as anti-inflammatory therapies to prevent PTB.
Materials and methods: The effect of IL-4 (10 ng/ml) on gestation-associated tissues was determined in response PAMPs; LPS (10 ng/ml), Pam3CSK4 (100 ng/ml) and FSL-1 (10 ng/ml). Tissue explants were pre-stimulated with IL-4 for 90 min, prior to PAMP stimulation for 24 h. Tissue free supernatants were assayed for IL-1β and MIP-1α levels by ELISA. IL-4 induced STAT6 phosphorylation was also examined by immunoblotting.
Results: IL-4 reduced IL-1β and MIP-1α production in term healthy placentas in response to all PAMPs studied. The percentage reduction compared to PAMP alone was for: LPS (IL-1β, 91%, mean [86−99%, range], $P = 0.002$; MIP-1α, 86% [83−89%], $P = 0.001$), Pam3CSK4 (IL-1β, 83% [78−86%], $P = 0.001$; MIP-1α 72% [62−91%], $P = 0.001$), and FSL-1 (IL-1β, 74% [43−91%], $P = 0.04$; MIP-1α, 95% [93−96%] $P < 0.001$). STAT6 phosphorylation in response to IL-4 was demonstrated in the placenta. The effect of IL-4 on the response to PAMPs by the amnion and choriodecidua was less consistent; IL-4 only reduced IL-1β and MIP-1α production in response to Pam3CSK4 [choriodecidua (IL-1β, 51% [32−58%], $P = 0.005$; MIP-1α, 36% [25−48%] $P = 0.035$), amnion (IL-1β 72% [0−44%] $P = 0.011$; MIP-1α, 48% [36−63%], $P = 0.017$)].
Conclusions: IL-4 can reduce the inflammatory response primarily in the placenta and to a lesser extent in the amnion and choriodecidua. Greater understanding of the IL-4 signalling pathway might reveal novel approaches for the development of therapeutics for treating women in preterm labour.

P0342
Neutralization of pathogenic Gram-positive bacteria by macrophages is independent from TLR2, -3, -4, -7, and -9 yet depends upon MyD88

A. Krueger,* M. Oldenburg,* R. Ferstl,† A. Sigmund,* S. Akira,‡ T. Kawai,‡ J. Buer,* H. Wagner,§ S. Bauer,¶ H. Hochrein & C. J. Kirschning***
**Institute of Medical Microbiology, University Hospital Essen, Essen, Germany, †Swiss Institute of Allergy and Asthma Research Davos, University of Zurich, Zurich, Switzerland, ‡Department of Host Defense Research, Institute for Microbial Diseases, University of Osaka, Osaka, Japan, §Department of Medical Microbiology Immunology and Hygiene, Technical University of Munich, Munich, Germany, ¶Institute for Immunology, Philipp University of Marburg, Marburg, Germany, **Department of Research Immunology, Bavaria Nordic GmbH, Martinsried, Germany*

Purpose/Objective: Blockade of pattern recognition receptors (PRRs) such as Toll-like receptors (TLRs) has been suggested by us and others as a strategy to inhibit sepsis pathology upon Gram-negative bacterial infection. Gram-positive bacterial infection, however, is also a major cause of septic shock but was recognized even by macrophages that lacked expression of functional TLR2, -3, -4, -7, and -9. However, macrophages lacking MyD88 were unresponsive to Gram-positive bacterial challenge.
Materials and methods: The read out of cellular bacteria recognition was Gram-positive bacteria counts in macrophage culture supernatants. Specifically, we quantified bacteria upon infection to monitor biocidal macrophage activity.
Results: That Gram-positive bacteria recognition was independent of TLR2 was surprising given the central role in Gram-positive bacteria recognition that has been assigned to TLR2 by the literature. Own findings and further literature, however, implied Gram-positive bacterial RNA as important PAMP. Therefore, we fractionate total RNA to narrow down the responsible RNA subpopulation and to characterize Gram-positive bacteria-driven cell activation in further detail.
Conclusions: Potentially, our results will point at novel means for interrupting pathogenesis toward septic shock in Gram-positive bacterial infection.

P0343
Novel functions of a regulator of lysosomal trafficking, LYST in TLR4 signal transduction

W. Cheng, A. Baier & K. Lee
Department of Molecular Immunology, Leibniz Research Center for Medicine and Biosciences (FZB), Borstel, Germany

Purpose/Objective: Toll-like receptors (TLRs) play a critical role in the recognition of microbial components in innate immune cells. Toll-like receptor 4 (TLR4) recognizes lipopolysaccharide (LPS) from Gram-negative bacteria and resent studies suggest that TLR4 is able to activate signaling pathways at endolysosomal compartment after

receptor internalization. However, little is known about the regulatory mechanisms of endolysosomal signaling mediated through TLR4 and if this pathway serves important protective functions for bacterial infections.

LYST is a regulator of lysosomal trafficking and mutations in the LYST gene cause the Chediak-Higashi syndrome (CHS) in humans and the phenotype of the beige-mouse (Kaplan et al., 2008). A prominent feature of this disease is the accumulation of enlarged lysosome-related granules in a variety of cells. CHS patients suffer from recurrent bacterial infections, however, the regulatory mechanism underlying LYST mediated anti-bacterial immunity is largely unclear. Hence, the objective of the study was to investigate the role of LYST in TLR4 signaling pathways and in the immune response against Salmonella infection.

Materials and methods: Utilizing a genetic system of LYST-deficient mice our study followed a multidisciplinary approach, which involved biochemical, cell biological and immunological methods to analyze the impact of lysosomal trafficking regulator LYST on TLR4 signaling and protective immunity against Salmonella infection.

Results: We observed that Lyst deficient cells exhibit defective TLR signaling, specifically in TLR3 and TLR4 pathways, but intact signaling through other TLRs, such as TLR2, TLR5, TLR7 and TLR9. Importantly, this correlated with significantly impaired immunity against *Salmonella* infection in Lyst-mutant *beige* mice. Also, in *in vivo* studies LYST-mutant *beige* mice exhibited a significantly reduced ability to produce inflammatory cytokines in response to LPS. Subsequent mechanistic *in vitro* experiments revealed impaired IRF3 phosphorylation in LYST mutant macrophages upon LPS stimulation, suggesting that LYST is involved in the control of endolysosomal signaling of TLR4, which activates the TRIF signaling pathway.

Conclusions: Our studies provide evidence for a so far unrecognized function of LYST as a linker between lysosomal function and TLR4 signaling.

P0344

Paracoccidioides brasiliensis and mannan use MR, CR3 and TLR4 to interact with macrophages but induce opposite activation profiles in macrophages of resistant and susceptible mice

C. Feriotti & V. L. G. Calich
Department of Immunology, Instituto de Ciências Biomédicas, University of São Paulo, São Paulo, Brazil

Purpose/Objective: In addition to alpha1,3 glucan, mannan and mannan-linked proteins are expressed in the outer layer of *Paracoccidioides brasiliensis* yeasts. Mannosyl residues are recognized by several membrane pathogen recognition receptors (PRRs), such as the mannose receptor (MR), complement receptor 3 (CR3) and Toll-like receptor 4 (TLR4) on macrophage membranes.

Materials and methods: The aim of this study was to clarify the role of these receptors in the interaction between *P. brasiliensis* and macrophages from resistant (A/J) and susceptible (B10.A) mice. In addition, the mRNA expression of SOCS3, a protein associated with M1 macrophages; was also evaluated.

Results: We verified that mannan and anti-MR antibody exert antagonistic effects, the former increasing and the latter decreasing the killing ability and nitric oxide production of macrophages. In addition, the specific blockade of MR, CR3 and TLR4 impaired fungal recognition and modulated the production of cytokines. Interestingly, both mannan and *P. brasiliensis* induced the production of IL-12 by B10.A macrophages, whereas TNF-α, IL-6 and TGF-β were produced by A/J cells. Normal B10.A and A/J macrophages expressed different levels of phagocytic and non-phagocytic PRRs. Mannan and *P. brasiliensis* infection led to decreased expression of MR and TLR2 on A/J macrophages, whereas CR3, TLR4 and TLR2 were reduced on B10.A cells. Accordingly the expression of SOCS3 mRNA was significantly higher in B10.A macrophages indicating a preferential M1 profile.

Conclusions: In conclusion, macrophages appear to use MR, CR3 and TLR4 to interact with *P. brasiliensis*; however, the resulting divergent activation profiles appear to be dependent on the different expression and engagement of PRRs by genetically distinct cells.

Platelets express functional IL-1R family members

A. Anselmo,* C. Soldani,* C. Mazzon,* M. Bacci,† A. Voza,‡ M. Nebuloni,* L. Mendolicchio,† A. Mantovani,* F. Riva* & C. Garlanda*
**Immunology and Inflammation, Istituto Clinico Humanitas, Milano, Italy, †Thrombosis Center, Istituto Clinico Humanitas, Milano, Italy, ‡Emergency Unit, Istituto Clinico Humanitas, Milano, Italy*

Purpose/Objective: TIR8 is a member of the IL-1R like (ILR) family, which acts as a negative regulator of TLR signalling playing non-redundant roles in avoiding inappropriate inflammatory responses in pathological conditions, including infections, colitis, autoimmunity and cancer.

Growing evidence indicates that LPS-mediated signal via TLR4 leads to platelet activation, platelet-leukocyte interaction and neutrophils extracellular trap (NETs) production in severe sepsis. These data prompted us to investigate the expression and function of other IL1R/TLR family members on platelets to better understand the complex interaction between leukocytes and platelets.

Materials and methods: TIR8, IL1R and IL18R expression and CD62P modulation was evaluated by FACS and confocal microscopy analysis.

Thrombus formation in $TIR8^{-/-}$ murine model was evaluated in CCl_4 induced acute inflammation by IHC analysis.

Results: We first investigated the expression of human TIR8 on platelets and megakaryocytic cell lines. Interestingly, we found that platelets and their precursors showed higher surface expression level as compared to other leukocytes. We next studied the expression of IL1R/TLR family members and their function in response to specific ligands. Data obtained showed that TIR8 as well as IL1RI and IL18R are expressed by human and murine platelets and megakaryocytic cell lines and that TIR8 surface expression is modulated by IL18, IL1b and LPS on megakaryocytic cell lines, involving dense-like granule trafficking. Moreover in patients with Systemic Inflammatory Response Syndrome (SIRS) TIR8 surface expression was downmodulated as compared to age matched healthy donors.

IL18R, IL1R and TLR4 activation induced P-selectin upregulation on both human and murine platelets surface and a dysregulated ADP-mediated aggregation, supporting a role of these receptors on the thrombogenic process.

Finally we used a genetic approach to investigate the role of TIR8 on platelet activation. Data obtained so far suggest that TIR8 is involved in platelet activation and liver sinusoid thrombus formation in response to CCl_4 induced acute inflammation.

Conclusions: Our results show that besides TLR family members, platelets also express functional ILR members, including IL1RI and IL18R and TIR8, and suggest a novel role for TIR8 and ILR members in the regulation of platelet activation.

P0346

Poly (I:C)-induced CXCL10 production in adrenocortical cells – implications for autoimmune Addison's disease?

A. Hellesen, E. Bratland & E. S. Husebye
Institute of Medicine, University of Bergen, Bergen, Norway

Purpose/Objective: Autoimmune Addison's disease (AAD) is caused by selective destruction of the steroid hormone-secreting cells of the

adrenal cortex. While T cells are thought to be key players in this autoimmune attack, the actual role played by the target organ has been somewhat overlooked. Adrenocortical cells have been shown to produce CXCL10 when exposed to pro-inflammatory cytokines, and this chemokine is found to be elevated in sera from AAD patients compared to healthy controls. As the adrenal cortex is permissive to certain viruses and bacteria, which may be sensed by Toll-like receptors (TLRs), we hypothesized that certain TLR ligands could also stimulate CXCL10 production in adrenocortical cells.

Materials and methods: Adrenocortical cells were stimulated with poly (I:C), a substitute for viral dsRNA, alone or in combination with pro-inflammatory cytokines. TLR3 expression in adrenocortical cells was evaluated by indirect immunofluorescence.

Results: We found that poly (I:C) stimulated CXCL10 secretion from adrenocortical cells in a TLR3-dependent manner. Furthermore, we observed a synergistic effect of pro-inflammatory cytokines and poly (I:C) on CXCL10 production.

Conclusions: The present findings could represent a potential link between viral infections of the adrenal cortex and AAD, wherein viral dsRNA and pro-inflammatory cytokines could induce the secretion of T-cell-recruiting CXCL10 from adrenocortical cells and thus drive the infiltration of auto-reactive T cells into the adrenal cortex. Future studies should therefore focus on which viral strains that could induce production of CXCL10 in adrenocortical cells and whether such chemokine secretion actually is chemotactic for auto-reactive T cells in AAD.

P0347

Pre-reperfusion treatment with OPN-305, a humanized anti–Toll-like receptor-2 antibody, reduces myocardialischemia/reperfusion injury in pigs

B. Keogh,* F. Arslan,† J. Houtgraaf,† K. Kazemi,† R. de Jong,† W. McCormack,† W. McCormack,‡ L. O'Neill,‡ P. McGuirk,§ L. Timmers,† M. Smeets,† L. Akeroyd,† M. Reilly,† G. Pasterkamp† & D. de Kleijn†

*In Vivo *Pharmacology, Opsona Therapeutics Ltd, Dublin, Ireland,* †*Laboratory of Experimental Cardiology, University Medical Center Utrecht, Utrecht, The Netherlands,* ‡*Molecular Biology, Opsona Therapeutics Ltd, Utrecht, The Netherlands,* §In Vivo *Pharmacology, Opsona Therapeutics Ltd, Utrecht, The Netherlands*

Purpose/Objective: Toll-like receptor 2 (TLR2) is an important mediator of innate immunity and ischemia/reperfusion-induced injury. We have previously shown that TLR2 inhibition reduces infarct size and improves cardiac function in a mouse model. However, the therapeutic efficacy of a clinical grade humanized anti-TLR2 antibody, OPN-305, in a large-animal model remained to be addressed.

Materials and methods: Pigs underwent 75 min ischemia followed by 24 h of reperfusion. Saline or OPN-305 (25, 12.5, 6.25, or 1.56 mg/kg) was infused intravenously 15 min before reperfusion. Cardiac function and geometry were assessed by echocardiography. Infarct size was calculated as the percentage of the area at risk and cardiomyocyte damage was assessed biochemically by serum Troponin-I concentrations.

Results: Flow cytometry analysis revealed specific binding of OPN-305 to porcine TLR2. *In vivo*, OPN-305 exhibited a secondary half-life of 8 days. Intravenous administration of OPN-305 before reperfusion significantly reduced infarct size (45% reduction, $P = 0.041$) in a dose-dependent manner. In addition, pigs treated with OPN-305 exhibited a significant preservation of systolic performance in a dose-dependent fashion, whereas saline treatment completely diminished the contractile performance of the ischemic/reperfused myocardium. OPN-305 has completed Phase I trials in healthy human volunteers (HV) and the PK/PD has been established. Treatment of HV with OPN-305 led to a significant decrease in IL-6 secretion post TLR2 agonist stimulation, which correlated with receptor occupancy and PK.

Conclusions: OPN-305 significantly reduced infarct size and preserved cardiac function in pigs after ischemia/reperfusion injury. Hence, OPN-305 is a promising adjunctive therapeutic for patients with acute myocardial infarction.

P0348

Prognostic value of the presence and expression of TLR7 in non small cell lung carcinoma (NSCLC) patients

S. Chatterjee,* L. Crozet,* D. Damotte,* M. Alifano,† M. C. Dieu-Nosjean,* W. H. Fridman,* C. Sautès-Fridman* & I. Cremer*

**Cordeliers Research Center UMRS872, Immune Microenvironment and Tumor Team 13, Paris, France,* †*Hospital Hotel Dieu AP-HP, Services d'anatomie-pathologie et de chirurgie thoracique, Paris, France*

Purpose/Objective: Lung cancer accounts for over one million deaths/year with a 5-year survival of 8–12%. TLR7 detects Pathogen- and Damaged-Associated Molecular Patterns triggering inflammatory responses with the production of proinflammatory cytokines and interferons. In a recent study we demonstrated the expression of TLR7 in primary NSCLC and observed that stimulation of cell lines with TLR7 agonist lead to the upregulation of antiapoptotic protein Bcl-2 and tumor cell survival and chemoresistance [1].This suggests an important role of TLR7 in tumor progression. In this study we thus wanted to correlate the expression of TLR7 with prognostic value among a cohort of NSCLC patients.

Materials and methods: We performed immunohistochemical staining of TLR7 on 278 paraffin embedded NSCLC samples.

Results: TLR7 expression was heterogeneous with 65% ($n = 181$) of the patients being TLR7 positive and 45% ($n = 97$) TLR7 negative. Overall survival was determined by Kaplan-Meier curves and log-rank test. At an optimal cutoff of 82% we found 21% ($n = 58$) of all the patients (stage I to III) had high expression of TLR7 (>82%) on the tumoral cells with a bad prognosis compared to the TLR7 low group ($P = 0.002$). A highly significant poor prognosis among the TLR7 high group was observed compared to the low group for the stage III patients ($P = 0.0003$). There was a significant difference between TLR7 high and low groups for adenocarcinoma patients ($P = 0.0031$) but no difference for the patients with squamous cell carcinoma.

Conclusions: These results suggest a bad prognostic role of TLR7 expression on tumoral cells in adenocarcinoma NSCLC patients.

As we demonstrated for the first time that TLR7 is involved in chemoresistance, we hypothesize that the multi drug resistance genes maybe upregulated in TLR7 expressing cells. We are performing gene profiling assays on sorted tumors to look for molecular markers that could be implicated in chemoresistance due to TLR7 stimulation.

[1] Cherfils-Vicini, J, et al. Triggering of TLR7 and TLR8 expressed by human lung cancer cells induces cell survival and chemoresistance. J Clin Invest. 1;120(4):1285–97, 2010

P0349

Role of TLR4 on recruitment/activation of microglia in the hypothalamus during obesity

J. C. M. Martins, J. Morari, D. S. Razolli & L. A. Velloso

Faculty of Medical Science, University of Campinas, Campinas, Brazil

Purpose/Objective: TLR4-dependent hypothalamic inflammation is a common feature of experimental diet-induced obesity. Long-chain saturated fatty acids present in the diet activate TLR4 signaling in microglia cells leading to the expression of inflammatory cytokines and subsequent induction of leptin resistance in hypothalamic neurons involved in the control offood intake and energy expenditure. It is currently unknown if diet-induced hypothalamic inflammation is dependent on bone-marrow (BM) derived cells or only in resident microglia. Here, we investigate the mechanisms of activation and

recruitment of monocytes to compose the activated microglia in the hypothalamus of experimental mice fed on high-fat diet (HFD), and the role played by TLR4 in this process.
Materials and methods: TLR4 defective mutant and wild-type (WT) mice were irradiated in a cobalt 60 source and submitted to BM transplantation from C57Bl6/GFP (with green fluorescence cells-GFP) or wild-type donors.To evaluate possible differences in activation/migration of microglial cells in the presence or absence of functional TLR 4, irradiated WT mice received BM from mutants ormutant mice were irradiated and submitted to BM transplant from mutants again. After recovery, mice were fed on a HFD for 8 weeks. After transplantation, GFP was detected by immunofluorescence co-stanning with macrophage markers in hypothalamic sections. RT-PCR was performed to evaluate the expression of genes involved in inflammation and ELISA was used to detect fracktalkine in the serum.
Results: Upon HFD feeding, active microglia cells are present in the hypothalamus after 8 weeks. When TLR4 mutant mice received BM from WT donors, microglial cells harboring WT-TLR4 are detected in the hypothalamus after 8 weeks; and, differently of TLR4 mutant mice, which are protected from diet-induced obesity (DIO), these transplanted mice present increased body mass, similar to WT mice, fed on HFD.
Conclusions: Therefore, the expression of a functional TLR4 is required to warrant the increase of adiposity during high-fat feeding. Amongst a number of chemokines evaluated, fractalkine was the one presenting highest and earliest levels in the hypothalamus of DIO mice. Thus, hypothalamic microglia cells originate from periphery by, at least in part, the action of fractalkine released from neurons.

P0350
Scavenger receptors SR-A/CD204 and CD36 differ markedly in signaling abilities but both receptors inhibit Th1 polarization of immune response

S. Jozefowski, R. Biedron & J. Marcinkiewicz
Department of Immunology, Jagiellonian University Medical College, Krakow, Poland

Purpose/Objective: Scavenger receptors SR-A/CD204 and CD36 are two major receptors responsible for oxidized low density lipoprotein (LDL) uptake by macrophages, leading to the transformation of these cells into foam cells in atherosclerotic plaques. Both receptors also function as pattern recognition receptors for bacteria and other pathogens, but studies on their roles have been hampered by the lack of selective ligands.
Materials and methods: We studied effects of specific SR-A or CD36 ligation with antibodies on nitric oxide and cytokine production by peritoneal macrophages (PEMs) as well as on functions of these cells in antigen presentation.
Results: Our results indicate that, upon ligation by specific antibody or by dextran sulfate, SR-A mediates inhibition of lipopolysaccharide (LPS)-stimulated production of interleukin (IL)-6 and of p40 subunit of IL-12, enhances production of IL-10, but has no effect on tumor necrosis factor-α, nitric oxide or chemokine RANTES production. Surprisingly, acetylated LDL behaved as an antagonist of SR-A. In contrast to anti-SR-A antibody, anti-CD36 antibody alone stimulated production of all inflammatory mediators tested in macrophages, with IL-10 production being exceptionally high. Results of further experiments revealed that effects of anti-CD36 antibody were mediated by Toll-like receptor 2 (TLR2), but not by TLR4, whereas effects of SR-A ligation were mediated by heterotrimeric Gi/o proteins and by phosphatidylinositol 3-kinases. In an *in vitro* system of antigen presentation by macrophages to specific $CD4^+$ lymphocytes both anti-CD36 and anti-SR-A mAbs inhibited production of the Th1-type cytokine interferon-γ.
Conclusions: Our results have revealed that, despite binding overlapping sets of ligands and being involved in the same macrophage functions, SR-A and CD36 differ markedly in signaling abilities. Selective effects of SR-A ligation contrast with generalized enhancement of immune responses occurring in SR-A-deficient macrophages, which seems to be largely unrelated to the loss of the receptor function of SR-A.

P0351
Serum albumin modulates pro-inflammatory responses induced by bacterial lipopolysaccharides in macrophage-like MM6 cells

J. M. W. R. McElhinney, J. M. M. Sayago, O. W. Taylor, C. A. Reynolds & N. Fernández
Department of Biological Sciences, University of Essex, Colchester, UK

Purpose/Objective: Bacterial lipopolysaccharide endotoxins (LPS) trigger potent and potentially life-threatening inflammatory responses. LPS-binding serum factors (LBP and CD14) and cell surface receptors (including CD14, CD55 and TLR4-MD2) of macrophages are key facilitators of these responses. Human serum albumin (HSA), the most abundant serum protein, is well characterised as a fatty acid carrier and regulator of blood pH. In addition, HSA has been implicated in host responses to invading pathogens and LPS. However, the role of HSA therein remains largely uncharted. Here, we sought to understand the molecular mechanisms associated with HSA-LPS interactions and their impact on host macrophage responses to LPS.
Materials and methods: We applied a combination of proteomic ligand-binding assays (surface plasmon resonance, ITC and PAGE-based mobility shift assays), to elucidate the molecular mechanisms associated with HSA-LPS interactions, and immunological techniques (ELISA and flow cytometry), to assess the impact of HSA-LPS interactions on the activation states of macrophage-like Mono Mac 6 cells.
Results: We found that the O-Antigen of LPS weakens the HSA-LPS interaction whereas truncations in the core region of LPS strengthen HSA binding. The interaction between HSA and LPS led to disaggregation of LPS multimers and the resultant HSA-LPS complexes target CD55 and LBP but not CD14 and TLR4-MD2. Activation of monomac 6 human macrophage-like cells, in terms of proinflammatory cytokine secretion and surface expression of LPS-related receptors, by different LPS chemotypes was markedly lower in the presence of HSA.
Conclusions: Our data suggests that HSA reduces the toxicity of LPS and thereby plays a pivotal role in mitigating the innate phase host response to invasive gram negative infection.

P0352
STING-dependent type I IFN induction by a cell permeable small molecule

T. Cavlar, A. Ablasser, C. Jakobs, M. Kampes & V. Hornung
Unit for Clinical Biochemistry, Institute for Clinical Chemistry and Pharmacology, University Hospital, University of Bonn, Bonn, Germany

Purpose/Objective: The innate immune system uses germline-encoded pattern recognition receptors to sense invading pathogens. The detection of conserved microbial structures initiates antimicrobial defense mechanisms that are geared to initiate immediate effector functions and to induce adaptive immune responses. In this respect, cytokines of the type I interferon family (IFNs) play an important role. Therefore, a well-defined type I IFN inducer is desirable, as this would allow targeted clinical applications.
Materials and methods: We tested various small molecule compounds in murine bone marrow cells *in vitro* for their capacity to induce antiviral activity. In this regard we studied IRF3 phosphorylation, type I IFN induction at mRNA and protein level.

Results: We characterized the mode of action of a cell permeable small molecule that strongly triggers type I IFN through robust activation of the TBK1/IRF-3 route. Our data demonstrate that this small molecule signals towards type I IFN production in a TLR- and RLR-independent manner, as stimulation of MYD88-, TRIF- and MAVS-deficient cells still results in potent type I IFN responses. Indeed, we can show that the loss of the ER resident sensor molecule STING leads to a complete abrogation of cytokine production. Furthermore, *in vivo* experiments using this compound as a vaccine adjuvant suggest that targeting STING allows the induction of potent adaptive immune responses.
Conclusions: Altogether, these data for the first time establish a selective, cell-permeable activator of the STING pathway, opening new avenues for therapeutic applications.

P0353
Studies on the molecular mechanisms controlling the differential capacity of human neutrophils and monocytes to express IL-6 in response to LPS

M. Zimmermann, N. Tamassia, M. Castellucci, M. Rossato, F. Bazzoni & M. A. Cassatella
Department of Pathology and Diagnostics, University of Verona, Verona, Italy

Purpose/Objective: IL-6 is a pleiotropic interleukin that acts either as pro-inflammatory or as anti-inflammatory cytokine. While human monocytes are well known to express IL-6 upon appropriate stimulation, whether human neutrophils do so remains still controversial. The aim of this study was to clarify, at molecular level, whether human neutrophils are able to express IL-6 in response to one of its major inducer in monocytes, namely lipopolysaccharide (LPS).
Materials and methods: Human neutrophils (>99.7% purity) and autologous Percoll-purified monocytes were isolated from buffy coats and incubated with 100 ng/ml ultrapure LPS for IL-6 gene expression studies by RT-qPCR, as well as for IL-6 release by ELISA (detection limit = 10 pg/ml). Under the same experimental conditions, both Polymerase II (Pol II) recruitment and histone 4 acetylation (H4Ac) at the IL-6 promoter were also assessed by chromatin immunoprecipitation (ChIP) assays.
Results: Neutrophils stimulated with LPS for 24 h released no or negligible amounts of IL-6 (<10 pg/ml), unlike autologous monocytes (> 10 ng/ml). In accordance, neither IL-6 mRNA, nor IL-6 primary transcripts (PT), could be detected in neutrophils stimulated with LPS for up to 6 h, contrary to what observed in monocytes. An absence of Pol II recruitment at the IL-6 promoter of LPS-stimulated neutrophils confirmed the lack of any IL-6 transcriptional activity. In contrast, significant levels of Pol II binding at the IL-6 promoter could be detected in LPS-treated monocytes as early as after 1 h of stimulation, and further increasing up to 5 h. Consistent with the latter findings, major differences were found between neutrophils and monocytes in terms of H4Ac levels (an epigenetic marker of transcriptionally active chromatin) present at the IL-6 locus. In fact, while H4Ac was readily detectable at the IL-6 promoter of resting monocytes, its levels dramatically increased after a 3 h LPS-stimulation. By contrast, neither constitutive, nor LPS-induced H4Ac recruitment at the IL-6 promoter was observed to occur in neutrophils.
Conclusions: Taken together, these results suggest that the differential capacity of human neutrophils and monocytes to express IL-6 upon LPS activation is likely controlled by epigenetic mechanisms acting at the promoter level.

P0354
The regulated IRAP-containing storage endosomes affect TLR9 signaling in dendritic cells

J. Babdor, M. Tohme, S. Mashalidi, P. van Endert, B. Manoury & L. Saveanu
INSERM, U1013, Paris, France

Purpose/Objective: Nucleic acids sensing by Toll-Like Receptor 9 (TLR9) induces an innate immune response that subsequently can enhance the adaptive immune response. Dendritic cells (DCs) play a central role in both immune responses. While the innate immune response relays on intracellular TLR9 translocation from the endoplasmic reticulum (ER) into the endo-lysosomal pathway, the adaptive immune response depends on the antigen presentation ability of the DCs. Full activation of TLR9 requires: 1) cleavage in the endosomes and 2) an association with MyD88, which recruits in $VAMP3^+$ early endosomes NF-Kb, for inflammatory cytokines production, and in lysosomes IRF7 for type I IFN induction. Antigen cross-presentation requires the antigen processing machinery, which in DCs includes the antigen trimming aminopeptidase Insulin Responsive AminoPeptidase (IRAP). The aim of this study is to investigate the possibility of a cross talk between the antigen cross-presentation endosomes ($IRAP^+$) and the TLR9 signaling endosomes.
Materials and methods: Using IRAP deficient and wt mice and DCs, we assess the inflammatory cytokines and type I IFN production after TLR9 stimulation, as well as TLR9 localization and it's trafficking after DCs stimulation by TLR ligands.
Results: The fluorescence microscopy studies demonstrated that the SNARE VAMP3 co-localize with IRAP and other markers in the regulated storage endosomes (Syntaxin 6 and Rab14). This co-localization has a functional impact since DCs and mice inactivated for IRAP show hypersensitivity to TLR9 ligands, as illustrated by an increase in the synthesis and secretion of pro-inflammatory cytokines and type-I IFNs in comparaison with wt.
Conclusions: In conclusion, the $VAMP3^+$ endosomes are identical to cell specific regulated storage endosomes that contain the antigen trimming aminopeptidase IRAP and TLR9. This implies that in the absence of IRAP, TLR9 trafficking is altered and consequently signaling is enhanced.

P0355
The regulation of Interleukin-10 and Interleukin-12 production in macrophages: Investigating the differential production of IL-10 and IL-12 in C57BL/6 and BALB/c mice

A. Howes,[*] X. Wu,[*] J. Zhao,[†] M. Saraiva,[‡] G. J. Bancroft[§] & A. O'Garra[*]
[*]Division of Immunoregulation, MRC National Institute for Medical Research, London, UK, [†]College of Biology Science, Sichuan University, Chengdu, China, [‡]Life and Health Sciences Research Institute (ICVS), University of Minho, Microbiology and Infection Research Domain, Braga, Portugal, [§]Faculty of Infectious and Tropical Diseases, London School of Hygiene and Tropical Medicine, London, UK

Purpose/Objective: The regulation of the immune response to pathogens is important to ensure their successful clearance with minimal host damage. Pattern recognition receptors (PRR) detect microbial products and induce cytokines such as interleukin-10 (IL-10) and interleukin-12 (IL-12) which shape the immunological response. IL-12 is a pro-inflammatory cytokine important for the differentiation of T helper 1 (Th1) cells which are critical for protection against intracellular pathogens. IL-10 is an immunosuppressive cytokine that amongst other functions can regulate the innate immune system by dampening dendritic cell and macrophage activity. IL-10 consequently minimises immune-driven host pathology during infection, but can also result in defective pathogen clearance. The regulation

of IL-10 and IL-12 is therefore of interest due to the central roles of these cytokines in the orchestration of an effective but regulated immune response.

Materials and methods: We have analysed PRR induced IL-10 and IL-12 production in macrophages at the protein level by ELISA and at the transcriptional level by qPCR. Microarray analysis and an investigation into the activation of various signaling pathways downstream of PRR stimulation by western blotting have also been carried out to further elucidate factors regulating the innate production of IL-10 and IL-12.

Results: We compared PRR driven cytokine responses of macrophages derived from various inbred strains of mice. We observed that macrophages generated from C57BL/6 and BALB/c mice, two commonly used strains which differ significantly in their resistance to several pathogens, produced reciprocal levels of IL-10 and IL-12 in response to several purified TLR ligands and heat-killed Gram-negative bacteria. Using this C57BL/6 versus BALB/c comparison as a model for our studies, we were able to further dissect the mechanisms regulating IL-10 and IL-12 and identified a central role for autocrine factors in the regulation of innate cytokine production.

Conclusions: Our investigation has revealed a mechanism for differential cytokine production observed in PRR activated C57BL/6 and BALB/c macrophages. These findings highlight key pathways responsible for the regulation of IL-10 and IL-12 and may provide valuable information on underlying factors contributing to the ability of these mouse strains to clear bacterial infections.

P0356
The role of 2′O-methylated tRNA in bacterial infections

S. Jöckel, A. Sünderhauf, A. Kaufmann & S. Bauer
Institute for Immunology, Philipps University Marburg, Marburg, Germany

Purpose/Objective: RNA is a potent immune stimulator for innate immune receptors such as Toll-like receptors (TLR). We analysed the immunostimulatory potential of bacterial transfer RNA (tRNA) from different strains in human PBMCs and FLt3l- derived murine pDCs *in vitro*.

Since 2′O-methylations in RNA molecules have been shown to act inhibitory on IFN-α production, we further focused on 2′-*O*-methylguanosin at position 18 (Gm18) of the tRNA molecule, which is introduced by the (Gm18)-2′O-ribose-methyltransferase trmH.

Materials and methods: Stimulation experiments of human PBMCs and murine FLt3l-derived DCs were conducted with tRNA of different bacterial strains. The bacterial tRNA was isolated by anionic exchange chromatography. For stimulation experiments tRNA was complexed to the cationic lipid DOTAP. IFN-α secretion was determined via ELISA.

We generated an *E. coli-Nissle* trmH-knock-out strain (EcN*Δ*trmH) by using the red-recombinase system.

Results: We could show that bacterial tRNA induces IFN-α production in human PBMCs and murine FLt3l-induced DCs via TLR7. Surprisingly it turned out, that a single 2′O-methylation of a conserved guanosine at position 18 (Gm18) of the tRNA molecule in some bacterial strains abrogated the IFN-α secretion. E. coli-Nissle wildtype tRNA did not trigger IFN-α secretion whereas tRNA derived from EcNΔtrmH strain leads to IFN-α production in murine pDCs.

Additionally the Gm18-containing tRNA from *E. coli-Nissle* showed an inhibitory effect on TLR7-activation and acts as a receptor antagonist.

Conclusions: Our results demonstrate that the IFN-α secretion may be regulated by the activity of the enzyme trmH and the amount of Gm18 methylation. Thus, the control of an IFN-α response in the gut might be beneficial for the pathogenity of bacteria and a tightly regulated IFN-α response may be helpful for the treatment of inflammatory bowel diseases.

One approach for answering these questions could be the recolonization of germ-free mice with EcNΔtrmH and different bacterial strains with subsequent DSS-colitis model. If any differences in the extent of the inflammatory response can be observed, one could gain new insights of the importance of the gut flora in connection with inflammatory bowel diseases.

P0357
The role of dsRNA receptors in human renal tubular epithelial cells during infection with BK virus

K. M. Heutinck,* A. E. V. da Silva,* J. Kassies,* S. Florquin,† K. C. Wolthers,‡ I. J. M. ten Berge§ & J. Hamann*
**Department of Experimental Immunology, Academic Medical Center, Amsterdam, The Netherlands, †Department of Pathology, Academic Medical Center, Amsterdam, The Netherlands, ‡Department of Clinical Virology, Academic Medical Center, Amsterdam, The Netherlands, §Department of Internal Medicine, Renal Transplant Unit, Academic Medical Center, Amsterdam, The Netherlands*

Purpose/Objective: The polyomavirus BK (BKV) frequently reactivates in kidney transplant recipients leading in about 5% of the patients to BKV-associated nephropathy, at present an important cause for graft dysfunction. Impaired immune surveillance, lytic viral replication in renal tubular epithelial cells (TECs), and allo-immune activity are factors that seem to contribute to the development of nephropathy. We previously found that the viral dsRNA receptors Toll-like receptor 3 (TLR3), melanoma differentiation associated protein 5 (MDA5) and retinoic acid inducible gene-I (RIG-I) regulate anti-viral, pro-inflammatory and pro-apoptotic responses in primary TECs. Here, we aim to study the interaction between TECs and BKV and address the involvement of dsRNA receptors in the immune response against the virus.

Materials and methods: dsRNA receptor expression was analysed by quantitative PCR and immunohistochemistry in renal transplant biopsies obtained during BKV infection ($n = 7$) and stable graft biopsies ($n = 5$) and in primary TECs infected *in vitro* with a clinical isolate of BKV. Expression of both viral genes and dsRNA sensors was determined by immunofluorescence and PCR.

Results: TLR3, MDA5 and RIG-I transcription was significantly enhanced in BKV infected biopsies ($P < 0.01$), a feature of dsRNA receptor activation. Immunohistochemistry demonstrated that tubuli expressed all three sensors. In primary TECs, BKV infection was characterised by expression of the viral protein 1 and large T antigen, and nuclear accumulation of viral proteins. Cytopathic changes became apparent 1 week after infection leading to cell lysis and release of infectious particles. At 6 and 48 h after BKV infection, dsRNA receptor expression was only marginally enhanced. These findings suggest that either BKV does not generate dsRNA molecules that are recognized by TLR3, MDA5 or RIG-I or that the virus suppresses antiviral immune responses and/or the production of type I interferons in primary TECs.

Conclusions: BKV infection is associated with increased expression of dsRNA receptors in renal transplant biopsies, yet expression of TLR3, MDA5 and RIG-I was hardly enhanced in BKV infected primary TECs.

The role of soluble Toll-like receptor 3 in human astrocytes

J. Seo,* E. Yang† & I. Choi‡
*Department of Microbiology, Yonsei University College of Medicine and Brain Korea 21 Project for Medical Science, Seoul, Korea, †Department of Microbiology, Yonsei University College of Medicine and Institute for Immunolgy and Immunological Disease, Seoul, Korea, ‡Yonsei University College of Medicine and Brain Korea 21 Project for Medical Science and Institute for Immunolgy and Immunological Disease, Department of Microbiology, Seoul, Korea

Purpose/Objective: Toll-like receptors (TLRs) are a group of pattern-recognition receptors that plays an important role in innate immune response against bacterial and viral infections. Among them, intracellular TLRs are localized in endolysosomal compartment and recognize foreign nucleic acids from a variety of pathogens. Recent studies have shown that soluble form of Toll-like receptor 9 (sTLR9) generated by proteolytic process is negatively regulates TLR9 signaling. Similarly, we found that a soluble Toll-like receptor 3 (TLR3) is generated by alternative splicing in human astrocytes. In this study, we examined whether a soluble TLR3 has negatively effect on TLR3 signaling in human astrocytes.
Materials and methods: Human astrocytes were transfected with a mock vector or a plasmid encoding soluble TLR3 and treated with poly(I:C) for different times. The lysates were analyzed by western blot using anti-phospho-IRF3, anti-IRF3, anti-phospho-IκBα, anti-IκBα, anti-TLR3 as well as anti-tubulin antibodies. And human astrocytes were co-transfected with a plasmid encoding TLR3-CFP and sTLR3-EGFP and treated LysoTracker either with or without poly(I:C) stimulation for 1 h and cells were fixed and analyzed by confocal microscopy. Also human astrocytes were incubated with poly(I:C)-coated beads and lysates were analyzed by western blot using anti-TLR3 antibody.
Results: poly(I:C)-induced the activation of IRF3 and IκBα was decreased in human astrocytes that express soluble TLR3 compared to control cells. And soluble TLR3 is co-localized with wild type of TLR3 in lysosomal compartment when poly(I:C) was treated. Intriguingly, soluble TLR3 binds poly(I:C) as wild type TLR3 does in human astrocytes.
Conclusions: Our results suggest that soluble TLR3 generated by alternative splicing negatively regulates TLR3 signaling through binding ligands [ex. poly(I:C)] competitively with wild type TLR3.

P0359

The role of UNC93B1 in localization of TLR3 on plasma membrane and in cell priming to nucleic acid agonists

J. Pohar,* N. Pirher,* M. Bencina,† M. Mancek-Keber* & R. Jerala‡
*Laboratory of Biotechnology, National Institute of Chemistry, Ljubljana, Slovenia, †Laboratory of Biotechnology – Ljubljana Slovenia, EN-FIST Centre of Excellence, National Institute of Chemistry, Ljubljana, Slovenia, ‡National Institute of Chemistry – Laboratory of Biotechnology – Ljubljana Slovenia/Faculty of Chemistry and Chemical Technology – University of Ljubljana – Ljubljana Slovenija, EN-FIST Centre of Excellence, Ljubljana, Slovenia

Purpose/Objective: Appropriate localization of nucleic acid-sensing TLRs (NAS TLRs) prevents autoimmune response. We observed that upregulation of hUNC93B1 promoted localization of differentially glycosylated hTLR3, but not other NAS TLRs at the plasma membrane. We set to investigate determinants of trafficking hTLR3 towards the plasma membrane and physiological processes that regulate transcription of *hUNC93B1*.
Materials and methods: We prepared chimeric constructs, where transmembrane segments or cytosolic domains of hTLR3 and hTLR9 have been exchanged. Their localization was visualised with confocal microscope.

Human umbilical vein endothelial cells (HUVEC) were stimulated with several TLR ligands or IFN-β. mRNAs of hUNC93B1and hTLR receptors were measured with qPCR. Differentially glycosylated form of hTLR3 was detected with WB. Surface localization of hTLR3 was detected with flow cytometer.

Human *UNC93B1* promoter region was examined for transcription factor binding sites using the MatInspector software.

For priming experiment Ramos-Blue cells were pretreated with the first agonist and subsequently treated with another agonist. Agonists used were poly(I:C) and CpG ODN. Activation of NF-κB/AP-1-inducible reporter was measured with a spectrophotometer.
Results: We determined that hTLR3 surface sorting motif for the UNC93B1-dependent surface localization resides in the hTLR3 ecto-domain. The analysis of *hUNC93B1* gene promoter region revealed that its transcription is regulated by several transcription factors triggered by the TLR3 activation and type I interferon signalling. Poly(I:C) and IFN-β upregulated transcription of UNC93B1 and increased the amount of differentially glycosylated hTLR3 at the surface of HUVEC cells. We demonstrated the physiological relevance of a positive feedback loop based on the upregulation of hUNC93B1 after hTLR3 stimulation by selectively sensitizing the responsiveness to hTLR9 stimulation after the prior exposure to poly(I:C), but not to ODN.
Conclusions: Our findings identified hTLR3 as the master regulator of hUNC93B1 that in turn governs the responsiveness of all NAS TLRs. The low amount of endogenous TLR3 agonist and the corresponding low risk of autoimmune reaction make this receptor an appropriate sentinel of viral infection at the cell surface and a regulator for sensitizing the response of NAS TLRs through upregulation of UNC93B1.

P0360

TLR4 expression in bone marrow-derived cells modulate diet-induced inflammation in insulin sensitive tissues

D. S. Razolli, J. C. M. -Martins, J. Morari & L. A. Velloso
Faculty of Medical Science, University of Campinas, Campinas, Brazil

Purpose/Objective: Recent studies have shown that saturated fatty acids from high-fat diets induce the activation of a TLR4-dependent innate immune response in insulin-sensitive tissues leading to insulin resistance and glucose intolerance. Mice lacking a functional TLR4 (C3H/HeJ) are protected from diet-induced obesity and show an improved response to insulin. The TLR4 receptor is expressed predominantly in immune cells, however a number of other tissues also can express this receptor. It is currently unknown if the TLR4-dependent impairment of insulin signaling is due to the activation of TLR4 receptors in immune cells and/or in insulin-sensitive tissues. The objective of the present study was to investigate if a defective TLR4 signaling only in bone-marrow derived cells is sufficient to modulate the whole-body insulin action.
Materials and methods: C3H/HeJ and wild-type (WT) mice were irradiated in a cobalt 60 source and submitted to bone marrow transplantation (BMT). After recovery, mice were fed on a high fat diet (HFD) or standard rodent chow for 8 weeks. Inflammatory markers were evaluated in the liver and visceral adipose tissue. In addition, we evaluated food intake, body mass gain, energy expenditure and the activation of markers of thermogenesis in brown adipose tissue. WT transplanted with BM from TLR4 mutant mice are protected from body mass gain in HFD.
Results: When TLR4 mutant mice received BM from WT donors this effect was blunted and mice gained weight. TLR4 mutant mice presented an increase in energy expenditure in chow when compared to WT mice, which was accompanied by and increased UCP1 mRNA expression in brown adipose tissue. HFD TLR4 mutant mice have an increased IL-10 mRNA expression both in liver and adipose tissue,

which was not observed to WT mice. This IL-10 increase also occurred in WT transplanted with TLR4 mutant BM and was blunted in TLR4 mutant transplanted with WT BM. TLR4 mutant mice fed on HFD also presented reduced IL-6 mRNA levels in liver, which was not observed in WT.

Conclusions: Thus, we show that TLR4 mutant mice are protected from diet-induced activation of inflammation in the liver, and present increased energy expenditure, suggesting that TLR4 signaling play a role in the control of whole body energy homeostasis.

P0361

TLR4 signalling shapes actin cytoskeleton to modulate B cell migration

L. Barrio, J. Sáez de Guinoa & Y. R. Carrasco

Department of Immunology and Oncology, Centro Nacional de Biotecnología, Madrid, Spain

Purpose/Objective: Naive B cells are constantly migrating throughout the follicular dendritic cell network in the follicles of secondary lymphoid organs. This motility is promoted in part by the chemokine CXCL13 and allows B cells to scan for potential antigens. Specific antigen recognition by the B cell receptor (BCR) triggers the humoral immune response. In addition, pathogenic molecules that reach the follicles can be recognized by receptors other than BCR as the Toll-like receptor (TLR) family. They recognize conserved molecular patterns from bacteria and virus, and triggers innate immune responses. Little is known regarding the effects of innate signals on B cell behaviour and the possible effects of this modulation in B cell function.

Materials and methods: We combined time-lapse microscopy and a 2D model of haptokinesis.

Results: Here we show that short-time stimulation via TLR4 enhances the B cell response to CXCL13 by increasing their polarization, adhesiveness and motility. This seems to be dependent on the MyD88-mediated signalling cascade of TLR4. The B cell chemotactic response to CXCL13 in Boyden chambers is also enhanced by TLR4 stimulation; this is accompanied by a twofold increase in the expression levels for CXCL13 receptor, CXCR5, at the B cell surface. We observed that TLR4 stimulated B cells have higher F-actin content and higher basal and CXCL13-triggered activation of the small Rho-GTPase Rac than non-stimulated B cells; no detectable differences were observed for the small Rho-GTPase Cdc42.

Conclusions: Thus, short-time stimulation through TLR4 seems to prime the actin cytoskeleton of naïve B cells for subsequent CXCL13 responses; this may improve the B cell chances to encounter a cognate antigen.

P0362

Toll-like receptor 1 and 2 play a role in recognition of *Coxiella burnetii* in humans

A. Ammerdorffer,* M. Oosting,* T. Schoffelen,* J. M. Rebel,† H. J. Roest,‡ M. van Deuren,* M. G. Netea,* L. A. Joosten* & T. Sprong§

**Department of Medicine, Radboud University Nijmegen Medical Centre, Nijmegen Intitute for Infection Inflammation and Immunity (N4i), Nijmegen, The Netherlands, †Central Veterinary Institute of Wageningen UR, Department of Infection Biology, Lelystad, The Netherlands, ‡Central Veterinary Institute of Wageningen UR, Department of Bacteriology and TSEs, Lelystad, The Netherlands, §Canisius-Wilhelmina Hospital, Department of Internal Medicine, Nijmegen, The Netherlands*

Purpose/Objective: The bacterium *Coxiella burnetii* is the causative agent of Q fever. Acute Q fever presents with fever, pneumonia or hepatitis, whereas chronic Q fever develops over several months to years following infection and is characterized by endocarditis or endovascular infection.

Toll-like receptors comprise a family of receptors which recognize molecular structures that are conserved in many microbial products. TLRs play a major role in activating the innate immune system. In this study, we investigated the role of specific TLRs in the recognition of *C. burnetii* in humans.

Materials and methods: Peripheral blood mononuclear cells were isolated from healthy donors. TLR function was inhibited using specific antibodies of either TLR1, TLR2, TLR4, TLR6 or TLR9. After 60 min of preincubation, PBMCs were stimulated with the heat killed reference strain *C. burnetii* Nine Mile. After 24, 48 h, or 7 days of stimulation, cytokine responses in the supernatant were measured. Furthermore, we studied the influence of functional single nucleotide polymorphisms (SNPs) in the different TLR genes regarding the recognition of *C. burnetii*. Therefore PBMCs of individuals, who were completely genotyped for polymorphisms in TLR1 (R80T, N248S, andS602I), TLR2 (R753Q and P631H), TLR4 (D299G and T399I), or TLR6 (S249P) were stimulated with the Dutch outbreak isolate *C. burnetii* X09003262. ELISA was used for cytokine measurements.

Results: Stimulation of PBMCs with *C. burnetii* Nine Mile resulted in a robust IL-1β, TNF-α, IL-6, IL-10, IFN-γ, IL-22 and IL-17 induction. The induction of proinflammatory cytokines, such as IL-1β, TNF-α and IL-6, was not affected after inhibition of TLR1, TLR4, TLR6 or TLR9. However, inhibition of TLR2 resulted in decreased production of IL-1β and IL-6. The SNP analysis confirmed the role of TLR2 regarding the recognition of *C. burnetii*, as individualsbearing the TLR2 R753Q SNP showed higher IL-1β and TNF-α induction. The anti-inflammatory cytokine IL-10 was not affected after inhibition of either TLR1, TLR4 or TLR6. In contrast, IL-10 induction decreased after TLR2 inhibition. Surprisingly, individuals homozygous for all three SNPs in TLR1 showed less production of IL-10.

Conclusions: These results indicate a role for TLR1 and TLR2 in recognition of *C. burnetii* and the induction of an early immune response in humans.

P0363

Tumor progression and resistance to chemotherapy induced by TLR7 stimulation in non small cell lung carcinoma

L. Crozet,* S. Chatterjee,* M. Gillard-Bocquet,* J. Cherfils,† M. C. Dieu-Nosjean,* D. Damotte,* W. H. Fridman,* C. Sautès-Fridman* & I. Cremer*

**Cordeliers Research Center UMRS872, Equipe 13 Micro-environnement immunitaire et tumeurs, Paris, France, †CNRS UMR 6267- INSERM U998- UNSA, Laboratoire de Biologie et Pathologie des Génomes, Nice, France*

Purpose/Objective: Novel cancer immunotherapies using TLR7 agonists are being developed, which are based on the amplification of immune responses. However, our recent studies demonstrate a pro-tumoral effect and resistance to chemotherapy induced by TLR7 stimulation of human lung tumor cell lines *in vitro*. Studies performed on human tumoral tissues revealed that TLR7 is both expressed *in situ* by tumor cells and by immune cells infiltrating tumor stroma (Cherfils-Vicini J. et al. JCI. 2010). Indeed *in vivo* TLR7 stimulation by its agonists, can lead to tumor progression or to tumor regression, through activation of antitumoral immune cells.

Materials and methods: In the present study human A549 NSCLC cells were grafted onto immunodeficient NOD/SCID mice, and murine LL/2 lung squamous cell carcinoma cells were grafted onto either NOD/SCID or immunocompetent C57Bl/6 mice.Tumor growth was followed after injection of TLR7 agonists and/or chemotherapy.

Results: We observed that injection of the TLR7 agonist, loxoribine, in NOD/SCID mice induces increased tumor growth and resistance to cisplatin of A549 cells compared to unstimulated conditions.These

results confirm the chemoresistance observed *in vitro*. On the contrary, loxoribine had no effect on LL/2 cells *in vitro* or *in vivo*, when grafted in NOD/SCID mice and had an anti-tumoral effect when LL/2 cells were grafted on C57Bl/6 mice. Interestingly an additional TLR7 agonist, CL264, induced tumor progression and resistance to chemotherapy when LL/2 cells were grafted in NOD/SCID mice. In immunocompetent C57Bl/6 mice low doses of CL264 induced anti-tumoral effects whereas high doses of CL264 induced pro-tumoral effects and chemo-resistance.

Conclusions: Taken together, these results indicate a fine regulation of TLR7 stimulation on both the immune system and tumoral cells, depending on the dose of the TLR7 ligand. Cancer immunotherapies using TLR7 agonists should take into account these new observations.

P0364

Virus-cell fusion as a trigger of innate immunity dependent on the adaptor STING

C. Holm,* S. B. Jensen,* M. R. Jakobsen,* N. Cheshenko,† K. A. Fitzgerald‡ & S. R. Paludan*

**Department of Biomedicine, Aarhus University, Århus C, Denmark, †Department of Pediatrics, Albert Einstein College of Medicine, New York, NY, USA, ‡Division of infectious Diseases and Immunology, University of Massachesetts, Boston, MA, USA*

Purpose/Objective: The innate immune system senses infection by detecting either evolutionarily conserved molecules essential for the survival of microbes or abnormal location of molecules.Recent research on the recognition of virus by innate immune mechanisms has been focused on the detection of nucleic acids derived either directly from the incoming virus or from RNA or DNA intermediates produced during viral replication. In this project, we investigated a novel mechanism for detection of infection with enveloped virus, which is independent of DNA or RNA detection.

Materials and methods: Virus-cell fusion was studied using virus like particles (VLPs) from HSV-1, which contain no genomic material or viral capsid but retain the ability to fuse with target cells. We used these VLPs to stimulate cells from mice deficient in signaling pathways previously shown to participate in innate recognition of virus. To study the fusion event further we also used two distinct cell-cell fusion assays based on the HIV fusion protein Env and highly fusogenic liposomes.

Results: We demonstrate the existence of a previously unknown innate detection mechanism induced by fusion between viral envelopes and target cells. Virus-cell fusion specifically stimulated a type I interferon response with expression of interferon-stimulated genes, *in vivo* recruitment of leukocytes and potentiation of signaling via Toll-like receptor 7 (TLR7) and TLR9. The fusion-dependent response was dependent on the stimulator of interferon genes STING but was independent of DNA, RNA and viral capsid.

Conclusions: We suggest that membrane fusion is sensed as a danger signal with potential implications for defense against enveloped viruses and various conditions of giant-cell formation.

Poster Session: Sensing and Communicating – Lectins and Lectin-Like Receptors

Characterisation of the myeloid inhibitory C-type lectin-like receptor (mMICL) knock-out mouse

P. Redelinghuys, R. A. Drummond, D. M. Reid & G. D. Brown
Immunology and Infection, Institute of Medical Sciences, University of Aberdeen, Aberdeen, UK

Purpose/Objective: The myeloid inhibitory C-type lectin-like receptor (mMICL) is expressed on cells of myeloid lineage including neutrophils.The presence of an immunoreceptor tyrosine-based inhibitory motif (ITIM) in its cytoplasmic tail and the widespread expression of its endogenous ligand/s in various tissues may suggest a role for this receptor in the maintenance of immune homeostasis and/or the regulation of inflammatory responses. To address these possibilities, we describe the generation and characterisation of the mMICL knock-out mouse.
Materials and methods: mMICL expression in wild-type and knock-out mice under steady state conditions was determined in tissues including peripheral blood, spleen and bone marrow. The distribution and composition of different myeloid and lymphoid populations in these tissues was also compared. mMICL knock-out and wild-type mice were aged for 24 months in order to assess any spontaneous development of disease. Furthermore, animals were also subjected to various models of sterile inflammation.
Results: In wild-type animals, mMICL showed high levels of expression in all immune tissues and was particularly pronounced in the bone marrow. No differences were observed in the distribution or composition of any myeloid or lymphoid cell populations, in the knockout mice. Ageing mMICL knock-out mice also showed no signs of spontaneous disease development.In a model of thioglycollate-induced peritonitis, mMICL expression in the recruited peritoneal leukocytes of wild-type mice reached a peak at 4 h which then decreased at 24 h and at later time points.Under the same conditions, mMICL knock-out mice showed a significantly greater recruitment of neutrophils 4- and 24-h post-i.p.
Conclusions: Our data suggests that, under steady state conditions, the absence of this inhibitory receptor does not contribute to the disruption of immune homeostasis. However, in response to inflammatory stimuli, early neutrophil-mediated responses are exacerbated. The mechanisms by which mMICL negatively regulates these responses are currently being investigated.

P0367
Characterisation of the orphan gene CLEC2L

O. Lysenko & A. Steinle
Institute for Molecular Medicine, Frankfurt am Main, Germany

Purpose/Objective: Natural Killer Gene Complex (NKC) encoded C-type lectin-like receptors (CTLRs) are expressed on various immune cells including T cells, NK cells and myeloid cells and thereby contribute to the orchestration and modulation of cellular immune responses. Certain members of these NKC-encoded CTLRs are grouped into the C-type lectin domain family 2 (CLEC2 family) that interact with CTLRs of the NKRP1 family expressed on cytolytic lymphocytes, e.g. AICL (encoded by *CLEC2B*) with NKp80. Noteworthily, CLEC2 and NKRP1 receptors are tightly genetically linked. While most CLEC2 family members are expressed by hematopoietic cells (e.g. CD69, AICL), we recently reported skin-restricted expression of the CLEC2 family member KACL (*CLEC2A)* on keratinocytes. Here we provide the first characterization of *CLEC2L*, another orphan gene of the CLEC2 family.
Materials and methods: *CLEC2L* tissue expression was addressed by quantitative real-time PCR. *CLEC2L* mutants were generated by site-directed mutagenesis. *CLEC2L*-encoded proteins and mutants were ectopically expressed in 293T cells for characterization by flow cytometry and immunoblotting. Soluble CLEC2L ectodomains were expressed in 293T cells and used for the generation of CLEC2L-specific antisera in chicken. Endogenous CLEC2L expression was addressed by immunohistochemistry using CLEC2L antisera.
Results: In contrast to other CLEC2 family members, the coding sequence of *CLECL* is highly conserved among mammals and the *CLECL* locus located outside of the NKC. Interestingly, expression of *CLEC2L* is also highly tissue-specific: *CLEC2L* transcripts are abundant in brains of man and mice, but present only at low levels or barely detectable in other tissues. Hence, we termed the *CLECL* gene product BACL (brain-associated C-type lectin). We show that BACL is readily expressed on the cell surface as homodimer linked by two disulfide bonds in the stalk region. BACL-specific antisera revealed strong expression of BACL by Purkinje neurons.
Conclusions: Here, we provide the first characterization of the orphan gene *CLEC2L* encoding a highly conserved, non-NKC-encoded, disulfide-linked, homodimeric CTLR of the CLEC2 family predominantly expressed in the brain, and thus termed BACL.

Galectin-1 secretion by mature dendritic cells supress *in vitro* Th-17 differentiation in humans

R. Varela-Calvino, C. Calviño-Sampedro, I. Gómez-Touriño, O. Cordero-Santamaría & J. Rodríguez
Bioquimica y Biologia Molecular, Universidad de Santiago de Compostela, Santiago de Compostela, Spain

Purpose/Objective: To determine the role played by galectin-1 secreted by mature dendritic cells (mDCs) in the differentiation of T helper cells, focusing on the generation of Th17 cells and the secretion of IL-17 *in vitro*.
Materials and methods: Human inmature dendritic cells were obtained by isolation and differentiation of peripheral blood monocytes using GM-CSF and IL-4. Immature dendritic cells were incubated with IL-1b, TNFa, IL-6 and prostaglandin E2 to obtain mDCs. To investigate the role of mDCs-secreted galectin-1 a mixed lymphocyte reaction using purified T cells (1:1 ratio T : mDC) was set up with or without a neutralising antibody to galectin-1. After the stimulation period, cytokine synthesis by T cells was analysed by ELISPOT and both galectin-1 and cytokines in the culture media by ELISA.
Results: Our results shows that mDCs synthesise and secrete up to 47 times higher levels of galectin-1 in comparison to those secreted by naïve CD4 T cells polarised *in vitro* towards a Th1, Th2 or Th17 phenotype. When T cells were incubated stimulated with allogeneic mDCs in the presence of sufficient amounts of a neutralising antibody to galectin-1 it was found that the number of cells secreting IFN-g rise dramatically indicating that galectin-1 reduces Th1 cell differentiation *in vitro*, in accordance with previous data. In addition and for the first time we show that in humans, neutralisation of galectin-1 secreted by mDCs also promotes IL-17A secretion and Th17 cell differentiation *in vitro*.
Conclusions: In conclusion, human Th17 cell differentiation is regulated by mDC-secreted galectin-1 *in vitro*. These results could explain the T cell phenotype observed in some human diseases where the synthesis of galectin-1 is reduced such as type 1 diabetes.

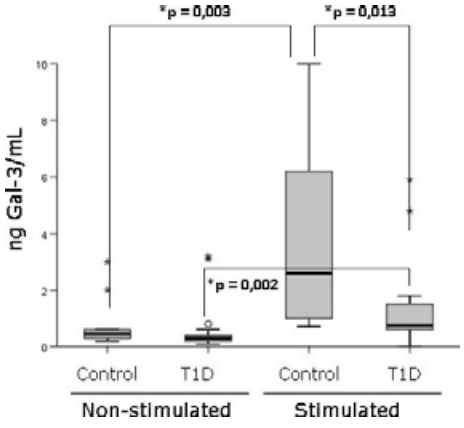
Galectin-3 expression in Th cell subsets: reduced secretion of this immunomodulatory lectin in type 1 diabetes patients

I. Gomez Tourino,* R. Varela Calvino,* C. Sanchez-Espinel,† A. Hernández-Fernández,† A. Gonzalez-Fernandez,† E. Pena-Gonzalez,‡ J. Rodriguez§ & J. M. Garcia-Lopez¶
**Biochemistry and Molecular Biology Department, Universidad de Santiago de Compostela, Santiago de Compostela, Spain, †Dpto. Inmunología. Centro de Investigaciones Biomédicas (CINBIO), Universidad de Vigo, Vigo, Spain, ‡Servicio de Endocrinología, Hospital do Meixoeiro, Complejo Hospitalario Universitario de Vigo, Vigo, Spain, §Laboratorio Central and Biochemistry and Molecular Biology Dpt., Complejo Hospitalario Universitario de Santiago and Universidad de Santiago de Compostela, Santiago de Compostela, Spain, ¶Servicio de Endocrinología and Medicine Dpt., Complejo Hospitalario Universitario de Santiago and Universidad de Santiago de Compostela, Santiago de Compostela, Spain*

Purpose/Objective: To determine the expression and secretion of the immunomodulatory lectin galectin-3 in several T helper cell subsets (Th1, Th2 and Th17) and evaluate potential differences in the synthesis of this immunomodulatory lectin between healthy controls and Type 1 Diabetes (T1D) patients.
Materials and methods: naïve CD4 T cells from healthy donors were polarized under Th1, Th2 and/or Th17 conditions, and Tbet, GATA-3, RORC2 and galectin-3 expression was determined by real-time PCR. Intracellular galectin-3 was measured by western blot. Peripheral blood mononuclear cells (PBMCs) were isolated from healthy controls and T1D patients. Secreted galectin-3 and cytokines were measured by ELISA.
Results: The *in vitro* polarization of naïve CD4 T cells towards a Th17 phenotype drives to the synthesis of elevated levels of galectin-3 in comparison with Th1 and Th2 subsets. In the case of T1D, CD3/CD28 stimulated PBMCs from these patients secrete significantly lower levels of galectin-3 when compared to those from healthy volunteers. This reduced secretion takes place in a pro-inflamatory environment, which is shown by an increased IFN-γ/IL-10 ratio.



Conclusions: Among the Th cell subsets, Th17 cells express the highest levels of galectin-3, suggesting an important role of the lectin in these cells. When this lectin is analyzed in the context of an autoimmune disease, such as T1D, diminished secretion of galectin-3 by PBMCs from those patients is observed; due to the apoptotic function of galectin-3 on T cells this defect could drive to the pathological survival of activated T cells, exacerbating the immune response.

P0370

Key role of the EGF receptor pathway in stress-induced upregulation of NKG2D ligands expression

P. Vantourout, C. R. Willcox, A. Turner & A. C. Hayday
Immunobiology, King's College London, London, UK

Purpose/Objective: The human MICA/B and ULBP(1−4) genes encode ligands for the activating receptor NKG2D expressed by several T cell subsets and NK cells. Of note, their surface expression is upregulated by several pathogens and by sterile stresses such as UV irradiation, oxidative stress, and transformation. This renders cells 'immunologically visible', reflecting which NKG2D and its ligands are common targets of immunoevasion. However, key mechanisms regulating NKG2D-ligand (NKG2DL) expression remain ill-defined. Upregulation by UVB has mostly been attributed to transcriptional activation induced by the DNA Damage Repair pathway. However, whereas surface NKG2DL expression is not detected, low levels of NKG2DL RNA are often detectable in healthy tissues, strongly suggesting post-transcriptional control mechanisms. As UV irradiation and other stresses can transactivate the EGF Receptor (EGFR), we investigated this as a pathway regulating NKG2DL RNA stability.
Materials and methods: Inhibition of EGFR greatly reduced upregulation of MICA/B and ULBP2 provoked by UVB and by other sterile stresses, consistent with which EGF upregulated cell surface NKG2DL expression and rendered cells NKG2D-dependent targets of cytotoxic NK and gd T cells. Canonical A/U rich elements (ARE) were identified in the 3' untranslated region of NKG2DL mRNAs which required re-annotation.
Results: The elements were distinct from microRNA binding sites previously identified in MICB RNA, and their profound destabilisation of mRNA was confirmed by Luciferase and GFP reporter systems. The RNA-binding proteins AUF1 and HuR were identified as targeting MICA/B and ULBP2 mRNAs for degradation. Finally, the signalling pathways (e.g. MAPKs) linking the EGFR to increased NKG2DL expression were also explored.
Conclusions: Our results provide new insight into stress-induced NKG2DL expression with a central role of the EGF receptor integrating responses to various stimuli long known to upregulate MICA/B and ULBPs. Of note, the EGFR pathway is often dysregulated in cancers, and may be integral to cell activation by viruses such as CMV.

P0371

Knockout of sialoadhesin enhances microglial accumulation during prion pathogenesis

B. M. Bradford,* P. R. Crocker† & N. A. Mabbott*
**Neurobiology Division, The Roslin Institute and R(D) SVS the University of Edinburgh, Edinburgh, UK, †College of Life Sciences, University of Dundee, Dundee, UK*

Purpose/Objective: The adhesion molecule sialoadhesin (Sialic acid-binding Ig-like lectin 1 [Siglec-1], CD169) binds sialic acid residues of glycoproteins and promotes endocytosis. Sialoadhesin is constitutively expressedby splenic marginal zone or lymph node subcapsular sinus macrophages which function to trap immune complexes. Sialoadhesin expression may also be induced in myeloid lineage cells upon exposure to blood-borne cytokines. The prion glycoprotein is heavily sialylated and may act as a ligand for sialoadhesin. To determine if sialoadhesin played a role in the uptake and pathogenesis of prion infectious-agent, scrapie challenge studies were performed in sialoadhesin deficient (SnKO) transgenic mice.
Materials and methods: Groups of SnKO mice and C57Bl/6 control mice were inoculated intracerebrally or intraperitoneally with mouse adapted scrapie agent ME7. Mice were studied at 5, 10 and 15 weeks for peripheral prion pathogenesis following intraperitoneal inoculation.

Results: Following intraperitoneal infection SnKO mice revealed no significant differences to C57Bl/6 mice in all aspects studied, including assessment of immune function via antigen trapping assays and disease-associated PrP accumulation in lymphoid follicles. Following intracerebral infection alterations were observed in brain region-specific microglial responses resulting in elevated levels of disease-associated vacuolation in hippocampal CA1 region and enhanced microglial proliferation and accumulation into multi-cellular aggregates.
Conclusions: The removal of sialoadhesin expression did not affect the peripheral pathogenesis of prion disease, therefore sialoadhesin is not required for the sequestration of the prion infectious agent into lymphoid germinal centres. Following intracerebral infection sialoadhesin-deficient mice displayed enhanced microglial response and proliferation in specific brain regions. These data suggest that the knockout of sialoadhesin may have altered microglial cell-cell recognition resulting in microglial multicellular aggregates. Alternatively damage to the blood brain barrier following intracerebral inoculation may have altered the priming of sialoadhesin-deficient microglia, leading to an enhanced pro-inflammatory response during infection and an increase in microglial proliferation.

P0372

Role of the C-type lectin receptor DCIR in cerebral malaria development

M. Maglinao,* R. Klopfleisch,† P. H. Seeberger* & B. Lepenies*
**Biomolecular Systems, Max-Planck-Institute of Colloids and Interfaces, Berlin, Germany, †Institute of Veterinary Pathology, Free University Berlin, Berlin, Germany*

Purpose/Objective: Malaria is one of the main global causes of death from infectious diseases. The vast majority of severe malaria cases and deaths are caused by infection with *Plasmodium falciparum* which is often associated with severe pathology including anemia, metabolic acidosis, impaired blood circulation, and cerebral malaria (CM). The murine *P. berghei* ANKA (PbA) infection is an established model of cerebral malaria, and blood-stage infection leads to CM induction in 80−100% of PbA-infected mice. While a number of studies have addressed the role of adaptive immunity in CM development, the contribution of pattern recognition receptors to CM is still poorly understood. C-type lectin receptors (CLRs) are of particular interest since engagement of CLRs on the one hand may lead to the initiation of immune responses but on the other hand may also result in maintaining immune homeostasis. The objective of this study was to investigate the contribution of the CLR dendritic cell immunoreceptor (DCIR) to CM development.
Materials and methods: $DCIR^{-/-}$ mice and the respective C57BL/6 wild-type control mice were infected i.p. with PbA-infected erythrocytes. Parasitemia was determined in Giemsa-stained blood smears from tail blood and mice were monitored daily for symptoms of CM. Leukocyte sequestration in the brain and the expression of activation markers by immune cells were measured by flow cytometry as well as immunohistochemistry. Cytokine levels were assessed by cytometric bead array. Statistical analyses were performed with unpaired Student *t* test and the log rank test to compare survival curves.
Results: Infection of C57BL/6 wild-type mice with PbA led to CM in 80% of infected mice, whereas $DCIR^{-/-}$ mice were highly protected from CM (only 20% CM development). Parasite loads were similar in $DCIR^{-/-}$ and wild-type mice indicating that DCIR deficiency did not affect parasite replication. To address the mechanism by which DCIR deficiency mediated protection from CM, leukocyte sequestration in the brain and levels of pro-inflammatory cytokines in serum were measured. Indeed, T cell sequestration was reduced in brains of PbA-infected $DCIR^{-/-}$ mice and cytokine levels in serum were markedly modulated compared to C57BL/6 wild-type mice.
Conclusions: This study indicates that DCIR is involved in CM induction, thus highlights the importance of CLRs for the innate immune response during the course of malaria.

P0373

Siglec-7 expression decreases in freshly isolated peripheral blood mononuclear cells (PBMCs) under diabetogenic conditions

G. Dharmadhikari,* K. Stolz,* A. Krämer,† S. Kelm* & K. Maedler*
**Centre for Biomolecular Interactions Bremen, University of Bremen, Bremen, Germany, †Department of Virology, University of Bremen, Bremen, Germany*

Purpose/Objective: In both, type 1 and type 2 diabetes mellitus; cytokine and chemokine production within pancreatic islets is detrimental for the insulin producing b-cells. Also, infiltration of macrophages in the pancreatic islets is a hallmark of islet inflammation. Siglecs (Sialic-acid binding immunoglobulin like lectins) are cell surface receptors expressed on haematopoietic cells which participate in such immune responses. We investigated their expression in freshly isolated PBMCs under diabetogenic conditions. Our experiments revealed decreased expression of Siglec-7 along with the activation of monocytes under such conditions.
Materials and methods: PBMCs were isolated from buffy coats of six non-diabetic individuals followed by culture with elevated glucose (22.2 mM)/ 0.5 mM palmitate, or cytokine mixture (2 ng/ml IL-1β/ 1000 U/ml IFN-γ) or 100 ng/ml Lipopolysaccharide (LPS), for 12 h. The mRNA expression of Siglec-7; immune cell marker CD25; as well as cytokine IL-6 was analyzed by RT-PCR. Siglec-7 was assessed by flow cytometry.
Results: LPS, elevated glucose and palmitate, as well as cytokine mixture induced activation of PBMCs as seen by the induction of IL-6 mRNA (380-, 80- and 50-fold, respectively), as well as by increased CD25 expression (45-, 10- and 5-fold, respectively) as compared to the untreated control ($P < 0.05$). Simultaneous decrease was observed in Siglec-7 mRNA expression; 80% by cytokine mixture, and 50% by elevated glucose and palmitate, whereas LPS decreased Siglec-7 mRNA expression only during the acute 2h-exposure (60% reduction).

The glucose/palmitate-induced effect was confirmed by flow cytometric analysis of Siglec-7 cell surface expression showed 35% decrease in percentage of Siglec-7 positive cells as well as 25% decrease in the mean fluorescence intensity.
Conclusions: Our results show that Siglec-7 is decreased under diabetogenic conditions wherein the PBMCs are in an activated state, hinting towards the inhibitory role of Siglec-7 in the activation of these immune cells during the development and progression of diabetes mellitus.

P0374

The Mincle-activating adjuvant TDB induces MyD88-dependent, TLR-independent Th1 and Th17 responses through IL-1R signalling

C. Desel,[1] K. Werninghaus,* M. Ritter,† K. Jozefowski,* D. Christensen,‡ C. Prazeres da Costa† & R. Lang*
**Institute of Clinical Microbiology Immunology and Hygiene, University Hospital Erlangen, Erlangen, Germany, †Institute for Medical Microbiology Immunology and Hygiene Department of Parasitology, Technical University Munich, Munich, Germany, ‡Statens Serum Institute, Vaccine Research and Development, Copenhagen, Denmark*

Purpose/Objective: Vaccination is the most successful strategy to prevent potentially life-threatening diseases. Protective immunity is often dependent on strong cellular immune responses rather than antibody production. However, the most used human adjuvant aluminium hydroxide is a weak inducer of Th1 responses. Trehalose-6, 6-dibehenate (TDB), the synthetic analogue of the mycobacterial cord

factor trehalose-6, 6-dimycolate is a potent adjuvant not only inducing a strong Th1 but also a pronounced Th17 immune response. We identified the C-type lectin Mincle as receptor for these glycolipids that triggers the FcRγ-Syk-Card9 pathway for APC activation and adjuvanticity. While APC activation *in vitro* was MyD88-independent and solely required Mincle, *in vivo* data revealed the adjuvant effect of TDB was strongly reduced in MyD88$^{-/-}$ mice.

Materials and methods: Thus, we dissected which MyD88-dependent pathways contribute to TDB-mediated adjuvanticity after immunisation with a tuberculosis subunit vaccine *in vivo*. In order to further characterize adjuvant-induced immune responses, we analysed recruitment kinetics of innate immune cells after intraperitoneal or subcutaneous injection into C57/Bl6, Mincle$^{-/-}$ and MyD88$^{-/-}$ mice and followed the vaccine's and APC's fate to the draining lymph nodes.

Results: We show here that development of antigen-specific Th1 and Th17 immune responses crucially depended on IL-1/IL-1 receptor mediated signals, whereas IL-18 and IL-33 were dispensable. Interestingly, ASC-deficient mice had impaired IL-17 but intact IFNγ responses, indicating partial independence of TDB adjuvanticity from inflammasome activation.

Neutrophils and inflammatory monocytes were the first cell types being recruited to the injection site in very high numbers upon immunisation. Neutrophil influx was equally dependent on recognition via Mincle and MyD88 signalling. However, depletion of neutrophils did not impair generation of Th1 and Th17 immune responses. Experiments interfering with recruitment of inflammatory monocytes are currently ongoing.

Conclusions: Taken together, the glycolipid adjuvant TDB relies on MyD88-dependent but TLR-independent pathways for efficient Th1/Th17 adjuvanticity. Pharmacologic and genetic abrogation of IL-1R signaling identified IL-1 as the major MyD88-dependent factor induced by TDB through Mincle-Card9 signaling.

P0375

The role of Galectin 3 in Con A induced liver injury

N. Arsenijevic,* V. Volarevic,* M. Milovanovic,* B. Ljujic,* N. Pejnovic,* U. Nilsson,† H. Leffler† & M. L. Lukic*

**Immunology, Center for Molecular and Stem Cell Research, Kragujevac, Serbia, †Organic Chemistry, Lund University, Lund, Sweden*

Purpose/Objective: Concanavalin A (Con A) induced liver injury is an established murine model of T cell mediated hepatitis. We used this model to study the role of Galectin 3 (Gal-3) in the induction of inflammatory pathology and hepatocellular damage.

Materials and methods: We tested susceptibility to Con A-induced hepatitis in galectin-3-deficient Gal-3($^{-/-}$) mice and analyzed the effects of pretreatment with a selective inhibitor of Gal-3 (TD139) in wild-type (WT) C57BL/6 mice, as evaluated by a liver enzyme test, quantitative histology, mononuclear cell (MNC) infiltration, cytokine production, intracellular staining of immune cells, and percentage of apoptotic MNCs in the liver.

Results: Gal-3($^{-/-}$) mice were less sensitive to Con A-induced hepatitis and had a significantly lower number of activated lymphoid and dendritic cells (DCs) in the liver. The level of tumor necrosis factor alpha (TNFα), interferon gamma (IFNγ), and interleukin (IL)-17 and -4 in the sera and the number of TNFα-, IFNγ-, and IL-17- and -4-producing cluster of differentiation (CD)4($^{+}$) cells as well as IL-12-producing CD11c($^{+}$) DCs were lower, whereas the number of IL-10-producing CD4($^{+}$) T cells and F4/80($^{+}$) macrophages were significantly higher in livers of Gal-3($^{-/-}$) mice. Significantly higher percentages of late apoptotic Annexin V($^{+}$) propidium-iodide($^{+}$) liver-infiltrating MNCs and splenocytes were observed in Gal-3($^{-/-}$) mice, compared to WT mice. Pretreatment of WT C57BL/6 mice with TD139 led to the attenuation of liver injury and milder infiltration of IFNγ- and IL-17- and -4-producing CD4($^{+}$) T cells, as well as an increase in the total number of IL-10-producing CD4($^{+}$) T cells and F4/80($^{+}$) CD206($^{+}$) alternatively activated macrophages and prevented the apoptosis of liver-infiltrating MNCs.

Conclusions: Gal-3 plays an important proinflammatory role in Con A-induced hepatitis by promoting the activation of T lymphocytes and natural killer T cells, maturation of DCs, secretion of proinflammatory cytokines, down-regulation of M2 macrophage polarization, and apoptosis of MNCs in the liver.

Balancing the activation of minor histocompatibility antigen specific T cells in transplantation

S. Firner,* D. Engeler,* B. Bolinger,† R. A. Kroczek,‡ T. Sparwasser§ & B. Ludewig¶

Institute of Immunobiology, Cantonal Hospital St. Gallen, St. Gallen, Switzerland, †The Peter Medawar Building for Pathogen Research, University of Oxford, Oxford, UK, ‡Molecular Immunology, Robert Koch Institute, Berlin, Germany, §TWINCORE Medical School, Institute of Infection Immunology, Hannover, Germany, ¶Institute of Immunobiology, Cantonal Hospital St. Gallen, St.Gallen, Switzerland

Purpose/Objective: T cell-mediated immune responses against vascular endothelial cells (ECs) represent a major obstacle in solid organ transplantation. A number of T cell-intrinsic and -extrinsic regulatory pathways impinge on chronic graft rejection. Here, we compared the impact of T cell-intrinsic negative regulatory circuits with T cell-extrinsic, regulatory T cell (Treg)-mediated attenuation during *in vivo* EC-T cell interaction.

Materials and methods: We used Tie2 mice expressing the β-galactosidase (βgal) antigen as a traceable minor antigen (mHA) under the control of the EC-specific Tie2 promoter. To model the interaction of ECs with specific T cells, we adoptively transferred βgal-specific $CD8^+$ T cells (Bg1) or $CD4^+$ T cells (Bg2) into Tie2 mice. To assess the impact of potential negative regulators Bg1 or Bg2 cells lacking the co-inhibitory molecules PD-1 or BTLA were used. To address whether Treg contribute to the control of EC-specific T cell activity, we used Tie2 × DEREG mice which facilitate ablation of Treg cells. Transplant rejection was assessed in a heterotopic heart transplantation model where Tie2 hearts are transplanted into B6 recipients.

Results: Bg2 and Bg1 cells were efficiently tolerized when the mHA was expressed systemically on ECs. Furthermore the lack of co-inhibition mediated by PD-1, BTLA or Treg cells did not prevent deletion of Bg1 cells, but differentially modulated initial Bg2 cells activation. Heterotopically transplanted heart grafts expressing the mHA in ECs remained immunologically ignored following transfer of mHA-specific $CD8^+$ T cells. However, ablation of the co-inhibitory molecules BTLA or PD-1 resulted in significant $CD8^+$ T cell activation leading to transplant vasculopathy. In contrast, mHA specific $CD4^+$ T cells induced vessel pathology in the presence or absence of negative regulation.

Conclusions: These data demonstrate that both T cell-intrinsic and -extrinsic negative regulation depends on the context of antigen presentation.

P0378

Distinct lympho-epithelial interactions control the segregation of IL-7-expressing cortical and aire-expressing medullary thymic epithelial niches

A. R. Ribeiro,* P. M. Rodrigues,* C. Meireles,* J. P. Di Santo† & N. L. Alves*

Infection and Immunity Unit, Instituto de Biologia Molecular e Celular, Porto, Portugal, †Innate Immunity Unit, Institut Pasteur, Paris, France

Purpose/Objective: Thymic epithelial cells (TECs) are chief instructors of T cell development. Functionally distinct cortical (cTECs) and medullary (mTECs) TECs derive from a common bipotent progenitor and the partitioning of these subsets relies on reciprocal signals provided by thymocytes. While the molecular cues that control mTEC maturation are partially elucidated, the underlying basis that regulates cTEC differentiation is largely unknown, due to the lack of detailed intermediate stages. Using IL-7 reporter mice, in which YFP expression identifies TECs that co-express high levels of *Il7* ($Il7^{hi}$TECs), we previously showed that $Il7^{hi}$TECs numbers gradually decline with age in a thymocyte-dependent manner. Conversely, $Il7^{hi}$TECs are sustained when T cell development is profoundly blocked in $Rag2^{-/-}Il2rg^{-/-}$ mice, suggesting that $Il7^{hi}$TECs represent a TEC precursor controlled by thymocyte-derived signals. Here, we study the lineage relationship between $Il7^{hi}$TECs and other well-characterized TEC subsets.

Materials and methods: Immunocompetent and $Rag2^{-/-}$ IL-7 reporter mice were used. Fetal thymic analysis, *in vivo* anti-CD3-treatment and *in vitro* thymic organotypic cultures were performed. TECs were analyzed by flow cytometry and immunofluorescence. Gene expression was assessed by qPCR on sorted TECs.

Results: $Il7^{hi}$TECs emerge early during thymic development, continually retain a $CD205^+$ $BP1^+$ cTEC phenotype, co-express *Dll4*, *Ccl25*, *Il7*, *Ctsl*, *Psmb11*, *Prss16* and segregate from *Aire*, *Ctss* and *Tnfrsf11a*-expressing $CD80^+$ $CD40^{hi}$ mTECs. RANK and LtβR-mediated signals promote the maturation of mTECs. We show that the decline in $Il7^{hi}$TECs induced by thymocyte-TEC interactions dissociates from the RANK- and LtβR-mediated maturation of mTECs, suggesting that $Il7^{hi}$TECs are not a direct progeny of mTECs. Studies of $Rag2^{-/-}$ mice, in which mTEC differentiation is defective, reveal that $Il7^{hi}$TECs persist throughout postnatal life, indicating that their homeostasis is regulated by signals provided by thymocytes beyond β-selection. In anti-CD3-treated $Rag2^{-/-}$ mice, the induction of DP thymocytes lacking TCR expression restores mTEC differentiation without significantly curtailing $Il7^{hi}$TECs.

Conclusions: Taken together, our results indicate that high IL-7 expression is a determinant of cTEC lineage and provide evidence that the homeostasis of the cortical epithelium is regulated by thymocyte-derived TCR-mediated interactions.

IL-24 expression during early wound healing phase is depended on an inflammatory environment

S. Kirsch,* K. Witte,* E. Witte,* S. Endesfelder,* K. Asadullah,† H. D. Volk,‡ W. Sterry,§ K. Wolk¶ & R. Sabat¶

Interdisciplinary Group of Molecular Immunopathology Dermatology/Medical Immunology, Charité University-Medicine Berlin, Berlin, Germany, †Target Discovery, Bayer Schering Pharma Inc., Berlin, Germany, ‡Institute of Medical Immunology, University Hospital Charité, Berlin, Germany, §Department of Dermatology, University Hospital Charité, Berlin, Germany, ¶Interdisciplinary Group of Molecular Immunopathology Dermatology/Medical Immunology Psoriasis Research and Treatment Center, Department of Dermatology, University Hospital Charité, Berlin, Germany

Purpose/Objective: Cutaneous wound healing is characterized by a precisely regulated action of different growth factors and cytokines. Its disturbance can lead to an impaired healing response, which represents a great medical problem. We demonstrated previously, that the novel IL-10 cytokine family members IL-22, IL-20, and IL-24, play a major role in psoriasis and skin homeostasis.

Materials and methods: Wound healing was investigated with an *in vivo* model using wildtype mice. Wound biopsies were examined by means of immunohistochemistry and quantitative real-time RT-PCR.

Results: By using an *in vivo* mouse model we demonstrated, that IL-20 was constitutively expressed, whereas no IL-22 expression was observed. In contrast, IL-24 was massively upregulated upon wounding. Here, immunohistochemistry revealed keratinocytes and CD3-positive cells as the main source of IL-24 in the early wound healing phase. In keratinocytes the IL-24 expression level was elevated after 24h stimulation with IL-4, IL-1b, IL-6, TNF-alpha and TGF-beta. We next investigated the expression of these mediators in non injured mouse skin as well as wound biopsies at indicated time points upon

wounding. T-cell derived cytokines were hardly induced in early wound healing phase. TGF-beta was constitutively expressed throughout the healing response. IL-1b, IL-6 and TNF-alpha were highly upregulated during the inflammatory phase and showed a similar expression kinetic as IL-24, which emphasizes a potential role for IL-24 upregulation. Interestingly, among these cytokines, IL-24 along with IL-1b were the highest expressed mediators relative to unwounded skin during the inflammatory phase.
Conclusions: IL-24 may have an important yet to be defined role in wound healing.

P0381

Molecular and cellular network in chronic lung inflammation and the impact of alveolar type II epithelial cells

A. Autengruber,* M. Gereke,* C. Hennig† & D. Bruder‡
**Immunregulation, Helmhotz Centre for Infection Research, Braunschweig, Germany, †Paediatric Pneumology and Neonatology, Hannover Medical School, Hannover, Germany, ‡Medical Microbiology, Otto-von-Guericke University, Magdeburg, Germany*

Purpose/Objective: For the development of therapies for chronic lung disorders, in depth understanding of the inflammatory processes are required. Therefore, the molecular and cellular network involved in the induction and regulation were characterized, with the specific focus on alveolar type II epithelial cells (AECII).
Materials and methods: Therefore, a transgenic mouse model for severe lung inflammation, based on the recognition of alveolar self-antigen by $CD4^+$ T cells, which closely resembles the pattern in human patients, was utilized. Cellular subsets in bronchoalveolar lavage (BAL) were compared using flow cytometric analysis. To characterize the inflammation-dependent changes on the AECII level, highly pure, primary AECII were isolated by flow cytometric negative selection. Transcriptional profiling was performed by Real-time RT-PCR. Furthermore, AECII were cultured and chemokines secreted by AECII as well as in BALF were detected using Proteome Profiler™ Array. To analyze the attraction of cells, *in vitro* migration was evaluated by transwell system. *In vivo* migration of CFSE-labeled $CD4^+$ T cells was evaluated at different time points using FACS.
Results: Analysis revealed an accumulation of immune cells in the inflamed airways. Protein profiling, in particular cytokines and chemokines, in bronchoalveolar lavage fluid (BALF) and AECII conditioned medium (AECIICM) from healthy and diseased mice showed inflammatory alterations. Inflammatory AECII revealed upon others elevated expression of co-inhibitory and co-stimulatory ligands which are known to pair with the corresponding receptors on activated T cells and regulatory T cells (Tregs) which have been shown to accumulate in the inflamed lungs. *In vitro* migration experiments revealed that soluble mediators in BALF and AECIICM have a specific and in part differential impact on the chemoattraction of neutrophils, dendritic cells and lymphocytes. *In vivo* $CD4^+$ T cell migration experiments revealed a dramatic accumulation of Tregs in the inflamed lung of recipient mice five days but not 1 day after adoptive transfer suggesting Treg expansion rather than attraction.
Conclusions: These data suggest an active contribution of inflammatory AECII to modulate autoreactive T cell responses and Tregs function. And a better understanding of the complex network composed of immune cells and soluble mediators which might determine the course of lung inflammation.

P0383

Polymorphonuclear neutrophil-derived elastase causes a dyshesion of pancreatic tumour cells and induces an epithelial-to-mesenchymal transition.

G. Hansch,* T. Grosse Steffen,* T. Giese* & M. M. Gaida†
**Immunology, Universitätsklinikum Heidelberg, Heidelberg, Germany, † Pathology, Universitätsklinikum Heidelberg, Heidelberg, Germany*

Purpose/Objective: Pancreatic ductal adenocarcinoma (PDAC) is frequently associated with a scattered, disseminated growth pattern, an epithelial-to-mesenchymal transition (EMT), and a localised inflammatory response, evident as infiltration of leukocytes, particularly of polymorphonuclear neutrophils. In this study we explored a possible connection between the growth pattern, the EMT and the inflammation.
Materials and methods: Biopsies of patients with PDAC ($n = 112$) were analysed with regard to the leukocyte infiltrate, the nuclear expression of §-catenin and of ZEB1, both established indicators of EMT, and of E-cadherin, an intercellular adhesion molecule. Moreover, cultivated pancreatic tumour cells were co-incubated with isolated PMN, and the transition of the epithelial cells to cells with mesenchymal characteristics was assessed by time-lapse video microscopy, and by determining the induction of genes and proteins pertinent to EMT.
Results: We found in biopsies with a strong inflammatory infiltrate a nuclear accumulation of §-catenin and of ZEB1 in the tumour cells and a reduced expression of E-cadherin, all indicating an EMT within the tumour. To follow up on the question of a connection between PMN and EMT, pancreatic tumour cells grown as monolayers were co-cultivated with PMN. Within hours, a rapid dyshesion of the tumour cells was seen, and a drastic shape change to elongated, spindle-shaped cells. Subsequent experiments showed that dyshesion was mediated by PMN-derived elastase, which degraded the intercellular adhesion protein E-cadherin. Concomitantly with loss of E-cadherin, an up-regulation of TWIST, a gene involved in EMT, was seen, as was the translocation into the nucleus of §-catenin and of ZEB1, followed by a down-modulation of cytokeratin.
Conclusions: In conclusion, PMN-derived elastase induces a dyshesion and a transition of the pancreatic tumour cells to mesenchymal cells (EMT) *in vitro*. Because in pancreatic cancer the disseminated growth pattern and the transition to a mesenchymal phenotype coincide with a PMN infiltrate, a contribution of the inflammatory response to the induction of EMT and hence to tumour progression is possible.

P0384

Respiratory epithelial cell adhesion to type I collagen downregulates MMP-1 expression in TB

S. Brilha & J. S. Friedland
Department of Infectious Diseases and Immunity, Imperial College London, London, UK

Purpose/Objective: In tuberculosis (TB), Matrix Metalloproteinases 1 and 9 (MMP-1/9) have crucial roles in extracellular matrix (ECM) breakdown which leads to tissue destruction and cavitation. Pulmonary ECM is primarily composed of type I collagen.

We hypothesised that ECM components and specifically type I collagen regulate gene expression and secretion of MMPs. We investigated the effect of type I-IV collagen, fibronectin and laminin on MMP-1/9 expression and secretion in Normal Human Bronchial Epithelial (NHBE) cells stimulated with conditioned medium from Mtb-infected monocytes (CoMtb). We also dissected adhesion-dependent effects on tissue inhibitors of MMPs (TIMPs).
Materials and methods: NHBE cells were seeded in tissue culture plates pre-coated with ECM components and stimulated for 24 h with

CoMtb or control culture medium. MMP-1, 2, 7 and 9 and TIMP-1/2 secretion was measured by ELISA and Luminex bead array. mRNA concentration was detected by real-time PCR.
Results: CoMtb-stimulation of NHBEs adherent to type I collagen caused downregulated MMP-1 and upregulated MMP-9 concentrations compared to control cells adherent to tissue culture plastic ($P < 0.01$). Collagen concentrations of 100 μg/ml decreased MMP-1 from 786 ± 48 pg/ml to 557 ± 44 pg/ml (31% reduction), while MMP-9 increased from from 12 939 ± 1560 pg/ml to 21 571 ± 1767 pg/ml (40% increase). At the transcriptional level, there was a 41% decrease in MMP-1 mRNA and a 34% increase in MMP-9 mRNA. MMP expression by unstimulated cells was not affected by the presence of collagen ($P > 0.05$). No differences were found in secretion of MMP-2 or 7. Type IV collagen, fibronectin and laminin did not affect MMP-1 secretion. There was no difference in TIMP-1/2 concentrations between cells adherent to type I collagen or tissue culture plastic ($P > 0.05$).
Conclusions: Adhesion to type I collagen downregulates MMP-1 and 9 gene expression and secretion from CoMtb stimulated NHBEs. In contrast, TIMP-1 and 2 were unaffected. Therefore, MMP activity depends on ECM-cell interactions which might be important in the regulation of the inflammatory tissue destruction characteristic of TB.

P0385
Respiratory epithelial cells mediate distinct inflammatory responses to different bacterial pathogens

M. Melin, A. Vuorela, H. Salo & O. Vaarala
Department of Vaccination and Immune Protection, National Institute for Health and Welfare, Helsinki, Finland

Purpose/Objective: Streptococcus pneumoniae (Pn), Haemophilus influenzae (Hi), and Moraxella catarrhalis (Mc) are potential respiratory pathogens, which generally colonize the nasopharynx of humans early in life. Carriage of these bacteria decreases with age, but the immunological mechanisms functioning against colonization are largely unknown. IL-17 expressing Th17 cells have been found to mediate mucosal immunity to many bacterial pathogens. In this study we aimed to characterize the cellular immune responses Pnc, Hi and Mc trigger in human cells.
Materials and methods: Nasopharyngeal epithelial cells (Detroit 562) were incubated with live bacteria for 1 h. The proportion of adherent bacteria was determined by plate counting. During the next 23 h the epithelial cells were cultured with antibiotics to inhibit bacterial multiplication. Blood peripheral mononuclear cells (PBMCs) collected from healthy adults were incubated with heat-killed bacteria for 96 h. The cytokines (mRNA) expressed by the epithelial and PBM cells were measured by RT-qPCR.
Results: Exposure to live bacteria induced a rapid proinflammatory response in the epithelial cells; expression of IL-1α, IL-1β, IL-6, IL-8, and TNF-α, was increased but no significant differences were seen between cells exposed to different bacteria after the first hour. However, after 24 h, epithelial cells exposed to Mc or Hi expressed increased levels of all these cytokines, whereas cells exposed to Pn did not differ significantly from unstimulated cells. The proportion of bacteria binding to the epithelial cells was highest for Mc and Hi. Stimulation of PBMCs with Pn, in contrast to Mc and Hi, induced a marked IL-17 biased immune response coupled with down-regulation of IL-10. Mc induced a stronger IFN-γ mediated, Th1-type, proinflammatory response in the PBMCs than Pnc or Hi. Bacterial exposure also induced expression of Foxp3, typically considered a marker for regulatory T cells.
Conclusions: The results indicate that Pnc, Hi and Mc induce distinctly different types of immune responses in respiratory epithelial cells and T cells, suggesting that the host immune mechanisms against these pathogens may differ. Airway epithelial cells have the capacity to modulate the activation of immune cells, which means that the innate responses bacteria induce in epithelial cells can affect the adaptive immune response.

P0386
Role of epithelial E-cadherin in gut immune homeostasis

H. Meinicke,* M. Brack,* A. Bremser,* P. Rauf,* H. Pircher,† M. P. Stemmler‡ & A. Izcue*
**Centre of Chronic Immunodeficiency, Max Planck Institute of Immunobiology and Epigenetics, Freiburg, Germany, †Immunology, Institute of Medical Microbiology and Hygiene, Freiburg, Germany, ‡Molecular Embryology, Max Planck Institute of Immunobiology and Epigenetics, Freiburg, Germany*

Purpose/Objective: The transmembrane molecule E-cadherin is an essential component of epithelial junctions. It has emerged that it also plays a role in the immune system, as lymphocytes can express E-cadherin-specific receptors. $CD4^+$ $Foxp3^+$ regulatory T cells (Treg) are enriched for the E-cadherin receptors CD103 and KLRG1, suggesting a link between $CD4^+$ Treg and E-cadherin recognition. As gut Treg are key to prevent intestinal inflammation, we decided to assess the role of intestinal epithelial E-cadherin on gut Treg homeostasis.
Materials and methods: To check the effects of lack of intestinal E-cadherin on the immune system we used genetically modified mice. Complete lack of E-cadherin is not compatible with embryonic development, and specific deletion of E-cadherin from the intestinal epithelium also leads to prenatal death. To circumvent this problem, we replaced one allele of E-cadherin by the closely related molecule N-cadherin. The other allele of E-cadherin was specifically deleted on intestinal epithelial cells using a Villin-Cre E-cadherin flox system, so that E-cadherin positive cells throughout the body express both E- and N-cadherin but intestinal epithelial cells only express N-cadherin (gut E-Cad KO mice). We have then analysed the intestinal and systemic immune compartment from these mice using flow cytometry, microscopy and quantitative PCR.
Results: Unlike E-cadherin-sufficient littermates, gut-E-Cad KO mice show flora-dependent intestinal inflammation. This was not due to the ectopic N-cadherin expression as N-cadherin transgenic mice harboring one wildtype copy of E-cadherin showed no phenotype. These mice also presented increased $CD4^+$ T cell numbers in the gut. Interestingly, the frequency of Treg among the intestinal $CD4^+$ T cell population was also increased, mostly due to the accumulation of $Foxp3^+$ cells expressing the cadherin receptor KLRG1. The frequency of Treg expressing the E-cadherin receptor CD103 did not change significantly. As a control, we did not find increased $KLRG1^+$ Treg in the gut from IL-10-deficient mice, which also have flora-dependent intestinal inflammation.
Conclusions: Mucosal lymphocytes are controlled by local factors, and E-cadherin expressed by gut epithelial cells could be involved in the control of the intestinal Treg pool.

P0388
Soluble factors from alveolar epithelial cells increase intracellular killing using nitric oxide independent pathways

D. Petursdottir, O. D. Chuquimia & C. Fernández
Immunology, Stockholm University, Stockholm, Sweden

Purpose/Objective: We have shown that factors from alveolar epithelial cells (AECs) increase macrophage intracellular killing of Bacillus Calmette-Guérin (BCG) through a nitric oxide-independent mechanism. We aim to identify a potential mechanism by which this increased killing is mediated.
Materials and methods: Bone marrow-derived macrophages (BMM) and pulmonary macrophages (PuM) were isolated from C57BL/6 mice

and infected with BCG. After a 4 h infection, bacteria were removed and cells incubated further in media with or without IFN-γ (20 ng/ml) or supernatants from AEC (AEC_{sup}). After culturing, intracellular bacterial killing was assessed, RNA was harvested and mRNA quantified using qPCR. Cytokines were also measured with ELISA.
Results: Treating BMM with IFN-γ, increased intracellular killing compared with that of cells cultured in medium alone whereas in PuM IFN-γ was ineffective. In both cell-types, IFN-γ treatment increased transcription of iNOS, IP-10 and IL-12 and secretion of IL-12 and IL-6. Transcription of suppressor of cytokine signaling (SOCS)1 was higher in PuM than BMM. SOCS1 expression was important for mediating the ineffectiveness of IFN-γ in increasing intracellular killing in PuM, as PuM from SOCS1/IFN-$\gamma^{-/-}$ mice showed enhanced killing after IFN-γ treatment. On the other hand, AEC_{sup} treatment did not affect iNOS, IP-10 nor IL-12 expression but increased Arg1 transcription and IL-6 secretion.
Conclusions: BMM and PuM responded to IFN-γ indicating that both cell types possess receptors able to recognize and transmit signals delivered by IFN-γ. The only difference was that IFN-γ only increased intracellular killing of BCG in BMM but not in PuM. On the other hand, treating cells with AEC_{sup} increased intracellular killing of BCG in both types of macrophages. This increased killing was not associated with increases in the pro-inflammatory effectors IL-12 or iNOS, indicating that the mechanism by which intracellular killing is increased after treatment with AEC_{sup} is not through an M1 activation pathway.

P0389

Synoviocytes change phenotype and function after Treg-depletion in arthritic mice

M. Böttcher,* C. Wunrau,† T. Pap† & T. Kamradt*
**Institute of Immunology, University Hospital Jena, Jena, Germany,*
†*Institute of Experimental Musculoskeletal Medicine, University Hospital Muenster, Muenster, Germany*

Purpose/Objective: Immunization with Glucose-6-phosphate isomerase (G6PI) induces arthritis in susceptible strains of mice. Depletion of regulatory T cells (Tregs) prior to immunization switches the usually acute, self-limiting course to a non-remitting, destructive arthritis. This provides a good possibility to study relevant molecular switches for the transition from acute, self-limiting to chronic, destructive arthritis within one mouse model.

To examine the role of fibroblast-like synoviocytes (FLS), which can support and modulate immune responses via the production of pro- and anti-inflammatory mediators, the expression of a panel of surface markers characteristic of FLS was determined. Next, the phenotype and function of FLS from mice with either acute, self-limiting or non-remitting, destructive arthritis was studied.
Materials and methods: FLS from DBA/1 mice that developed either the acute or the chronic form of arthritis have been isolated from the joints over a time course of 56 days.To investigate the phenotype of FLS flow cytometric methods as well as quantitative realtime-PCR and ELISA studies have been performed. For the functional clarification of those cells the matrix-associated transepithelial resistance invasion (MATRIN) assay and a cartilage attachment assay have been used.
Results: It was found that murine FLS stably express several surface markers over several passages *in vitro*. Furthermore, FLS from Treg-depleted mice produced significantly more cytokines [e.g. Interleukin 6 (IL-6)] upon stimulation with other cytokines, growth factors and TLR ligands. This increased susceptibility to cytokine-stimulation in chronic animals compared to acute ones is observable throughout the disease course (56 days). Additional functional differences include the collagen-destructive potential and the potential to attach and eventually invade wild type cartilage. Here, FLS from Treg-depleted chronic arthritic mice showed a higher invasive and destructive potential.
Conclusions: Our results are compatible with the hypothesis that synoviocytes from Treg-depleted, arthritic mice acquire an autonomously aggressive phenotype that contributes to the switch from acute to chronic arthritis.

The regulatory effect of lactobacilli on *Staphylococcus aureus* induced inflammatory response in intestinal epithelial cells and immune cells

Y. Haileselassie,* M. A. Johansson,* C. Zimmer,* D. H. Petursdottir,* J. Dicksved,† M. petersson,‡ J. O. Persson,‡ C. Fernandez,* S. Roos,† U. Holmlund* & E. Sverremark-Ekström*
**Department of Immunology, Stockholm University, Stockholm, Sweden,*
†*Department of Microbiology, Swedish University of Agricultural sciences, Uppsala, Sweden,* ‡*Department of Mathematics, Stockholm University, Stockholm, Sweden*

Purpose/Objective: Dysbiosis early in life has been associated with immune mediated disease, such as allergy and inflammatory bowel disease. Previously we have shown differences in the early gut microbiota between children who developed allergic disease at five years of age and children that remained non-allergic. The mechanisms how the microbiota interacts with and influences the immune maturation after birth remain unclear. Here we aimed to investigate how different species of bacteria influence the response of the intestinal epithelial cells (IEC) and the immune cells.
Materials and methods: We exposed intestinal epithelial cell (IEC) lines (HT29 and SW480) to culture supernatants from seven *Lactobacillus (L.)* strains and three *Staphylococcus (S.) aureus* strains. Further peripheral blood mononuclear cells (PBMC) from healthy donors were stimulated with bacteria conditioned IEC supernatants. The level of cytokines and chemokines in the IEC and PBMC supernatants were analyzed qualitatively and quantitatively using human proteomic array and ELISA.
Results: The IEC lines produced a very limited set of cytokines and chemokines following bacterial exposure. Only *S. aureus* 161.2 induced an inflammatory response by the IEC characterized by the production of CXCL-1 and CXCL-8/IL-8. In PBMC, most of the tested *Lactobacillus* and *Staphylococcus* strains were able to induce IL-6 production, but only *S. aureus* 161.2 induced IFN-γ and IL-17. The simultaneous presence of epithelial factors did not significantly alter the response. Notably, the *S. aureus* induced IFN-γ and IL-17 production by PBMC, but not CXCL-8/IL-8 production by IEC, was down regulated by the simultaneous presence of any of the different *Lactobacillus* strains.
Conclusions: *S. aureus* 161.2 induced a strong inflammatory response in both PBMC and IEC, but there was a limited influence of IEC secreted factors on the PBMC response. Interestingly, Lactobacilli attenuated the *S. aureus* induced inflammatory response by immune cells, but not that of IECs, indicating a specific regulatory role on immune cells, although the mechanisms need to be further investigated.

P0391

The role of ceramide kinase in regulating LPS and TNF-alfa induced inflammation in A 549 cells

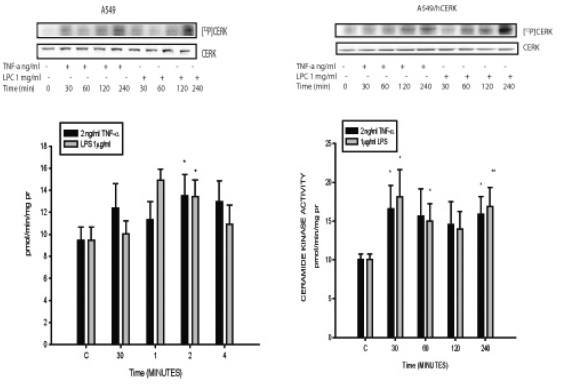
V. Hinkovska-Galcheva,* A. J. Morris,† S. Van Way‡ & J. A. Shayman§

**Internal medicine, University of Michigan, Ann Arbor, MI, USA, †Internal medicine-Cardiology Molecullar and Cellular Biochemistry, University of Kentucky, Lexington, KY, USA, ‡Department of Pediatrics, University of Michigan, Ann Arbor, MI, USA, §Department of Internal Medicine-Nephrology, University of Michigan, Ann Arbor, MI, USA*

Purpose/Objective: Purpose: Activation of Toll-like receptors (TLRs) by specific pathogens leads to the production of proinflammatory mediators to initiate an inflammatory process. This is followed by a counter-regulatory, anti-inflammatory response to prevent excessive damage to the host. Tumor necrosis factor (TNF-α), one of the first cytokines to be released after activation of TLRs, is a key pro-inflammatory cytokine, and was reported that is down regulated by ceramide and its metabolite ceramide-1-phosphate (C1P)*(Rozenova K, et al., JBC, 2010; Lamour N, et al., JBC, 2011; Jozefowski et al, J Immun., 2010)*. Additionally, it has been reported that activation of TLR4 signaling by lipopolysaccharide (LPS) is dependent upon production of ceramide by acid sphingomyelinase (*Cuschieri et al., Surg Infect, 2007*). We reported recently ceramide-dependent PP2A regulation of TNF-α - induced IL-8 production in respiratory epithelial cells (Cornell T, et al., A. J. of Physiology, 2009). Objective: We are studying the regulation of inflammatory response through the action of phosphatases such as PP2A. Specifically, we hypothesized that in respiratory epithelial cells, LPS and TNF-α-induced inflammation is dependent upon activated ceramide kinase (CERK) and the resulting production of ceramide-1-phosphate (C1P).

Materials and methods: Methods: We used A549 cells stably transfected with hCERK. Additionally, cells were transfected either with siRNA duplex oligonucleotides targeting, CERK, PP2A or PP1 or with non-targeting siRNA duplex oligonucleotides (control) using Lipofectamine (Invitrogen).

Results: Results: Both LPS and TNF-α stimulation of A549 and A549/hCERK transfected cells increased CERK activity and also increased CERK phosphorylation. Mass spectrometry analysis revealed a significant increase of C1P. CERK activation impacted PP2A expression and activity, and led to changes in the regulation of Il-8 and TNF-α production. We also observed co-localization of CERK and PP2A by co-immunoprecipitation and by confocal microscopy using GFP-PP2A and RFP-CERK over-expression constructs.



The time-dependent formation of ceramide-1-phosphate (C1P) in activated A549 and A549/hCERK transfected cells. Cells were labeled with[^{32}P]H_3PO4 for 4 hours and then activated with 2nmol/ml TNF-α and 1mg/ml LPS. This increase CERK phosphorylation which correlated in parallel experiments with increases in intracellular C1P levels as measured by ^{32}P-labeling. Cells lysates were immunoprecipitaded with anti-hCERK antibody and examined by immunoblot using rabbit anti-phosphoserine antibody.

Conclusions: Conclusions: CERK appears to be a key enzyme involved in regulating inflammation by increasing C1P and influencing the activity of the regulatory phosphatase, PP2A. These studies were funded by AHA 0930039N.

Poster session: Ageing

Aged T cell subsets are characterized by a distinct microRNA signature

N. Teteloshvili,* A. van den Berg,* R. J. van der Lei,* P. G. Jellema,* N. van der Geest,† L. Brouwer,† A. M. H. Boots† & B. J. Kroesen*
*Department of Pathology and Medical Biology, University Medical Center Groningen, Groningen, The Netherlands, †Department of Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen, The Netherlands

Purpose/Objective: Decline of immunological responsiveness in elderly is at least in part attributed to changes in the composition of the T cell compartment. Recently, microRNAs (miRNA) have emerged as novel players in the regulation of T cell function. Little is known, however, on the expression of specific miRNAs and their role in altered T cell function with age. Aim of the study was to investigate the age associated changes in miRNA expression within defined T cell subsets in young and old healthy individuals.
Materials and methods: T cell subsets (naïve, memory, CD4 and CD8 cells) derived from young and elderly healthy subjects were sorted based on CD3, CD4 and CD45RO expression. RNA was isolated and miRNA expression patterns were determined for pooled T cell subsets ($n = 5$) using the agilent human miRNA microarray platform (V2) based on Sanger miRbase (release 10.1). Results were validated by qRT-PCR. A computational analysis was performed to identify miRNA putative targets and related molecular pathways.
Results: Hierarchical clustering showed differential expression of miRNAs mainly between naïve and memory subsets. Age related differential expression was observed predominantly within the naïve CD45RO$^-$ T-cell population. Seventeen miRNAs showed at least twofold up- or downregulation in aged naïve T cells. Analysis of individual samples revealed a statistically significant age related upregulation for miR-21, miR-223 and miR-451 by qRT-PCR. Computational analysis revealed putative miRNA targets associated with cell proliferation, apoptosis and insulin signaling pathways.
Conclusions: Age-related changes in miRNA expression are found predominantly within the CD45RO$^-$T cell compartment. It remains to be established if the differentially expressed miRNAs identified within the CD45RO$^-$ T cell subset in this study, converge with the accumulation of end-differentiated CD45RO$^-$ effector T cells re-expressing CD45RA.

P0396
Ageing alters the frequency and function of CD161$^+$ CD8+ T cells

K. S. M. van der Geest,* W. H. Abdulahad,* P. L. Chalan,* M. G. Huitema,* B. J. Kroesen,† E. Brouwer* & A. M. H. Boots*
*Rheumatology and Clinical Immunology, University Medical Center Groningen (UMCG), Groningen, The Netherlands, †Medical Biology, University Medical Center Groningen (UMCG), Groningen, The Netherlands

Purpose/Objective: Age-associated changes of immune function may affect recognition of pathogens, autoantigens and cancer cells. Ageing is associated with accumulation of T cells which express NK markers. Recently, circulating CD8+ T cells expressing the NK marker CD161 have been identified as potent producers of pro-inflammatory cytokines (IFN-gamma, IL-17) in young individuals. So far, little is known about the influence of ageing on CD161$^+$ CD8+ T cells. Therefore, we determined whether ageing alters the frequency and function of circulating CD161$^+$ CD8+ T cells.
Materials and methods: We assessed the relative and absolute number of CD161^{high} and CD161^{int} CD8+ T cells in peripheral blood from 62 healthy donors with increasing age (20−91 years). We analyzed intracellular expression of IFN-gamma and IL-17 by CD161^{high} and CD161^{int} CD8+ T cells from young (20−40 years) and old donors (>60 years) after stimulation with PMA/calcium ionophore + BFA. In the same donors, we also assessed intracellular expression of perforin and granzyme B in unstimulated CD161^{high} and CD161^{int} CD8+ T cells.
Results: In general, absolute numbers of CD8+ T cells decreased with age. Both the proportion and absolute number of circulating CD161^{high} CD8+ T cells decreased with age. Whereas the proportion of CD161^{int} cells increased with age, the absolute number of these cells remained stable. In contrast to CD161$^-$ CD8+ T cells, nearly all CD161^{high} and CD161^{int} cells produced IFN-gamma, regardless of age. CD161^{high} cells produced IL-17 and expressed the transcription factor RORgt. Interestingly, this potency to produce IL-17 was decreased in old donors. In general, CD161^{int} cells hardly produced IL-17. Both CD161^{high} and CD161^{int} cells expressed perforin. Although the majority of CD161^{int} cells produced granzyme B in young and old donors, granzyme B expressing CD161^{high} cells could be only detected in old donors.
Conclusions: We show that the frequency and function of CD161$^+$ CD8+ T cells is altered in non-pathological ageing. Firstly, CD161^{high}CD8+ T cells clearly decrease with age. Secondly, CD161^{high}CD8+ T cells produce less IL-17 in old individuals and become better equiped with cytotoxic effector molecules. How this affects the response to novel pathogens, autoantigens and cancer cells remains to be established.

P0397
Ageing shifts the Treg-Th17 balance

K. S. M. van der Geest,* W. H. Abdulahad,* M. G. Huitema,* B. J. Kroesen,† E. Brouwer* & A. M. H. Boots*
*Rheumatology and Clinical Immunology, University Medical Center Groningen (UMCG), Groningen, The Netherlands, †Medical Biology, University Medical Center Groningen (UMCG), Groningen, The Netherlands

Purpose/Objective: Ageing may affect various lymphocyte subsets, including regulatory T cells (Tregs) and T helper 17 (Th17) cells. Conflicting results on Treg numbers in young and old donors have been reported.Furthermore, whereas various studies in young donors have shown a remarkable plasticity between Tregs and Th17 cells, little is known about the Treg-Th17 balance in healthy elderly people. Therefore, the aim of our study was to determine whether ageing shifts the Treg-Th17 balance.
Materials and methods: We assessed the number of naïve (CD25^{int}CD45RA+) and memory (CD25^{high}CD45RA-) Tregs in donors with increasing age. Furthermore, we assessed the propensity for production of IL-17 by memory Tregs and the total CD4+ memory population in young and old donors.
Results: First, we found that ageing is associated with a decrease of circulating naïve Tregs. This loss of naïve Tregs in the elderly could be entirely attributed to the loss of CD31+ recent thymic emigrant Tregs. Unlike naïve Tregs, the number of circulating memory Tregs increased with age. Next, we found that a small fraction of memory Tregs was able to produce IL-17, but this was lower in the elderly compared to young donors. In fact, the total CD4+ memory population from older donors produced less IL-17 compared to young donors, and an increased memory Treg/Th17 ratio was observed in the elderly.
Conclusions: In conclusion, the number of circulating naïve Tregs gradually decreases with age, as less recent thymic emigrant Tregs are present in the elderly. In contrast, the combined observation of increased numbers of memory Tregs and decreased numbers of Th17 cells tilts the balance towards Tregs in healthy elderly people. This finding would be in line with previous studies indicating that anti-

inflammatory immune responses are essential to preserve health in old age by neutralizing the pro-inflammatory state that tends to develop later in life (inflamm-ageing).

Altered regulation of Lck in T cells with aging

T. Fulop, H. Garneau, A. Le Page, C. Fortin, A. Larbi, G. Dupuis, N. Allard & K. Tsvetkova
Université de Sherbrooke, Medicine, Sherbrooke, QC, Canada

Purpose/Objective: Our aim was to study whther the tyrosine phosphatase SHP-1, a key regulator of T cell signal transduction machinery is, at least in part, responsible for the impaired T cell activation in aging.
Materials and methods: T cells separated from young and elderly subjects. T cell stimulated via TCR. Use of WB, confocal microscopy, FACScan, biochemical enzyme assays and thymidine incorporation assay.
Results: We showed that a dysregulation of the Csk/PAG loop in activated T cells from elderly individuals favored the inactive form of phosphorylated Lck (Tyr505). Dynamic movements of these regulatory proteins in lipid raft microdomains was also altered in T cells of aged individuals. We showed that SHP-1 activity was upregulated in T cells of aged donors compared to young subjects. Pharmacological inhibition of SHP-1 resulted in recovery of TCR/CD28-dependent lymphocyte proliferation and IL-2 production of aged individuals to levels not significantly different than those of young donors. Furthermore, we report differences in the active (Y394) and inactive (Y505) phosphorylated forms of Lck in response to T cell activation in elderly donors.
Conclusions: Our data suggest that the regulatory role of SHP-1 in T cell activation extends to its involvement in Lck-dependent negative feedback in aging. Modulation of SHP-1 activity could restore altered T cell functions in aging, suggesting a powerful tool for improvement of immunosenescence.

CMV-specific T cells with highly effector capacity are associated with 2-years all-cause mortality in healthy elderly individuals

S. Ferrando-Martinez,* E. Ruiz-Mateos,† R. S. de Pablo-Bernal,† J. Delgado,‡ R. Solana,§ M. A. Muñoz-Fernandez* & M. Leal†
**Gregorio Marañon University Hospital, Laboratory of Molecular Immuno-Biology, Madrid, Spain, †Biomedicine Institute of Sevilla, Laboratory of Immunovirology, Sevilla, Spain, ‡Hospital San Juan de Dios del Aljarafe, Internal Medicine, Sevilla, Spain, §Department of Immunology IMIBIC, Reina Sofia University Hospital, Cordoba, Spain*

Purpose/Objective: To analyze CMV-specific T cell response in healthy elderly and its relatioship with human mortality.
Materials and methods: Sixty-seven subjects of the CARRERITAS cohort were selected according with the following inclusion criteria: (1) older than 50 years old, (2) without hospitalization during the last years, (3) without active infections, (4) without comorbidities or pharmacological treatment affecting the immune sistem and (5) positive IgG serology for cytomegalovirus (CMV) infection. T cell CMV-specific response was analyzed by multiparametric flow cytometry (IFNg, TNFa, IL2, MIP1a, CD107a and PRF1 production in response to the pp65 peptide pool).
Results: CMV-specific T cell response polyfunctionality was decreased in non-survivors. In addition, this subjects showed increased percentages of highly effector T cells expressing CD107a and perforine (CD107a+PRF1+) without IFNg coexpression. The CD107a+PRF1a+ subset was increased in both, CD4 and CD8 T cells and was correlated with higher percentages of CD57-expressing T cells. A multivariate analysis showed that percentages of CD8 T cells expressing CD107a+PRF1+ (but not CD4 T cells nor the age) were independently associated with time to death.
Conclusions: Aberrant accumulation of the CMV-specific CD8+PRF1a$^+$ CD107a+ T cell response is associated with lower human survival. This population could be a a predictive marker of a immune collapse.

**Department of Stomatology Area Pathology, Bauru School of Dentistry University of São Paulo, Bauru, Brazil, †Department of Prosthodontics, Bauru School of Dentistry University of São Paulo, Bauru, Brazil*

Purpose/Objective: This study aimed to evaluate the cytokine production by monocytes, challenged *in vitro* with *C. albicans*, obtained from peripheral blood of elderly denture wearers with denture stomatitis (DS), compared with elderly denture wearers without DS and elderly and young non-denture wearers.
Materials and methods: The isolated monocytes were cultivated in 24-well flat-bottomed culture plates, in the absence or presence of lipopolysaccharide (LPS) or heat-killed *C. albicans* ATCC 90028. After 18 h, the supernatant was collected and submitted to the enzyme-linked immunosorbent assay (ELISA) for determination of the pro-inflammatory cytokines tumor necrosis factor-alpha (TNF-α), interleukin-6 (IL-6), CXCL8, IL-1β, monocyte chemotactic protein-1 (MCP-1) and anti-inflammatory cytokines IL-10 and transforming growth factor-β (TGF-β).
Results: The results demonstrated, in general, changes in monocytes from the elderly with DS, as compared to other groups: lower spontaneous production of CXCL8 and MCP-1; lower levels of TNF-α, IL-6, IL-1β, CXCL8, MCP-1 and IL-10 after stimulation with LPS; and reduced production of TNF-α and IL-6 after stimulation with *C. albicans*. Comparing young and old, regardless of the presence of DS, the results revealed changes in the monocytes of the elderly: a lower production of TGF-β, spontaneous and after stimulation with *C. albicans*.
Conclusions: In conclusion, the dysfunctional *in vitro* production of pro- and anti-inflammatory cytokines by monocytes from elderly patients with DS may represent an additional aspect associated with susceptibility to the development and to the persistence of DS. Still, the dysfunction in monocytes of elderly groups, regarding the *in vitro* production of TGF-β, may represent aspects related to immunosenescence.

P0403
Cytomegalovirus (CMV) dependent and independent changes in the ageing of the human immune system: a transcriptomic analysis

S. Marttila,* T. Kuparinen,* J. Jylhävä,* L. Tserel,† P. Peterson,† A. Hervonen,‡ M. Jylhä‡ & M. Hurme*
**Department of Microbiology and Immunology, The School of Medicine, University of Tampere, Tampere, Finland, †Institute of General and Molecular Pathology, University of Tartu, Tartu, Estonia, ‡The School of Health Sciences, University of Tampere, Tampere, Finland*

Purpose/Objective: Ageing is associated with profound decline of the immune capacity, which is manifested as increased morbidity and mortality. It has been proposed that chronic antigen stress, mainly from persistent CMV infection, may have a causative role in immunosenescence. The persistent CMV infection has for example been associated with accumulation of exhausted, non-proliferative CD8+ cells that lack the expression of costimulatory receptors CD27 and

CD28, a hallmark of decreased immune competence. However, the number of individuals affected by CMV increases with increasing age, so that the great majority of the elderly are affected by CMV. Thus it can be difficult to establish which ageing-associated changes are due to increased CMV prevalence and which are only due to increased chronological age. We now wanted to identify genes and pathways that are affected with ageing independently of CMV infection.

Materials and methods: We performed a transcriptomic analysis of peripheral blood mononuclear cells (PBMCs) with Illumina Human HT12 v4 BeadChip in a cohort of CMV seropositive (CMV+, $n = 140$) and seronegative (CMV-, $n = 6$) nonagenarians using CMV seronegative young individuals ($n = 11$, 19–30 years of age) as controls. Data was analysed with Chipster (CSC) and the affected pathways were identified with IPA software (Ingenuity Systems).

Results: Our results show that the gene expression profiles of $CMV^-$and CMV+ nonagenarians are different from each other. When comparing to the CMV^-controls we found 667 and 559 genes to be differentially expressed in CMV^- and CMV+ nonagenarians, respectively; 333 of these were common to both groups. Similarly, there were differences in canonical pathways affected; 45 and 16 pathways were affected in CMV^- and CMV+ nonagenarians, respectively, and 10 of the pathways were common. Interestingly, NK-cell and TCR-signalling pathways were affected only in the CMV^- nonagenarians. The up regulation of pro-inflammatory genes and pathways was however common to both groups.

Conclusions: Our data indicate that the CMV dependent and independent changes in the ageing of the immune system are fundamentally different. The results imply that inflamm-aging is independent from CMV infection, but that the cell-mediated immune functions, mediated by T cells and NK cells, are different depending on the CMV serostatus.

P0404

Effects of prolonged intense exercise on the adaptive immune response in elderly and young athletes

M. A. Moro-García,* R. Alonso-Arias,* B. Fernández-García† & C. López-Larrea*

**Hospital Universitario Central de Asturias, Immunology, Oviedo, Spain, †Department of Morphology and Cell Biology, Universidad de Oviedo, Oviedo, Spain*

Purpose/Objective: Exercise induces a series of changes on the immune system depending on their intensity and duration. In fact, transient states of immunosuppression are induced after intense physical activity and yet beneficial exercise anti-inflammatory effects have been described over many diseases and longevity.

Materials and methods: To study the impact of intense exercise for long periods of life on adaptive immunity at different ages we compared phenotypical and functional features of T lymphocytes of young ($n = 27$) and elderly athletes ($n = 15$) with young ($n = 30$) and elderly non-athletes ($n = 30$). We characterized leukocyte and lymphocyte subpopulations by flow cytometry and measured the T cell proliferation and activation response (CD69) against anti-CD3. We also studied the percentage of recent thymic emigrants (RTEs) by quantification of TREC by real-time PCR. Specific antibody titers against CMV were determined by ELISA.

Results: Leucopenia was found in both groups of athletes, mainly explained by low levels of neutrophils and lymphocytes. Exercise induced higher frequencies of NK, B lymphocytes and CD8+ T cells, whereas CD4+ T lymphocytes showed significant lower levels in the elderly athletes. Moreover, young athletes showed significant differences in all parameters that define the immune risk profile (IRP), with characteristics of an aging immune system, but we did not find differences between elderly groups. Less differentiated subsets of T lymphocytes were more frequents in non-athletes, with the exception of CD8+ T lymphocytes in young individuals. The analysis of TREC content in the elderly groups showed no significant difference in either the CD4+ or CD8+ T lymphocytes. In the young non-athletes group we observe an increase in the content of TREC in CD8+ T cells, but not in CD4+ T cells. Moreover, functional response of CD4+ and CD8+ T lymphocytes was significantly impaired only in young but no in elderly athletes.

Conclusions: Intensive training for long periods throughout life induces important phenotypical and functional changes on the adaptive immune response. These changes are most striking in young individuals and they damped with physiologic immune aging.

P0405

Intensity of the humoral response to CMV throughout the life configure phenotypical and functional status of the immune system in elderly

R. Alonso-Arias, M. A. Moro-García, A. Echeverría-de Carlos & C. López-Larrea

Hospital Universitario Central de Asturias, Immunology, Oviedo, Spain

Purpose/Objective: CMV infection exerts an enormous impact on human immunity being associated with an immune impaired response and also with a variety of chronic diseases and the overall survival in elderly individuals. History of CMV infection, and not only infection *per se*, may be determining the changes induced on the immune response.

Materials and methods: To study the impact of titers of anti-CMV antibodies on immune system we compared phenotypical and functional features of T lymphocytes of 92 healthy elderly donors and 70 young healthy controls. We characterized lymphocyte subpopulations by flow cytometry and measured the T cell proliferation and activation response (CD69) against CMV. We also studied the percentage of recent thymic emigrants (RTEs) by quantification of TREC by real-time PCR. Specific antibody titers against CMV were determined by ELISA.

Results: Titers of anti-CMV antibodies was used as a measure of accumulated antibodies throughout the life, and in fact titers were significantly higher in elderly and correlated positively with the specific CD4+ T cells responses to CMV. In elderly, the antibody titers were associated with the differentiation degree and the TREC content in CD4+ T cells, were correlated to other parameters belonged to the IRP and emerged as a conditioning factor over the ability to respond to immunization *in vivo*. Lack of correlations in young subjects may be due to lower anti-CMV antibody titers that they show. However, at similar levels of antibodies differences in highly differentiated and naïve T cells between young and elders were accentuated as titers increase. The reduction in absolute counts of naïve CD4+ T cells, also observed in individuals with higher titers, may be acting as a strategy to compensate the expansion of differentiated cells and to avoid the increase of total T cells.

Conclusions: In summary, our data show that titers of anti-CMV antibodies and not only CMV-seropositivity influence the differentiated status and the immunocompetence in the elderly, emerging as an important target in the improvement of the immune system function in elderly.

Long term injected with D-galactose altered the immune responses in C57BL/6J mice

J. Liau* & M. L. Chen†
*Chang Jung Christian University, Graduate Institute of Medical Sciences, Tainan, Taiwan, †Department of Nutrition and Health Sciences, Chang Jung Christian University, Tainan, Taiwan

Purpose/Objective: Age-related changes of the immune system contribute to the increased susceptibility of elderly persons to infectious diseases. Mice chronically injected with D-galactose (D-gal) have been used as an animal aging model. However, less attention has been paid to the changes of systemic immune responses on D-gal induced aging mice.
Materials and methods: To investigate the changes of cytokines on D-gal injected mice. The C57BL/6J mice of model control (MC), Gal-100, Gal-150 and Gal-500 groups were subcutaneous injected with 0, 100, 150 and 500 mg/kg/day for 8 weeks. The brain and supernatants form immune cell culture were collected for cytokines assay.
Results: Our results indicated that Aβ were significantly increased in Gal-500 group, opposite to the activity of the mice. Furthermore, 150 mg/kg/day D-gal injected mice had higher cytokines production, especially TNF-α level in brain homogenates, but not in Gal-500 group. Moreover, D-gal injection toward decreased the IL-2 secretion, and increased the IL-4 production by splenocytes.
Conclusions: This study demonstrated that mice injected with 150 mg/kg/day D-gal could induce inflammatory cytokines production in brain, but not affect by 500 mg/kg/day injection group. There need more studies to confirm the mechanism of immune responses in D-gal induced aging mice.

Renal replacement therapy enhances CD8 T cell differentiation in young end-stage renal disease patients

R. W. J. Meijers,* N. H. R. Litjens,* L. E. A. de Wit,* A. W. Langerak,† A. van der Spek,† C. C. Baan,* W. Weimar* & M. G. H. Betjes*
*Erasmus Medical Center, Internal Medicine, Rotterdam, The Netherlands, †Erasmus Medical Center, Immunology, Rotterdam, The Netherlands

Purpose/Objective: End-stage renal disease (ESRD) patients have a defective T cell mediated immune system, which is related to excessive premature immunological ageing. The aim of this study is to examine whether this premature ageing is changed by renal replacement therapy (RRT).
Materials and methods: For this purpose, we studied circulating T cells of healthy individuals ($n = 60$), ESRD patients without RRT ($n = 30$, eGFR<15 ml/min), and patients treated with hemodialysis ($n = 30$) or peritoneal dialysis ($n = 30$). Groups were matched for age, sex and CMV serostatus. Three different assays were employed which are indicative for the immunological age of the T cell system. First, the T cell receptor excision circle (TREC) content was measured, which indicates the output of naïve T cells from the thymus. Relative telomere length (RTL) was determined as a measure for proliferative history and immunophenotyping was used to establish the differentiation status of circulating T cells.
Results: ESRD patients were significantly more affected ($P < 0.05$) compared to HC with respect to the parameters determined, i.e. ESRD patients had significant less TRECs ($P < 0.001$), shorter telomeres within both $CD4^+$ as well as $CD8^+$ T cells and were more differentiated towards memory T cells lacking expression of co-stimulatory molecule CD28. The percentage of pro-inflammatory $CD8^+$ CD28null T cells was significantly higher ($P < 0.001$) compared to HC. The $CD8^+$ T cells of younger patients on RRT have a significant ($P < 0.05$) shorter telomeres, a higher population of terminally differentiated $CD8^+$ T cells ($P < 0.01$) and a higher population of memory $CD8^+$ T cells that do not express CD28 ($P < 0.05$) as compared to the age related ESRD patients who did not receive RRT.
Conclusions: Based on the analysis of ageing parameters we conclude that the immunological age of T cells from ESRD patients is increased by on average 20–30 years compared to HC. RRT mainly affects the differentiation and proliferation of the $CD8^+$ T cell compartment in younger ESRD patients.

This study was financially supported by the Dutch Kidney Foundation (KSPB.10.12).

Responsiveness of CD28-negative T cells to alternative costimulatory signals

J. Leitner,* D. Herndler-Brandstetter,† B. Grubeck-Loebenstein,† G. Zlabinger* & P. Steinberger*
*Institute of Immunology, Center for Physiology Pathophysiology and Immunology Medical University of Vienna, Vienna, Austria, †Institute for Biomedical Aging Research Immunology Division, Austrian Academy of Sciences, Innsbruck, Austria

Purpose/Objective: Repeated stimulation of immune cells or persistence of pathogens results in a state called immunosenescene. Loss of CD28, the most potent costimulatory receptor on human T cells, is generally regarded to be a main predictor of biological aging of the immune system. Since CD28 negative T cells cannot receive signals via this potent costimulatory pathway, insufficient activating signals might contribute to the senescence state of these subsets. There are a number of other alternative costimulatory pathways, which can efficiently stimulate human T cells. Therefore we addressed whether alternative

costimulatory signals are able to overcome this senescent phenotype and restore immune function of CD28-negative T cells.
Materials and methods: Using an experimental system termed T cell stimulator cells we activatedCD28-negative CD8 T cells from elderly individuals in the presence of the costimulatory ligands CD166, ICOSL, CD70, 4-1BBL, MIC-A and CD58. Proliferative response and cytotoxic capability was analyzed.
Results: We found CD58 to generate the most potent costimulatory signal in these T cell subset.
Conclusions: The CD2-CD58 axis has an important role for the activation of CD28 deficient T cells.

Safranal ameliorates antioxidant enzymes and suppress lipid peroxidation and nitric oxide formation in aged male rat liver

S. Saeed,* S. K. Farahmand* & T. Farkhondeh†
**Neshabur Faculty of Medical Science, Physiology, Neshabur, Iran, †Physiology department Faculty of Science Mashhad University of Medical Sciences Mashhad Iran., Physiology, Mashhad, Iran*

Purpose/Objective: Free radical production and oxidative stress are known to increase in liver during aging, and may contribute to the oxidative damage. The objective of this study was to observe the changes in activities antioxidant enzymes (superoxide dismutase, glutathione-S-transferase, catalase), lipid peroxidation levels and serum nitric oxide occurring in livers of rats of 2, 10 and 20 months age groups, and to see whether these changes are restored to 2 months control levels rats after administration of safranal.
Materials and methods: The aged rats (10 and 20 months) were given interapertoneal injection of safranal (0.5 mg/kg/day) daily for 1 month. We measured the activities ofantioxidant enzymes (superoxide dismutase, glutathione-S-transferase, catalase), lipid peroxidation levels and serum nitric oxide occurring in livers of rats of 2, 10 and 20 months age groups.
Results: The results obtained in the present work revealed that normal aging was associated with significant decrease in the activities of antioxidant enzymes, and an increase in lipid peroxidation in livers and nitric oxide content in serum of aging rats.
Conclusions: The results of the present study demonstrate that safranal could be a candidate to suppress the development of age-induced damages by protecting against oxidative stress and increasing antioxidant defenses.
Keywords: Safranal; antioxidant; liver; aging; rat

The butanol fraction of OAH19B ameliorates in monosodium iodoacetate-induced osteoarthritis

D. W. Nam,* J. W. Kang,* D. Y. Choi,* J. D. Lee,* D. S. Park,* J. E. Huh,† Y. H. Baek* & B. K. Seo*
**Department of Acupuncture & Moxibustion, Kyung Hee University, Seoul, Korea, †Kyung Hee University, Oriental Medicine Research Center for Bone & Joint Disease East-West Bone & Joint Research Institute, Seoul, Korea*

Purpose/Objective: The aim of the present study is to investigate the potential therapeutic action of the OAH19B, a new herbal agent from butanol fraction of a mixture of *Aralia cordata* Thunb and *Cimicifuga heracleifolia*, on pain and cartilage damage compared with those of celecoxib in a monosodium iodoacetate-induced OA model.
Materials and methods: Experimental osteoarthritis was induced by the intraarticular injection of monoiodoacetate (MIA) into the right knee joints of rats.
Results: Both the oral administration of OAH19B dose-dependently and significantly inhibited cartilage damage in the knee joint and decreased the weight distribution deficit associated with MIA injection. OAH19B also significantly inhibited the degradation of GAG, while celecoxib did not affect cartilage destruction in the cartilage explants culture. OAH19B significantly decreased the levels of IL-1b, MMP-3, iNOS and COX-2 mRNA expression and immunostaining in the knee joints of MIA-injected rats. However, celecoxib decreased only the expressions of IL-1b and COX-2 mRNA and protein in the MIA-induced OA model.
Conclusions: In conclusion, OAH19B has both antinociceptive and cartilage protective effect by inhibitingproinflammatory cytokines and MMP-3 in the MIA-induced OA model. OAH19B, which was also more effective than celecoxib at preventing cartilage destruction, may be useful for the treatment of OA.

Thymectomy in early childhood: immunosenescence in later life?

M. Prelog,* R. Würzner,† R. Geiger‡ & M. Zlamy‡

**Department of Pediatrics, Würzburg, Germany, †Department of Hygiene and Medical Microbiology, Innsbruck, Austria, ‡Department of Pediatrics, Innsbruck, Austria*

Purpose/Objective: The study was aimed to investigate whether thymectomy in early childhood due to cardiac surgery may lead to alterations of peripheral naïve T-cells as found in immunosenescent elderly people.

Materials and methods: Forty-three patients who had thymectomy >15 years ago, 19 healthy, age-matched controls (HC) and nine HC aged >60 years were included. Indicators of T-cell-immunosenescence were studied: proportions of peripheral $CD45RA^+$ $CD27^+$ CCR7+ naïve T-cells, the T-cell-receptor-excision-circles (TRECs) as markers for recent thymic emigrants (RTE, $CD45RA^+$ $CD127^+$ CD31+), Ki67-expression as a marker of peripheral replication, T-cell-receptor (TCR) diversity and IL-7 as a proliferative cytokine for T-cells.

Results: Naive T-cells of TP were significantly decreased compared to HC but still higher than HC > 60 years. In TP, total counts of RTE were almost equal to HC > 60 years. Proportions of intestinal derived $CD127^+$ CD103+ naïve CD8+ T-cells were significantly increased in TP compared to HC and HC > 60 years. TP demonstrated significantly lower TRECs in naïve T-cells which correlated with time post thymectomy and a higher percentage of Ki67-expresssing naïve T-cells. IL-7 levels of TP were similar to HC > 60 years. TP showed less polycloncal TCR distribution than HC.

Conclusions: The findings indicate that changes of the peripheral naïve T-cell subset in TP may resemble the findings of immunosenescent elderly persons after thymic involution. The peripheral naïve T-cell-homeostasis after thymectomy is maintained mainly by extrathymic expansion of pre-existing naïve T-cells to compensate the diminished thymic output. The pathophysiological role of these alterations, such as infectious complications or autoimmunity in later life, has to be determined in long-term follow-up.

Characterization of three new HLA-A alleles

S. I. Lozano-Ramos,* J. Gil,† E. Campos,† C. Ambros,† P. Caro,† S. Mantecon,† L. Mongay,† P. A. Correa,‡ M. J. Herrero,† R. Colobran§ & E. Palou†
*Immunologia-LIRAD, Germans Trias I Pujol Hospital, Badalona, Spain, †Immunologia-LIRAD, Blood Tissue Bank Germans Trias I Pujol Hospital, Badalona, Spain, ‡Immunologia-LIRAD, Blood Tissue Bank – Germans Trias i Pujol Biomedical Research Institute Foundation, Badalona, Spain, §Immunologia-LIRAD, Blood and Tissue Bank – Germans Trias i Pujol Biomedical Research Institute Foundation – Vall D'Hebron University Hospital Research Institute Foundation, Badalona, Spain

Purpose/Objective: During the routine in the HLA laboratory is common to find some patients or donors who don«t exactly match with the databases of HLA. The characterization of new alleles is a very necessary task in the improvement on haematopoietic transplant, solid organ transplantation. In this report we describe the identification of three new HLA-A alleles found in three individuals typed in our lab.
Materials and methods: The new alleles were detected during routine HLA typing by SBT, whose results showed a mismatched position with a known allele in each case. All three HLA-A alleles were cloned and nucleotide sequenced in isolation.
Results: The first new allele is equal to A*68:02:01:01 but with one nucleotide change at position 127 in exon 2 resulting in a coding change at codon 19 (GAG'AAG) with the replacement of a glutamic acid (E) by a lysine (K). In the protein structure this amino acid residue is in a beta sheet in the α1 domain. The nucleotide sequence is available at Genbank, accession number JQ815887, andthe*WHO Nomenclature Committee* assigned the name A*68:92.

The second allele is identical to A*29:02:01:01 except for one nucleotide change in the 188 position in exon 2 resulting in a coding change at codon 39 (GAĈ GGC) with the replacement of an aspartic acid (D) by a glycine (G). This position codifies a residue located in a loop between two beta sheets of the α1 domain which interacts with the peptide and with the TCR. The nucleotide sequence is available at Genbank, accession number JQ815888, and the *WHO Nomenclature Committee* assigned the name A*29:38.

The last one is equal to A*23:01:01:01 with one nucleotide change in position 615 resulting in a silent mutation at codon 181 (CGĈCGT) which codifies an arginine. In this case this allele was found in a LAL patient who was candidate for haematopoietic stem cell transplantation and who shares the mutation with her father. The nucleotide sequence is available at Genbank, accession number JQ815889, and the *WHO Nomenclature Committee* assigned the name A*23:01:09.
Conclusions: We have described three new HLA-A alleles, found in different individuals: two of them carry amino acidic changes in the α1 domain, A*68:92 and A*29:38, while the last one shows a silent change, A*23:01:09.

P0419
IFI16 is an early sensor of Listeria monocytogenes DNA in the cytosol stimulating IFN-beta expression

K. Hansen,* S. B. Jensen,* T. A. Decker,† K. A. Horan* & S. R. Paludan*
*Institute of Biomedicine, Aarhus University, Aarhus, Denmark, †Department of Microbiology Immunology and Genetics, University of Vienna, Vienna, Austria

Purpose/Objective: Infection with *Listeria monocytogenes* (*L. monocytogenes*) induces a potent innate immune response. Induction of the immune response is dependent on bacterial secretion of listeriolysin O (LLO) which mediates the escape of *L. monocytogenes* to the cytosol after entry by phagocytosis. Previous studies have shown *L. monocytogenes* DNA and cyclic dinucleotide monophosphates secreted by bacteria as potent inducers of IFN-b.

IFI16 is a predominantly nuclear protein which distributes to the cytosol upon viral infection and UV irradiation. Recent studies show that IFI16 directly interacts with cytosolic DNA to induce IFNb.
Materials and methods: THP1, a non-adherent monocyte-like cell line differentiated into macrophage-like cells was used for all studies. *L. monocytogenes* homogenates were prepared by sonication of bacterial overnight cultures and treated with RNase or DNase before transfection into cells. Short-hairpin-RNA was used for knock-down of the intracellular DNA sensor IFI16. Co-localisation between bacterial DNA and IFI16 was investigated by confocal microscopy.
Results: In THP-1 cells *L. monocytogenes*-induced a potent IFN-b expression. This induction was dependent on bacterial escape into the cytoplasm. Short-hairpin-RNA knock-down of the intracellular DNA sensor IFI16 strongly reduced *L. monocytogenes*-induced IFN-b expression indicating a role of IFI16 in the sensing of *L. monocytogenes*.

Transfection with *L. monocytogenes* homogenates induced IFN-b expression in differentiated THP1 cells, and this was sensitive to DNase treatment of the homogenates. Furthermore, we observed *L. monocytogenes* DNA present in the cytoplasm during infection and this co-localized with IFI16 and the adaptor molecule STING.
Conclusions: Based on these results we conclude that IFI16 is a sensor of *L. monocytogenes* DNA in macrophages stimulating IFN-b expression.

P0420
MHC Class I-restricted recognition of Immunodominant viral or tumoral epitopes by human CD4 T cells

X. Saulquin, A. Arnold Leger, L. Gautreau, F. Legoux & M. Bonneville
INSERM U892, Centre de Recherche en Cancérologie, Nantes, France

Purpose/Objective: It is generally considered that MHC class I-restricted antigens are recognized by $CD8^+$ T cells whereas MHC-class II-restricted antigens are recognized by CD4 T cells. Several examples of MHC class-I restricted $CD4^+$ T cells have been reported but the functional relevance of MHC I crossreactvity of the CD4 T cell compartment has not been assessed yet. This has been addressed through the systematic analysis of human HLA-A*0201-restricted CD4 T cells directed against various immunodominant viral or tumoral antigens.
Materials and methods: *ex vivo* frequencies of human $CD4^+$ T cells specific for several viral or tumoral A2/peptide complexes were assessed through a pMHC multimer-based enrichment approach in immune or non-immune donors. MHC class I-restricted CD4 T cell lines and clones directed against (liste des *pitopes ELA, PGT, pp65, HCV1 É) were generated and analyzed for specificity, functional avidity and ability to recognize various target cell lines *in vitro*.
Results: $CD4^+$ T cells directed against every pMHC class I complexes tested were detected in all donors. CD4 T cell lines and clones recognized target cell lines *in vitro* in a peptide MHC-class I dependent but CD4 coreceptor-independent manner. While these cells were seldom overrepresented in immune donors, they expressed TCR of very high affinity and showed a different cytokine production profile compared to their CD8 T cells counterparts.
Conclusions: This study shows that MHC I-crossreactive CD4 T cells, though present in all individuals, are scarce and not usually engaged in adaptive immune responses against the corresponding pMHC class I complex. Nevertheless, these cells represent a natural source of high affinity TCR that could be exploited for TCR gene transfer strategies.

P0421

Recruitment and phosphorylation of the subsynaptic pool of LAT at the immune synapse requires the SNARE protein VAMP7

C. Hivroz,* P. Larghi,* D. Williamson,† K. Chemin,* J. M. Carpier,* S. Dogniaux,* K. Gaus† & T. Galli‡

**Inserm U932, Institut Curie, Paris, France, †Cellular Membrane Biology Group, Centre for Vascular Research, Kensington, Australia, ‡Institut Jacques Monod, Mtnem Inserm ERL U950, Paris, France*

Purpose/Objective: The LAT adaptor plays a crucial role in T cell antigen receptor (TCR) induced signalling. Two pools of LAT are present in T cells, one at the plasma membrane and one in intracellular sub synaptic vesicles. Recent results have shown that TCR activation results in the recruitment and phosphorylation of LAT from these sub synaptic vesicles. This raises the question of the mechanisms involved in the recruitment and fusion of these intracellular LAT pools. The purpose of this study was to characterize the mechanisms involved in the docking of the intracellular pool of LAT. We herein investigated the role of the vesicular SNARE protein, VAMP7, in the docking of LAT containing sub synaptic vesicles at the plasma membrane and in TCR signalling.
Materials and methods: The role of VAMP7 in LAT recruitment at the immune synapse was investigated using high resolution imaging techniques, including total internal reflection fluorescence microscopy (TIRFM), and photo-activatable localization microscopy (PALM). This was performed in Jurkat T cells silenced for VAMP7 expression using a lentivirus encoding two different shRNAs specific for VAMP7 and a control shRNA. Signalling in T cells was analyzed by Western blot analysis as well as by purification of signalosomes induced by TCR activation. Some of the results were reproduced in primary $CD4^+$ T cells from VAMP7 KO mice.
Results: Our results show that VAMP7 decorated vesicles are recruited and fuse at the plasma membrane of T lymphocytes upon TCR triggering. Moreover, they show that VAMP7 co-localizes with the intracellular pool of LAT and is required for LAT recruitment and phosphorylation at the immune synapse. Finally, analysis of the TCR induced signalling in T cells invalidated for VAMP7 expression reveals that the LAT containing signalosome induced by TCR triggering, does not form correctly but that yet some signalling occurs, i.e. ZAP70 is phosphorylated as well as SLP76.
Conclusions: Our data show that upon TCR triggering the VAMP7 SNARE protein controls docking and fusion of pre-existing intracellular pools of LAT at the immune synapse and that these events are required to induce the formation of signalling complexes. One implication of our results is that control of recruitment and fusion of endocytic compartments plays a crucial role in TCR signalling. Another implication is that the TCR signalling cascade is not linear but rather involved recruitment at the right place of components of the signalling pathway. These results thus suggest that imbalances in signalling regulation might be due to impaired intracellular trafficking of signalling molecules.

P0422

TCR or BCR CDR3 spectratypes differ between blood and spleen and between old and young patients, and can be used to detect myelodysplastic syndrome

R. Mehr,* Y. M. Pickman* & D. Dunn-Walters†

**The Mina & Everard Goodman Faculty of Life Sciences, Bar Ilan University, Ramat Gan, Israel, †Department of Immunobiology, School of Medicine Guy's Campus, Kings' College London, London, UK*

Purpose/Objective: Complementarity determining region 3 (CDR3) is the most hyper-variable region in B cell receptor (BCR) and T cell receptor (TCR) genes, and the most critical structure in antigen recognition and thereby in determining the fates of developing and responding lymphocytes. There are several millions of different CDR3 sequences of the TCR Vβ chain in human blood and about the same number of B cell clones. CDR3 length distributions (also called spectratypes) show variations between individuals and over time. However, the complexity of CDR3 length distribution patterns and the large amount of information included in each sample (e.g. 32 length distributions of the TCRα chain, and 24 length distributions of TCRβ) calls for the use of machine learning tools for full exploration.
Materials and methods: We have used supervised machine learning methods to analyze CDR3 length distributions from a variety of sources.
Results: We have found that the splenic B cell CDR3 length distributions are characterized by low standard deviations and few local maxima, compared to peripheral blood distributions. In addition, we show that healthy elderly people's B cell CDR3 length distributions can be distinguished from those of the young. Finally, we show that a machine learning model based on TCR CDR3 distribution features, mainly on TCRVβ22, can detect the myelodysplastic syndrome (MDS) with approximately 93% accuracy.
Conclusions: In summary, supervised learning models, based on a selection of distribution based features, may facilitate the use of CDR3 spectratyping as a monitoring tool for the health of the immune system.

P0423

The influenza nucleoprotein-specific memory B-cell pool is composed of multiple clonotypes with little clonal hypermutation

S. Reiche, Y. Dwai & C. Jassoy

Institute for Virology, University of Leipzig, Leipzig, Germany

Purpose/Objective: Immunization against influenza virus induces a pauciclonal expansion of antigen-specific B-cells. The resulting clonal plasma cell pools contain a highly diverse spectrum of somatically mutated cells. To examine how the antigen-specific B-cell diversity is maintained, we examined the repertoire of influenza nucleoprotein (NP)-specific memory B-cells 2 weeks after vaccination.
Materials and methods: Influenza NP-specific memory B-cells were isolated in a multi-step process from peripheral blood using protein-coated magnetic beads. The purity of the NP-specific B-cells was determined by ELISpot. Immunoglobulin G variable regions were amplified from single B-cells by RT-PCR, sequenced, cloned and expressed as recombinant monoclonal antibodies. Antigen specificity was determined by ELISA.
Results: Influenza NP-specific B-cell preparations were highly pure. More than 60 different clonotypes belonging to IGHV subgroups 1, 3, 4, 5, and 7 were identified in three subjects. The clonotype repertoire varied significantly between the subjects. Somatically mutated variants were detected for a minority of the clonotypes. Several memory B-cells had low numbers of somatic mutations.
Conclusions: Large numbers of different clonotypes and few somatically mutated variants indicate that the memory B-cell repertoire is primarily composed of different clonotypes rather than somatically mutated variants. Additionally, despite probable multiple exposures to influenza virus the vaccination induced several new influenza nucleoprotein-specific memory B-cell clonotypes in all donors.

Titer and avidity of IgG antibodies against Toxoplasma gondii and conventional PCR in patients with ocular diseases

L. C. de Mattos,* A. I. C. Ferreira,* C. C. Brandão de Mattos,* F. B. Frederico,† G. C. Almeida Jr,† C. S. Meira‡ & V. L. Pereira-Chioccola‡

**Molecular Biology, Faculdade de Medicina de Sao Jose do Rio Preto, Sao Jose do Rio Preto, Brazil, †Hospital de Base — FUNFARME, Ophthalmology Outpatient Clinic, Sao Jose do Rio Preto, Brazil, ‡Parasitology, Insituto Adolfo Lutz, Sao Jose do Rio Preto, Brazil*

Purpose/Objective: To evaluate titers and avidity of IgG antibodies against *Toxoplasma gondii* and the presence of genomic DNA of *T. gondii* in peripheral blood of patients with toxoplasmic retinochoroiditis versus other ocular diseases.

Materials and methods: The sera of ocular disease patients were analyzed by indirect immunofluorescence, enzyme immunoassay and avidity tests and genomic DNA was investigated by conventional PCR. Statistical analysis used Fisher's exact test and the unpaired t test.

Results: Of the total sample, 65.7% (163/248) of patients were positive by ELISA and 34.3% (85/248) were non-reactive for IgG antibodies against *Toxoplasma gondii*. According to indirect immunofluorescence, titers of anti-*T. gondii* antibodies higher than 4000 were more common in patients with toxoplasmic retinochoroiditis compared to patients with other ocular diseases (8.1% versus 1.0%). No patients had IgM antibodies. Avidity of more than 60 prevailed in both groups. PCR identified genomic DNA more commonly in patients with toxoplasmic retinochoroiditis (21/62 — 33.9%) than in those with other ocular diseases (1/101 — 0.9%).

Conclusions: Toxoplasmic retinochoroiditis is common in patients with ocular diseases. Most patients with toxoplasmic retinochoroiditis have lower titers of highly avid IgG antibodies against *T. gondii*. PCR results suggest that *T. gondii* is found circulating in blood regardless of the presence of ocular lesions related to toxoplasmosis.

Poster Session: B Cells & Plasma Cells

P0425
A crucial function of the ligand-binding domain of Siglec-G, an inhibitory receptor of B1 cells

S. Hutzler, L. Özgör & L. Nitschke
Department of Biology, University of Erlangen-Nuremberg, Erlangen, Germany

Purpose/Objective: Siglec-G is a transmembrane protein of the Siglec family, which inhibits BCR signalling specifically on B1 cells. With it first extracellular Ig-like domain Siglec-G binds a2,3- and a2,6-linked sialic acids. These ligand interactions can take place to glycoproteins either on the same cell surface (in cis) or to ligands on other cell surfaces (in trans). We wanted to analyse whether the ligand-binding domain is important for the biological function of Siglec-G.
Materials and methods: We generated a Siglec-G R120E knockin mouse with a mutation in the critical amino acid involved in ligand-binding. We also developed a monoclonal anti-Siglec-G antibody, which did not exist so far, to study the Siglec-G expression pattern.
Results: Siglec-G R120E mice showed a large increase of the B1 cell population in the peritoneal cavity and in the spleen. B1 cells of these mice showed a better survival *in vitro* and expressed a changed BCR repertoire. Furthermore, Siglec-G R120E mice showed increased levels of serum IgM and increased $Ca2^{+}$ responses of their B1 cells. These phenotypes strongly resemble the phenotypes of Siglec-G-deficient mice. With our new anti-Siglec-G antibody we detected a quite uniform expression pattern on B cell subsets, therefore the B1-cell specific functions of Siglec-G cannot be attributed to a higher expression pattern on the surface of B1 cells, when compared to conventional B2 cells.
Conclusions: These experiments demonstrate an essential role for the ligand-binding of Siglec-G. We presume that the binding to sialic acid containing cis-ligands on the B1-cell surface regulates its inhibitory signalling function.

P0426
A role for IgG1 in immunity to Salmonella infection

Y. Zhang,* S. Essex,* N. Cumley,† J. Heath,* C. MacLennan,* S. Kracker,‡ R. May,† C. Buckley,* A. Cunningham* & K. M. Toellner*
**MRC Centre for Immune Regulation College of Medical and Dental Science, The University of Birmingham, Birmingham, UK, †College of Bioscience, The University of Birmingham, Birmingham, UK, ‡Deutsches Rheuma-Forschungszentrum (DRFZ), Berlin, Germany*

Purpose/Objective: The immune response to *Salmonella* infection initially is characterized by Th1 type cellular immunity, while germinal center and high affinity antibody development is delayed. Long-term protection from infection is mediated by humoral immunity. In mice the dominant Salmonella-specific antibody isotype is IgG2a, whereas IgG1 is only a minor component of the primary response. IgG2a dominance suggests that this isotype is most adapted to control challenge with *Salmonella*. Here, we have assessed whether IgG1 plays a significant role in immunity to *Salmonella typhimurium* (Stm) challenge.
Materials and methods: IgG1-deficient or wild-type mice were vaccinated with *Salmonella* outer membrane proteins. Five weeks later, mice were infected with high dose of Salmonella (SL3261). Complement dependent bacterial killing assay and phagocytosis assay were used to further detect the role of IgG1 for Salmonella infection.
Results: While wild type mice are protected at this stage, IgG1-deficient mice had much higher bacterial burdens in livers and spleens. Protection from *Salmonella* infection inversely correlated with the concentration of *Salmonella*-specific IgG1. This was not due to deficiencies in high affinity antibody production: Total antigen-specific IgG levels were similar to wild type mice, due to compensatory production of IgG2a and IgG3. Experiments with haptenated protein show that absence of high-affinity IgG1 is compensated by maturation of high-affinity antibody of other IgG subclasses. T cell memory and polarization of T cells in the early secondary response is also not affected, nor is the capacity to promote complement-dependent lysis. *In vivo* and *in vitro* experiments show that protection by opsonisation of *Salmonella* with immune serum and antibody mediated*Salmonella* uptake by macrophages is severely reduced.
Conclusions: IgG1 leads to compensatory Ig class switching to other affinity matured IgG classes, but these do not efficiently protect from Salmonella reinfection. IgG1 is mediating efficient opsonization and macrophage uptake, while no effect is seen from IgG1 deficiency on complement dependent lysis or on T cell responses.

P0427
A spontaneous mutation with low B cell phenotype discovered during the analysis of the function of Themis2 in B cells

H. Hartweger,* M. Peirce,† V. Peperzak,‡ D. Tarlinton‡ & V. Tybulewicz*
**Immune Cell Biology, MRC National Institute for Medical Research, London, UK, †Kennedy Institute of Rheumatology, University of Oxford, London, UK, ‡Immunology Division, The Walter and Eliza Hall Institute of Medical Research, Parkville, Vic., Australia*

Purpose/Objective: Thymocyte-expressed molecule involved in selection (Themis) is expressed in T lymphocytes and has recently been reported to have a role in thymocyte positive selection. Themis2, sharing similar domains and high sequence similarity with Themis, is expressed in B lymphocytes, macrophages and dendritic cells. We hypothesized that Themis2 might have an analogous role in B cell development or activation to Themis in T cells and therefore created a Themis2-deficient mouse strain. During the generation of this strain we serendipitously found a spontaneous mutation leading to the loss of most mature B cells.
Materials and methods: We derived mice from a Themis2-targeted KOMP-CSD embryonic stem cell clone. These mice have been bred to recombinase bearing deleter-strains to obtain Themis2-deficient animals, which were analysed for Themis2 expression as well as defects in B cell development or activation.
Results: We show that Themis2 is expressed in all populations of B cells analysed, with lowest levels in germinal centre B cells and recently activated B cells. Redundant expression of other Themis family members was not found in any B cell population, either in wildtype or Themis2-deficient mice.

Analysis of Themis2-deficient mice has confirmed complete ablation of Themis2. Preliminary results indicate no defects in B cell development or activation or after immunisation with T-dependent antigens.

During the analysis of these mice however, we observed a defect in early B cell development in the bone marrow, which did not correlate with the Themis2 genotype. Further breeding experiments indicate that this defect is segregating freely from Themis2 with an X-linked recessive, Mendelian inheritance pattern. Sanger-sequencing of cDNA from these mice of the coding sequence of Bruton's tyrosine kinase, the most likely candidate for the spontaneous mutation, did not reveal any mutations.
Conclusions: The ubiquitous expression of Themis2 in the B cell compartment and its transcriptional regulation after activation suggests a yet unknown role for Themis2 in B cell biology. Currently, we plan to further analyse these mice for defects in immune responses or B cell activation in response to various, other stimuli. We will use exome sequencing in order to pinpoint the spontaneous mutation, which we have termed *atropos*.

P0428

Accumulation of circulating autoreactive naïve B cells reveal defects of early B cell tolerance checkpoints in patients with Sjögren's syndrome

E. Corsiero,* N. Sutcliffe,* H. Wardemann,† C. Pitzalis* & M. Bombardieri*
*EMR, William Harvey Research Institute, London, UK, †Molecular Immunology Group, Max Planck Institute for Infection Biology, Berlin, Germany

Purpose/Objective: Sjögren's syndrome (SS) is an autoimmune disease characterized by high affinity circulating autoantibodies and characteristic B cell disturbances with a predominance of naïve and a reduction of memory B cells in the periphery. It is unknown at what stages of B cell differentiation tolerance checkpoints are defective in SS. Here we aimed to determine the frequency of self-reactive and polyreactive B cells in the circulating naïve compartment of SS patients.
Materials and methods: Single IgD^+CD27^- naïve B cells were FACS sorted from 4 SS patients and RNA used to amplify Ig VH and VL genes which were then cloned and expressed as recombinant monoclonal antibodies displaying an identical specificity of the original B cells. B cells from two healthy donors (HDs) were used as control. Recombinant antibodies were tested towards different autoantigens to determine the frequency of autoreactive and polyreactive clones.
Results: A total of 66 individual recombinant antibodies were generated from naïve B cells of SS patients. Analysis of the VH and VL gene usage showed no significant differences between SS and HD. Our data showed increased reactivity towards ANA (43% SS clones versus 25% HD clones) and ENA (19% SS clones) but not increased polyreactivity in peripheral naïve B cells from SS patients, demonstrating an accumulation of autoreactive naïve B cells in the periphery of SS.
Conclusions: Here using a novel strategy to express recombinant antibodies from single B cells we demonstrated an elevated frequency of autoreactive naïve B cells in the circulation of SS patients strongly suggesting the existence of early defects in B cell tolerance checkpoints in SS.

P0429

Alpha-1-antitrypsin promotes B regulatory lymphocytes

P. Cal, M. Mizrahi, D. Ochayon & E. C. Lewis
Clinical Biochimestry, Ben Gurion University of the Negev, Beer Sheva, Israel

Purpose/Objective: B lymphocytes appear to play a role in autoimmune diabetes and also during islet allograft rejection. B regulatory lymphocytes, on the other hand, protect non-obese diabetic (NOD) mice from diabetes in an IL-10-dependent mechanism and also promote T regulatory cells. Alpha-1-antitrypsin (hAAT), an acute phase anti-inflammatory protein, induces immune tolerance during islet allograft transplantation in a mechanism that involves T regulatory cells. Recent findings suggest that B cells are required for hAAT-mediated protection of islet allografts.
Aim: Examine whether hAAT increases the proportion of B regulatory cells in culture and in various animal models.
Materials and methods: Splenocytes from GFP-IL-10 transgenic mice were added stimulatory concentrations of CD40 ligand ($CD40_L$), LPS and B cell activating factor (BAFF), in the presence or absence of hAAT (0.5 mg/ml). Cell-specific IL-10 production was evaluated by Flow Cytometry. GFP-IL-10 transgenic mice were treated with hAAT (60 mg/kg) and then grafted with allogeneic skin. The proportion of B regulatory cell population out of B cells was evaluated in draining lymph nodes (DLN) 7 days later by Flow Cytometry. Peritoneal cavity cell populations were assessed in hAAT transgenic mice ($hAAT^{+/+}$) and wild-type mice during non-sterile inflammation, as provoked by cecal puncture. All surgical procedures were SHAM-controlled.
Results: In cultures stimulated with $CD40_L$, LPS and BAFF, hAAT caused IL-10-positive B regulatory cell population size to increase 1.57 ± 0.06-, 1.5 ± 0.03- and 1.34 ± 0.04-fold, respectively ($P < 0.001$). In skin-grafted hAAT-treated mice, IL-10-producing B regulatory cell population size increased 3.06 ± 0.12-fold compared to skin-grafted untreated mice. $hAAT^{+/+}$ mice responded to non-sterile inflammation with a 3.56 ± 0.65-fold increase in peritoneal IL-10-positive B regulatory cells compared to wild-type mice.
Conclusions: B regulatory cells may play a role in the immunoregulatory activity of hAAT. Further studies are required to elucidate the mechanism of B regulatory expansion by hAAT.

P0430

Analysis of CD22 knockin mice with mutated ligand-binding and signalling domains

J. Müller, M. Woehner, I. Obermeier & L. Nitschke
Biology Chair of Genetics, University of Erlangen-Nuremberg, Erlangen, Germany

Purpose/Objective: CD22 is a transmembrane protein, which mediates the inhibiton of the calcium signal after BCR crosslinking. The extracellular domain of CD22 can bind to its ligands α2,6-linked sialic acids, while the cytoplasmic domain contains inhibitory motifs. The purpose of this study was to analyse the ligand-binding and signalling domain of CD22 independently and thereby determine their functional interplay.
Materials and methods: We generated CD22-R130E *knockin* mice, which have a mutated binding pocket in the extracellular domain of CD22. These molecules are no longer able to bind their ligand α2,6-linked sialic acid. We also generated CD22-Y5,6F and CD22-Y2,5,6F mice with mutated ITIM-domains, so that the inhibitory SHP-1 phosphatase is no longer able to bind the CD22 cytoplasmic tail.
Results: In the bone marrow (BM) we found a reduction of recirculating B cells in the CD22-Y5,6F and CD22-Y2,5,6F mice similar to the phenotype of CD22-deficient mice. In contrast CD22-R130E mice did not show this phenotype. In the spleen all mice showed a reduced marginal zone B cell population. Similar to CD22-deficient B cells, only CD22-Y2, 5, 6F B cells showed increased turnover, as determined by BrdU incorporation *in vivo*. Ca^{2+} measurements revealed a decreased flux after BCR stimulation in CD22-R130E B cells, whereas the CD22-Y5,6F and CD22-Y2,5,6F B cells showed a higher Ca^{2+} flux. The CD22-R130E mutation affected the CD22 association to the BCR.
Conclusions: These data indicate that the maintenance of B cells in the marginal zone is dependent on the ligand-binding of CD22, as well as on the CD22 mediated signalling. However the reduction of recirculating B cells in the BM seems to be caused by the mutations in the ITIM domains of CD22. We could find a increased turnover rate, despite lower B cell numbers in the bone marrow and therefore conclude that B cells with defect signalling domains have a higher apoptose rate. These cells undergo apoptosis before they recirculate into the BM. The calcium flux after BCR crosslinking seems to be mediated by both the ligand-binding domain as well as by the signalling tail of CD22. In summary we found an important role for both functional domains of CD22 considering B cell homing, apoptosis and signalling.

P0432

B cell response to pneumococcal RrgA and RrgB antigens and its relationship with carriage in children and adults

M. S. Ahmed,* A. Kasbekar,† C. Loh,† S. Leong,‡ M. McCormick,‡ M. Barocchi,§ V. Masignani,§ B. Flannagan* & Q. Zhang*
**Clinical Infection Microbiology and Immunology, Institute of Infection and Global Health, Liverpool, UK, †ENT, Alder Hey Children's Hospital, Liverpool, UK, ‡ENT, Royal Liverpool and Broadgreen University Hospital, Liverpool, UK, §Vaccinology, Novartis Vaccine, Sienna, Italy*

Purpose/Objective: *Streptococcus pneumoniae* remains a leading cause of childhood morbidity and mortality around the globe, even after three decades of 23-valent polysaccharide (PPV23) and one decade of 7-valent conjugate vaccines (PCV7) have been available in the market. Pneumococcal pilus plays an important role in their adherence to host respiratory epithelium. Pilus proteins (RrgA and RrgB) were found to be associated with increased bacterial colonization and invasiveness and a heightened inflammatory response in the host. We are investigating the B cell response to pilus proteins (RrgA and RrgB), developed in consequence to natural colonisation of pneumococcus;whether this priming can sufficiently induce immunological memory to protect against pneumococcal carriage and the potential of these proteins as mucosal vaccines in children.
Materials and methods: Adenotonsillar tissues, peripheral blood and nasal swab samples were collected from patients undergoing adenotonsillectomy. Nasal swab was cultured for pneumococcal carriage. Adenotonsillar mononuclear cells (MNC) were cultured with or without concentrated pneumococcal culture supernatants (CCS), to assess memory B cell responses by ELISPOT and to detect antibody responses by ELISA. Serum and salivary antibodies to pneumococcal RrgA and RrgB pilus proteins were measured by ELISA and by Western Blot.
Results: Preliminary results suggest that, pneumococcal colonisation is common in young children, which tends to decline with advancing age. The natural immunity to RrgA and RrgB proteins mount with progression of age. Anti-RrgA response seemed to develop earlier than anti-RrgB.
Conclusions: Serum antibody titres were higher in culture-negative children than those who were culture-positive for pneumococcus, suggesting that these antibodies are protective against pneumococcal carriage.

P0433

B-cell exposure to self-antigen induces regulatory B cells as well as IL-6- and TNF-a-producing B cell phenotypes in healthy humans

B. Kristensen,* A. Langkjær,* B. E. Hansen,* H. Schultz,* L. Hegedüs† & C. H. Nielsen*
**Infection Medicine and Rheumatology Clinic, Institute for Inflammation Research, Copenhagen, Denmark, †Department of Endocrinology and Metabolism, Odense University Hospital, Odense, Denmark*

Purpose/Objective: The ability of human B cells to secrete IL-10 after stimulation with self-antigens and to regulate self-antigen-induced T-cell responses in humans is still unclear. The present study was undertaken in order to determine whether exposure of normal human B cells to human thyroglobulin, a self-antigen with relevance to autoimmune thyroid disease, induced a regulatory phenotype or a pro-inflammatory phenotype in subsets of B or $CD4^+$ T cells.
Materials and methods: Thyroglobulin-pulsed B cells were isolated from healthy donors and co-cultured with autologous T cells. The production of IL-10 and TGF-β, in addition to the pro-inflammatory cytokines, TNF-α and IL-6 were observed and recorded.
Results: Pulsing with foreign antigen, tetanus toxoid, induced a Th1-response with minimal IL-10. Pulsing of B cells with thyroglobulin stimulated 1.10 ± 0.50% of B cells and 1.00 ± 0.20% of $CD4^+$ T cells for IL-10 production, compared to 0.29 ± 0.19% of B cells ($P = 0.01$) and 0.13 ± 0.15% of $CD4^+$ T cells ($P = 0.006$) following TT-pulsing. Thyroglobulin-stimulated IL-10 secreting B cells were enriched within $CD5^+$ and $CD24^{high}$ cells. While thyroglobulin-pulsed B cells induced only modest proliferation of $CD4^+$ T cells whereas B cells pulsed with TT induced vigorous proliferation.
Conclusions: Thus, B cells mediate self-antigen specific IL-10, TNF-α and IL-6 production in co-cultures with T cells and contributes actively to secretion of these cytokines.

P0434

B1 cells but not B2 cells exert regulatory activities through cell-cell contact independent pathway

S. Y. Lin & B. L. Chiang
Graduate Institute of Immunology and Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan

Purpose/Objective: B1 cells which are distinguished from conventional B2 cells belong to a special peripheral B lymphocyte subset and are mainly found in peritoneal and pleural cavities. Since B1 cells constitutively produce natural IgM in the absence of exogenous antigenic stimulation, they are thought to be parts of innate immunity. The basal level of IL-10 by B1 cells increases in response to stimulation with lipopolysaccharides or CpG. On the other hand, B2 cells could not produce IL-10 actively until they interact with T cells, stimulate with Ig and CD40, or contact with Toll-like receptor ligands. Based on the different characters of these two B cell populations, we speculate that B1 cells might play a regulatory role to suppress proliferation of T cells. In this study, we like to investigate further on the regulatory activities exerted by both B1 and B2 cells.
Materials and methods: We used wild type BALB/c mice and C.129P2 (B6)-*Il10*^{tm1Cgn}/J mice, which are IL-10 knock-out mice, to test whether $CD90.2^-CD5^+$ B1 cells and $B220^+$ B2 cells could suppress proliferation of $CD4^+$ T cells which are activated by anti-CD3 and anti-CD28 antibodies. Moreover, we used transwell experiment to clarify whether the immunosuppressive function of B1 cells is dependent on cell-cell contact. Naïve T cells were labeled with CFSE. These T cells activated by anti-CD3 and anti-CD28 antibodies cultured with B1 cells or B2 cells with transwell study or not. After 3 days, T cells were separated from B cells and analyzed by FACScan as well as [^{3}H] thymidine incorporation. The cultured supernatants were collected to measure the cytokine profiles by ELISA.
Results: Allogeneic stimulated proliferation of T cells was significantly suppressed by wild type B1 cells cultured supernatant. Neither wild type B2 cells cultured supernatant nor B1 and B2 cells cultured supernatant from IL-10 knock-out mice could suppress T cells proliferation. In addition, B1 cells could significantly inhibit T cells proliferation even with transwell experiment. The cytokines productions of T-B2 co-culture were IL-10, IL-2 and IFN-γ while the cytokines productions of T-B1 co-culture were abundant IL-10 and some IFN-γ.
Conclusions: These data suggested that B1 cells might play a regulatory role to suppress T cells proliferation by secretion of IL-10 and it is cell-cell contact independent. In the future, B1 cells might be studied further for their application to modulate immunological diseases.

P0435

Bcl3 overexpression leads to loss of marginal zone B cells

N. Hövelmeyer, M. Wörns, P. Adams & A. Waisman
Institute for Moleculare Medicine, Mainz, Germany

Purpose/Objective: B cell homeostasis is regulated by multiple signaling processes including BAFF- B cell receptor and NF-kB signaling. Bcl-3 is a nuclear member of the IκB family that was originally identified as an oncogene in a subset of patients with chronic lymphatic leukemia. After nuclear translocation, Bcl3 associates with the NF-κB subunits p50 and p52 thereby enhancing cell proliferation and carcinogenesis through activation of cyclin D1 expression. Thus, Bcl-3 acts mainly as an oncogenic coactivator of NF-κB, although it is also able to repress NF-κB target gene transcription. Bcl-3 is required for lymphoid organogenesis and germinal center responses since mice deficient for Bcl-3 are immunodeficient due to microarchitectural defects of the lymphoid organs.

Materials and methods: We used a mouse strain allowing for the conditional and tissue specific overexpression of Bcl-3 upon Cre-mediated recombination. The coding sequence of Bcl-3 was inserted into the ROSA26 locus under control of the CMV early enhancer/chicken β actin promoter. Expression of Bcl-3 is prevented by a loxP flanked transcriptional STOP cassette. The compound overexpression of Bcl-3 and eGFP is permitted only after Cre-mediated recombination of the transcriptional STOP cassette in cells and tissues in which Cre is expressed.We used FACS analysis, ELISA and different immunizations protocols to investigate the role of Bcl3 overexpressin in B cells.

Results: Mice overexpressing Bcl3 appeared normal with a slight increased spleen at the age of 8 weeks. This increasement becomes more pronounced with age. FACS analysis revealed an accumulation of follicular B cells while the marginal zone B cells are absent. Further, B cells isolated from $Bcl3^{BOE}$ mice show reduced proliferative capacity upon a-IgM and LPS stimulation. But these B cells keep the ability to prolong survival *in vitro*. Moreover, T dependent immunization in $Bcl3^{BOE}$ mice revealed increased numbers of germinal center B cells.

Conclusions: Our results show a crucial role of Bcl-3 in survival of follicular B cells and terminal B cell differentiation.

P0436

Conjugate vaccination generates isotype-switched memory B-cells which depend on bystander T-cell help for their activation

E. Clarke,* N. Williams,* R. Heyderman† & A. Finn*
**School of Cellular and Molecular Medicine, University of Bristol, Bristol, UK, †Malawi-Liverpool Wellcome Trust Clinical Research Programme, University of Malawi College of Medicine, Blantyre, Malawi*

Purpose/Objective: Polysaccharide (PS) conjugate vaccines generate PS-specific memory B-cells (B_{MEM}) through the recruitment of $CD4^+$ T-cells, upon which the induction of B_{MEM} depends, via a conjugated protein (PT). However, in isolation the B_{MEM} thus generated appear unable to sustain immune protection following the waning of the initial serum antibody response. We have sought to establish whether this fundamental limitation of the conjugate vaccines reflects the ineffective activation of the B_{MEM} population as a result of the lack of cognate T-cell help subsequently available to them.

Materials and methods: A group of healthy adults ($n = 20$) who had previously been vaccinated routinely with a Men C conjugate vaccine were boosted with a Men C * tetanus toxoid (TT) conjugate vaccine. Men C and TT specific B_{MEM} in the circulation were enumerated using a memory ELISpot assay. The role of bystander T-cells and other non-cognate stimuli in driving the differentiation of B_{MEM} into Pc was subsequently established using antigen stimulation experiments employing both immunomagnetic cell separation and transwell experiments.

Results: Conjugate vaccination generated IgG^+CD27^+ B_{MEM} but not IgM^+CD27^+ B_{MEM} specific for Men C. We demonstrate that both the Men C and TT-specific B_{MEM}, generated following the administration of the conjugate vaccine continue to require $CD4^+$ T-cells in order to differentiate effectively into plasma cells.Nonetheless, bystander T-cells are able to provide such signals to the PS-specific B_{MEM} with comparable effect to the cognate T-cell help available solely to the TT-specific B_{MEM} population. Heat-killed meningococci drive the differentiation of the PS-specific B_{MEM} through bystander T-cell activation which is further enhanced by non-cognate T-cell independent innate signals. The bystander effects of T-cells activated by the conjugated TT within the vaccine were also demonstrated on B_{MEM} *in vivo*.

Conclusions: These data support the hypothesis that the differentiation of PS-specific B_{MEM}, at the time of bacterial encounter, depends on the capacity of bacterial PT to effectively activate bystander T-cells. Thus, priming such responses through including bacterial PT within conjugate vaccine preparations should be further evaluated.

P0437

CpG-ODN induces PD-L1 expression on human B cells and CpG ODN -treated B cells decreased IL-5 and IL-13 production from antigen-stimulated human $CD4^+$ cells

S. Kubo,* T. Yamada,* K. Ougi† & S. Fujieda*
**Otolaryngology, Fukui University, Yoshida-gun Fukui Pref., Japan, †Otolaryngology, Shinseikai Toyama Hospital, Toyama Pref., Japan*

Purpose/Objective: Co-stimulatory molecules are important for regulating T cell activation and immune response. Programmed death ligand 1 (PD-L1) also known as CD274 or B7-H1 has emerged as an important immune modulator that can block T cell receptor signaling. We investigated the effect of CpG-ODN on the human B cells *in vitro*. The expression of co-stimulatory molecule of B cells and its function were analyzed.

Materials and methods: B cells and T cells were separated from human peripheral blood mononuclear cells with magnetic beads. We have investigated whether PD-L1, and other costimulatory ligands could be expressed in human B cells stimulated by CpG-DNA. We sought to determine the effect of CpG-DNA-treated B cells on T helper 2 (Th2) cytokine production in Cry j 1 (Japanese pollen antigen)-stimulated human CD4-positive cells from patients with seasonal allergic rhinitis caused by Japanese cedar pollen.

Results: CpG-DNA strongly induced the coinhibitory molecule ligand, PD-L1 of human B cells. Results show that nuclear factor-kappa B (NF-κB) signaling is involved directly in CpG-DNA- induced PD-L1 expression in human B cells. CpG-DNA-treated B cells reduced Cry j 1-induced IL-5 and IL-13 production in CD4-positive cells. When the binding of PD-1 to PD-L1 was inhibited by PD-1-Ig, this chimera-molecule reversed the previously described reductions in IL-5- and IL-13-production. In contrast, the CpG-B-treated B cells increased both IFN-γ and IL-12 production in the presence of Cry j 1-stimulated CD4-positive cells. CpG-DNA simultaneously reduced the expression of B7RP-1 (also known as inducible costimulator ligand (ICOSL), B7-H2) and the ligand of CD30 (CD30L).

Conclusions: CpG ODN increased PD-L1-expression. CpG ODN -treated B cells decreased IL-5 production from antigen-stimulated human $CD4^+$ cells. These results suggested that the treatment of CpG-DNA suppressed antigen-specific IL-5 production via PD-1- PD-L1 ligation. This study reinforces the idea of CpG-DNA being a potential therapeutic modality through B cells and its signaling pathway being a target for drug interventions against allergic diseases.

P0438

Dietary omega-3 fatty acids induce a stronger B cell response in mice with antigen-induced inflammation

S. Thorleifsdottir,* V. Tomasdottir,* A. Vikingsson,† I. Hardardottir‡ & J. Freysdottir*

*Departmen of Immunology and Centre for Rheumatology Research, Faculty of Medicine University of Iceland, Landspitali The National University Hospital of Iceland, Reykjavik, Iceland, †Centre for Rheumatology Research, Landspitali The National University Hospital of Iceland, Reykjavik, Iceland, ‡Biochemistry and Molecular Biology, Faculty of Medicine University of Iceland, Reykjavik, Iceland

Purpose/Objective: Omega-3 fatty acids may, in addition to their anti-inflammatory effects, affect resolution of inflammation. They are substrates for specialized pro-resolving lipid mediators that block production of pro-inflammatory mediators, inhibit infiltration of polymorphic neutrophils and stimulate phagocytosis by macrophages. The effects of omega-3 fatty acids on the adaptive phase of the resolution of inflammation has not been much studied. The objective of this study was to determine the effects of omega-3 fatty acids on the adaptive immune response in antigen-induced peritonitis.

Materials and methods: Female C57BL/6 mice were fed diets without or with 2.8% fish oil for 4 weeks. Peritonitis was induced by vaccination with mBSA in Freund«s adjuvant followed by an i.p. injection of mBSA. The mice were euthanized before and 1, 2, 5 and 10 days after mBSA injection. mBSA-specific antibodies in serum were determined by ELISA, peritoneal B cells analyzed by flow cytometry and germinal center B cells and mBSA in spleen evaluated by staining cryosectioned spleen sections.

Results: Germinal centers increased in size and number following administration of mBSA. There were more germinal centers and the germinal centers were larger in spleen from mice fed the omega-3 fatty acid diet than in mice fed the control diet. Serum levels of mBSA specific IgG and IgM antibodies increased slightly following mBSA administration. Mice fed the omega-3 fatty acids had higher serum levels of mBSA specific IgM antibodies than mice fed the control diet. However, serum levels of IgG were similar in the two dietary groups. There were more peritoneal B cells in mice fed the omega-3 fatty acid diet than in mice fed the control diet.

The amount of mBSA present in the spleen increased in both groups, reaching maximum 2 days after administration of mBSA. Mice fed the omega-3 fatty acid diet had less mBSA in their spleen on day 2 than mice fed the control diet.

Conclusions: These data indicate that the adaptive B cell response is more intense, with increased number of B cells, increased levels of mBSA specific IgM antibodies and increased number and size of splenic germinal centers in mice fed the fish oil diet than those fed the control diet. Therefore, dietary fish oil may enhance B cell response in antigen-induced inflammation and provide better protection in future encounters with the antigen.

Differential regulation of IRF4 during extrafollicular B cell differentiation, and its role for Ig class switching

L. A. George, Y. Zhang, K. Nakamura, I. MacLennan, G. Anderson, P. Lane, W. Jenkinson, J. Marshall & K. M. Toellner

Immunity and Infection, University of Birmingham, Birmingham, UK

Purpose/Objective: The transcription factor IRF4 is essential for immunoglobulin class switch recombination (CSR) and plasma cell differentiation. Whilst high levels of IRF4 induce terminal differentiation to plasma cells, low-level expression of IRF4 is associated with CSR. Our aim was to study the kinetics of IRF4 induction and dissect the role of high and low-level IRF4 expression in CSR.

Materials and methods: To study IRF4 induction, we immunised quasi monoclonal (QM) mice, which have a high frequency of B cells specific for the model antigen 4-hydroxy-3-nitrophenylacetyl (NP), with NP conjugated to Ficoll (NP-Ficoll). This induces B cell activation with CSR, followed by parallel differentiation of both plasma cells and T-independent germinal centre B cells.

To test the role of IRF4 for Ig class switching in different phases of the antibody response, mice with NP-specific B cell receptors deficient in NFκB1 or overexpressing mir125 were produced.

Results: We show that low-level expression of IRF4 is induced within minutes of B cell activation. These become B blasts that undergo CSR. Three days after immunisation, B cells differentiate into germinal centre cells that lose IRF4 expression or extrafollicular plasmablasts. Plasmablasts express high levels of IRF4 and Blimp1, and do not undergo further CSR.

We show that whilst both NFκB1 and mir125b regulate IRF4 and plasma cell differentiation, they have different effects on the early phase IRF4 induction and Ig class switching in B blasts.

Conclusions: The results are compatible with a role for low-level expression of IRF4 for CSR in early B blasts.

P0440

Expression and functionality of proteinase activated receptor-2 (PAR-2) in murine B cells

M. Campbell,* A. Crilly,* G. McGarvie,* R. Plevin,† W. R. Ferrell,‡ C. S. Goodyear‡ & J. C. Lockhart*

*School of Science, Centre for Musculoskeletal Science, University of the West of Scotland, Paisley, UK, †Strathclyde Institute of Pharmacy and Biomedical Science, University of Strathclyde, Glasgow, UK, ‡Institute of Infection Immunity and Inflammation, University of Glasgow, Glasgow, UK

Purpose/Objective: PAR-2 is a seven transmembrane G protein coupled receptor (GPCR) that when activated by proteolytic cleavage results in the production of cytokines and chemokines(1). PAR-2 is expressed on numerous immune and non immune cells(2), however, it has previously been reported to be absent on B cells(3), although this remains controversial. The current study aims to address this controversy by demonstrating both PAR-2 expression and a functional role for PAR-2 in murine B cells.

Materials and methods: PAR-2 expression on murine B cells was assessed by flow cytometry. B cells were negatively enriched from C57BL/6 splenocytes using magnetic separation. Purified B cells were activated *in vitro* with the specific PAR-2 activating peptide SLIGRL-NH_2 (100 μM), supernatants collected 1, 4 and 24 h after stimulation, and analysed by ELISA for IL-6 and IL-10. Ca^{2+} signalling was measured by flow cytometry and pERK1/2 by western blotting. For sub-setting studies, spleens, bone marrow and peritoneal lavages were collected from female *F2rl1*$^{-/-}$ (PAR-2 deficient) and wild type C57BL/6 littermates, and cells stained with fluorescent antibodies for analysis by flow cytometry.

Results: Our data reveal that PAR-2 is expressed at low levels on splenic B cells, and this can be augmented by activation with SLIGRL-NH_2.The activation of B cells with SLIGRL-NH_2 also induced the increased secretion of IL-6 and IL-10. Furthermore, receptor activation induced Ca^{2+} mobilisation and the phosphorylation of ERK1/2 in B cells, indicative of intact PAR-2 signalling. Interestingly, the absence of PAR-2 in *F2rl1*$^{-/-}$ mice resulted in alterations in the composition of the B cell compartment, namely B1a and marginal zone B cells.

Conclusions: This study is the first to demonstrate the expression of functional PAR-2 on murine B cells, and implicates PAR-2 as a regulatory factor in the homeostasis of the innate-like B cell repertoire.

P0441

Expression of Toll-like receptors 7 and 9 in B cell populations of patients with Sjögren's syndrome

M. Karlsen, T. Hansen, R. Jonsson & S. Appel
Medicine and Dentistry, The Gade Institute, Bergen, Norway

Purpose/Objective: Sjögren's syndrome (SS) is a rheumatic autoimmune disease, with focal lymphocyte infiltrations and inflammation in exocrine glands, resulting in destruction of glandular tissue. Primarily, salivary and lachrymal glands are affected, leading to reduced production of saliva and tears. A conse-quence of this is dry eyes and dry mouth (sicca syndrome). Other organs can also be involved in SS, and patients have, as many other rheumatic patients, major problems with fatigue. The cause of SS is so far not known, and there is no cure available. Only symptomatic treatment can be offered, and even if the inflammation is halted, it is not certain that the glands can be regenerated.

To generate new and more effective treatments for these patients, more information on the development and cause of this disease is needed. As SS is characterized by the production of autoantibodies, B cells have been recognized as important cells in the pathogenesis of SS and other rheumatic diseases. Toll-like receptors (TLR) are pattern recognition receptors that induce activation responses after ligand binding, and they are found on many immune cells. TLR7 and 9 are localized intracellulary in the endosomal compartment where they recognize nucleic acids. Both have been suggested to be involved in autoreactivity towards 'self'.

Materials and methods: In this study we utilized peripheral blood mononuclear cells to investigate the expression levels of TLR7 and TLR9 in various B cell subsets of SS patients and healthy controls using eight colour flow cytometry.

Results: Preliminary data suggests that memory B cells from SS patients have elevated expression levels of TLR 7 and 9.

Conclusions: Further analyses will be needed to evaluate possible functional differences of these cells.

P0442

FCGR3A-158V/F polymorphism may correlate with hypogammaglobulinaemia in patients after Rituximab treatment

E. Villegas,* J. Iglesias,* N. Martínez-Pomar,* A. M. Gutiérrez† & N. Matamoros*
**Immunology, Son Espases Hospital, Palma de Mallorca, Spain,*
†Hematology, Son Espases Hospital, Palma de Mallorca, Spain

Purpose/Objective: Rituximab is a chimeric monoclonal antibody directed toward CD20, a B-cell surface marker that has been proven effective in depleting normal and malignant B cells *in vivo*. Rituximab is widely used in the treatment of B-cell malignancies and induces almost a complete depletion of normal B lymphocytes in peripheral blood for an average of various months. In some cases, Rituximab treatment causes prolonged hypogammaglobulinaemia. It has been reported that the presence of valine (V) at position 158 of FCGR3A (CD16) has a higher affinity to human IgG than the phenylalanine (F) allele. The hypogammaglobulinaemia after Rituximab treatment could be correlated with this polymorphism.

Materials and methods: This study initially included 16 patients who received treatment with Rituximab. The FCGR3A gene polymorphisms were determined by allele specific polymerase chain reaction (PCR). Genomic DNA was extracted from peripheral blood using a DNA isolation kit under the manufacturer's instructions.

Results: The patients tested for the FCGR3A-158V/F polymorphism were classified in low-affinity group (158 F/F) and high-affinity group (158 F/V and 158 V/V). Of the 16 patients initially tested for the polymorphism, 5 in Rituximab maintenance and 11 hypogammaglobulinemic subjects after Rituximab treatment, 3 patients had homozygous F/F, 11 had heterozygous V/F and 2 had homozygous V/V.

Conclusions: The aim of this study is to demonstrate the possible correlation between immunoglobulin levels after Rituximab treatment and the FCGR3A-158V/F polymorphism. In theory, patients classified in low-affinity group may have lower levels of immunoglobulins in comparison with high-affinity group. The confirmation of this result may imply the introduction of these studies as a diagnostic test and provide a more accurate Rituximab treatment to avoid secondary hypogammaglobulinaemia.

Functional elimination of double-stranded DNA-specific B Lymphocytes suppresses disease activity in SCID model of mouse lupus

S. Chausheva, N. Mihaylova, V. Gesheva, N. Kerekov, K. Nikolova-Ganeva & A. Tchorbanov
Immunology, Institute of Microbiology Bulgarian Academy of Sciences, Sofia, Bulgaria

Purpose/Objective: Self-specific B cells play a main role in pathogenesis of Systemic lupus erythematosus (SLE). The elimination of B and T cells involved in the pathological immune response is a reasonable approach for effective therapy of SLE. In the present study we established an autoimmune model by transferring purified B and T cells from MRL/lpr mice to SCID mice and tested the effects of the chimeric molecule that selectively targeted pathological autoreactive B-lymphocytes.

Materials and methods: The protein chimeric molecule was constructed by coupling an DNA- mimotope peptide DWEYSVWLSN to a monoclonal anti-CD32 (FcγRIIb) antibody. This engineered molecule is able to cross-link cell surface immunoglobulin with the inhibitory FcγRIIb on DNA-specific B cells.

Female SCID mice were transferred with isolated $B^{+}T$ cells from MRL/lpr mice and the animals were treated with DNA- peptide chimera.

Cytokine assays, ELISpot, Signal transduction, Proliferation assay, ELISA and FACS analyses were also performed.

Results: The specific elimination of the DNA-specific B cells in MRL-transferred SCID mice restricts not only anti-dsDNA IgG production, but also autoreactive T cell activation and proliferation. In contrast, untreated MRL-transferred SCID mice experienced an increase of disease-associated antibody levels and developed glomerulonephritis similar to intact MRL/lpr mice.

Conclusions: In the present study we report a possible way to restrict the communication between autoimmune B and T cells, leading to suppression of lupus syndrome in MRL/lpr cell-transferred SCID mice. The functional elimination of autoantigen-specific B cells leaves autoreactive T cells alone without potency of prolonged pathogenetic effects.

In the present transferred SCID model of mouse lupus we have a possibility to study post-elimination disease processes and autoreactive T cell behavior after treatment with the protein-engineered antibody.

Gene profiling of human interleukin-10 producing regulatory B cells

W. Lin, E. W. M. Chua, N. Shadan, S. M. Mustafah, I. C. H. Low, J. Lum, K. Duan, J. J. Y. Tai, A. Larbis, F. Zolezzi, M. Poidinger, S. C. Wong & S. Calbo

Immunos, Singapore Immunology Network (SIgN), Singapore, Singapore

Purpose/Objective: B cells which possess regulatory function (Bregs) have been identified in mouse models of multiple sclerosis, rheumatoid arthritis and colitis. These Bregs are characterized by their ability to produce interleukin-10 (IL-10) which down-modulate inflammation. Similarly, we were able to detect IL-10 producing Bregs in human blood and spleen after *ex vivo* short time stimulation. Since IL-10 producing Bregs did not have a particular phenotype, a detailed profiling of this Breg subpopulation is needed in order to identify them more accurately based on unique cell surface markers and transcription factors.

Materials and methods: B cells were stimulated for 48 h with CpG and anti-Ig which are the most potent stimuli for inducing IL-10 secretion in B cells. Bregs were then isolated based on IL-10 secretion. Microarray analysis was performed in order to identify differentially expressed genes between IL-10 negative (IL-10-) and IL-10 positive ($IL\text{-}10^{+}$) B cell populations.

Results: Both naïve and memory B cells can secrete IL-10. Microarray analysis showed hierarchical clustering of B cells based on IL-10 expression. A total of 614 genes were found to be differentially expressed between the IL-10- and $IL\text{-}10^{+}$ B cell populations.

Conclusions: All subsets of B cells have the potential to produce IL-10 following CpG and anti-Ig stimulation. Our microarray findings may allow the identification of new subpopulations of human B cells with potential immunoregulatory function.

P0445

Generation of B-cell memory from the in-vitro-induced germinal center B cells

D. Kitamura

Division Molecular Biology, Research Institute for Biomedical Sciences, Tokyo University of Science, Noda, Chiba, Japan

Purpose/Objective: During T-cell dependent immune responses, antigen-bound B cells proliferate extensively to form germinal centers (GC) in the peripheral lymphoid organs and then differentiate into either long-lived plasma cells (LLPCs) or memory B (B_{mem}) cells, which constitute a B-cell part of the immunological memory. To understand the molecular mechanisms for the development of LLPCs and B_{mem} cells, we sought to construct an *in vitro* model system that recapitulates the GC reaction.

Materials and methods: Mouse naïve B cells were cultured on the feeder cells expressing CD40L and BAFF (named 40LB) with cytokines, IL-4 in the primary, and IL-21 in the following secondary culture. The B cells from these conditions were transferred into syngeneic mice, and after certain days, the mice were analyzed by flow cytometry, ELISA, and ELISPOT.

Results: In this culture system, the B cells extensively proliferated to generate germinal center-phenotype B (induced GC B: iGB) cells expressing switched or unswitched Ig classes. The iGB cells after primary culture with interleukin (IL)-4 develop into B_{mem} cells *in vivo* that elicit rapid immune responses in the presence of cognate helper T cells, whereas the secondary culture with IL-21 inhibits the B_{mem} development and allows their development into LLPCs that produce significant amount of IgG1 for more than one month in the bone marrow. The subsequent IL-21 withdrawal partially restores the B_{mem} development and abolishes the LLPC development. In addition, the transfer of the secondary iGB cells that are specific to a certain membrane antigen inhibited tumor formation of concomitantly transferred melanoma cells expressing the same antigen in the lungs of the recipient mice. Furthermore, we have established a system to selectively expand antigen specific iGB cells using the 40LB cells expressing a membrane-bound antigen and Fas-ligand.

Conclusions: This novel culture system has enabled *in vitro* differentiation from naïve B cells into B_{mem} or LLPC precursors, which can colonize and mature in their destined sites *in vivo*, and therefore will be useful to elucidate molecular mechanisms for the late B-cell development in GC. It also offers a model system to develop a B-cell-mediated anti-tumor therapy, in which patients will be transferred with autologous iGB cells selected for binding to a specific tumor antigen.

P0446

HA-specific memory B cell responses to pandemic 2009 H1N1 and seasonal influenza viruses in children and adults

W. Mahallawi,* A. Kasbekar,† C. Loh,† K. Hoschler,‡ M. McCormick,§ S. Leong,§ P. McNamara¶ & Q. Zhang*

**Institution of Infection and global health, University of Liverpool, Liverpool, UK, †Alder Hey Children's Hospital, University of Liverpool, Liverpool, UK, ‡Virus Reference Department, Health Protection Agency, London, UK, §ENT Department, Royal Liverpool University Hospital, Liverpool, UK, ¶ENT Department, Alder Hey Children's Hospital, Liverpool, UK*

Purpose/Objective: Backgrounds: Influenza is a highly contagious and acute respiratory infection caused by influenza virus in the mucosa of respiratory tract. Nasal-associated lymphoid tissues (NALT) are mucosal immune organs in the nasopharynx, among which adenoids and tonsils are major components of human NALT.

Aims of study (i) to investigate whether prior exposure/infection of pandemic 2009 H1N1 virus (pH1N1) primes for immunological memory in human NALT and, (ii) To determine whether it cross reacts with seasonal H1N1 and H3N2 viruses.

Materials and methods: Adenotonsillar tissues were obtained from children and adults undergoing adenoidectomy and /or tonsillectomy due to adenoidal hypertrophy or tonsillitis. Adenotonsillar MNC were cultured in RPMI medium with or without the addition of influenza antigens. Peripheral blood samples were also taken for immunological analysis. HA-specific memory B cell responses to pandemic 2009 H1N1, seasonal H1N1 and H3N2 viruses were analysed by Elispot assay, following stimulation by surface antigens derived from respective influenza viruses. Serum anti-HA IgG antibody and haemagglutination inhibition titres were measured by ELISA and a standard HAI assay respectively.

Results: In individuals who had evidence of prior exposure to the 2009 H1N1 virus (who had anti-pH1N1 HAI titre $^{3}40$), there were significant numbers of pH1N1 HA-specific memory B cells which respond not only to the homologous pH1N1, but also cross-react to the sH1N1 viruses. However, there was no significant memory B cell response to the seasonal H3N2 HA after the pH1N1 antigen stimulation. Stimulation with the sH1N1 antigen induced only a moderate increase in the numbers of HA-specific ASC to the homologous sH1N1 and heterologous pH1N1, and no significant increase in numbers of specific ASC to sH3N2. In contrast, the pH1N1 antigen stimulation induced significantly higher HA-specific memory B cell responses, not only to the homologous pH1N1, but also to the heterologous sH1N1 than the sH1N1 antigen in patients with serum anti-pH1N1 HAI titre $^{3}40$. There was a significant correlation between numbers of HA-specific antibody secreting cells (ASC) to pH1N1 and that to sH1N1 after stimulation by the pH1N1 surface antigens.

Conclusions: Pandemic 2009 H1N1 influenza virus induces strong HA-specific memory B cell responses which cross react with the seasonal H1N1 but not seasonal H3N2 viruses.

P0447

Hypoactive Syk elicits B cell-mediated autoimmunity and a pre-diabetic state

S. Königsberger,* J. Prodöhl,* V. Weis,* M. Andreas,* M. Stehling,* T. Schumacher,† R. Böhmer* & F. Kiefer*
*Department Vascular Cell Biology, Max Planck Institute for Molecular Biomedicine, Muenster, Germany, †Department of Neurooncology, Neurology Clinic and National Center for Tumor Diseases, University Hospital of Heidelberg, Heidelberg, Germany

Purpose/Objective: The closely related non-receptor protein tyrosine kinases Syk and Zap-70 are of central importance in transducing signals from antigen receptors to downstream signaling mediators, a process ensuring proper selection, maturation and activation of lymphocytes. Partially overlapping protein expression patterns and reported functional redundancies at the signal transduction level still raise the question to which degree the kinases can replace each other in the immune system.
Materials and methods: To fully elucidate kinase interchangeability *in vivo*, we generated mice, which carry a Zap-70 cDNA 'knock-in' at the locus of Syk that is controlled by intrinsic Syk promoter elements and disrupts wildtype Syk expression.
Results: Kinase replacement strongly reduced Erk1/2-mediated survival and proper selection of developing B cells, demonstrating critical dependence on BCR signaling quality. The observed alteration in BCR signaling quality was accompanied by a preferential development and survival of marginal zone B cells, prominent knock-in serum autoreactivity, high levels of anti-insulin antibodies, proteinuria and an age-related glomerulonephritis. Development of concomitant fasting glucose intolerance in Zap-70 knock-in mice highlights aberrant B cell selection through hypoactive Syk as a potential novel risk factor for type 1 diabetes and suggests attenuated BCR signaling output as a mechanism to cause biased cellular and Ig repertoire selection.
Conclusions: Consequently, lowering Syk kinase activity in B cells through e.g. somatic mutation, alternative splicing / exon skipping or changes in promoter methylation might therefore contribute to autoimmune predisposition.

P0448

IL-2 induced MAPK-ERK pathway triggered human plasma cell differentiation through BACH2 Repression

C. Delaloy, G. Caron, S. Le Gallou, C. Pastoret, K. Tarte & T. Fest
Rennes University Hospital, INSERM U917, Rennes, France

Purpose/Objective: Terminal differentiation of B lymphocytes into plasmocytes (PCs) involves a well-established transcription factor cascade. However, temporal dynamics of cell signaling pathways regulating transcription factor network during germinal center (GC) reaction remain poorly defined.
Materials and methods: To gain insight into the molecular processes and extrinsic factors required for B cell differentiation, we set up a controlled primary culture system combining BCR signal, Toll like receptor activation and T cell help in the form of CD40L and cytokines to differentiate human naïve B cells into PCs..
Results: We identify T-cell-produced IL-2 to be critically involved in ERK1/2 triggered PC differentiation. This early signaling event controlling specification to plasma cell fate operates independently of proliferation and survival functions. Compared to no cytokine activated B cells, IL-2-primed B cells display a gene expression profile of a more differentiated fate.Chemical inhibition of the MAPK-ERK pathway impairs IL-2 mediated PC differentiation and rescues the expression profile of several key genes, maintaining GC B cell fate. One of them encodes the transcription factor BACH2, which represses BLIMP1 the master regulator for PC differentiation, and whose expression is physiologically shutdown in centrocytes. Partial inhibition of BACH2 is sufficient to drive PC differentiation in absence of IL-2, and suppresses the effects of ERK1/2 inhibition on IL-2 induced PC differentiation as well. These results support the notion that the concentration of BACH2 fine-tunes the gene regulatory network involved in PC differentiation. The molecular mechanism of ERK-dependent BACH2 repression is under investigation.
Conclusions: Altogether we identify IL-2 as a novel early master regulator required to overcome the repressive forces that block PC differentiation through ERK activation and BACH2 inhibition, sustaining BLIMP1 expression.

P0449

IL-21 derived from human follicular helper T cells acts as a survival factor for secondary lymphoid organ, but not for bone marrow, plasma cells

R. Ana Belen, B. Rodriguez-Bayona, A. Campos-Caro & J. A. Brieva-Romero
Hospital universitario Puerta Del Mar, Unidad De Investigación, Cádiz, Spain

Purpose/Objective: OBJETIVE: IL-21 induces the differentiation of activated B lymphocytes into plasma cells (PC), but its direct effect on PC remains uncertain. This study analyzes the role of IL-21 on human *in vivo* -generated PC.
Materials and methods: MATERIAL AND METHODS: Expression of constitutive IL-21R on human PC from different organs was examined by flow cytometry. IL-21R mRNA from PC was quantified by RT-PCR. Tonsillar and bone marrow (BM) PC were purified by a combination of magnetic-selection and FCC-sorting. PC cultures without/with IL-21 or purified follicular helper T (Tfh) cells. Analysis of proliferating cells was performed by detecting BrdU incorporation. Apoptotic PC were determined by labeling active caspases with the fluorochrome-labeled inhibitor FAM-VAD-FMK. Measurement of Ig secreted to culture supernatants was performed by ELISA.
Results: RESULTS: IL-21R was clearly expressed on PC from human tonsil, lymph node and spleen (secondary lymphoid organs, SLO), but barely on terminally mature BM. PC. IL-21 enhanced Ig-secretion by isolated SLO PC, but not BM PC. Tonsillar Tfh lymphocytes are known to secrete IL-21. Purified Tfh-cells induced a marked increase of Ig-production by tonsillar PC, and this effect was impaired when endogenous IL-21-production was blocked. IL-21 provoked a rapid and transient phosphorylation of STAT3 in tonsillar PC. Tfh-cells or exogenous IL-21 reduced tonsillar PC apoptosis and increased PC recovery, but dit not modify their non-proliferating status.
Conclusions: CONCLUSIONS: These results suggest that IL-21 derived from Tfh-cells may act as a survival factor for SLO PC *in vivo*.

P0450

Immunoglobulin gene usage and specificity of plasmablasts generated during secondary dengue infections

R. Appanna,* M. H. Xu,* V. Hadinoto,* K. Joensson,* Y. X. Toh,* T. Balakrishnan,* Y. S. Leo,† C. I. Wang* & K. Fink*
*Singapore Immunology Network, Agency for Science Technology and Research A*STAR, Singapore, Singapore, †Department of Infectious Diseases Communicable Disease Centre, Tan Tock Seng Hospital, Singapore, Singapore*

Purpose/Objective: Memory B cells generated after exposure to dengue viral (DENV) infection are a central component in shaping immune memory. Re-exposure to dengue virus of a different serotype is often associated with increased viral replication and disease pathogenesis. In repeated infection, the rapid activation of memory B cell leads to the generation of massive amounts of cross-reactive anti-

bodies. In the acute phase of a secondary infection, this B cell memory pool probably outcompetes the newly generated virus specific B cells.
Materials and methods: To characterize the specificity of plasmablasts and memory B cells generated during and after acute infection, we performed single cell RT-PCR for sequence analysis of Ig variable regions.
Results: Contrary to the polyclonal plasmablast repertoire we found that memory B cells isolated one month after disease were surprisingly oligoclonal and of different genetic composition than plasmablasts. Our current data revealed highly preferential usage of the VH1 gene in DENV binding plasmablasts. In contrast, skewed cell memory VH family repertoires (VH3) were noted in long lasting circulating cells isolated over a month after infection. Whether VH gene usages reflect a specific antigen/epitope selection is currently under investigation.
Conclusions: These data further suggest that plasmablasts represent a population of re-activated memory B cells with a potentially different origin than circulating steady state memory B cells.

P0451

Implication of proteins syntaxin-3 and syntaxin-4 in constitutive secretion of ig from human plasma cells

M. L. Gómez Jaramillo, L. Delgado-Pérez, G. Jiménez Gómez, E. Reales Rodríguez, V. Rivas Guerrero, R. M. Mateos Bernal, A. García-Poley, J. A. Brieva Romero & A. Campos-Caro
Hospital Universitario Puerta Del Mar, Unidad De Investigación, Cádiz, Spain

Purpose/Objective: Plasma cells (PC) are B-lymphocytes terminally differentiated with the purpose of manufacturing and secreting immunoglobulins (Ig). This study explores the presence of several SNARE proteins in human PC and examines their functional roles on Ig secretion process.
Materials and methods: The U266 human myeloma cell line was used as model of Ig secreting cell line. Expression of constitutive SNARE proteins on human PC was examined by Western-blot and protein localization was analysed using immunofluorenscence confocal microscopy. Experiments of loss of function were performed by nucleofection of U266 with specifics iRNA. Overexpression assays were generated by transfection of constructs for native SNAREs and deleted protein lacking the transmembrane domain, both in fusion with Ruby as a reporter gen. Transfected cells, either iRNA o plasmid, were isolated by FACS-sorting and cultured for 24 h. IgE levels into the cultured supernatants were measured by ELISA and the corresponding cell pellets were used to analyse the inhibition or overexpression of each protein by Western-blot.
Results: Syntaxin-3 and Syntaxin-4 were detected in human PC and human cell line U266. The predominant location of Syntaxin-3 and Syntaxin-4 is on the cell surface but they could be also observed intracellularly. Although both Syntaxins shown to interact with SNAP-23, functional studies demonstrated a different role of these proteins in Ig-secretion. Interference of Syntaxin-4 expression, but not of Syntaxin-3, significantly inhibited Ig secretion in PC. Overexpression of wild-type Syntaxin-4 induced a marked decrease of Ig-secretion whereas overexpression of the mutant form of the protein did not modify significantly this secretion. Increase of both wild-type Syntaxin-3 and mutant form did not cause changes on Ig secretion levels.
Conclusions: The present study demonstrates that Syntaxin-4, but no Syntaxin-3 plays a critical role in the Ig-secretion and this data suggest that Syntaxin-4 along with SNAP-23 appears to be a component of the SNARE complex in human PC Ig-secretion.

P0452

Increase of IgA+, but not IgM+ memory B cells after vaccination with Pneumovax23

A. Meyer-Bahlburg, K. Schütz & U. Baumann
Hannover Medical School, Pediatric Pneumology and Neonatology, Hannover, Germany

Purpose/Objective: The mature B cell compartment is comprised of at least two B cell subpopulations, namely naïve follicular mature and marginal zone B cells. Whereas naïve follicular mature B cells are crucial during T cell dependent immune responses, marginal zone B cells are the main player during T cell independent immune responses. In humans, IgM+ memory B cells in the peripheral blood have been suggested to represent equivalents of splenic marginal zone B cells. However, this view remains very controversial.
Materials and methods: We therefore analyzed the changes in the composition of the B cell compartment in peripheral blood of healthy individuals following immunizations with Pneumovax23 inducing primarily a T cell independent immune response.
Results: Whereas we could not observe a significant change within the IgM+ memory B cell compartment we found a significant increase, both in relative and absolute numbers, in IgA+ memory B cells. Moreover, a 'non-responder' to vaccination, defined by no significant increase in Pneumovax-specific IgM or IgG, had very low, but still few, IgA+ memory B cells in peripheral blood.
Conclusions: Our data show, that Pneumovax23 primarily induces an IgA+ memory B cell reponse. Although it is well known that individuals with IgA deficiency show often normal responses to pneumococcal infection and vaccinations with Pneumovax23, these results suggest that IgA is primarily induced in response to these antigens and might serve as a predictor for the immune response.

P0453

Innate $CD19^+$ $CD45Rlo$ cell population exhibit high proliferation rates in homeostatic conditions and is able to respond after TLR stimulation

B. De Andres,* I. Cortegano,* C. Prado,* B. Palacios,* M. Alía,* C. Ruiz,* N. Serrano,† M. A. R. Marcos† & M. L. Gaspar*
**Centro Nacional de Microbiología, Unidad de Inmunobiología, Madrid, Spain, †Centro de Biología Molecular, Consejo Superior de Investigaciones Científicas, Madrid, Spain*

Purpose/Objective: We described previously a novel splenic B cell population $CD19^+$ $CD45R^{lo}CD21^{lo}$ (19^+45R^{lo}) from embryonic origin, that preferentially home on perifollicular areas of unmanipulated follicles. These cells harbor a plasmablast phenotype (Blimp-1+Xbp-1+Pax-5+) and spontaneously release IgG1 and IgA. Here, we show that these cells are different from classical follicular, transitional, marginal zone B cells, B1 cells, the innate response activator B cells (IRA), and aged-associate B cells (ABCs).
Materials and methods: Multiparemetric flow cytometry analyses were performed on samples from different lymphoid organs. BrdU uptake and adoptive transfers of sorted $19^+45R^{lo}Ly5.1^+$ cells on $Rag2\gamma^{-/-}$ mice were performed. PCR array experiments from cell cycle genes were performed on sorted samples. IL6, IL10, IL12 and GM-CSF were quantified by RT-qPCR, magnetic bead arrays, and intracellular flow cytometer cytokine detection. Constitutive phosphorylation of p-ERK was also determined by flow cytometry studies. TLRs ligand stimulation, BAFF/IL4 and T-dependent stimuli were used for *in vitro* activation of 19^+45R^{lo} cells.
Results: 19^+45R^{lo} cells are present in Peyer's Patches, peripheral blood and spleen but not in lymph nodes or thymus. In the spleen they appear from 7 days post-natal age and are minimally present in CBA/CaHN (btk-). In homeostatic conditions, 50% of 19^+45R^{lo} cells are labeled after *in vivo* 17-day continuous administration of BrdU.

Purified 19^+45R^{lo}Ly5.1+ cells transferred on Rag2$\gamma^{-/-}$ mice survived up to 40 days. PCR array experiments performed on sorted 19^+45R^{lo} cells compared to 19^+45R^+ and to peritoneal B1 cells, confirmed an active cell cycling signature of 19^+45R^{lo} cells. *In vitro* stimulation of sorted 19^+45R^{lo} cells with LPS, CpG, and BAFF/IL4 induced cell proliferation and IgG1/IgA secretion. IL10-transcripts were found in resting 19^+45R^{lo} cells that also released IL10 after activation with LPS and BAFF/IL4. Finally, constitutive p-ERK1/2 was present in 19^+45R^{lo} cells, reflecting a pre-activation stage.

Conclusions: We conclude that 19^+45R^{lo} cells represent a novel component of the innate adaptive immune system with unique features, responsible of rapid IgG- and IgA-humoral responses. Additionally, we propose that 19^+45R^{lo} cells may play a potential immunoregulatory role in the initial phases of the encounters with common pathogens.

Interaction between B-1 cell and B16 melanoma cell: a mutual increase in cell survival

M. F. L. Laurindo, F. G. Thies, A. F. Popi, R. R. Novaes e Brito, E. C. Perez & M. Mariano

UNIFESP, Microbiology Immunology and Parasitology, São Paulo, Brazil

Purpose/Objective: B-1 cells can be differentiated from B-2 cells because they are predominantly located in the peritoneal and pleural cavities and have distinct phenotypic patterns and activation properties. The role of both cell populations in cancer progression is still controversial. Previous work in our laboratory showed that physical interaction of B-1 cells with B16 cells *in vitro* leads to an increase in tumor cells metastatic potential. The aim of this study is to elucidate possible effects of this interaction on B-1 cells.

Materials and methods: Peritoneal B-1 cells were cultured alone or with B16 cells.B-1 cell survival and proliferation were evaluated by flow cytometry using propidium iodide and CFSE respectively. Considering that IL-10 is an autocrine growth factor that is used by B-1 cells to support their self renewal, we hypothesized that B-1/B16 cell interaction would increase the production of IL-10 by B-1 cells. The cytokine production was analysed by Th1/Th2/Th17 cytokines cytometric bead array (CBA) kit. Expression of STAT3, pSTAT3 and Bcl2 was assessed by Western Blot.

Results: B-1/B16 cells contact increased B-1 cells survival and proliferation *in vitro*. In order to clarify if contact between these two cell populations was necessary to increase B-1 cell survival; B-1 cells were cultivated on transwell which were placed on tumor cells or with B16-conditioned medium. In both conditions, it was observed an increment in B-1 cell survival. We also observed that after direct or indirect contact of B-1/B16 cells, B-1 cells became resistant to high dose of radiation. Analysis of cytokine secretion showed a strikingly increase in IL-10 production by B-1 cells after contact with B16 cells, associated with higher levels of STAT3 phosphorylation.

Conclusions: Our data clearly show that interaction of B-1 cells with melanoma cells, besides changing the tumoral lineage also affect B-1 cells, leading to both increased cell viability and rate of proliferation. Further, soluble factors that were secreted by B16 cells were sufficient to augment B-1 cell viability and IL-10 production. Impressively, after direct or indirect contact with the B16 cells, B-1 cells became resistant to radiation-induced cell death. Thus, future studies that assess the importance of concomitant immunity and other conventional therapies in cancer treatment are needed.

Interleukin-21-induced granzyme B-expressing B lymphocytes regulate T cells and infiltrate human solid tumors

S. Hofmann,* K. Dahlke,† K. Sontheimer,† M. Hagn,‡ C. Kaltenmeier,* T. F. E. Barth,§ T. Beyer,* F. Reister,¶ D. Fabricius, R. Lotfi,* O. Lunov,† G. U. Nienhaus,†† T. Simmet,† R. Kreienberg,¶ P. Möller,§ H. Schrezenmeier* & B. Jahrsdörfer***

**Institute of Clinical Transfusion Medicine and Immunogenetics, University of Ulm, Ulm, Germany, †Institute of Clinical Pharmacology, University of Ulm, Ulm, Germany, ‡Cancer Immunology Program, Peter MacCallum Cancer Centre, Melbourne, Vic., Australia, §Institute of Pathology, University of Ulm, Ulm, Germany, ¶Department of Gynecology and Obstetrics, University of Ulm, Ulm, Germany, **Department of Pediatrics, University of Ulm, Ulm, Germany, ††Karlsruhe Institute of Technology (KIT), University of Karlsruhe, Karlsruhe, Germany*

Purpose/Objective: B cells can exhibit potent regulatory functions. Conflicting data exist regarding the role of B cells in lymphocytic infiltrations of tumors. Here, we demonstrate, that granzyme B (GrB)-expressing B cells in adjacency to IL-21-providing T cells can be found in the tumor microenvironment of various solid tumors including breast, ovarian and cervical carcinomas. GrB-dependent regulation of T cell responses is known from both, regulatory T cells (T_{reg}) and plasmacytoid dendritic cells.

Materials and methods: Cell culture, FACS analysis, laser scanning confocal microscopy, Western blotting, histology.

Results: In the current study, we find that IL-21 induces human B cells to express high levels of GrB and to develop regulatory potential towards co-cultured T cells by GrB-dependent degradation of the T cell receptor z-chain. More detailed characterization of IL-21-induced GrB^+ B cells reveals a $CD19^+$ $CD38^+$ $CD1d^+$ $CD147^+$ phenotype and expression of further regulatory molecules including IL-10, IDO and CD25. Of note, $CD5^+$ B cells exhibit a significantly higher potential to express GrB than $CD5^-$ B cells, and GrB induction is accompanied by activation of both B cell receptor- and Toll-like receptor-associated signaling pathways.

Conclusions: In summary, we demonstrate for the first time, that IL-21 induces GrB-expressing regulatory B cells, which can be detected in the microenvironment of solid tumors and which may contribute to the modulation of cellular adaptive immune responses by T_{reg}-like mechanisms. Our findings may provide the basis for the development of novel diagnostic and cell therapeutic approaches to the management of malignant, autoimmune and graft-versus-host pathologies.

P0456

Interleukin-33 mediates activation and proliferation of effector and regulatory B cells

S. Sattler,* L. Hussaarts,† G. S. Ling,* A. Romaine,* D. Xu,‡ F. Y. Liew‡ & F. P. Huang*

**Department of Medicine, Imperial College, London, UK, †Department of Parasitology, Leiden University Medical Centre, Leiden, The Netherlands, ‡Division of Immunology Infection and Inflammation, University of Glasgow, Glasgow, UK*

Purpose/Objective: IL-33 is a novel IL-1 family cytokine with seemingly contrasting pro- and anti-inflammatory properties. Different types of immune cells express the IL-33 receptor ST2 and therefore can respond to IL-33 to initiate and regulate immune responses. Importantly, IL-33 has also been implicated in a wide range of inflammatory conditions such as allergic, autoimmune and cardiovascular diseases.

In the past, many IL-33 related studies have been performed using recombinant human IL-33 in murine systems. We have observed previously that human IL-33 induces CD25 expression and IL-10 production in murine B cells. During this work we aimed to further

characterize the potential pro- and anti-inflammatory properties of murine IL-33 on the activation and function of B cells.
Materials and methods: *In vivo* and *in vitro* B cell activation in response to IL-33 stimulation was studied by analyzing B cell functional markers by flow cytometry. IL-33 mediated B cell proliferation was investigated by CFSE dilution and thymidine uptake experiments.
Results: We report here that, although the murine cytokine is as expected significantly more potent, both human and mouse IL-33 induce B cell CD25 and IL-10 expression. The effect on B cell activation is largely independent of the genetic background of the mouse models tested. Interestingly however, mice of different backgrounds show significant differences in the IL-33 induced IL-10 production by B cells. We also found that IL-33 induces proliferation of splenic CD19+ B cells as well as upregulation of ST2 expression on their surface, suggesting that IL-33 may act on B cells directly. However, our findings from further *in vitro* experiments using isolated splenic B cells indicate that an indirect effect of IL-33 is also involved in driving the B cell responses. In addition, IL-33 induces upregulation of the low-affinity Fc receptor for IgE, CD23, as well as the costimulatory molecule CD86 on B cells.
Conclusions: Considering the diverse and crucial roles of B cells in both Th1 and Th2 immune responses, this work adds valuable information to our understanding of the immunological effects mediated by the novel cytokine IL-33.

P0457
Long-lasting and protective IgM antibody responses against Salmonella typhi

C. Perez-Shibayama,* C. Gil-Cruz,* L. Cervantes-Barragan,† R. Pastelin-Palacios,‡ E. Hisaki,§ Q. Chai,* A. Isibasi,¶ C. Lopez-Macias¶ & B. Ludewig*
**Kantonal Hospital St. Gallen, Institutte of Immunobiology, St Gallen, Switzerland, †Deparment of Pathology and Immunology, Washington University School of Medicine, St Louis, MO, USA, ‡Deparment of Biology, Faculty of Chemisty UNAM, Mexico City, Mexico, §National School on Biological Sciences IPN, Immunology, Mexico city, Mexico, ¶Mexican Social Security Institute IMSS, Medical Research Unit on Immunochemistry, Mexico city, Mexico*

Purpose/Objective: IgM antibodies can efficiently clear bacterial infections through the activation of the classical complement pathway. However very little is known about the mechanisms that govern the generation of long-lasting IgM. *S. typhi* porins are a candidate sub-unit vaccine that induces protective antibody responses. Here, we studied the mechanisms by which *S. typhi* porins induce a sustained IgM antibody response and the role of these antibodies in the protection against infection with *S. typhi*..
Materials and methods: Porins-specfic IgM antibodies were measured by ELISA and antibody-secreting cells were enumerated by ELISpot analysis. CD4 T cell responses were assessed following *in vivo* re-stimulation using intracellular cytokine staining. Porins-specific IgM hybridomas were generated and monoclonal antibodies used for *in vivo* protection assays.
Results: Boostered immunization with porins induced long-lasting, T helper cell-dependent IgM responses. Marginal zone B cell contributed to the first wave of IgM production after primary immunization, whereas a $CD4^+$ T cell-dependent germinal center reaction generated long-lasting memory B cells of the IgM type following booster immunization. Importantly, transfer of porins-specific IgM monoclonal antibodies protected mice from challenge with *S. typhi*.
Conclusions: In conclusion, long-lasting IgM memory B cell responses against porins represent an important layer of antibacterial protection against *S. typhi* infection.

P0459
Marginal zone B cells in autoimmune arthritis

A. K. E. Palm & S. Kleinau
Uppsala University, Cell and molecular biology, Uppsala, Sweden

Purpose/Objective: Breakage of self-tolerance and induction of autoimmune arthritis is achieved in susceptible strains of mice by immunization with bovine (B) collagen type II (CII) in Freund's complete adjuvant (FCA). We have recently shown that naturally BCII-reactive marginal zone B cells (MZB) in the spleen expand rapidly following this immunization. Here we have investigated when and where true autoreactive B cells to murine (M) CII in relationship to BCII develop in collagen-induced arthritis (CIA), with emphasis on the MZB population.
Materials and methods: Cell suspensions were prepared from the spleen and peripheral lymph nodes from DBA/1 mice at different time points after BCII immunization. Mice immunized with ovalbumin (OVA) in FCA or FCA only served as controls. The B cell response was analyzed by flow cytometry and ELISpot. Serum was analyzed for antigen specific antibodies in ELISA.
Results: We show here that the initial autoimmune B cell response to MCII is induced and mediated by MZB in the spleen. The response is comparable to that towards BCII. One week later a B cell response to MCII appears in the lymph nodes. Notably, a small MZB-like population in the lymph nodes expand almost twofold after immunization with BCII but not with OVA or FCA. These cells are defined as $B220^{pos}CD23^{low}CD1d^{high}$ and are distinguishable from follicular B cells (FOB). The MZB-like cells are also $CD80^{high}Fc\gamma RIIb^{high}$ $MHCII^{low}$in contrast to FOB. IgM antibodies to MCII are found in serum a few days after BCII immunization with initially less titres than to BCII. In contrast, IgG antibodies to MCII are detectable at higher titres than to BCII about 2 weeks after immunization.
Conclusions: MZB trigger the autoimmune response in CIA. The autoreative B cell response in the lymph nodes develops later, involving FOB and the generation of IgG antibodies. The expansion of a MZB-like population in the lymph nodes is specific for the autoimmune reaction and may be of importance for the pathogenesis of CIA. However, the question remains whether these MZB-like cells have migrated from the spleen and whether they are CII-specific.

P0460
Oral immunization with T dependent antigen gives lifelong IgA immunity with long-lived plasma cells and memory B cells distinct the ones formed after systemic immunization

M. Bemark,* P. Bergqvist,* A. Stensson,* L. Hazanov,† R. Komban,* R. Mehr† & N. Y. Lycke*
**Microbiology and Immunology, University of Gothenburg, Gothenburg, Sweden, †Bar-Ilan University, Faculty of life science, Ramat Gan, Israel*

Purpose/Objective: There is a discrepancy in the literature with regard to if mucosal immunization leads to long-term protection and development of memory. We reasoned that this could reflect differences between T dependent and independent responses and devised a system to address the response to a T dependent oral antigen.
Materials and methods: A strictly T cell dependent oral antigen was created by conjugating the hapten NP to the T dependent mucosal antigen cholera toxin to create NP-CT that was used for oral immunizations in mice.
Results: Repeated oral immunization resulted in strong antigen-specific IgA responses, with up to 15% of the gut plasma cells being NP-specific. Transfer of NP-specific GFP-labelled B cells prior to immunization demonstrated that the response was initiated in stomach-proximal Peyer's patches (PP) through invasion of pre-existing germinal centres (GC), then spread to more distal PP and finally to MLN and spleen. The presence of clonally related sequences

in different organs and between PP indicated that activated B cells could travel between germinal centres, a notion that was further strengthened by that transferred GC B cells could invade PP GC after iv transfer if antigen was present. Oral immunization with NP-CT resulted in secretion of specific IgA into the gut and IgA and IgG in serum for more than 2 years. A strong boost response 1 year after immunization demonstrated that memory B cells had formed. Transfer of GFP+ NP-specific B cells prior to immunization resulted in traceable long-lived class-switched memory B cells that expressed CD73, CD80 and CD273 and were situated in B cell follicles in PP, MLN and spleen. Oral priming followed by systemic challenge resulted in a strong response with rapid formation of plasma cells in the small intestinal mucosa, spleen and bone marrow, while systemic immunization followed by oral challenge did not generate any response. A difference in memory B cells formed after oral and systemic responses was further demonstrated in transfer experiment, where PP, and to lesser extent MLN, memory B cells preferentially produced IgA and spleen ones IgG in recipient mice.

Conclusions: We conclude that oral immunization with a T dependent antigen generates life-long immunity with long-lived plasma cells and memory B cells, and that there are distinctions between memory B cells formed after oral and systemic immunization.

P0462

Pro- and anti-inflammatory plasma cells can be distinguished by the expression level of sialyltransferase regulating IgG sialylation

M. Ehlers,* A. Winkler,† C. Hess† & V. Holecska†

**Institute for Systemic Inflammation Research, University of Luebeck, Luebeck, Germany, †German Rheumatism Research Center, Laboratory of Tolerance and Autoimmunity, Berlin, Germany*

Purpose/Objective: The Fc glycosylation pattern determines the pro- or anti-inflammatory effector function of IgG antibodies, whereby sialylated IgGs are anti-inflammatory. However, how differentially glycosylated IgG antibodies develop is unknown. We sought to examine the Fc glycosylation of antigen-specific IgG molecules and plasma cells (PC) after induction of inflammation or tolerance.

Materials and methods: We administered chicken ovalbumin (OVA) under inflammatory or tolerance conditions to mice and analyzed OVA-reactive IgG Fc glycosylation and the expression level of the alpha 2, 6 sialyltransferase in OVA-reactive PCs.

Results: Stimulation with protein antigens under inflammatory conditions induces PCs expressing low levels of alpha 2,6-sialyltransferase and producing de-sialylated IgGs. In contrast, PCs induced upon tolerance failed to downregulate alpha 2,6-sialyltransferase expression and secreted immunosuppressive sialylated IgGs.

Conclusions: Our data show a novel antigen-specific immunoregulatory mechanism mediated by PCs expressing high levels of alpha 2,6 sialyltransferase and producing anti-inflammatory sialylated IgGs that are formed upon tolerance induction. Thus, pro- and anti-inflammatory PCs can be distinguished by the expression level of alpha 2,6 sialyltransferase.

P0463

Profiling B cell responses toward bacterial pathogens in human tonsils

E. Faenzi,* F. Buricchi,* E. Viciani,† A. Manetti,† M. Barocchi,† G. Galli,* F. Castellino,* G. Del Giudice* & O. Finco*

**Novartis Vaccines and Diagnostics, Research Translational Medicine, Siena, Italy, †Novartis Vaccines and Diagnostics, Research Microbial Molecular biology, Siena, Italy*

Purpose/Objective: The first contact between microorganisms and the human host takes place at the mucosal sites, in particular the upper respiratory tract and oro-pharyngeal mucosa. Data currently available on primary and recall B cell response in nasopharyngeal-associated mucosa are limited, due to the fact that more frequently the immune memory response to a pathogen or a vaccine is analyzed in PBMC isolated from peripheral blood. Therefore, the understanding of the mechanisms underlying the effector and memory response at the site of host-pathogen interaction is of great interest in the vaccine field.

The aim of the present study was to evaluate effector and memory B cells from palatine tonsils of patients that underwent surgery due to recurrent tonsillitis (RT) or obstructive sleep apnea syndrome (OSAS) by ELISpot assay.

Materials and methods: In order to avoid high background signal due to hyper-activated condition of B cells in tonsils, we have developed an *ad-hoc* protocol to enumerate simultaneously IgG and IgA antigen-specific B cells. The optimized protocol was applied to enumerate IgG+ and IgA+ plasmacells (PC) and memory B cells (MBC) specific for selected antigens of *S.aureus*, *S.pneumoniae* and Group A streptococcus.

Results: Frequencies of plasmacells and MBC were calculated as percentages of total IgG/IgA positive B cells in tonsils of 41 subjects aged from 4 to 42. Microbiologic culture data from tonsil swabs were also available for each analyzed sample.

Conclusions: We investigated if there were any differences in the antigen recognition profile between plasmacells and MBC of the same tonsil and tried to define a relationship between microbiological data and the pattern of the B cell response in tonsils.

P0464

Reassessment of immunoglobulin joining-chain expression during B cell development: an early marker of plasma cell differentiation in germinal centers

F. Lechouane, Z. Oruc, V. Pascal, M. Cogné & C. Sirac

Centre National de la Recherche Scientifique UMR 7276, Contrôle de la réponse immune B et des lymphoprolifération, Limoges, France

Purpose/Objective: Immunoglobulin Joining (IgJ)-chain is a 15 kDa peptide expressed by antibody secreting cells and required for assembly of pentameric IgM and dimeric IgA. It is required for the transport of these polymeric immunoglobulins (pIg) to the mucosal surface. Despite this definite role, it still remains controversial to what extent plasma cells producing monomeric Ig isotypes also express this peptide. Likewise, the exact stage of IgJ-chain production during B cell differentiation into plasma cell is not clearly defined.

Materials and methods: To address this issue, we created a trangenic murine lineage that express the GFP under the control of the well-defined murine *IgJ* gene enhancer/promoter. This model allows us to follow IgJ-chain expression during *in vivo* and *in vitro* differentiation of B cells into plasma cells.

Results: We found that all plasma cells express a high level of GFP in every lymphoid organ observed including spleen and bone marrow. We confirmed that GFP positive cells also expressed IgJ protein. Interestingly, we detected a B cell subpopulation that express a lower level of IgJ-chain (GFP^{int} cells) in secondary lymphoid organs. Flow cytometry, immunohistochemistry and transcriptional analyses showed that these cells consisted in a large proportion of germinal center (GC) cells. However, Pax5 appeared to be slightly decreased in these GFP^{int} cells compared to resting B cells, while Prdm1 and Xbp1 expression are unchanged. *In vitro* stimulation of spleen B cells with LPS confirmed the expression of IgJ-chain in all $CD138^+$ plasmablasts but also revealed a population of $CD138^-/GFP^+$ activated B cells. ELISPOT experiments performed on these IgJ-chain expressing B-cells indicates these cells secreted larger amount of Ig than their IgJ-negative counterpart.

Conclusions: At first, this IgJ-GFP model is a reliable tool for PC tracking. Secondly, our results indicate that IgJ is already produced in

B-cells that seem to be pre-committed in the PC differentiation. Characterizing more precisely the features of this population would allow us to better understand early events of PC differentiation.

P0465

Regulatory B cells can modulate maturation and function of human dendritic cells and are partially defective in systemic lupus erythematosus

C. Jamin,* A. Morva,* A. Achour,* S. Lemoine,* A. Saraux,† P. Youinou* & J. O. Pers*
**Brest University Medical School Hospital, Immunology, Brest, France,*
†*Brest University Medical School Hospital, Rheumatology, Brest, France*

Purpose/Objective: Mature dendritic cells (DCs) are stimulators of T-cell immune response, whereas immature DCs support T-cell tolerance. It has been demonstrated that murine B cells can hinder the inflammatory response by inhibition of IL-12 production by DCs. The current study was aimed at determining the regulatory capacity of human B cells on DC maturation and function.
Materials and methods: Peripheral blood monocytes from six healthy donors (HDs) and six systemic lupus erythematosus (SLE) patients were differentiated into immature DCs with GM-CSF and IL-4, and into or mature DCs with LPS and IFNγ. B lymphocytes were activated by CD40 and TLR9 and cultured with DCs. Expression of HLA-DR, CD80, CD86 and IL-12 by the DCs were evaluated by flow cytometry. The DC-dependent proliferation of CFSE-labelled T cells was also evaluated in the presence of B lymphocytes. Phenotypic analyses of B cells and inhibitory experiments were performed in co-cultures.
Results: Activated B lymphocytes restrained the development of monocytes into immature DCs and their differentiation into mature DCs. They decreased the density of HLA-DR from mature DCs, the expression of CD80, CD86, and also the production of IL-12 Furthermore, they inhibited the DC-induced T cell proliferation. These modulations were mediated by $CD19^{+}IgD^{low}CD38^{+}$ $CD24^{low}CD27^{-}$ B lymphocytes and needed CD62L for the control of CD80 and CD86, and a soluble factor for the control of IL-12. Mature SLE DCs were insensitive to the regulation of IL-12.
Conclusions: Human B cells can regulate DC maturation and function and consequently T cell-dependent inflammatory response. This regulation is partially deficient in SLE due to refratory DCs. This may influence inappropriate balance in SLE between effector inflammatory response and tolerance induction.

P0466

Regulatory role of B-1 cells in streptozotocin-induced diabetes in mice

A. M. Alvares, M. C. T. Novo, A. F. Popi & M. Mariano
Federal University of Sao Paulo, Microbiology Immunology and Parasitology, São Paulo, Brazil

Purpose/Objective: Recently, an important role of B cells in promoting type 1 diabetes has been demonstrated. Concomitantly, it has also been shown that B-1a cells, a subtype of B lymphocytes, can be involved in various autoimmune diseases. Based on these data, this study aims to investigate the involvement of B-1 cells in the development of murine streptozotocin (STZ)-induced diabetes.
Materials and methods: BALB/c and BALB/*xid* (B-1 cell-deficient mice) male mice strains were treated intra-peritoneally with STZ (40 mg/kg) for 5 days. It is important to note that BALB/c mice do not develop diabetes when this dose of STZ was used. Blood glucose levels (BGL), cellular profile in the peritoneal cavity and cellular pancreatic islet infiltration were evaluated in experimental and control animals by flow cytometry. Further, pancreas were processed and analyzed histologically or immunohistochemically for insulin expression.
Results: Our findings showed that BALB/*xid* mice become diabetic after STZ treatment with BGL higher than BALB/c control mice ($P < 0.001$). Corroborating this data, the amount of insulin labeled beta cells of STZ-treated BALB/*xid* mice was always lower than control groups. Surprisingly, B-2 population increase in the peritoneal cavity of STZ-treated mice 10 days after treatment ($P < 0.001$) while $CD4^{+}$ T cells increase only in BALB/*xid* diabetic mice ($P < 0.01$). Histological analysis showed lower number of pancreatic islets in diabetic mice (BALB/*xid*) as compared with pancreas in BALB/c mice. Additionally, the cellular evaluation of pancreas showed infiltrating T cells in these mice. To evaluate the role of B-1 cells in diabetes induction, peritoneal B-1 cells obtained from BALB/c mice were purified based on expression of $CD19^{+}$ $CD23^{-}$ by FACSAriaII Cell Sorter and adoptively transferred intra-peritoneally to BALB/*xid* mice before or after the STZ treatment. BALB/*xid* mice adoptively transferred were not diabetic after STZ-treatment and B-1 cells were observed infiltrating pancreatic islets 2 days after STZ treatment.
Conclusions: Our data demonstrate that B-1 cell-deficient mice showed higher reactivity to STZ treatment with more severe symptoms, intensive pancreas damage, insulin deficiency and high BGL. In addition, B and T cells increase in peritoneal cavity of BALB/*xid* STZ-treated mice while B-1 cells migrate to pancreatic islets of non diabetic mice.

P0467

Revealing the role of Akt

E. Cox, N. Hövelmeyer & A. Waisman
University Medical Center of the Johannes Gutenberg-University, Institut for Moleculare Medicine, Mainz, Germany

Purpose/Objective: The serine/threonine kinase Akt is expressed in three isoforms (Akt1, Akt2 and Akt3) which share a similar structure and analogue functions. Using distinct downstream pathways they regulate cellular metabolism, cell survival and proliferation, being important for peripheral B-cell maturation and early stages of T cell development. In B cells Akt is a critical check point in different phases of proliferation and differentiation. Especially the generation of marginal zone and B1 B cells depends on Akt1 and Akt2. In this study we investigated in more detail the role of Akt in B cell development and maturation.
Materials and methods: T. Wunderlich created a mouse allowing for the expression of an N-terminally myristoylated murine AKT carrying in addition a C-terminally attached Myc TAG (ROSA-AKT-C) in cell types that express the Cre recombinase (unpublished). The myristoylation signal recruits AKT-C to the plasma membrane where AKT becomes phospho-activated. This mouse was crossed to CD19 Cre mice leading to a B cell specific overexpression of Akt (AKT^{BOE}). For FACS analysis of $Akt^{BOE}$and CD19 Cre control mice we isolated cells from bone marrow, spleen, lymphnodes, mesenteric lymphnodes, as well as cells from the peritoneal cavity and Peyer's patches. Furthermore, we used CD19-sorted B cells for functional survival and proliferation assays.
Results: Akt^{BOE} mice displayed a spleenomegaly accompanied by enlarged lymph nodes compared to control mice. FACS analysis of bone marrow showed a reduction of re-circulating B cells while immature B cells were not affected. In the spleen we found a loss of CD23 expression by B cells. Further, we found increased absolute numbers of B and T cells and more neutrophiles, monocytes and mature macrophages in the spleen. Finally, the investigation of immunoglobulin titers by ELISA revealed reduced IgM, IgG1 and IgG3 serum levels.
Conclusions: The B cell specific overexpression of Akt underlines its importance in B cell maturation and homeostasis.CD23 serves as a

lymphoma-marker because of its differential expression on various types of lymphoma. The fact that Akt^{BOE} mice have almost no CD23 expression on B cells hinds towards some kind of lymphoma in these mice.

P0468

Ro52- and Ro60-specific B cell pattern in the salivary glands of patients with primary Sjögren's syndrome

L. A. Aqrawi,* K. Skarstein,† G. Øijordsbakken† & K. Brokstad*
**The Gade Institute, Broegelmann Research Laboratory, Bergen, Norway,*
†*The Gade Institute, Section for pathology, Bergen, Norway*

Purpose/Objective: Primary Sjögren's syndrome (pSS) is characterised by the presence of autoantibodies against the ribonucleoprotein (RNP) particles Ro/SSA and La/SS-B, and mononuclear cell infiltration of exocrine tissues, especially salivary and lachrymal glands. Low numbers of autoantigen-specific memory B cells and elevated levels of plasma cells have previously been detected in the peripheral blood (PB) of pSS patients compared to controls[1)]. Since both Ro52 and Ro60-specific cells have been detected in the salivary glands (SG) of pSS patients, we aimed to characterise the SSA-specific B cell pattern in SG biopsies.
Materials and methods: A series of double immunohistochemical stainings were performed on paraffin-embedded tissue from 10 well-characterised pSS patients for each Ro52 and Ro60 along with CD19, CD20, CD27, or CD5, respectively.
Results: Ro52 and Ro60-specific cells detected in SG tissue were found to be CD19+ B cells located outside the CD19+/CD20+ B cell zones (BCZ) and also interstitially. These SSA-specific cells were also quantified. No SSA-specific cells were observed within the CD20+ BCZ. Hence, no SSA-specific memory B cells were detected in these individuals. Contrary to this, SSA-specific cells were found to be CD19+/CD27++, demonstrating that they are differentiating short or long-lived plasma cells. Also, no SSA-specific cells were CD5+, indicating that they do not belong to the B-1 B cell subset.
Conclusions: Together our findings suggest that these lower levels of SSA-specific memory B cells in PB and absence of SSA-specific memory B cells in SG of pSS patients could be resulting from activation of these cells into plasma cells at the site of inflammation.

Sustained B-cell receptor signaling prevents B cell terminal differentiation into plasma cells

F. Lechouane,* A. Bonaud,* L. Delpy,* S. Casola, † Z. Oruc,* G. Chemin,* M. Cogné* & C. Sirac*
**CNRS UMR7276, Immunology, Limoges, France,* †*IFOM, The FIRC Institute of Molecular Oncology Foundation, Milan, Italy*

Purpose/Objective: B-cell terminal differentiation into antibody secreting plasma cells (PC) features a transcriptional shift driven by the activation of plasma cell lineage determinants. Little is known about the signals inducing this change in transcriptional networks and the role of the B Cell Receptor (BCR) in terminal differentiation remains especially controversial.
Materials and methods: We used immunoglobulin light chain transgenic mice expressing suboptimal surface BCR levels and LMP2A knock-in animals with defined BCR-like signal strengths to explore the influence of BCR signaling in terminal differentiation independently of cognate antigens.
Results: We observed a strong increase of PC numbers both *in vivo* and *in vitro* upon weak, antigen-independent constitutive BCR signaling. The PI3K/Akt pathway appears to be involved in this exacerbated terminal differentiation. Interestingly, in our models, terminal differentiation occurs independently of antigen trigerring, germinal center formation or T-cell help yet giving rise to long-lived PC in spleen. In striking contrast, strong constitutive BCR signaling, mimicking chronic contact with cognate antigen, completely prevented both *in vitro* and *in vivo* PC differentiation.

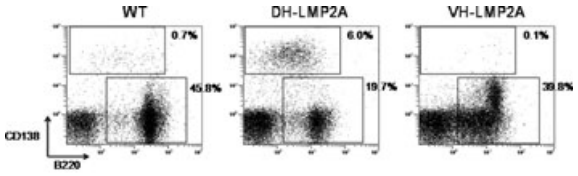

Figure 1. Plasma cell development in BCR-negative LMP2A mice models. DH-LMP2A mice display a weak BCR-like signal while VH-LMP2A display a strong constitutive signal. Spleen cells from 8 weeks old mice were analysed.

Conclusions: We demonstrated an inverse correlation between BCR signal strength and PC development. These findings provide new insights onto the role of the BCR in PC differentiation and point to the need to resolve BCR signaling to guarantee terminal differentiation.

P0471

Syk is required in B cells for effective antibody responses

J. Ackermann, J. Nys, E. Schweighoffer & V. Tybulewicz
MRC National Institute for Medical Research, Immune Cell Biology, London, UK

Purpose/Objective: Spleen tyrosine kinase (Syk), a pivotal kinase in B cell signalling, is recruited to phosphorylated tyrosines in immunoreceptor tyrosine-based activation motifs (ITAMs) after stimulation of the B cell receptor. Binding to these motifs leads to phosphorylation of Syk and subsequent activation of important downstream signalling molecules. Syk-deficient mice have no mature B cells due to a complete block in B cell development at the immature stage. To study immune responses of Syk-deficient primary B cells, we used a mouse model, which allows inducible deletion of Syk.
Materials and methods: To achieve inducible deletion of Syk in mature B cells, we used mice, carrying Cre recombinase fused to two mutated oestrogen receptors and a floxed allele of the S*yk* gene together with either a wildtyp or a knockout allele of the *syk* gene. These mice were treated with tamoxifen to induce Syk deletion. Immune responses and B cell activation in these mice were analysed *in vivo* and *in vitro*.
Results: B cell numbers drop after inducible Syk deletion, but a significant proportion of Syk-deficient B cells survives on a long time scale. We showed that Syk-defcient B cells are unresponsive to BCR stimulation and less responsive to stimulation of TLR recptors. Mice with Syk-deficient B cells had reduced titers of immunoglobulin after immunization with thymus-dependent or thymus-independent antigens. In addition mice with Syk-deficient B cells show strongly impaired germinal centre formation.
Conclusions: A long-lived B cell population remains after deletion of Syk. These cells appear to be impaired in responding to BCR and TLR stimulation and have impaired abilities to form germinal centre B cells.

P0472

The deubiquitinases A20 and CYLD do not share overlapping functions during B cell differentiation and activation

Y. Chu,* V. Soberon,* R. Beyaert,† R. Massoumi,‡ G. van Loo† & M. Schmidt-Supprian*

Max Planck Institute of Biochemistry, Molecular Medicine, Martinsried, Germany, †Department for Molecular Biomedical Research, Ghent University, Ghent, Belgium, ‡Department of Laboratory Medicine, Lund University, Malmoe, Sweden

Purpose/Objective: The deubiquitinases TNFAIP3/A20 and CYLD are critical negative regulators of signaling events leading to the activation of NF-κB transcription factors. They share similar mechanisms by removing non-degradative K63-linked polyubiquitin chains from an overlapping set of substrates. Loss of A20 in B cells results in impaired immune homeostasis, chronic inflammation and autoimmunity. In contrast, the consequences of CYLD-deficiency in B cells are controversial, ranging from an absence of effects to dramatic B cell hyperplasia. These differences could be due to varying compensation by A20. The aim of this study is to address a potential redundancy between A20 and CYLD in B cells.

Materials and methods: We generated mice lacking both A20 and CYLD in B cells and studied B cell differentiation in these mice. In addition, we investigated the responses of the A20/CYLD-deficient B cells to different B cell mitogens by measuring the activation status, proliferation and cytokine production *in vitro*.

Results: The combined loss of A20 and CYLD did not exacerbate the developmental defects of A20-deficiency in B cells. In addition, loss of both A20 and CYLD did not have additive effects on B cell activation, proliferation and the NF-κB-dependant production of the proinflammatory cytokine IL-6.

Conclusions: We concluded from this study that the lack of phenotypic effects in CYLD-deficient mice is not due to compensation by A20 but that A20 and CYLD do not functionally cooperate during B cell differentiation and activation.

P0473

The *in vivo* role of Blimp-1 SUMOylation in B Cell Development

C. Reichhold,* B. Tirosh† & A. Waisman*

Institute for Molecular Medicine, University Medical Center Johannes Gutenberg University Mainz, Mainz, Germany, †Faculty of Medicine Pharmacologyute for Molecular Medicine, Hebrew University, Jerusalem, Israel

Purpose/Objective: Recent *in vitro* studies have shown the importance of SUMOylation (a ubiquitin-like posttranslational modification) on lymphocyte development, in particular early lymphocyte and Plasma cell (PC) development. PC development and differentiation is controlled by BLIMP-1, a transcriptional repressor that is necessary and sufficient to allow B cells to differentiate into antibody secreting cells. The study presented here uses a B cell specific Sentrin protease 1 (SENP1, a deSUMOylation protease) conditional knockout mouse model to investigate the influence of SUMOylation on lymphocyte development, mainly focusing on BLIMP-1 dependent PC development.

Materials and methods: The role of BLIMP-1 SUMOylation was investigated in SENP1 conditional knockout mice crossed to CD19-Cre and AID-Cre lines, therefore lacking SENP1 from early B cell developmental stage and following the germinal center reaction, respectively. Different B cell subsets were analyzed by flow cytometry, quantitative real time-PCR and Western blot. Sheep red blood cells were used for *in vivo* stimulation whereas Lipopolysaccharide and IL-4 was used for *ex vivo* stimulation.

Results: We discovered that BLIMP-1 undergoes a reversible modification with SUMO-1, which facilitates BLIMP-1 turnover and proteasomal degradation. Increase in SENP1 activity stabilized BLIMP-1, while a decrease promoted its degradation. This data indicates that SUMOylation of BLIMP-1 regulates its intracellular stability. In *in vivo* experiments we can show an impairment of B cell development due to a decreased amount of total B cells in these mice. Furthermore, in naïve mice, we observe increased numbers of immature B cells in spleen and lymph nodes and of germinal center B cells in Peyer's patches, as well as in spleens of sheep red blood cell immunized mice. We could also show *ex vivo* an impaired ability of B cell survival after Lipopolysaccharide (LPS) and IL-4 stimulation.

Conclusions: This study shows a direct influence of posttranslational SUMOylation on B cell development in an *in vivo* mouse model. In our preliminary data the elevated germinal center B cell numbers underline the influence of SUMOylation on BLIMP-1 activity, as impaired SUMOylation of BLIMP-1 leads to its degradation and therefore an absence of termination of the germinal center reaction.

P0474

The kinetics of a memory B cell response to virus like particles in mice

F. Zabel,* D. Mohanan,* A. Link,† J. Bessa,‡ P. Saudan,§ T. M. Kuendig* & M. F. Bachmann*

Department of Dermatology, University Hospital Zurich, Zurich, Switzerland, †Molecular Partners AG, Immunology, Zurich, Switzerland, ‡Roche AG, Research, Zurich, Switzerland, §Cytos Biotechnology AG, VP Research, Zurich, Switzerland

Purpose/Objective: Vaccine-induced specific antibodies are usually responsible for protection against infection. The most common protective mechanism of antibodies is binding to pathogens which neutralizes their infectious potential and enhances their elimination by phagocytes. The most potent antibodies are produced by B cells which have undergone a germinal centre reaction. Within germinal centres, the BCRs of the specific B cells switch from IgM to IgG and hypermutate by the insertion of point mutations in their variable regions. Upon hypermutation, B cells are selected through iterative cycles of best fit for the antigen by follicular dendritic cells (FDC) and follicular T helper cells. While the GC reaction is usually relatively short-lived and ends a few months after elimination of the pathogen, memory B cells persist in the host for very long time-periods and may rapidly respond upon re-encounter of the antigen. In contrast to the well understood differentiation of naïve B cells into memory and/or plasma cells, relatively little is known about the fate of memory B cells upon re-exposure to antigen. Since classical vaccines often only induce protective antibodies after several injections, it is important to understand how triggering of memory B cells may affect the development of high affinity and long lasting antibody responses.

In this study we followed the kinetics of the specific memory B cell response in terms of antibody production and frequencies of specific B cells.

Materials and methods: To address this question, we used virus-like particles derived from the bacteriophage Qβ, which are highly immunogenic due to their repetitive structure. To trace memory B cells, congenic Ly5.1+ C57BL/6 mice were immunized with Qβ, splenic memory B cells were isolated and transferred intravenously into naïve Ly5.2+ C57BL/6. Twenty-four hours later recipient mice were challenged with Qβ.

Results: Transferred memory B cells homed the spleen. Although they did not proliferate as much as naïve B cells after immunization they differentiated more quickly into plasma cells and secreted more antibodies. The number of plasma cells found in spleen is similar in a primary and memory response. However, a higher number of plasma cells were found in the bone marrow, the main source of humoral immunity, after transfer of memory B cells.

Conclusions: Memory B cells respond to antigen by rapid differentiation into plasma cells rather than extensive proliferation. The induced plasma cells preferentially home to the bone marrow and produce larger amounts of antibodies than plasma cells derived from naïve cells.

P0475
The lymphoid/myeloid potential of B-1 cells is sustained by WNT/beta catenin pathway

M. C. T. Novo & A. F. Popi
UNIFESP, MIcrobiology Immunology and Parasitology, São Paulo, Brazil

Purpose/Objective: The Wnt/beta-catenin signaling pathway has been shown to play an important role in controlling the proliferation, survival, and differentiation of hematopoietic cells. Several Wnt/β-catenin signaling components substantially influence hematopoietic cell fate. We have shown that B-1 cells are self-renewing cells and spontaneously express both myeloid and lymphoid restricted transcription factors. B-1 lymphocytes play a major role in autoimmunity and are related to CD5+ B-cell lymphomas and leukemias, such as CLL (chronic lymphatic leukemia). Previously, we have shown that this pathway influences B-1 cell proliferation *in vitro*. Considering that Wnt/beta-catenin signaling network as a critically important regulator of hematopoiesis, we have investigated the effect of quercetin, a classical Wnt inhibitor, on B-1 cells hematopoietic lineage-restricted genes expression.
Materials and methods: Peritoneal B-1 cells were obtained and cultivated as described by Popi *et al.* (*Immunology* 2009;126(1): 114–22). Treatment of B-1 cells with the Wnt inhibitor quercetin induced an inactivation of the Wnt pathway and suppressed cell proliferation. Herein we have analyzed the effect of Wnt inhibition on the expression of lymphoid and myeloid genes by B-1 cells by real time PCR.
Results: We have demonstrated that Wnt/beta-catenin signaling is inhibited by quercetin treatment of B-1 cells *in vitro*. Wnt pathway inhibition by quercetin induces silencing in Pax-5 and CD19 expression by B-1 cells. However, expression of myeloid associated genes by B-1 cells is still observed after quercetin treatment.
Conclusions: Inhibition of Wnt pathway interferes with the commitment of B-1 cells to B-cell lineage, suggesting that Wnt pathway plays an important role during B-1 cell differentiation. Considering that quercetin could inhibit leukemic cell growth without suppressing normal hematopoiesis, the role of Wnt pathway on B-1 cell proliferation and differentiation could be closely related to their ability to generated leukemic cells. Based on this, B-1 cells could be considered an *in vitro* model to study the molecular networks that orchestrate the transformation of cancer stem cell.

P0476
The role of B lymphocytes in alpha-1-antitrypsin mediated allogeneic allograft protection

M. Mizrahi, P. Cal, D. Ochayon, G. Shahaf & E. C. Lewis
Ben-Gurion university, clinical bichemistry, Beer sheva, Israel

Purpose/Objective: Type-1 diabetes (T1D) is characterized by immune-mediated islet beta cell destruction. Islet transplantation restores normoglycemia and is considered for clinical implementation in T1D patients. There is evidence for B lymphocyte involvement in T1D as well as in islet allograft rejection. However, a protective role for B cells is suggested by the occurrence of islet allograft rejection in B cell-knockout mice. Alpha-1-antitrypsin (AAT) is an anti-inflammatory circulating protein that promotes tolerance towards islet allografts and prevents diabetes in non-obese diabetic (NOD) mice in a yet unknown mechanism. Aim: To characterize the effect of AAT on B lymphocyte responses in the context of allogeneic islet transplantation.
Materials and methods: Spleen-derived B lymphocytes were studied. B cell activation-related responses and expression of B cell activating factor (BAFF) receptor were determined under stimulatory conditions in the presence or absence of human AAT (hAAT, 0.5 mg/ml). *In vivo,* B cell proliferation response evoked by allogeneic skin transplantation was evaluated in draining lymph nodes (DLN) in transgenic mice that express constitutive hAAT ($hAAT^{+/+}$). To determine whether the allo-protective role of hAAT is B cell-dependent, B cell-depleted $hAAT^{+/+}$ chimeras were generated; the mice were rendered diabetic by streptozotocin and then transplanted with allogeneic islets.
Results: In the presence of hAAT, B cells exhibited a decline in CD40 ligand-induced co-stimulatory molecules CD86 and CD80 (6.3 ± 0.1% and 33.7 ± 4.1%, respectively; $P < 0.05$). B cells stimulated with anti-IgM $(Fab)_2$ displayed 35 ± 5.2% less surface BAFF receptor in the presence of hAAT. In cultures stimulated with CD40 ligand, LPS or BAFF, hAAT diminished inducible B cell proliferation 2.79 ± 0.13-fold, 4.62 ± 0.63-fold and 2.04 ± 0.21-fold, respectively ($P < 0.05$). Skin allograft-evoked B cell proliferation was 4.36 ± 1.1-fold lower in $hAAT^{+/+}$ mice than in WT recipients ($P = 0.0398$). While $hAAT^{+/+}$ transgenic mice accepted islet allografts, chimeric $hAAT^{+/+}$ mice (<7% circulating B cells) rejected allografts by 30 days after transplantation.
Conclusions: Our results suggest that hAAT modulates B cell responses in a manner that benefits islet allograft survival, and its protective properties are B cell-dependent.

P0477
The role of the deubiquitinating enzymes CYLD and A20 in B-cell maintenance and maturation

M. Hahn,* D. Schlüter,† A. Nikolaev,* A. Waisman* & N. Hövelmeyer*
**Institut for Moleculare Medicine, University of Mainz, Mainz, Germany, †Otto-von-Guericke University of Magdeburg, Institute for Medical Microbiology, Magdeburg, Germany*

Purpose/Objective: The NFκB-pathway plays a central role in the mammalian immune system regulating processes, ranging from development and survival of the lymphocytes to controlling the immune response to invading pathogens. In addition it was shown that it is a mechanistic link between inflammation and cancer and therefore its regulation is extremely important. CYLD and A20 are both negative regulators of the NFκB pathway by removing activating lysine-63 linked ubiquitin chains from numerous NFκB signaling molecules. Furthermore A20 is able to target those for proteasomal degradation by editing lysine-48 linked ubiquitin chains. Our aim was to shed light upon the role of the deubiquitinating enzymes CYLD and A20 in B cell maintenance, maturation, controlling the NFκB-pathway and cancer development.
Materials and methods: We crossed $CYLD^{Fl/Fl}$ mice to mice that lack A20 expression in B cells ($A20^{Fl/Fl}$CD19Cre), thereby creating a mouse strain deficient for both FL-CYLD, and A20 in B cells. These B cells over-express sCYLD, a naturally occurring splice variant of FL-CYLD, lacking the binding domains for TRAF2 and NEMO.
Results: These mice exhibit an expansion of the B cell compartment in the peripheral lymphatic organs as well as an increase in germinal center B cell formation. B cells isolated from these mice show prolonged survival and increased proliferation after α-IgM and CpG stimulation compared to CD19Cre control mice. In contrast to the B cell specific knockout of A20, which showed a significant reduction of marginal zone cells and a shift to the B2 B cell compartment in the peritoneal cavity, B cell specific double KO has an increased marginal zone B cell population and an increased B1a B cell population in the peritoneal cavity. Interestingly, these double KO mice exhibit a significantly elevated B1a cell population

in all secondary lymphatic organs, together with a three-fold increase of CD5 expression on B cells in the blood.

Conclusions: These data indicate a role of CYLD or respectively sCYLD downstream of A20. In addition the abundant appearance of B1 cells in lymphatic organs coupled with an increased expression of CD5 and CD23 on B cells, enhanced B cell receptor (BCR) signaling and survival might point to chronic lymphocytic leukemia (CLL) development.

P0478

The role of the inhibitory receptor SiglecG in the development of autoimmunity

S. Bökers,* M. Espeli,† K. G. C. Smith† & L. Nitschke*
**Biology, University of Erlangen-Nuremberg, Erlangen, Germany, †CIMR/Medicine, University of Cambridge, Cambridge, UK*

Purpose/Objective: Siglec-G is a member of the Siglec (sialic acid-binding immunglobulin-like lectin) family and acts as an inhibitory receptor of B1 cells. Siglec-G deficient mice show an expanded population of B1 cells, which have a higher calcium response to B-cell receptor signalling. Furthermore, higher serum IgM titers were observed. However, Siglec-G deficient mice in the BALB/c background did not develop spontaneous autoimmunity, which led us to further characterise the potential role of SiglecG in autoimmune models.

Materials and methods: SiglecG deficient mice in the BALB/c background were challenged with chicken type II collagen to induce rheumatoid arthritis. The SiglecG deficient mice were backcrossed into the SLE prone and fas-deficient MRL/MpJ fas/lpr background using speed congenics.

Results: We demonstrate that BALB/c Siglec-G deficient mice challenged with collagen-induced arthritis showed a more severe course of disease in terms of incidence and clinical score of arthritis signs than wildtype mice. These results were confirmed via H&E staining on knee sections.

Five month old Siglec-G-deficient MRL/MpJ fas/lpr mice show no difference in average life span compared to wildtyp MRL/MpJ fas/lpr mice but the incidence and severity of arthritis was more pronounced in Siglec-G deficient MRL/MpJ fas/lpr mice. Female Siglec-G knockout MRL/MpJ fas/lpr mice had an earlier onset of proteinuria (>300 mg/dl). Furthermore we observed a higher titer of anti-dsDNA IgG antibodies and rheumatoid factors in Siglec-G-deficient MRL/MpJ fas/lpr mice.

Conclusions: Even though SiglecG deficient mice in the BALB/c background do not show spontaneous autoimmunity, based on our data we conclude that the loss of the inhibitory receptor SiglecG can contribute to the development of autoimmunity, both in mouse SLE and rheumatoid arthritis models.

P0480

The role of toll-like receptor 9 in B-cell activating factor (BAFF) expression and function in normal human B-cells

E. Y. Abu-rish,* Y. Amrani† & M. J. Browning‡
**Department of Infection Immunity and inflammation, University of Leicester, Leicester, UK, †Department of infection immunity and inflammation, Institute of Lung Health, University of Leicester, Leicester, UK, ‡Immunology, University Hospitals of Leicester, Leicester, UK*

Purpose/Objective: B-cell autoreactivity is a characteristic abnormality in several autoimmune diseases. The inappropriate activation of toll-like receptors (TLRs) and/or the over-expression of B-cell activating factor (BAFF) have increasing importance in breaching B-cells' self-tolerance. In systemic lupus erythematosus (SLE), activation of TLR7 and TLR9, accompanied by high serum levels of BAFF, are implicated in disease pathogenesis. In murine B-cells, TLR9 activation resulted in up-regulating BAFF expression, while such a direct effect has not yet been established in normal human B-cells (nhB-cells). We therefore studied the effect of CpG-2006, a synthetic TLR9 ligand, on the expression of BAFF and its receptors (BAFF-R, TACI and BCMA) by nhB-cells.

Materials and methods: qPCR, flow cytometry and ELISA assays were utilized to investigate the effect of 3μg/ml CpG-2006 on BAFF expression at the level of mRNA, intracellular and membrane-bound protein expression, and secreted protein expression, respectively. BAFF receptors expression, in response to 3 μg/ml CpG-2006 was explored using flow cytometry. The functional role of membrane-bound BAFF was studied in BCR co-simulation and blocking assays.

Results: BAFF expression, in response to CpG-2006, was significantly upregulated at the level of mRNA, intracellular and membrane-bound protein. In contrast, we did not detect secreted BAFF in culture supernatants of CpG-2006-stimulated nhB-cells. CpG-2006, in addition, promoted the expression of TACI receptors, but not of BAFF-R or BCMA, in nhB-cells. We found that CpG-stimulated B-cells co-stimulated B-cell receptor-induced cellular proliferation of nhB-cells, an effect that was completely blocked by a BAFF-specific monoclonal antibody. Finally, CpG-2006 treatment of nhB-cells sensitised them to proliferate in response to exogenous BAFF, whereas exogenous BAFF had no effect on the proliferation of untreated B-cells. This effect was not mediated through TACI, as a TACI-specific blocking antibody failed to inhibit BAFF-mediated cellular proliferation.

Conclusions: Taken together, these novel findings demonstrate a functional cross-talk between TLR9 and BAFF signaling in nhB-cell, resulting in autocrine B-cell activation, and have implications for the roles of TLR9 and BAFF in the pathogenesis of SLE.

P0481

TLR9, CD40 or BCR stimulated human naïve and memory B cells exhibit differential responsiveness to the survival effect of IL-21

C. Antonio, J. Pons, N. Lanio, N. Matamoros & J. M. Ferrer
Son Espases Hospital, Immunology Service, Palma de Mallorca, Spain

Purpose/Objective: IL-21 is one of the most potent cytokines for human B cell proliferation and differentiation. IL-21 also influences B cell survival. The stimulatory or inhibitory effect of IL-21 depends on the maturation and activation status of the B cell, the co-stimulatory accompanying signals and the presence of other cytokines. The aim of this study was to evaluate the response of human naïve and memory B cells to IL-21 after TLR9, CD40 or BCR engagement.

Materials and methods: B cells were obtained from PBMC by negative selection using magnetic beads. Purified CFSE-free or CFSE-labelled B cells were cultured 3 days in the presence of ODN, anti-CD40 antibody or anti-IgM alone or in combination with human recombinant IL-21. Collected cells were stained with anti-CD19PCy7 and anti-CD27PCy5 monoclonal antibodies and analyzed by flow cytometry. Annexin V-FITC and Propidium Iodide staining protocol was used to evaluate the apoptosis of CSFE-free naïve ($CD19^+$ $CD27^-$) and memory ($CD19^+$ $CD27^+$) B cells. Proliferation was measured by CSFE dilution in previously gated CSFE-labelled cells.

Results: Spontaneous apoptosis was higher in memory than in naïve B cells. All stimuli alone protected both B cell subsets from spontaneous apoptosis. When IL-21 was tested alone, only naïve B cells were rescued from apoptosis. In contrast, IL-21 addition reverted the protective effect of all other stimuli on naïve B cells. In memory B cells, IL-21 was also able to revert the protective effect of anti-IgM and CpG-ODN but not anti-CD40.

Anti-IgM, anti-CD40, or IL-21 alone did not induce proliferation of naïve or memory B cells. CpG-ODN alone induced proliferation only on memory B cells. The combination of IL-21 with anti-IgM did not induce proliferation. IL-21 and anti-CD40 induced greater proliferation of memory than naïve B cells. The addition of IL-21 decreased

CpG-ODN induced proliferation of memory B cells and modestly increased proliferation of naïve B cells.
Conclusions: Memory B cells are more sensitive to spontaneous apoptosis than naïve B cells and less prone to be rescued by individual stimuli. Although a survival factor for unstimulated naïve B cells, IL-21 abrogates activation-induced survival of naïve B cells. On the contrary, IL-21 selectively supports memory B cell responses to T dependent stimulus.

P0482

WASp and N-WASp regulate the germinal center response and production of auto-antibodies

C. Dahlberg,* S. Petersen,* E. D. Jordö,* M. Baptista,* M. Karlsson,* S. Snapper† & L. Westerberg*
**Karolinska Institutet, Medicine Solna, Stockholm, Sweden, †Harvard Medical School, Children's Hospital, Boston, MA, USA*

Purpose/Objective: Wiskott-Aldrich syndrome (WAS) is a rare, potentially life threatening X-linked primary immunodeficiency disease. Forty to 70% of the patients develop any form of autoimmunity. WAS is caused by the WAS protein (WASp). We hypothesized that mice lacking WASp family members have a skewed development and activation of B cells due to intrinsic B cell dysfunction and decreased protective shield of the splenic marginal zone to blood-borne antigens.
Materials and methods: To determine the role of WASp and the homologues molecule N-WASp in B cell biology we have used WASp knock out (WKO) mice and mice lacking WASp and N-WASp in B cells (cDKO mice). To induce breakdown of tolerance with emergence of auto-antibodies, we immunized mice with apoptotic cells.
Results: Compared to reduced uptake and decreased immune response after non-self antigen immunization, WKO and cDKO mice had normal uptake of apoptotic cells in the marginal zone and formed large germinal centers after apoptotic cell immunization. However, compared to germinal center B cells in wild type mice, B cells retained longer and proliferated less in germinal centers of WKO and cDKO mice, suggesting decreased capacity to undergo affinity maturation. When compared to wild type mice, WKO and cDKO mice had significantly higher DNA-specific IgM antibodies before and after immunization with apoptotic cells. After repeated apoptotic cell immunizations the immunological tolerance was broken in wild type mice that produced DNA-specific IgG antibodies, while WKO and cDKO mice failed to produce anti-DNA IgG antibodies.
Conclusions: Together, our data show that mice lacking WASp family members respond with an atypical immune response to self-antigens such as apoptotic cells. WKO and cDKO B cells formed low quality GC-like structures upon self-antigen challenge and produced mainly auto-reactive IgM antibodies. Our data will increase the knowledge of why patients with primary immunodeficienies such as WAS develop autoimmune diseases.

An optimal pMHCI/CD8 interaction exists which affords maximum pMHCI sensitivity without loss of CD8$^+$ T-cell specificity

T. Williams,* M. Clement,* A. K. Sewel,* D. A. Price,* M. Bailey† & L. Wooldridge*

**Infection and Immunity, Cardiff University, Cardiff, UK, †Molecular and Cellular Biology, University of Bristol, Bristol, UK*

Purpose/Objective: CD8$^+$ T-cells recognize 'foreign' peptide fragments, in the context of 'self' major histocompatibility complex class I (MHCI) molecules on the surface of host cells. The detection of T-cell antigens is unique because it involves the binding of two receptors (TCR and CD8) to a single ligand (pMHCI). The pMHCI/CD8 interaction is characterized by very low solution binding affinities (K_D = 137 μM). An incremental enhancement in CD8 binding (~1.5-fold) has previously been shown to result in enhanced recognition of pMHCI, thereby demonstrating the huge potential of CD8 in strategies to enhance T-cell immunity. I aim to define the strength of the pMHCI/CD8 interaction which affords maximal enhancement of pMHCI recognition whilst still retaining specificity of pMHCI recognition by the TCR.

Materials and methods: In this study, I used a system of MHCI mutants which vary in the strength of the pMHCI/CD8 interaction. Using tetramer technology, I constructed a panel of A*0201 pMHCI tetramers that exhibit an abrogated (DT227/8KA), weak (A245V), normal (wild-type), slightly enhanced (Q115E), intermediately enhanced (A245V/K^b) and super-enhanced (K^b) interaction with CD8. The latter two mutations were also combined with a reduced affinity β2-microglobulin mutation (β2M K58E). This tetramer panel was then used to examine how the strength of the pMHCI/CD8 interaction influences pMHCI recognition at the cell surface and the specificity of pMHCI recognition.

Results: TCR recognition of pMHCI at the cell surface increases as the strength of the pMHCI/CD8 interaction is increased. Loss of pMHCI tetramer staining specificity was observed at pMHCI/CD8 strengths exceeding a threshold K_D of ~30 μM. Thus, an optimal pMHCI/CD8 binding interaction exists (between a K_D of 97 and 30 μM) which increases pMHCI sensitivity without the loss of specificity.

Conclusions: This data defines the strength of the pMHCI/CD8 interaction which affords maximal enhancement of pMHCI recognition whilst still retaining specificity of pMHCI recognition. Due to the non-polymorphic nature of CD8, strategies to enhance the antigen specific T-cell response by targeting CD8 would be globally applicable to any system in which enhanced T-cell immunity is desirable.

Purpose/Objective: CD8 T-cell responses can be primed by strong cytotoxic T cell epitopes even in the absence of CD4 epitopes or DC-activating adjuvants. The aim of this work is to analyze the role of CD40/CD40L interaction on the induction of helper-free CD8 T cell responses.

Materials and methods: Different strains of mice were immunized with different cytototoxic T cell epitopes emulsified in incomplete Freund adjuvant. CD40/CD40L interaction was blocked *in vivo* and *in vitro* by anti-CD40L antibodies. DC maturation as well as IFN-gamma/CD40L expression by primed CD8 T cells was measured by flow cytometry. Also, IFN-gamma production was analyzed by ELISA and ELISPOT.

Results: We found that CD8 T-cell responses induced by immunization with strong cytotoxic T cell epitopes were inhibited *in vivo* by CD40L blockade. *In vitro*, peptide stimulation of splenocytes from immune mice induced CD40L on CD8 T cells and DC maturation, which was partially inhibited by anti-CD40L antibodies. Interestingly, CD40L blockade also inhibited CD8 responses, even in the presence of already mature DC, suggesting a role for CD40L not only in DC maturation but also in CD8 costimulation. These peptides had features of CD4 epitopes, since they helped the induction of responses against other less immunogenic CD8 epitopes. Finally, analysis of peptide epitopes used in human vaccination clinical trials showed that they also induced CD40L on CD8 cells.

Conclusions: These results suggest that CD40L expression induced by strong CD8 peptide epitopes can facilitate activation of helper-free CD8 responses.

P0486

CD8beta ADP-ribosylation regulates CD8 coreceptor function

T. Lischke,* V. Schumacher,* R. Hurwitz,† F. Koch-Nolte* & H. W. Mittrücker*

**Institute for Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, †Core Facility Biochemistry/Proteinpurification, Max Planck Institute for Infection Biology, Berlin, Germany*

Purpose/Objective: The coreceptor of conventional CD8$^+$ T cells consists of a CD8ab heterodimer and correct interaction of CD8a, CD8b, TCR, and MHC-I is decisive for antigen recognition and effective signal transduction. ADP-ribosyltransferase 2 (ART2) is an ectoenzyme expressed on T cells that utilizes extracellular nicotinamide adenine dinucleotide (NAD) to transfer ADP-ribose to arginine residues of membrane proteins. Here we show that CD8b on murine CD8$^+$ T cells becomes ADP-ribosylated *in vitro* and *in vivo* in the presence of extracellular NAD.

Materials and methods: ADP-ribosylation leads to loss of binding of certain anti-CD8b antibodies (YTS156.7.7 and 53−5.8). Other anti-CD8b antibodies (H35-17) still recognize CD8b indicating that NAD causes only modification of certain epitopes and not a general loss of CD8b.

Results: The ADP-ribosylation of CD8b is mediated by ART2, because loss of ART2 expression results in lack of CD8b ADP-ribosylation even in the presence of high doses of NAD. Furthermore, loss of ADP-ribosyl cyclase 1 (CD38), an ectoenzyme that degrades extracellular NAD, results in inevitable CD8b ADP-ribosylation upon any cell isolation procedure. ADP-ribosylation of CD8b is stable for several hours and re-appearance of unmodified CD8b is mainly due to the replacement of ADP-ribosylated surface CD8b by newly generated molecules, but there also appear to be mechanisms that remove ADP-ribose residues from surface CD8b. Finally, NAD treatment of ovalbumin-specific endogenous CD8$^+$ T cells or of T cells from OT1 transgenic mice substantially reduces binding of ovalbumin-MHC-I tetramers. Since activated CD8$^+$ T cells downmodulate ART2 expression, reduction of tetramer binding is less pronounced on effector CD8$^+$ T cells. Nevertheless, an *in vivo* cytotoxicity assay revealed impaired CD8$^+$ T cells function after i.v. NAD injection.

Conclusions: In summary, we propose that ADP-ribosylation of CD8b can regulate the coreceptor function of CD8 on CD8$^+$ T cells in the presence of elevated levels of extracellular NAD. Our current studies aim at elucidating the role of this mechanism for the regulation of CD8$^+$ T cell responses.

Cross reactivity prediction based on hierarchical clustering of pMHC complexes

D. A. Antunes, J. P. Silva, M. F. A. Mendes, M. M. Rigo, J. A. B. Chies, M. Sinigaglia & G. F. Vieira

Department of Genetics, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

Purpose/Objective: Cross-reactivity was initially described as being triggered by the great similarity between the amino acid sequences of virus-derived peptides presented in the context of the Major Histocompatibility Complex (MHC). These peptide:MHC (pMHC) complexes are recognized by Cytotoxic T Lymphocytes (CTLs), which are the effector agents of cellular immunity. However, immunologists have already described many events of cross-reactivity between epitopes sharing <50% of the linear amino acid sequence, and this phenomenon has proven to be far more difficult to predict.

Materials and methods: In the present work, we analyzed 60 unrelated pMHC complexes presenting virus-derived peptides, in the context of the most frequent human MHC allele (HLA-A*02:01). These complexes were obtained from the CrossTope Data Bank for Cross-Reactivity Assessment, being 5 crystal structures and 55 *in silico* predicted structures. Images of the TCR-interacting surface of these complexes, presenting the electrostatic potential distribution, were used to extract data from the points of interaction with the TCR. Values of these regions were used as input for multivariate statistical methods, aiming to predict possible targets of cross-reactivity. Aiming to compare our approach with other available strategies, we also used the same dataset as input to the *webPIPSA*.

Results: Our dataset included some peptides with already known cross-reactivity, and a Hierarchical Cluster Analysis (HCA) of these data agreed with this experimental background, presenting better results than the *webPIPSA* server. For instance, we included 10 variants of the wild-type epitope HCV-$NS3_{1073}$. All the variants with *in vitro* confirmed cross-reactivity were placed in the same group ('HCV-cluster'), while the noncross-reactive variant (from HCV genotype 3) was placed in a completely unrelated group. There is yet another complex included in the 'HCV-cluster', presenting the 'LLWTLVVLLO' peptide, from the Human herpesvirus 4 (LMP_{2329}). It is important to note that this peptide does not share even a single amino acid with the target peptide (CVNGVCWTV) and, nevertheless, presented almost the same structural pattern when presented in the context of HLA-A*02:01.

Conclusions: This result stresses the power of this structural approach in prospecting new cross-reactive targets.

P0488

Differential antigen-dependency of $CD4^+$ and $CD8^+$ T cells

A. Behrendt,* H. Rabenstein,* J. Ellwart,† M. Horsch,† J. Beckers† & R. Obst*

**Institute for Immunology, Ludwig-Maximilians-University, Munich, Germany, †Helmholtz Center Munich, Institute for Molecular Immunology, Munich, Germany*

Purpose/Objective: T cell expansion and effector differentiation are triggered and, perhaps, maintained by antigen, but the proliferative behaviors of $CD4^+$ and $CD8^+$ T cells have rarely been compared side by side.

Materials and methods: TCR transgenic $CD4^+$ or $CD8^+$ T cells were stimulated for two days *in vitro* with CD3 and CD28 monoclonal antibodies and proliferation was followed upon transfer into mice expressing cognate antigen or not. CFSE dilution and cell cycle analysis were employed to characterize proliferative patterns of both subsets. To investigate the contribution of coinhibitory signaling and inflammatory stimuli, we employed blocking antibodies against coinhibitory molecules and bystander MCMV infection. Gene expression analysis was used to assess general differences between $CD4^+$ and $CD8^+$ T cells under conditions of transient or persistent TCR stimulation.

Results: We found $CD4^+$ T cell proliferation to be dependent on prolonged antigen presence, such that $CD4^+$ T cell proliferation ceased quickly after transfer into antigen-free mice, whereas $CD8^+$ T cells continued dividing. Furthermore, only $CD8^+$ T cells differentiated into effector cells and retained cell cycle activity following transient TCR stimulation. Gene expression analysis illustrated global differences in the transcriptomes of both subsets. We excluded $CD4^+$ T cell proliferation to be abrogated by coinhibitory signals or lacking inflammatory stimuli. Additionally, autonomous proliferation of $CD8^+$ T cells was independent of any MHC I signals. Our T cell data correlated with the decreased turnover of MHC II, but not MHC I, on activated dendritic cells *in vivo*.

Conclusions: Proliferation of $CD4^+$ and $CD8^+$ T cell subsets differentially dependent on antigen: $CD4^+$ T cells require persistent TCR stimulation for extended divisions and effector differentiation. However, a limited TCR stimulus is sufficient to drive proliferation and effector cell differentiation of $CD8^+$ T cells without maintenance of antigen presentation. This is reflected in the biology of MHC I, whose expression, unlike MHC II, is not stabilized on dendritic cells upon their activation *in vivo*.

P0489

in vivo elimination of drug-resistant tumor cells by cytotoxic T cells through a perforin/granzyme B-dependent mechanism

E. Catalan,* J. I. Aguilo,* M. Perez,* A. Anel,* M. M. Simon† & J. Pardo‡

**Bioquimica y Biologia Molecular y Celular, University of Zaragoza, Zaragoza, Spain, †Metschnikoff Laboratory, Max-Planck Institute of Immunobiology, Freiburg, Germany, ‡Bioquimica y Biologia Molecular y Celular/Instituto de Nanociencia de Aragon (INA), University of Zaragoza/ARAID, Zaragoza, Spain*

Purpose/Objective: Cytotoxic T (Tc) and NK cells are key effectors in the control and/or elimination of tumor or virus-infected target cells. For this purpose they employ two distinct strategies, the engagement of death receptors and the granule secretory pathway, including perforin (perf) and granzymes (gzms). The main outcome of both processes is the induction of apoptosis of target cells. We have previously shown that *ex vivo*-derived perf and gzmB expressing virus-specific Tc cells are able to induce several distinct pro-apoptotic pathways *in vitro*.However, the relevance of these findings for the elimination of tumor cells *in vivo* is still not clear, a crucial question to predict the effectiveness of Tc cell-based immunotherapy protocols against cancer cells.

Materials and methods: By using virus-pulsed mice defective (knock out) in one or more components of the granule secretory pathway perf, gzmA, gzmB − we have now analysed the role of perf-dependent and -independent pathways in Tc cell-mediated elimination of transformed cells *in vivo*. To this aim, we have used fluorescence label tumor cells pulsed with virus antigens and analyse their specific elimination in the peritoneal cavity of primed mice.

Results: Efficient elimination of pulsed tumor cells by virus-specific Tc cells is critically dependent on perf. However, the relative contribution of the two major proteases, i.e. gzmA and gzmB, to tumor cell death was shown to depend on the amount of initial viral load. Thus, in mice infected with low viral doses (10 cfu), perf and gzmB are the major executors of tumor cell death, with gzmA only playing a minor role. Moreover, under these physiological conditions, perf and gzmB-expressing Tc cells are even able to eliminate multidrug resistant-tumor cells defective in the mitochondrial apoptotic pathway (i.e. overexpression of Bcl-X_L).

Conclusions: Our findings suggest that perf and gzmB-expressing Tc cells, previously educated to specifically recognise transformed cells are

a promising immunotherapeutic means to efficiently control tumor growth in patients refractory to conventional chemotherapies.

P0490

Interleukin-15 amplifies the pathogenic activity of $CD4^+$ CD28- T cells in multiple sclerosis patients

B. Broux, B. Van Wijmeersch, P. Stinissen & N. Hellings
Biomedical Research Institute, Hasselt University, Diepenbeek, Belgium

Purpose/Objective: Immune ageing, or immunosenescence, contributes to the increased morbidity and mortality seen in the elderly. Premature immunosenescence is shown to occur in patients with multiple sclerosis (MS). The main characteristic of immunosenescence is the expansion of $CD4^+$ $CD28^-$ T cells in the peripheral blood. We showed that these cells accumulate in brain lesions of MS patients. $CD4^+$ $CD28^-$ T cells have a cytotoxic profile, shown by expression of the cytotoxic molecules perforin, granzyme B and NKG2D, an activating natural killer (NK) cell receptor. For NK cells, it is known that NKG2D expression and cytotoxicity increase in response to interleukin (IL)-15, which is upregulated in the serum and cerebrospinal fluid of MS patients. The aim of our study is to investigate whether IL-15 enhances cytotoxicity of $CD4^+$ $CD28^-$ T cells as seen for NK cells.
Materials and methods: Flow cytometric analysis was used to investigate proliferation, expression of cytotoxic molecules and degranulation of $CD4^+$ $CD28^-$ T cells in response to IL-15. Coculture with the NKG2D ligand expressing cell line U251 assessed the contribution of NKG2D ligation to degranulation of $CD4^+$ $CD28^-$ T cells. To identify IL-15 producing cells in the brain, immunohistochemistry was performed on MS lesion tissue and normal brain tissue of non-demented controls.
Results: We show that IL-15 preferentially induces proliferation of $CD4^+$ $CD28^-$ T cells as compared to their $CD28^+$ counterparts. Phenotypically, IL-15 significantly increases expression of NKG2D, perforin and granzyme B by $CD4^+$ $CD28^-$ T cells. Also, the production of interferon-gamma is increased, and this increase is significantly higher in MS patients. When IL-15 is presented to $CD4^+$ $CD28^-$ T cells, their release of cytotoxic granules is significantly enhanced. This degranulation is not dependent on NKG2D ligation, but blocking of NKG2D diminished this process. In MS lesions, we found that microglia/macrophages are the main IL-15 producing cells, and that $CD4^+$ T cells are found in close proximity to them, suggesting *in vivo* stimulation.
Conclusions: In summary, our findings indicate that $CD4^+$ $CD28^-$ T cells, which accumulate in brain lesions of MS patients, are functionally boosted by IL-15 producing cells. This process amplifies their cytotoxicity, contributing to local damage.

P0491

MAIT cells induce proinflammatory cytokine production in monocytes through the secretion of granzymes A and K

A. Kurioka, C. Cosgrove, C. Clough, C. Willberg & P. Klenerman
Peter Medawar Building for Pathogen Research, University of Oxford, Oxford, UK

Purpose/Objective: Mucosal-associated invariant T (MAIT) cells are a population of $CD161^{++}$ CD8 T-cells expressing the semi-invariant T-cell receptor iVα7.2, but their functions remain unclear.Here we examine the unique expression profile of cytolytic molecules in these cells. Granzyme (Gzm) A and Gzm K are trypsin-like serine proteases originally believed to function exclusively as pro-apoptotic proteases, but recent studies suggest that these molecules may possess proinflammatory functions.We therefore tested the hypothesis that granzyme release from MAIT cells induces proinflammatory cytokine production from target cells.
Materials and methods: Surface and intracellular staining followed by FACS analysis was performed using PBMCs isolated from 21 healthy donors, 12 chronically infected HIV patients and 13 chronically infected HCV patients. Enriched monocytes were treated with endotoxin removed Gzm A and Gzm K at 200nM (Enzo Life Sciences) before intracellular cytokine staining.Wilcoxon's matched pairs test was used for analyzing paired data, and the Mann-Whitney U test was used to compare unpaired data.
Results: We report that MAIT cells are characterized by a lack of Gzm B and perforin, but highly express Gzm A (99.5% $P < 0.0001$) and Gzm K (95.1% $P < 0.0001$) compared to CD161- CD8 T-cells. Furthermore, we found a dramatic increase of Gzm A ($P = 0.0007$) and Gzm B ($P < 0.001$) in total CD8 T-cells in HIV patients compared to healthy donors, while Gzm K was found to be reduced in HIV ($P = 0.0046$) and HCV patients ($P = 0.0282$). We show that extracellular Gzm K induces secretion of IL-1β in a time-dependent manner from monocytes. We also developed a novel FACS-based cytotoxicity assay to show that MAIT cells degranulate in an MR1-dependent manner in response to bacterially exposed APCs but they show low cytotoxicity to target cells.
Conclusions: MAIT cells express high levels of proinflammatory Gzms A and K but low levels of Gzm B and perforin. Triggering of these cells leads to degranulation but does not induce killing of target cells and induces secretion of IL-1β from monocytes.Together with their ability to secrete IL-17 and gut-liver homing characteristics, high expression of Gzm A and Gzm K most likely contributes to the antimicrobial and host defence properties of MAIT cells. Such activity may also play a role in tissue inflammation in diseases such as chronic HCV infection.

P0493

Monoclonal anti-CD8 therapy induces disease amelioration in collagen-induced arthritis in the B10.Q mouse model

H. Carvalheiro & M. M. Souto-Carneiro
Immunology, Center for Neuroscience and cell Biology, Coimbra, Portugal

Purpose/Objective: $CD8^+$ T cells are known to infiltrate the synovium in rheumatoid arthritis (RA) in high numbers. However, their role in the pathogenesis of RA still needs to be fully understood. Using the collagen-induced arthritis (CIA) model in B10.Q mice, we aim at uncovering the potential of $CD8^+$ T cell depletion to stop the progression of the disease as well as its reversal.
Materials and methods: Arthritis was induced and scored in male 14–16 week-old B10.Q mice immunized with type II collagen emulsion. $CD8^+$ T cells from the peripheral blood were characterized for cell surface markers and intracellular cytokine production at three different time points: before CIA, at an intermediate arthritis level and at the peak of the disease, where they were then treated with a specific depleting anti-CD8 mAb (YTS169.4). Arthritic mice in the control group were treated with a mock antibody.
Results: The peripheral blood of B10.Q mice showed to decrease their $CD8^+$ T cell numbers in the periphery as the arthritis scores increased. It was also observed that the circulating $CD8^+$ T cells, despite diminishing in absolute numbers with the increase of arthritis scores, present a high percentage of the activation cell marker CD69, with the highest levels of expression observed at the peak of the disease. The intracellular production of granzyme B and proinflammatory cytokines such as TNFα and IFNγ by $CD8^+$ T cells also increased with arthritis scores.

Upon treatment with anti-CD8 mAb, the arthritis scores improved within 4 days of treatment, and remained consistently low for a period of 10 days. The control group maintained high arthritis scores. The resurgence of the $CD8^+$ T cells in the peripheral blood of $CD8^+$ T cell depleted mice is associated with the recovery of arthritis scores.

Conclusions: These results indicate that $CD8^+$ T cells have an activated phenotype in CIA in the B10.Q mouse model. The depletion of $CD8^+$ T cells from arthritic mice leads to an amelioration of the disease, which can indicate that $CD8^+$ T cells may have a greater role in the progression and maintenance of experimental arthritis.

P0495

System L amino acid transporter 1 (slc7a5) expression is crucial for T cell blastogenesis

L. V. Sinclair, P. M. Taylor & D. A. Cantrell
Cell Signalling and Immunology, University of Dundee, Dundee, UK

Purpose/Objective: Triggering of the T cell antigen receptor (TCR) causes T cells to up-regulate glucose, amino acid and iron uptake and switch to glycolysis. The objective of the present study was to identify the System L amino acid transporters that import large neutral amino acids (LNAA) such as leucine into T cells and then assess the importance of these transporters for T cell function. We now show that the System L amino acid transporter composed of the transporter light chain slc7a5, and heavy chain CD98 is expressed in immune activated but not naïve T cells. Moreover, the expression of this transporter complex is essential for T cell growth and proliferation.
Materials and methods: To address the importance of slc7a5 mediated amino acid transport in T cells, we have backcrossed mice expressing floxed slc7a5 alleles to mice expressing Cre recombinase under the control of the CD4 promoter. This drives T cell specific deletion of slc7a5, allowing analysis of the role for slc7a5 in peripheral T cells.
Results: CD4Cre $slc7a5^{fl/fl}$ mice have a normal peripheral T cell compartment indicating that this amino acid transporter is not required for T cell selection in the thymus or for the trafficking and homeostasis of the naïve T cell pool. However, $slc7a5^{-/-}$ T cells have a selective defect in T cell antigen receptor induced LNAA transport and fail to increase cell mass in response to immune activation. $slc7a5^{-/-}$ immune activated T cells cannot proliferate *in vitro* and *in vivo* and show defects in CD8 T cell differentiation to cytotoxic T cells. Moreover, $slc7a5^{-/-}$ CD4 T cells fail to differentiate to Th1 and Th17 although Treg differentiation is unaffected by lack of slc7a5. One striking observation was that $slc7a5^{-/-}$ T cells are unable to sustain expression of the glucose transporter Glut1 and hence have defective glucose uptake and cannot switch to a glycolytic metabolism. These studies afford the insight that the coordination of amino acid uptake and protein synthesis is essential for the glycolytic switch in T cells and for T cell activation.
Conclusions: The present data identify the regulated expression of System L amino acid transporter as a key event for T cell clonal expansion and demonstrate the importance of TCR regulated amino acid transport for peripheral T cell differentiation.

P0496

The effect of immunomodulation on IL-17^+ $CD8^+$ T cells in MS patients

E. Peelen,* M. Thewissen,† S. Knippenberg,* J. Smolders,‡ P. Menheere,§ J. W. Cohen Tervaert,† R. Hupperts¶ & J. Damoiseaux**
**School for Mental Health and Neuroscience, Maastricht University Medical Center, Maastricht, The Netherlands, †Department of Internal Medicine, Maastricht University Medical Center, Maastricht, The Netherlands, ‡Department of Neurology, St. Antonius Ziekenhuis, Nieuwegein, The Netherlands, §Department of Clinical Chemistry, Maastricht University Medical Center, Maastricht, The Netherlands, ¶Department of Neurology, Orbis Medical Center, Sittard, The Netherlands, **Laboratory for Clinical Immunology, Maastricht University Medical Center, Maastricht, The Netherlands*

Purpose/Objective: In multiple sclerosis (MS), Th17 cells are believed to be pathogenic. We postulate that also IL-17^+ $CD8^+$ T cells are pathogenic since $CD8^+$ T cells are found in MS brain lesions and >70% of these cells are IL-17 positive. Therefore, we investigated the immune modulating effects of beta interferon (IFN-β), glatiramer acetate (GA) and vitamin D (VitD), on circulating $IL17^+$ $CD8^+$ T cells in MS.
Materials and methods: PBMC were isolated from healthy controls (HC; $n = 30$) and relapsing-remitting (RR) MS patients in remission (no medication: $n = 17$, IFN-β: $n = 18$, GA: $n = 13$) and during a relapse (no medication: $n = 12$, IFN-β: $n = 10$). Additionally, PBMC from 15 IFN-β treated RRMS patients, receiving 20 000 IU $VitD_3$/day for 12 weeks, were isolated at baseline and at 12 weeks. Intracellular FACS analysis was performed on PBMC to assess the IL-17^+ cell fraction in the $CD8^+$ T cell population. Data are given as median with corresponding interquartile range. Due to a correction for multiple testing, a P-value < 0.01 was considered significant.
Results: Compared to HC, MS patients in remission had higher IL-17^+ $CD8^+$ T cell percentages (0.3% [0.2−0.4] and 0.5% [0.3−0.5], respectively; $P = 0.001$), while MS patients during a relapse showed a trend towards higher percentages (0.5% [0.3−0.8]; $P = 0.016$). In patients in remission, the fraction IL-17^+ $CD8^+$ T cells did not differ between the three treatment groups. In MS patients during a relapse, IL-17^+ $CD8^+$ T cell percentages were similar in untreated and IFN-β treated patients (0.4% [0.2−1.4] and 0.7% [0.3−0.8], respectively). IL-17^+ $CD8^+$ T cell percentages were comparable before and 12 weeks after VitD supplementation (0.3% [0.2−0.5] and 0.4% [0.3−0.6], respectively).
Conclusions: These results show elevated IL-17^+ $CD8^+$ T cell percentages in MS patients. This, in combination with their presence in MS lesions, suggests a role for these cells in MS pathogenesis. However, therapy with either GA, IFN-β or vitamin D seemed unable to downregulate these cells in the circulation.

P0497

Viral dsRNA-activated human dendritic cells produce IL-27 which selectively promotes cytotoxicity in naïve CD8$^+$ T cells

R. de Groot, A. van Beelen, G. Bakdash, E. Taanman-Kueter, E. de Jong & M. Kapsenberg
Cellbiology, Academic Medical Center, Amsterdam, The Netherlands

Purpose/Objective: Dendritic cells (DCs) are central in shaping immune responses by activating naïve T-cells, not only CD4$^+$ helper T cells but also CD8$^+$ cytotoxic T cells. Viral recognition programs DCs to express signal three molecules that promote the differentiation of effector CD8$^+$ T cells. Besides IL-12, another DC-derived IL-12-family member, IL-27, has been reported to contribute herein. Therefore, we studied the relative roles of IL-12 and IL-27 in the induction of CD8$^+$ T cell responses by human DCs.

Materials and methods: FACS sorted naïve CD8$^+$ T cells were activated either by anti-CD3/CD28 stimulation in the presence of recombinant human IL-12 and IL-27 or by viral dsRNA-activated human peripheral blood BDCA1$^+$ DCs in the presence of neutralizing antibodies against IL-12 or the IL-27 receptor. After 3–6 days CD8$^+$ T cell proliferation, granzyme B expression, cytokine production and cytotoxicity were determined.

Results: Whereas IL-12 potently induces inflammatory cytokines (i.e. IFN-g and TNF-a, but not IL-2), IL-27 excels in inducing proliferation and a cytotoxic profile (granzyme B, cytotoxicity of target cells) in human naïve CD8$^+$ T cells. Compared to bacterial cell wall peptidoglycan, viral dsRNA-mimic poly (I:C) is superior in priming human BDCA1$^+$ DCs to produce IL-12 and IL-27, which promote inflammatory cytokines and a cytotoxic profile in differentiating CD8$^+$ T cells, respectively.

Conclusions: This data supports the concept that viral dsRNA-activated human dendritic cells produce IL-27, which acts as a specialized pro-cytotoxic, anti-viral cytokine that promotes development of effector CD8$^+$ T cells.

Poster Session: Effector Th Cell Subsets and Plasticity

Activity of T helper cells in patients with primary Sjogren's syndrome

G. Sudzius,* A. Siaurys,* D. Mieliauskaite,† I. Butrimiene,† Z. Mackiewicz‡ & I. Dumalakiene*

**Department of Immunology, State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania, †Department of Innovative Diagnostic Treatment and Health Monitoring Technology, State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania, ‡State Research Institute Centre for Innovative Medicine, Department of Regenerative Medicine, Vilnius, Lithuania*

Purpose/Objective: To investigate whether T helper (Th1, Th2 and Th17) cells activity can differentiate in peripheral blood of patients with primary Sjögren's syndrome (pSS), non- Sjögren's sicca syndrome (nSS-sicca) and healthy controls.

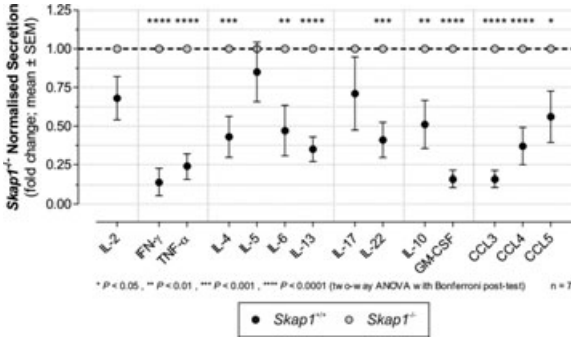
Materials and methods: We isolated peripheral blood mononuclear cells (PBMCs) from 34 pSS, 13 nSS-sicca patients and 13 healthy controls. We stimulated PBMCs using phorbol-12-myristate-13-acetate and ionomycin, labelled for CD4, IFN-γ, IL-4 and IL-17A and analyzed these cells using flow cytometry.

Results: According to our results no differences between nSS-sicca and healthy controls were found and we combined them in to one control group. Activity of Th1, Th2 and Th17 cells according to IFN-γ, IL-4 and IL-17A expression in patients with pSS were similar to control group. We found the significantly increased percentage of both IFN-γ and IL-17 producing Th17/Th1-like cells in pSS patients as compared to control group. We observed a significant correlation between all Th subsets activity in control group. Th1 correlated with Th17, with Th2 and Th17/Th1-like. Th2 correlated with Th17 and Th17/Th1-like. Th17 correlated with Th17/Th1-like. However, we observed correlation only between Th1 with Th2 and Th17 and Th17/Th1-like with Th17 in pSS group (see Table 1).

Table 1. Correlation of Th subsets in primary Sjögren's syndrome patients and control group

pSS group	Th subpopulation	Th1	Th17	Th2	Th17/Th1
	Th1	–	$r = 0.3654$ $P = 0.0261$	$r = 0.4657$ $P = 0.0048$	ns (not significant)
	Th17	$r = 0.3654$ $P = 0.0261$	–	ns	$r = 0.7485$ $P < 0.0001$
	Th2	$r = 0.4657$ $P = 0.0048$	ns	–	ns
	Th17/Th1	ns	$r = 0.7485$ $P < 0.0001$	ns	–
Control group	Th1	–	$r = 0.6811$ $P = 0.0001$	$r = 0.4997$ $P = 0.0093$	$r = 0.6184$ $P = 0.0008$
	Th17	$r = 0.6811$ $P = 0.0001$	–	$r = 0.3981$ $P = 0.0440$	$r = 0.7667$ $P < 0.0001$
	Th2	$r = 0.4997$ $P = 0.0093$	$r = 0.3981$ $P = 0.0440$	–	$r = 0.4925$ $P = 0.0106$
	Th17/Th1	$r = 0.6184$ $P = 0.0008$	$r = 0.7667$ $P < 0.0001$	$r = 0.4925$ $P = 0.0106$	–

Conclusions: The significantly increased percentage of Th cells producing both IFN-γ and IL-17A in peripheral blood suggest a possible role of Th17/Th1-like cells in the pathogenesis of pSS. We observed different correlation between Th subsets activity in pSS and in control groups. These results are especially important considering the fact that Th subsets activity levels seem to be unaltered in patients and controls. Therefore, we conclude that an imbalance of relationship between Th subsets activity plays a role in pSS pathogenesis.



P0499
Adaptor Src kinase-associated phosphoprotein-1 (SKAP1) differentially suppresses production of multiple cytokines and chemokines in $CD4^+$ T-cells

P. Riha & C. E. Rudd

Department of Pathology, University of Cambridge, Cambridge, UK

Purpose/Objective: While immune cell adaptor Src kinase-associated phosphoprotein-1 (SKAP1, formerly known as SKAP-55) regulates integrin-mediated adhesion of T-cells, little is known whether it plays additional roles in modulating other aspects of immune responses. In this study, we report that while SKAP1 positively regulates T-cell adhesion, it elicited a paradoxical inhibitory effect on a selected group of cytokines and chemokines.

Materials and methods: Primary naïve *Skap1*$^{+/+}$ and *Skap1*$^{-/-}$ $CD4^+$ T-cells were stimulated by various concentrations of immobilized anti-CD3, anti-CD28 or unspecific IgG antibodies and the production of CCL3, CCL4, CCL5, CXCL10, GM-CSF, IFN-γ, IL-1α, IL-2, IL-4, IL-5, IL-6, IL-10, IL-13, IL-17, IL-21, IL-22, IL-27, TGF-β and TNF-α was simultaneously measured by FlowCytomix assay. In parallel, the dynamics of T-cell proliferation and cell viability was assessed by CFSE dilution and 7-AAD exclusion assays, respectively. The activity of mitochondrial oxidases was detected by MTT assays.

Results: SKAP1 suppressed the production of cytokines and chemokines such as IFN-γ, TNF-α, GM-CSF and CCL3 in the response to the T-cell receptor (TCR) stimulation. Th1 cytokines were affected more than Th2 cytokines, although the inhibition pattern did not strictly follow the division between Th1 and Th2 phenotype. SKAP1-dependent inhibition was not reversed by increasing the strength of the TCR signal, but unlike in the case of the other factors, IL-2 and CCL4 production could be restored by CD28 co-ligation. IL-17 production was relatively resistant to SKAP1-dependent inhibition. While this adaptor did not alter magnitude and dynamics of T-cell proliferation, it also limited the survival of non-dividing, but not proliferating $CD4^+$ T-cells.

Conclusions: SKAP1 represents the first example of an adaptor that can both enhance integrin-dependent T-cell adhesion and supress the production of certain cytokines and chemokines reducing polarization of the cytokine milieu towards Th1 phenotype.

Basophils control disease activity and T cell responses in experimental murine colitis

M. Rodriguez Gomez,* Y. Talke,* C. Hofmann,† I. Ketelsen,* F. Hermann,* B. Reich,* N. Goebel,* S. Shahzad-Nawaz* & M. Mack*

*Department of Internal Medicine II, University Hospital Regensburg, Regensburg, Germany, †Department of Internal Medicine I, University Hospital Regensburg, Regensburg, Germany

Purpose/Objective: Basophils have been recognized as important inducers of T helper cell 2 (Th-2) responses in models of vaccination and infection. However, little is known about their role in autoimmunity. Using the colitis model of adoptive transfer of $CD4^+$ $CD62L^+$ T helper cells into lymphopenic hosts we analyzed whether basophils regulate T cell responses and modulate disease activity. We hypothesized that basophils are activated by proliferating T cells after transfer and influence colitogenic T cells.

Materials and methods: *In vivo* basophils were depleted with antibodies against FceR1 and CD2003R or expanded with repeated injections of recombinant interleukin (IL-) 3. The phenotype of T cells and cytokine expression were quantified by *in vivo* cytokine capture assay, intracellular staining and quantitative RT-PCR. The weight of the mice, histological scores, colon mRNA levels and flowcytometric analysis of infiltrating cells were used to measure disease activity. *In vitro* basophils were isolated by FACS-sorting (using the markers FcεR1 and CD49b) and incubated with activated T cells.

Results: We show that adoptively transferred T cells rapidly proliferate, produce large amounts of IL-3 and expand the number of basophils. These basophils modify the phenotype of T cells during early expansion, counter-regulate disease inducing Th-1 responses and control the development of colitis. Depletion of basophils results in long lasting upregulation of proinflammatory Th-1 responses and exacerbation of colitis, while expansion of basophils with IL-3 almost completely blocks Th-1 cytokines and improves colitis. *In vitro*, basophil derived IL-4 or IL-6 is able to inhibit IFN gamma and IL-2 production in T helper cells, while only the combined release of both cytokines also suppresses TNF production.

Conclusions: These data show a beneficial role of basophils in a T cell driven model of autoimmunity and identify basophils as potential target in inflammatory bowel diseases.

P0501

$CD4^+$ T cell homeostasis in a monogenic autoimmune disease APECED

N. Heikkilä, H. Mannerström, S. M. Laakso, H. Jarva & T. P. Arstila

Haartman Institute, University of Helsinki, Helsinki, Finland

Purpose/Objective: Autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED) is a recessive autoimmune syndrome caused by loss-of-function mutations in the Autoimmune Regulator (AIRE) gene. The clinical picture includes autoimmunity targeting especially endocrine organs, chronic mucocutaneous candidiasis and various ectodermal defects. AIRE is a transcriptional factor participating in negative selection of thymocytes and maintenance of peripheral deletional tolerance, but the details of the pathogenesis remain unknown. In APECED the peripheral $CD8^+$ T cell homeostasis is imbalanced and associated with elevated levels of a homeostatic cytokine interleukin-7 (IL-7). In this study we display properties of $CD4^+$ T cell population in APECED.

Materials and methods: Peripheral blood mononuclear cells from APECED patients and healthy controls were stimulated with anti-CD3 antibody, permeabilized and stained with fluorescent dyes for flow cytometric analysis. IL-7 plasma levels were determined by ELISA.

Results: In patients the number of $CD4^+$ $CD45RA^-CCR7^-$ cells, considered effector cells, is increased while the number of $CD4^+$ $CD45RA^+CCR7^+$ cells, considered naïve cells, is diminished. Also the number of recent thymic emigrants (RTE), defined as $CD45RA^+CD31^+$ cells and thought to reflect the thymic conditions, is diminished. Patients' $CD4^+$ population exhibits an increased expression of interferon gamma and interleukin-4, markers of type 1 and type 2 helper T cells respectively. The expression of interleukin-17 was marginal both in patients and controls. No cells expressing two intracellular cytokines at the same time were detected. The alterations in cytokine levels are particularly marked in the $CD4^+$ RTE population. The expression of IL-7 receptor in $CD4^+$ cells is decreased and inversely proportional to the elevated plasma IL-7 concentration in patients. This is associated with increased proliferation rate and decreased CCR7 expression in $CD4^+$ $CD45RO^-$ population.

Conclusions: In APECED the $CD4^+$ cells are hyperreactive. Their differentiation begins prematurely as RTE cells show characters of type 1 or type 2 helper T cells. The perturbations in $CD4^+$ population are related to IL-7 dysregulation. This is of particular interest because IL-7 axis has been linked to other multifactorial autoimmune diseases such as multiple sclerosis.

CD40L expression identifies human and mouse $CD8^+$ helper T cells

M. Frentsch,* J. J. Listopad,† R. Stark,* N. Matzmohr,* A. N. Hegazy,‡ S. Meier,* F. Gebhardt,§ A. Fröhlich,‡ A. R. Schulz,* J. C. Hafalla,¶ K. Matuschewski,¶ M. Löhning,‡ D. Busch,§ T. Blankenstein† & A. Thiel*

*Regenerative Immunology and Aging, Berlin-Brandenburg Center for Regenerative Therapies, Berlin, Germany, †MDC, Tumorimmunology, Berlin, Germany, ‡Experimental Immunology, Charite University Medicine, Berlin, Germany, §TUM, Institute for Medical Microbiology, Munich, Germany, ¶Parasitology Unit, MPI for Infection Biology, Berlin, Germany

Purpose/Objective: CD40L expression on activated $CD4^+$ T-*helper*-cells (T_h) is one of the most potent signals for T-cell depended activation of APC and is recognized generally as a hallmark for T_h cells. Recently, we detected that CD40L is expressed also by a major memory subset of $CD8^+$ T cells, which concomitantly are not cytotoxic, shown by lack of Granzyme B, Perforin and degranulation (CD107a).

Materials and methods: human & mouse cells.

Results: In various immune responses against pathogens as *Listeria monocytogenes*, LCMV or *Plasmodium berghei* as well as SV40 T antigen expressing tumor cells we detected up to 50% CD40L expressing $CD8^+$ T cells among the antigen-specific $CD8^+$ T-cell populations. In peripheral blood of healthy human donors on average 25% of memory $CD8^+$ T cells express CD40L. These $CD40L^+$ $CD8^+$ T cells display plasticity with respect to their cytokine profile similar to $CD4^+$ T_h cells and accordingly express cytokines as IL-2, IL-4, IL-17 or IFNγ. Furthermore, *in vitro* assays revealed that $CD40L^+$ $CD8^+$ T cells resemble also functional properties of T_h cells and therefore are able to activate properly B cells or DC, shown e.g. by IgG or IL-12 secretion, respectively.

To analyze the impact of CD40L expression on $CD8^+$ T cells *in vivo* we challenged $Rag1^{-/-}$ mice with tumor cells and injected wt or $CD40L^{-/-}$ $CD8^+$ T cells. Application of wt $CD8^+$ T cells prevented the establishment of a solid tumor, whereas injection of $CD40L^{-/-}$ $CD8^+$ T cells alone resulted in a non-controlled tumor progression similar to non-treated tumors demonstrating that $CD8^+$ T-cell mediated immunity can be heavily impaired in the absence of $CD8^+$ T-cell inherent CD40L expression.

Conclusions: Our results disclose an essential functional relevance of CD40L expressed by $CD8^+$ T cells. Especially, in situations of reduced

$CD4^+$ T-cell help, MHC-II antigen presentation or in tumor-driven tolerogenic conditions with limited danger signals $CD40L^+$ $CD8^+$ T cells may exert essential helper responsibilities for immunity and thus are potent T cells to execute or support effective anti-tumor or anti-pathogen immune therapies.

P0503

Characterisation of IL-10-producing $CD4^+$ T cells induced by IL-27: implications in autoimmune inflammation?

A. Young, T. O'Hagan & D. C. Fitzgerald
Centre for Infection and Immunity, Queens University Belfast, Belfast, UK

Purpose/Objective: Interleukin 27 (IL-27) is a heterodimeric cytokine that was originally believed to be pro-inflammatory by polarising naïve $CD4^+$ T cells to a Th1 cell phenotype. IL-27 has more recently been shown to exhibit a range of potent anti-inflammatory effects on T cells, including the up-regulation of Interleukin 10 (IL-10) production in Interferon-γ^+ (IFN-γ^+) T cells. However there is ambiguity regarding the phenotype and function of IL-10^+ IFN-γ^+ T cells and the role these cells may play in autoimmune diseases such as Experimental Autoimmune Encephalomyelitis (EAE), an animal model of Multiple Sclerosis (MS).
Materials and methods: $CD4^+$ T cells were activated with anti-CD3 and anti-CD28 antibodies *in vitro* for up to 72hrs in non-polarising (NP), Th1, iTreg and Tr1 cell polarising conditions in the presence or absence ($^{+/-}$) of IL-27 and analysed by flow cytometry and ELISA. For *in vivo* investigations, SJL mice were immunised with Proteolipid Protein $_{139-151}$ ($PLP_{139-151}$) in Complete Freunds Adjuvant (CFA) to induce Relapsing Remitting EAE (RR-EAE), and were examined for the presence of IL-10^+ IFN-γ^+ T cells at multiple phases of disease in the periphery and CNS.
Results: IL-10 producing $CD4^+$ T cells driven by IL-27 exhibited high expression of T-bet while lacking Foxp3 and IL-21 (associated with iTreg and Tr1 cells respectively). By ELISA, IL-27 up-regulated IFN-γ and IL-10 secretion, while inhibiting IL-5, another Tr1-associated cytokine. This phenotype was enhanced under Th1 polarising stimuli. *In vivo*, IL-10^+ IFN-γ^+ $CD4^+$ T cells were detectible in low numbers in spleen, lymph node and in spinal cord at multiple disease phases of EAE with variation according to disease phase.
Conclusions: In conclusion these studies show that IL-10^+ $CD4^+$ T cells induced by IL-27 *in vitro* express markers of Th1 cells. *In vivo*, IL-10-producing Th1 cells were present in the periphery and CNS of mice with RR-EAE. Taken together our findings suggest that IL-27 drives the development of IL-10-producing Th1 cells which may modulate autoimmune inflammation.

Chemoimmunotherapy of MC38 mouse colon carcinoma: cyclophosphamide and dendritic cell vaccine treatment induces the differentiation of $CD4^+$ lymphocytes

J. Wojas-Turek,* E. Pajtasz-Piasecka,† J. Kicielinska,† J. Rossowska,‡ D. Dus‡ & E. Piasecki*
**Laboratory of Virology, Institute of Immunology and Experimental Therapy, Wroclaw, Poland, †Laboratory of Experimental Anticancer Therapy, Institute of Immunology and Experimental Therapy, Wroclaw, Poland, ‡Laboratory of Glycobiology and Cell Interactions, Institute of Immunology and Experimental Therapy, Wroclaw, Poland*

Purpose/Objective: The study aimed to determine the $CD4^+$ cell differentiation induced by the administration of the chemotherapeutic agent and dendritic cell (DC)-based vaccines in MC38 colon carcinoma-bearing C57BL/6 mice.
Materials and methods: C57BL/6 mice with advanced MC38 tumor were injected with cyclophosphamide (CY). After three days, mice were injected with vaccines consisted of bone marrow-derived dendritic cells pulsed with tumor lysate (BM-DC/TAg) and/or dendritic cells of JAWS II line genetically modified for IL-2 production (JAWS II/IL-2) or with control gene JAWS II/Neo. Cell vaccines were administrated in three consecutive weeks. Tumor growth delay over control was estimated. On the 7th day after the last injection, spleens were harvested and splenocytes were stimulated with Concanavalin A (ConA). The percentage of $CD4^+$ cells expressing transcription factors characteristic for lymphocytes Th1, Th2, Th17 and Treg in stimulated splenocytes was analyzed. The production of interferon γ (IFN-γ), interleukin (IL-)4 and IL-17A by cells stimulated with ConA was evaluated.
Results: Administration of cyclophosphamide followed by dendritic cell vaccines caused tumor growth delay compared to CY alone. Chemoimmunotherapy increased the percentage of Th1, Th2 and Th17 and decreased the percentage of Treg cells among $CD4^+$ splenocytes stimulated with ConA, especially when vaccines contained BM-DC/TAg^+ genetically modified JAWS II cells. Additionally, this combined therapy resulted in increase in IFN-γ, IL-4 and IL-17A production by stimulated spleen cells.
Conclusions: Taken together, these findings suggest that administration of CY followed by DC-based vaccines induces the differentiation of Th1, Th2 and Th17 splenocytes and cause decrease in percentage of Treg cells in $CD4^+$ spleen cells. Observed changes in the number of $CD4^+$ T cell of each subsets during chemoimmunotherapy may be valuable prognostic factor and a basis for future improvements of anticancer therapy

The financial support of the study is granted by the National Science Center of Poland (decision number DEC-2011/01/N/NZ4/01725).

Comparison of effector and regulatory cytokine expression of T cells in the target organ of experimental monophasic and relapsing autoimmune disease

U. Kaufmann, M. Diedrichs-Möhring & G. Wildner
Ophthalmology, Klinikum der Universität München, München, Germany

Purpose/Objective: Human autoimmune diseases usually present with a chronic or relapsing course, while most animal models are monophasic. We could establish a rat model of relapsing autoimmune uveitis (EAU), an intraocular inflammatory disease, which enables us to investigate the underlying immune reactions. We compared the intraocular immune cell populations isolated during the course of relapsing with that of monophasic EAU.
Materials and methods: Rats were immunized with retinal soluble antigen (S-Ag) peptide PDSAg (inducing monophasic EAU) or interphotoreceptor retinoid-binding protein (IRBP) peptide R14 (inducing relapsing EAU) in CFA. Intraocular cells were collected at various time points during ocular inflammation and stained *ex vivo* for TCR-$\alpha\beta$ and intracellular IFN-γ, IL-17, IL-10 and Foxp3 expression.
Results: During the course of monophasic uveitis intraocular T cells coexpressing IFN-γ with IL-17, as well as IFN-γ or IL-17 with IL-10, respectively, increased. In contrast, in relapsing EAU the number of IL-17^+ , IFN-γ^+IL-17^+ and IL-17^+ IL-10^+ cells decreased at resolution, while IFN-γ^+ cell numbers remained elevated also during relapses. In general, only cell populations that express only one of the tested cytokines slightly increased or remained stable during recurrences. $Foxp3^+$ cells increased in both, monophasic and relapsing EAU.
Conclusions: The change of the intraocular T cell populations during EAU and the large numbers of T cells producing multiple cytokines point to a strong population dynamics in the eye. We observed differences between monophasic and relapsing disease with respect to IFN-γ^+ and IL-17^+ populations. The strong increase of IL-10^+ T cells in

the eyes during monophasic EAU suggests a regulatory role of these cells with a potential to prevent relapses, rather than Foxp3 expressing cells, which increased in both monophasic and relapsing EAU.

P0506
Der P 1 induces FOXP3$^+$ GATA3$^+$ T cells in allergic individuals

L. L. Reubsaet,* R. Giezeman,* J. Meerding,* H. G. M. Arets,† I. M. de Kleer,‡ B. J. Prakken,* F. van Wijk & J. Beekman****
**Center for Molecular and Cellular Intervention, UMC Utrecht, Utrecht, The Netherlands, †Department of Pediatric Respiratory Medicine, UMC Utrecht, Utrecht, The Netherlands, ‡Laboratory of Immunoregulation, Department for Molecular Biomedical Research (DMBR) – VIB, Ghent University, Ghent, Belgium , , ,*

Purpose/Objective: Functionally distinct T helper cell subsets such as regulatory T cells (Treg) and T helper 2 (Th2) cells play an important role in allergy. Originally FOXP3 and GATA3 were shown to be the master transcription factors for Treg and Th2 cells, respectively. However accumulating evidence, mainly from murine models, indicates that these transcription factors are not restricted to a single T cell lineage and GATA3 expression has been implicated in controlling Treg physiology under inflammatory conditions. So far data on the differential function of these transcription factors in humans are lacking and it remains to be investigated whether these have additional functions in human disease. We studied the *in vitro* induction of FOXP3 and GATA3 upon antigen-specific activation.
Materials and methods: We stimulated peripheral blood mononuclear cells (PBMC) of allergic children and non-sensitized healthy controls with allergens like Der P1 and Bet V1. After various days of culture cells were analyzed for transcription factors GATA3 and FOXP3, phenotypic markers and different cytokines to evaluate differences in Th2 and Treg responses.
Results: In allergic individuals, besides a pronounced Th2 response with high GATA3, IL4 and IL13 expression, a select population of cells was found to co-express both GATA3 and FOXP3. These double positive cells were highly proliferative upon allergen stimulation and produced Th2 cytokines, but at lower levels than the GATA3 single positive cells. In addition, they were able to potently suppress T cell proliferation and the production of IFNgamma and TNFalpha *in vitro*.
Conclusions: In conclusion, we identified a unique allergen-specific CD4$^+$ T cell population that co-expresses GATA3 and Foxp3 and displays functional features of both a Th2 and Treg phenotype. These data further indicate that GATA3 and FoxP3 cannot be used to uniquely define human T helper cell subsets.

P0507
Distinct differentiation requirements and functional properties of microbe-specific human Th17 cells

C. E. Zielinski,* D. Jarrossay,† F. Ronchi,† A. Lanzavecchia† & F. Sallusto†
**Department of Dermatology and Allergology, Charité University-Medicine Berlin, Berlin, Germany, †Cellular Immunology, Institute for Research in Biomedicine, Bellinzona, Switzerland*

Purpose/Objective: Th17 cells have emerged as a new T helper cell lineage involved in the clearance of extracellular bacteria and fungi. A dys-regulated Th17 response, however, can induce severe tissue destruction and autoimmunity. Therefore, mechanisms must be in place to shield the host from immune-mediated damage. In this study our aim was to analyze mechanisms by which human Th17 cell responses could be restrained in settings of infections.
Materials and methods: We developed an *in vitro* assay for the generation of human antigen specific T helper cells using whole microbial antigens.
Results: We demonstrate that human Th17 cells transiently produce the anti-inflammatory cytokine IL-10 upon stimulation. Interestingly, IL-10 expression was accompanied by reciprocal down-regulation of IL-17, leading to a functional regulatory Th17 cell phenotype after the peak of the effector response. The ability of Th17 cells to express IL-10 was, however, restricted to certain antigen specificities. *Ex vivo* isolated *C. albicans* specific Th17 cells could not produce IL-10 in comparison to *S. aureus* specific Th17 cells. This was due to differential priming requirements of these Th17 cell sub-populations. IL-1beta instructed naïve T cells to develop into a pro-inflammatory non-IL10 expressing Th17 cell subset. Th17 cell priming with *S. aureus*, however, was not IL-1beta dependent, leading instead to the generation of IL-10 producing Th17 cells with self-regulatory activities.
Conclusions: Thus, using a novel approach that combines the *in vitro* priming of naïve T cells by whole microbes with the *ex vivo* analysis of memory T cells we were able to unmask the existence of two types of Th17 cells that differ in priming requirements, TCR repertoire and function. This approach revealed that IL-1beta is a molecular switch for determining a functional memory for IL-10 expression. This has important consequences for the physiological termination of pro-inflammatory immune responses and the limitation of bystander damage in certain pathogen microenvironments. Targeting IL-1beta early in the differentiation process of Th17 cells (as we demonstrate with IL1ra therapy in CAPS patients) might therefore represent a promising therapeutic strategy to confer anti-inflammatory properties to cellular mediators of autoimmune diseases.

P0508
Distinctive features of classic and non-classic (Th17-derived) human Th1 cells

M. Capone, L. Maggi, V. Santarlasci, M. C. Rossi, V. Querci, E. Maggi, F. Liotta, L. Cosmi, S. Romagnani & F. Annunziato
Internal Medicine, University of Florence, Florence, Italy

Purpose/Objective: T helper 17 (Th17) lymphocytes represent a third arm of the CD4$^+$ T cell effector responses in addition to Th1 and Th2 cells. Th17 cells have been found to exhibit high plasticity because they rapidly shift into the Th1 phenotype in the inflammatory sites. In human beings, Th1 cells derived from Th17 cells express CD161, whereas classic Th1 cells do not, and they have been named as non-classic Th1 cells.
Materials and methods: In this study, we examined similarities and differences between classic and non-classic human Th1 cells by assessing a panel of T-cell clones, as well as CD161$^+$ or CD161$^-$CD4$^+$ T cells derived *ex-vivo* from the circulation of healthy subjects or the synovial fluid of patients with juvenile idiopathic arthritis.
Results: The results showed that non-classic Th1 cells could be identified because of CD161 expression, as well as the consistent expression of retinoic acid orphan receptor C, IL-17 receptor E, CCR6 and IL-4-induced gene 1, which were all virtually absent in classic Th1 cells.
Conclusions: The possibility to distinguish these two cell subsets by using such a panel of markers may allow the opportunity to better establish the respective pathogenic role of classic and non-classic (Th17-derived) Th1 cells in different chronic inflammatory disorders.

P0509

GM-CSF production by $CD4^+$ T cells from MS patients

E. Peelen,* J. Damoiseaux,† S. Knippenberg,* A. H. Muris,* J. Smolders,‡ J. W. Cohen Tervaert,§ R. Hupperts¶ & M. Thewissen§
**School for Mental Health and Neuroscience, Maastricht University Medical Center, Maastricht, The Netherlands, †Laboratory for Clinical Immunology, Maastricht University Medical Center, Maastricht, The Netherlands, ‡Department of Neurology, St. Antonius Ziekenhuis, Nieuwegein, The Netherlands, §Department of Internal Medicine, Maastricht University Medical Center, Maastricht, The Netherlands, ¶Department of Neurology, Orbis Medical Center, Sittard, The Netherlands*

Purpose/Objective: Th17 cells are believed to be the main pathogenic T cells in multiple sclerosis (MS). Recent studies in experimental models of MS suggest that GM-CSF producing T cells might be even more pathogenic. Data on GM-CSF in MS patients are scarce. We hypothesize that GM-CSF expression is elevated within the $CD4^+$ T cell compartment of MS patients.
Materials and methods: PBMC and $CD4^+$ T cells were isolated from MS patients ($n = 31$ and $n = 33$, respectively) and healthy controls (HC; $n = 21$ and $n = 20$, respectively). GM-CSF mRNA expression was assessed by real-time quantitative PCR and is expressed relative to GAPDH expression levels. Intracellular flow cytometry was performed on PBMC from HC and MS patients (untreated, glatiramer acetate (GA) or interferon beta (IFN-β) treated patients) to determine the fraction of $GM\text{-}CSF^+$ cells within the $CD4^+$ T cell compartment. Differences between cohorts were assessed with the Mann-Whitney U-test and Bonferroni correction was used to compensate for multiple testing. A P-value <0.025 was considered significant.
Results: GM-CSF mRNA expression levels are higher in PBMC as compared to $CD4^+$ T cells ($n = 52$; $24.2-10^{-3}$ [9.5×10^{-3}—45.5×10^{-3}] and $n = 53$; 9.1×10^{-4} [5.6×10^{-4}—13.3×10^{-4}], respectively; $P < 0.0001$). GM-CSF mRNA levels do not differ between MS patients and HC in PBMC (24.0×10^{-3} [9.2×10^{-3}—43.9×10^{-3}] and 24.4×10^{-3} [9.9×10^{-3}—46.9×10^{-3}], respectively) or in $CD4^+$ T cells (7.6×10^{-4} [5.6×10^{-4}—1.2×10^{-4}] and 10.9×10^{-4} [5.4×10^{-4}—1.6×10^{-4}], respectively). Preliminary data show that, compared to HC, the $GM\text{-}CSF^+CD4^+$ T cell percentage is elevated in MS patients without treatment. Compared to HC, the fraction of these cells was comparable in MS patients on IFN-β treatment and lower in MS patients treated with GA.
Conclusions: GM-CSF mRNA expression levels are comparable between MS patients and HC. Preliminary data suggest that the $GM\text{-}CSF^+CD4^+$ T cell percentage in the circulation is elevated in MS patients compared to HC. Medication, especially GA, seems to be able to reduce $GM\text{-}CSF^+CD4^+$ T cell numbers.

P0510

Heterogeneous concentrations of interleukin-27 and the environment specific effects of interleukins-17 and -27 in humans

M. Forrester,* L. Robertson,* B. Keavney,† R. Barker* & M. Vickers*
**Immunology and Infection, Institute of Medical Sciences University of Aberdeen, Aberdeen, UK, †Molecular Cardiovascular Medicine, Institute of Human Genetics Newcastle University, Newcastle, UK*

Purpose/Objective: Data suggest both pro-and anti-inflammatory functions for IL-27. We therefore investigated the role of IL-27 in humans, with particular emphasis on its heterogeneity and relationships with IL-17.
Materials and methods: IL-27 levels by ELISA in (i) plasma of 879 healthy humans from 163 families (ii) after induction by IL-17 from PBMC.
Results: Concentrations were heterogeneous, spanning two orders of magnitude.Heritability (19%) was relatively low, indicating most variation was environmentally determined.As ~10% individuals had high levels, one of the subunits of IL-27 is Epstein-Barr virus -induced gene 3 (EBI3) and ~5—10% of individuals are uninfected with the virus, we tested whether prior infection with EBV, or CMV, was associated with IL-27 values but little correlation was seen.IL-27 has been reported to inhibit IL-17 production, so we also measured IL-17 values in a subset of individuals and, surprisingly, demonstrated a strong positive correlation, but low correlations with other pro-inflammatory cytokines. We also verified that IL-27 inhibited IL-17 production *in vitro*, but were unable to confirm its stimulation of IL-10 secretion.
Conclusions: IL-27 levels are very heterogeneous in human populations, but correlate with IL-17 levels, which suggests how the two cytokines might interact*in vivo*.

P0511

Human T helper 17 responses: the effect of T-cell density

H. Purvis, A. E. Anderson & C. M. U. Hilkens
Musculoskeletal Research Group, Institute of Cellular Medicine, Newcastle upon Tyne, UK

Purpose/Objective: Both the cytokine milieu and quality of T-cell activation are capable of determining effector $CD4^+$ T-cell development. We recently found that low strength T-cell activation promotes T helper 17 (Th17) cell responses via a Ca^{2+} /NFATc1 dependent mechanism. Here we have extended these investigations by assessing the effect of T-cell density, on Th17 cell responses. T-cell density is a parameter often overlooked within *in vitro* investigations, but is capable of modulating many parameters including the expression of certain Th17 cell related transcription factors.
Materials and methods: Memory $CD4^+$ T-cells were activated with anti-CD3/anti-CD28 beads at a high strength stimulus of 1:1 cell:bead ratio, in the presence of pro-Th17 cell cytokines IL-1β, TGF-β, and IL-23. Cell density was decreased from 1×10^6 to 0.0625×10^6 cells/ml, maintaining a 1:1 cell:bead ratio. After 6 days the proportion and number of IL-17- and IFN-g-producing cells was determined by intracellular cytokine staining and flow cytometry.

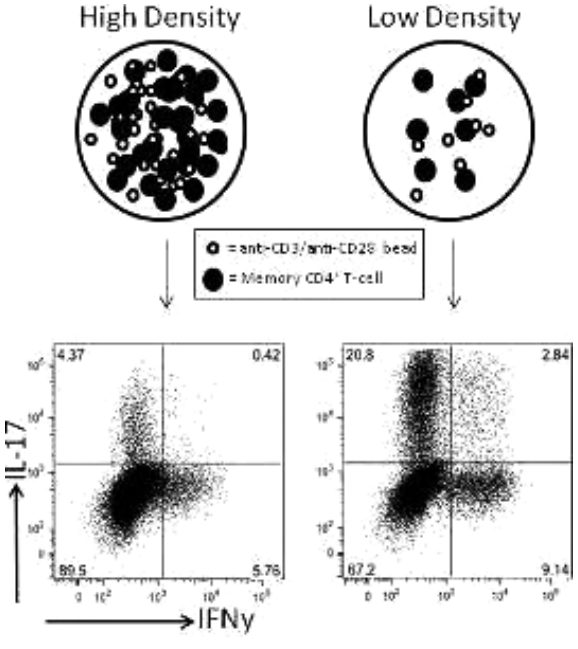

Figure 1. Low T-cell density promotes Th17 responses.

Results: Our results demonstrate that low cell density significantly increased both the proportion and absolute numbers of IL-17$^+$ cells. Titration of pro-Th17 cell cytokines revealed that the effect was not due to excess cytokine availability. Furthermore, Th1 cell responses, in the presence of IL-12, were unaffected by cell density, suggesting an IL-17-selective effect of cell density. STAT3 and Aryl hydrocarbon Receptor (AhR) are two transcription factors involved in promoting Th17 cell responses. Previous studies have indicated that STAT3 and AhR activation and expression may, in part, be dictated by cell density. We found an increased level of STAT3 phosphorylation and AhR expression in low density T-cells, compared to high density T-cells, possibly explaining how activation of T-cells at low density favours Th17 cell responses.
Conclusions: These findings provide new insights into the complex range of factors capable of affecting Th17 cell responses, and have important implications for *in vitro* differentiation models.

P0512
IL-17 signaling is related to disease severity in chemically induced type 1 diabetes

J. N. U. Yaochite,* C. Caliari-Oliveira,* M. R. Davanso,* D. Carlos,* K. C. R. Malmegrim,† C. R. B. Cardoso,‡ L. N. Z. Ramalho,§ P. V. B. Palma,† J. S. Silva,* F. Q. Cunha,¶ D. T. Covas† & J. C. Voltarelli*
**Basic and Applied Immunology, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, †School of Medicine of Ribeirão Preto, Regional Hemotherapy Center, University of São Paulo, Ribeirão Preto, Brazil, ‡Department of Clinical Toxicological and Bromatological Analysis, School of Pharmaceutical Sciences of Ribeirão Preto University of São Paulo, Ribeirão Preto, Brazil, §Department of Pathology, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, ¶Department of Pharmacology, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil*

Purpose/Objective: IL-17-secreting CD4$^+$ T cells play an important pathogenic role in several models of autoimmune diseases. However, their involvement in diabetes development is still not well understood, and controversial data are present in the literature. The aim of this study was to examine the role of IL-17 during the initial phase of diabetes development.
Materials and methods: The diabetes was induced in C57BL/6 (WT) and IL-17 receptor deficient (*Il17r* KO) mice after five consecutive injections of streptozotocin (STZ). Pancreas and pancreatic lymph nodes were harvested six days after the last dose of STZ. Pancreatic lymph nodes were analyzed by flow cytometry and the histopathological alterations in the pancreatic islets were evaluated by H&E and immunohistochemistry staining.
Results: Six days after STZ administration, we observed that *Il17r* KO mice showed decreased levels of blood glucose when compared to diabetic WT mice (241 ± 25.65 mg/dl versus 337.2 ± 24.06 mg/dl, respectively). To assess whether this resistance was accompanied by a reduced islet inflammation, pancreatic sections from *Il17r* KO and WT were analyzed. Histological results showed that diabetic WT mice exhibited typical islet inflammation, whereas *Il17r* KO islets had none or few inflammatory cells. In addition, we observed a preservation of beta cells mass in *Il17r* KO mice, demonstrated by insulin staining, when compared to WT mice. To explore the possibility that alterations in regulatory T cells or IFN-γ-producing T cells might play a role in the resistance of the *Il17r* KO mice to the development of diabetes we assessed the frequency of these populations in the spleen and pancreatic lymph nodes. We observed that *Il17r* KO mice exhibited increased frequencies of regulatory T cells (CD4$^+$ CD25$^+$ Foxp3$^+$) in PLNs when compared to WT mice. We did not observe differences in CD3$^+$ CD4$^+$ IFN-γ^+ or CD3$^+$ CD8$^+$ IFN-γ^+ populations in spleen and PLNs.
Conclusions: Thus, differences in disease severity cannot be explained by alterations in IFN- γ -producing T cells. However, the IL-17 signaling appears to counter regulate the regulatory T cell induction in PLNs and influence the diabetes development. Finally, the IL-17 signaling is involved in the initiation of the early events of beta cell destruction in STZ-induced diabetes model.

P0513
IL-21 limits human T helper effector cell differentiation by antagonizing IL-2 signaling

J. de Wit,* T. Jorritsma,* H. Klaasse Bos,* F. S. van de Bovenkamp,* J. Neefjes† & S. M. van Ham*
**Sanquin Research and Landsteiner Laboratory, Department of Immunopathology, Academical Medical Center, University of Amsterdam, Amsterdam, The Netherlands, †Division of Cell Biology, The Netherlands Cancer Institute, Amsterdam, The Netherlands*

Purpose/Objective: Induction and regulation of follicular T helper (Tfh) cells are still a matter of debate. IL-21 has been shown to maintain the Tfh subset, whereas IL-2 signaling inhibits Tfh differentiation. However, regulation of Tfh after migration into the germinal center is not completely understood, since regulatory T cells are unable to migrate into the germinal center. With this study we further investigate the role of IL-21 and IL-2 in the regulation of effector functions of human T helper cells.
Materials and methods: We used *Salmonella*-infected B cells to induce optimal Tfh differentiation of naïve and memory T cells, and studied T helper cell activation and differentiation by intracellular cytokine staining and mRNA transcription levels.
Results: Using *Salmonella*-infected human B cells, we show that the Tfh cytokine IL-21 regulates the contraction phase of activated CD4$^+$ T cells. Although IL-21 enhances T cell proliferation at the beginning of activation, proliferation and differentiation is arrested at later stages. We found that IL-21 counteracts effector cell formation through inhibition of endogenous IL-2 synthesis. In line with this, addition of IL-2 almost completely restores proliferation and Th differentiation in presence of IL-21.
Conclusions: Thus, Tfh can downmodulate the immunresponse via secretion of IL-21, preventing hyper inflammatory responses in the germinal center.

IL-4 negatively regulates IL-5 memory expression in T helper type 2 cells

H. Chang, N. Andreas & A. Radbruch
Cell Biology, Deutsches Rheuma-Forschungszentrum Berlin, Berlin, Germany

Purpose/Objective: T helper type 2 (Th2) cells are characterized by their expression of interleukin-4 (IL-4), IL-5, and IL-13. It has been well established that for the expression of these cytokines the transcription factor GATA-3 is required. While the memory for IL-4 reexpression in Th2 cells has been intensively studied, regulation of IL-5 and IL-13 reexpression is less clear. Thus, we have analyzed the stability and plasticity of IL-5 memory expression in Th2 cells.
Materials and methods: In order to analyze the IL-5 expression on single cell level, we have isolated IL-5 expressing cells with the IL-5 cytokine secretion assay from *in vitro* generated Th2 cells. We have analyzed the fidelity of IL-5 reexpression in the presence or absence of the Th2 instructive signal IL-4 and have also analyzed the IL-4 dependence of IL-33 induced IL-5 expression.
Results: Our results show that although IL-5 expression is induced via the IL-4/STAT6/GATA-3 axis, blockade of IL-4 with anti-IL-4

antibodies during subsequent reactivation greatly enhanced the frequency of Th2 cells expressing IL-5. IL-5 memory expression was directly inhibited as IL-4 inhibited the reexpression of IL-5 in Th2 cells previously sorted based on IL-5 expression. IL-4 also inhibited IL-5 expression in Th cells which ectopically overexpressed GATA-3. The presence or absence of IL-4 did not influence the reexpression of IL-4 or the expression of GATA-3 in Th2 cells. In addition we could also demonstrate that IL-5 expression induced by stimulation of Th cells in the presence of IL-33 was also inhibited by IL-4.
Conclusions: We could show that the memory expression of IL-5 in Th cells is inhibited by the presence of IL-4. Thus, we have identified a negative regulatory feedback mechanism which limits the expression of IL-5 in memory Th2 cells through autocrine IL-4 signaling. This could present a mechanism which limits IL-5 mediated immunopathology in Th2 immune responses.

Inhibition of TNFRII signalling by anti-TNFa polarizes naïve $CD4^+$ T cell towards IL-10^+ cells with strong regulatory phenotype and function

A. Ten Brinke, M. A. Boks, J. R. Kager-Groenland & S. M. van Ham
Immunopathology, Sanquin Blood Supply, Amsterdam, The Netherlands

Purpose/Objective: TNFα is a potent pro-inflammatory cytokine playing a pivotal role in several autoimmune diseases. Neutralizing TNFα inhibits T cell proliferation and IFNγ production, and enhances suppressive capacity of regulatory T cells (Treg). Little is known about the effect of TNFα blocking agents on naïve T cell differentiation.
Materials and methods: In order to investigate the role of TNFα in T cell polarization, we blocked TNFα with adalimumab, a human monoclonal antibody against TNFα. We have previously shown that IL-10-generated tolerogenic (t) DC are excellent inducers of regulatory T cells (Treg) that strongly suppress T cell reactivity. As IL-10 tDC produce high amounts of the pro-inflammatory cytokine TNFα, we used these DC to investigate effects of presence or absence of anti-TNFα on naïve T cells priming. Primed T cells are analyzed by intracellular cytokine staining, micro array analysis and tested for functional suppression in a suppression assay.
Results: Here, we report that neutralizing TNFα during priming of naïve $CD4^+$ T cells favors development of IL-10^+ Th cells at the expense of IFNγ expressing effector Th cells. TNF inhibits IL-10 via TNFRII, which becomes expressed a few days after naïve T cell activation. Neutralization of TNFα did not affect initial $CD4^+$ T cell activation, but negatively affected later stages of T cell priming by counteracting full T cell differentiation and increasing cell death. Whole genome gene expression analysis revealed a regulatory gene profile of anti-TNFα-treated T cells. Indeed, neutralizing TNFα during naïve T cell priming enhanced the suppressive function of the anti-TNFα-treated T cells in a functional suppression assay.
Conclusions: Taken together, inhibition of TNFα*TNFRII interaction affects late stage effector T cell development and shifts the balance of Th differentiation towards immune regulation, which might be beneficial in TNFα blocking therapies.

Interferon gamma protects mice from CNS autoimmunity also in the absence of IL-17A and IL-17F

T. Regen,* J. Huppert,* N. Yogev,* I. Prinz† & A. Waisman*
**Institute for Molecular Medicine, University Medical Center of the Johannes Gutenberg University, Mainz, Germany, †Hannover Medical School, Institute of Immunology, Hannover, Germany*

Purpose/Objective: The role of interferon (IFN)-gamma-producing T helper (Th) 1 and interleukin (IL)-17-expressing Th17 lymphocytes in multiple sclerosis (MS) and its animal model, experimental autoimmune encephalomyelitis (EAE) is still subject to intense investigations. Here we sought to decipher the specific involvement of these Th cell subsets during manifestation and the clinical phase of EAE.
Materials and methods: A major hallmark of encephalitogenic Th17 cells is the expression of IL-17A and IL-17F, which together form the heterodimeric effector cytokine. Therefore, we used a double-knockout mouse lacking both isoforms of IL-17 (IL-17AFKO). Additionally, this mouse was crossed to the routinely used IFN-gamma deficient mouse, resulting in triple-knockout IL-17AFKO/IFNgKO animals. Mice were subjected to EAE induction with monitoring of the disease course and subsequent flow cytometric analysis of CNS infiltrates.
Results: As demonstrated before, following active MOG peptide immunization, IFNgKO mice developed an exacerbated EAE disease course compared to wild type C57Bl/6 controls. In contrast, IL-17AFKO animals failed to induce prominent disease which was accompanied by a dramatic reduction of CNS-infiltrating immune cells. This phenotype could be partially reversed in triple-knockout animals as these mice showed a delayed onset of EAE with severity of disease reaching the level of wild type controls. Essentially, these results were confirmed in a model of passive EAE where *in vitro*-restimulated mutant T cells were adoptively transferred into wild type recipients. Transfer of IFNgKO as well as triple-knockout cells resulted in disease of comparable levels whereas IL-17AFKO cells failed to induce any signs of EAE.
Conclusions: These results argue for a non-redundant role of IL-17 (AF) for the induction of experimental neurodegenerative disease. Moreover, the beneficial role of IFN-gamma in EAE seems to be independent of the action of IL-17. Finally, our results clearly point towards T cells as carriers of these effects.

P0518

Level of CD44 activation marker expression distinguishes allo-reactive TH17 from TH1 cells

J. Schumann, U. Schließer, C. Appelt, G. Grütz & B. Sawitzki
Medical Immunology, Charité – Institute of Medical Immunology, Berlin, Germany

Purpose/Objective: CD44 is the most prominent activation marker which distinguishes memory and effector from naïve T cells. It is rapidly up-regulated upon T cell stimulation. CD44 is a surface protein and functions as adhesion protein, which mediates rolling over endothelial cells and thereby infiltration into inflamed tissue (for review see Baaten et al., 2012). Interestingly, Il-17 producing T cells dominate over IFNγ$^+$ TH1 cells in peripheral tissues such as lung, liver and gut (Park et al., 2006; Weaver et al., 2009). Here we compared the required TCR signaling strength and activation marker expression of allo-reactive IL-17 or IFNγ producing T cells.
Materials and methods: CD4 MACS sorted cells from lymph nodes and spleen of C57Bl/6 mice were co-cultured with allogeneic bone marrow derived DCs (BMDCs) from BALB/c mice for four days and analyzed by flow cytometry.
Results: Interestingly, covalently labeling of $CD4^+$ T cells with proliferation dye such as CFSE prior to co-culture with allogeneic BMDCs reduced the frequency of CD44 high and IL-$17A^+$ T cells. Similarly, pre-treatment of $CD4^+$ T cells with cytochalasin, which inhibits TCR synapse formation and thus signaling, leads to a decrease in IL-17^+ T cells while IFNγ producing T cells remain nearly unaffected. In order to further investigate whether generation of IL-17^+ T cells needs a strong T cell activation we pre-incubated the BMDCs with increasing amounts of LPS. Indeed, the percentage of IL-17^+ T cells increases with the level of LPS-induced MHCII/CD86 expression on DCs. Furthermore, while $IL17^+$ cells show a very high CD44 expression, IFNγ$^+$ cells are characterized by intermediate CD44 expression. Moreover, co-culture of T cells under TH17 polarizing

conditions increases the percentage of CD44 high T cells, while TH1 polarization results in a reduction of high CD44 expressing T cells. Preliminary results revealed that CD44 low expressing cells accumulate mainly in blood and spleen, but not in peripheral tissues.
Conclusions: Taken together our data demonstrate that a high TCR signaling strength results in an increased formation of IL-17$^+$ T cells. Moreover, allo-reactive IL-17$^+$ cells express high levels of CD44 while IFNγ^+ cells show reduced CD44 expression. Strong CD44 expression on T cells increases the ability to migrate to tissues.

P0519
NFATc2 and c-Jun have unique and non-redundant functions in regulation of chromatin conformation at the TNF promoter in T helper lymphocyte subsets

Y. V. Shebzukhov & S. A. Nedospasov
Inflammation Biology, German Rheumatism Research Centre Berlin a Leibniz Institute, Berlin, Germany

Purpose/Objective: Tumor necrosis factor (TNF) is one of the key primary response genes in the immune system activated by variety of stimuli. The purpose of this study was to analyze chromatin conformation at the TNF promoter region in different subsets of T helper (Th) lymphocytes, assuming that it may be different from one found in macrophages.
Materials and methods: For the analysis of chromatin conformation at the TNF promoter in mouse T cells we probed DNA accessibility in chromatin with restriction nucleases and micrococcal nuclease. Quantitative RT-PCR was used for the evaluation of TNF mRNA. Western blotting was applied for the analysis of major transcription factors in nuclear fractions of T cells.
Results: We found that the proximal TNF promoter has a closed chromatin conformation in primary T helper cells and acquires an open state only after activation or polarization under Th1 and Th17, but not under Th2 conditions. Transcription factors NFATc2 and c-Jun are required for such chromatin remodeling at the proximal TNF promoter in T cells, but the two appear to have different roles in this process. NFATc2 plays the primary role in the acquisition of open chromatin conformation at the proximal TNF promoter upon activation, while phosphorylated c-Jun is necessary for the maintenance of this open conformation in cells polarized under Th1 and Th17 conditions.
Conclusions: Transcription factors NFATc2 and c-Jun play unique and non-redundant roles in regulation of chromatin conformation at the TNF promoter in T helper cells.

P0520
Novel factors involved in Th17 cell differentiation

H. Ahlfors,* S. Rautio,† T. Äijö,† H. Lähdesmäki† & B. Stockinger*
**Molecular Immunology, MRC National Institute for Medical Research, London, UK, †Department of Information and Computer Science, Aalto University, Espoo, Finland*

Purpose/Objective: Naive CD4$^+$ T helper (Th) cells can differentiate in the presence of IL6 and TGFb into Th17 cells, which provide immunity against extracellular bacterial and fungal pathogens but are also implicated in pathological responses, such as autoimmune diseases. Aryl hydrocarbon receptor (AhR), also known as a dioxin receptor, is a transcription factor, which is upregulated during the Th17 cell differentiation. Our objective is to identify and define the underlying regulatory mechanisms and signalling networks that determine the steps essential for generating Th17 phenotype.
Materials and methods: We have performed a detailed kinetics study to dissect the gene expression profile of Th17 cells under conventional or modified polarizing conditions and using mouse strains with different affinity of AhR. FACS sorted naïve CD4$^+$ T cells were activated with plate-bound anti-CD3 and anti-CD28. Th17 differentiation was induced with a combination of cytokines TGFb and IL6 and modified with IL1b or IL21 or AhR ligand FICZ. An endpoint assessment of an aliquot for each condition was tested after 72 or 96h for intracellular expression of IL-17A as well as secreted cytokines. The gene expression profiles were analysed using Illumina mouse whole genome beadarrays and mRNA-seq technology.
Results: Preliminary results show that thousands of genes are differentially expressed in the developing Th17 cells compared to naïve or activated T cells. These differentially expressed genes include key transcription factors, such as *Rorc*, *Rora* and *Batf*, Th17 cell hallmark cytokines *Il17a*, *Il17f* and *Il22* as well as characteristic surface markers *Il23R* and *Ccr6*. Some of these molecules are also controlled by AhR as their expression is differentially regulated in AhR$^{-/-}$ CD4$^+$ T cells or by stimulating the WT CD4$^+$ T cells with FICZ.
Conclusions: These results will provide a solid basis for identification of novel factors and signalling pathways crucial for the development of proper Th17 phenotype as well as for further studies aiming at perturbing the Th17 differentiation process.

P0522
Plasmablasts induce human CD4$^+$ T follicular helper cells via secretion of IL-6

K. M. Chavele, E. Merry & M. R. Ehrenstein
Rheumatology, UCL Infection and Immunity, London, UK

Purpose/Objective: CD4$^+$ T follicular helper (TFH) cells are a distinct lineage specialized in providing B-cell help characterized by the expression of CXCR5, ICOS and the transcription factor Bcl-6. We explored whether B cells reciprocally modulated TFH cells.
Materials and methods: Different subsets of human CD4$^+$ T cells and CD19$^+$ B cells were isolated by FACS sorting from peripheral blood and cultured *in vitro*. TFH cell number and function were assessed by FACS and *in vitro* assays.
Results: *In vitro* depletion of B cells from anti-CD3/28 stimulated PBMCs resulted in a twofold reduction in Bcl-6 expression within the CXCR5$^+$ ICOS$^+$ TFH cell population ($P = 0.0008$). The numbers of TFH cells was significantly increased when responder T cells (CD4$^+$ CD25$^-$CD127$^+$) (Tresp) were stimulated (anti-CD3/IL-4) in the presence of B cells (8 ± 0.5 [with B cells] versus $4 \pm 0.8\%$ [no B cells], $P = 0.0002$). In these co-cultures the percentage of TFH cells correlated with the percentage of plasmablasts (CD19$^+$ CD38^{high} CD27^{high}) ($P = 0.0456$).Moreover, purified plasmablasts were significantly more potent in increasing the number of TFH cells in these cultures ($8 \pm 1\%$) compared to naïve B cells (CD19$^+$ CD38$^{-/low}$CD27$^-$) ($3 \pm 0.7\%$, $P = 0.01$).In addition, plasmablasts were more potent inducers of functionally active TFH cells from naïve CD4$^+$ T cells (CD45RA$^+$CD27$^+$) ($18 \pm 2\%$) than naïve B cells ($10 \pm 1\%$ $P < 0.0001$).*In vitro*, induction of TFH cells from naïve CD4$^+$ T cells was significantly correlated with *in vitro* IL-6 production ($P = 0.001$) and plasmablasts produced more IL-6 compared to naïve B cells (5 ± 1 versus $1 \pm 0.4\%$, $P = 0.05$).Blockade of IL-6 in co-cultures of naïve CD4$^+$ T cells and plasmablasts significantly decreased acquisition of a TFH cell phenotype ($P = 0.0013$). RA patients have significantly more circulating TFH cells compared to healthy individuals ($P = 0.003$) and consistent with our *in vitro* data, RA patients responding to Tocilizumab (IL-6R blockade) therapy showed a marked reduction in circulating TFH cell numbers (pre: 1.2 ± 0.1 versus post: $0.4 \pm 0.06\%$) and IL-21 production, which was associated with reduced plasmablast formation.
Conclusions: In conclusion, our data provide new insights into the reciprocal regulation between human plasmablasts and TFH cells and the pivotal role of IL-6. Tocilizumab reduced TFH cell numbers in

patients with RA highlighting a novel mechanism of action for this therapy.

P0523
Plasticity of CD4 T cells in rheumatoid arthritis

F. Pirronello, J. Leipe, H. Schulze-Koops & A. Skapenko
Division of Rheumatology and Clinical Immunology, Medizinische Klinik und Poliklinik IV University of Munich, München, Germany

Purpose/Objective: Th17 cells are a subset of CD4 helper T cells defined by the production of interleukin 17 (IL-17). Th17 cells are physiologically involved in the host defense but are also known to be a major contributor in the pathogenesis of autoimmune diseases. An increased number of Th17 cells has been reported in patients with rheumatoid arthritis (RA). The mechanisms leading to this predominance of Th17 cells in RA are not yet fully understood. Recent evidence suggests that Th cell differentiation is a plastic process implying a change in the phenotype depending on inflammatory conditions. An altered T cell plasticity might therefore contribute to the shift towards the Th17 phenotype observed in RA.
Materials and methods: To verify this hypothesis, naïve CD4 T cells were isolated from the blood of RA patients ($n = 5$) with early, untreated disease and healthy controls (HC) ($n = 5$) and subjected to a first round of differentiation under Th17-inducing conditions followed by a cytokine secretion assay and fluorescence activated cell sorting of Th1 and Th17 cells. Sorted cells were then cultured for a second round of differentiation under Th1- and Th17-inducing conditions. The cytokine secretion profile was assessed by flow cytometry.
Results: Sorting of Th1 or Th17 cells generated pure populations of IFNγ- or IL-17-producing cells. Re-differentiation of Th17 cells under Th1-inducig conditions resulted in a cell population containing up to 80% of IFNγ-producing cells in both RA and HC (83.4 ± 6% versus 76.7 ± 7.7%, respectively). Whithin the IFNγ producing cells the frequencies of IFNγ single producers were 21.2 ± 10.4% in RA and 16 ± 3.3% in HC, while the IFNγ/IL-17 double producers were 62.5 ± 13.8% in RA and 60.3 ± 8.3 in HC. The re-differentiation of Th1 cells under Th17-inducing conditions was comparable between RA patients and HC and resulted in 16.3 ± 18.1% (RA patients) and 17.8 ± 9.8% (HC) IL-17-producing cells, respectively. Interestingly, these newly generated IL-17-producing cells preserved the ability to produce IFNγ.
Conclusions: The data indicate that re-differentiation of Th17 cells into Th1 from RA patients did not differ from that of HC. Whether the deregulated re-differentiation capacity of CD4 T cells in RA might contribute to the increase of Th17 cells in the disease will require further investigation.

P0524
Regulation of IL-31 expression in human T helper cell subsets

E. Maier, D. Werner, A. Duschl & J. Horejs-Hoeck
Department of Molecular Biology, University of Salzburg, Salzburg, Austria

Purpose/Objective: IL-31, a four-helix bundle cytokine of the IL-6 family, was shown to be associated with Th2 mediated pathologies including atopic dermatitis, allergic contact dermatitis and allergic asthma. Since only one study shows that rather activated murine Th2 cells than Th1 cells are the source of IL-31, the present study aims to investigate the regulation of IL-31 expression in human *in vitro* polarized Th cells subsets in more detail.
Materials and methods: Human naïve $CD4^+$ T cells were isolated from buffy coats and cultured under distinct polarizing conditions and IL-31 secretion was analyzed by ELISA. EMSA studies were carried out to identify the transcription factors responsible for *IL31* expression. To assess the role of these transcription factors for *IL31* transcription luciferase reporter gene assays and siRNA-mediated silencing experiments were performed.
Results: Analysis of IL-31 production in Th1, Th2, Th9, Th17 and iTreg cells revealed that IL-31 is predominantly released by IL-4 dependent Th cell subsets, namely Th2 and Th9 cells. Notably, IL-31 secretion from Th9 cells is significantly reduced compared to Th2 cells. Suppression of IL-31 secretion in Th9 cells relies on TGF-β1, the main factor inducing the switch from Th2 to Th9 cells. Whereas TGF-β1 reduces the release IL-31, IL-33 a cytokine described to augment Th2 cytokine secretion enhances the release of IL-31 in Th2 cells. Since IL-4 induces signaling via STAT6 and IL-33 activates the NF-κB pathway, we investigated the role of these molecules for IL-31 expression. EMSA, siRNA silencing experiments and luciferase reporter gene assays clearly demonstrate crucial involvement of both transcription factors in activating *IL31* gene transcription.
Conclusions: We show that IL-31 is secreted by human $CD4^+$ Th cell subsets that develop in the presence of IL-4. With STAT6, NF-κB, TGF-β1 and IL-33 four key factors in IL-31 expression have been identified. Taken together, this study provides new insights in the regulation of IL-31 in human Th2 and Th9 cells.

P0525
T follicular helper cells survive as long-term memory cells

J. P. Weber, F. Fuhrmann & A. Hutloff
Chronic Immune Reactions, German Rheumatism Research Centre Berlin (DRFZ) a Leibniz Institute, Berlin, Germany

Purpose/Objective: T follicular helper (TFH) cells represent the subpopulation of $CD4^+$ T cells which provides help for antigen-specific B cells in the germinal centre response. Without TFH cells, neither memory B cells nor long-lived plasma cells can be generated. TFH cells are generated from naïve T cells during an immune response and are imprinted by their master transcription factor Bcl-6. It has been a long-standing question if TFH cells can persist in the body as long-term memory cells or if they die after the germinal centre response has been terminated.
Materials and methods: To answer this question we sorted TCR-transgenic TFH and non-TFH effector cells from an ongoing germinal centre response and transferred them into secondary hosts.
Results: When re-transferred into mice with an ongoing immune reaction, antigen-specific TFH cells preferentially migrated to the B cell follicle, indicating that transferred TFH cells are capable of typical homing and function.

When re-transferred into naïve mice (hence T cells did not receive further signals via the TCR), effector cells rapidly contracted with a small population of both TFH and non-TFH cells surviving as memory cells in peripheral lymphoid organs for at least 4 weeks in the absence of antigen. TFH cells strongly downregulated their signature genes Bcl-6, CXCR5, and PD-1 in the memory phase. However, upon rechallenge with antigen they rapidly upregulated these markers again, and had a strongly enhanced potential to produce IL-4 and IL-21.
Conclusions: TFH cells can survive as long-term memory cells but lose their signature markers. A very high expression of CXCR5 and low expression of CCR7 equips re-activated TFH memory cells with a chemokine receptor profile favouring a quick migration to the B cell follicle. In contrast with non-TFH memory cells, re-activated TFH cells have a cytokine profile to efficiently support B cells in germinal centre reactions once again.

P0526

Temporal and spatial dynamics of IL-10 expression in an *in vivo* tolerance model

L. J. Carney, C. A. Sabatos-Peyton & D. C. Wraith
Cellular and Molecular Medicine, University of Bristol, Bristol, UK

Purpose/Objective: Regulation of the inflammatory response to self antigen is of vital importance to limit immunopathology. Dysregulation of this response can lead to autoimmune diseases such as Multiple Sclerosis (MS).Our present research utilises myelin basic protein (MBP) peptide Ac1-9 specific T-cell receptor (TCR) transgenic Tg4 mice to study EAE (Experimental Autoimmune Encephalomyelitis). We have previously shown that repeated intranasal administration of a high affinity form of the immunodominant epitope of MBP AcA-SQYRPSQR [4Y] induces peripheral tolerance in Tg4 mice.Tolerance is characterised by the induction of anergic, IL-10 secreting, FoxP3-, T-bet$^+$ Th1 derived regulatory T cells (IL-10 Tregs). *In vivo* studies have established that IL-10 is required for tolerance, however, it is still unknown how IL-10 functions temporally and spatially over the course of tolerance induction. In this study, we utilised an IRES-GFP IL-10 transcriptional reporter model, to establish the temporal and spatial dynamics of IL-10 expression *in vivo* in a tolerance model.
Materials and methods: IL-10 GFP reporter mice were created by crossing Tg4 mice with C57BL/6 Tiger mice. Mice were treated intranasally a minimum of ten times with 80 μg [4Y] peptide or PBS, organs isolated and CD4$^+$ cells isolated either 2 hor 3 days following the final treatment.
Results: The kinetics and anatomical distribution of GFP$^+$ CD4$^+$ T cells in tolerised mice will be discussed further below.
Conclusions: IL-10 GFP reporter mice facilitated the detection of IL-10 expression in lymphoid organs at various stages of intranasal tolerance induction. Using this reporter mouse we aim to gain a better understanding of the dynamics of IL-10 production, shown to be crucial for successful peptide immunotherapy in autoimmune disease.

P0527

Th1/Th17 balance is controlled by HIF-1a under Hypoxia

H. Shehade, V. Francois, M. Moser & G. Oldenhove
Department of molecular biology Immunobiology, Free University of Brussels (ULB), Gosselies, Belgium

Purpose/Objective: During an immune response, inflammation can damage tissue microvasculature and reduce cellular oxygen supply. This process is referred as tissue hypoxia. When O_2 availability decreases, the transcription factor HIF-1a, a key metabolic sensor, is stabilized and regulates cellular adaptation to hypoxia. The objective of this project was to test whether HIF-1a regulates T cell fate during inflammation and to define the molecular mechanisms of this control.
Materials and methods: Naive CD4$^+$ T cells were cultured under Th1 and Th17 polarizing conditions and then transferred to 1% (Hypoxic) or 20% (Normoxic) O_2 environment. As strategy, we have used genetically deficient mice, bicistronic vectors allowing the overexpression of selected genes, flow cytometry and real time PCR to investigate the mechanisms involved in T helper adaptation to hypoxia. T cell transfer model of chronic colitis is ongoing to investigate the *in vivo* relevance of our observations.
Results: We found that, unlike Th17 cells, Th1 cells lose their effector function (as assessed by IFN-g production) when cultured under hypoxia. Of note, HIF-1a$^{-/-}$ Th1 cells were insensitive to hypoxia underlining a critical role for HIF-1a in Th1 inhibition by hypoxia. Similarly, the production of IFN-g by IL-10$^{-/-}$ Th1 was not altered in hypoxia, supporting a role for IL-10 probably by sustaining STAT3 phosphorylation. In support of this hypothesis, STAT3 was phosphorylated constitutively in both Th1 and Th17 cells under hypoxia, but not normoxia, and STAT3$^{-/-}$ Th1 cells produced similar amounts of IFN-g in normoxic and hypoxic conditions, suggesting that, in hypoxic Th1 cells, STAT3 may favor HIF-1a accumulation. The mechanism by which HIF-1a decreased Th1 activation could involve the inhibition of STAT4 activation as suggested by our preliminary data.
Conclusions: We found that hypoxic culture conditions result in decreased Th1 activation while sparing Th17. Our results suggest that IL-10 secretion by Th1 cells induces a STAT3 dependent feedback leading to HIF-1a accumulation, which may in turn inhibit the STAT4 signaling pathway.

P0528

The role of Interleukin-6 in the immune responses against Listeria monocytogenes

I. Yan,* J. Hoge,* V. Schumacher,* S. Huenemoerder,* S. Rose-John† & H. W. Mittruecker*
**Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, †Biochemistry, Medical Faculty, Christian-Albrechts-Universität zu Kiel, Kiel, Germany*

Purpose/Objective: The cytokine Interleukin-6 (IL-6) plays a protective role in immune responses against bacterial infections. However, the mechanisms of IL-6-mediated protection are only partially understood. IL-6 can signal via a complex of membrane-bound IL-6Rα (mIL-6Rα) and gp130 (classical signaling). Under some conditions, IL-6Rα is shed from the surface. Soluble IL-6Rα still binds IL-6 and the IL-6/sIL-6Rα complex can interact with gp130 and induce signaling (trans-signaling).
Materials and methods: In this project, we apply the *Listeria monocytogenes* infection model to investigate the role of IL-6 in the immune response against bacterial infection.
Results: Following *L. monocytogenes* inoculation, IL-6Rα was rapidly lost from the surface of all analyzed leukocytes subsets. We also observed decrease of IL-6Rα surface expression in IL-6-deficient mice excluding IL-6 mediated receptor internalization or anti-IL-6Rα mAb blockade. *In vitro*, IL-6Rα could be rapidly shed via a P2X7 dependent mechanism. However, shedding *in vivo* occurred independently of P2X7. Loss of IL-6Rα expression was also not correlated to loss of surface expression of other targets of sheddases such as CD62L or CD27.

Analysis of the acquired immune response against *L. monocytogenes* revealed a failure of IL-6-deficient mice to generate IL-17A producing CD4$^+$ T cells. However, IL-17A production by γδT cells was not dependent on IL-6. Generation of *L. monocytogenes*-specific CD8$^+$ T cells and CD4$^+$ Th1 cells was also not affected by the absence of IL-6.
Conclusions: In summary, our results demonstrate that surface expression of IL-6Rα is highly dynamic during *L. monocytogenes* infection pointing to a role of IL-6 classical signaling and trans-signaling during infection. And although IL-6 is essential for the function of Th17 cells, the generation of *L. monocytogenes*-specific T cells response is largely independent of IL-6.

The role of the aryl hydrocarbon receptor in T helper 17 polarisation: strain comparisons

M. D. Hayes,* C. MacManus,* M. Heizmann,* A. G. Smith,† I. Kimber* & R. J. Dearman*
**Faculty of Life Sciences, University of Manchester, Manchester, UK, † MRC Toxicology Unit, University of Leicester, Leicester, UK*

Purpose/Objective: The aryl hydrocarbon receptor (AhR) has been the subject of much research as an environmental toxin receptor. Attention has focused primarily on the response to dioxin, with one of the key discoveries being that differences in physiological and toxic responsiveness can be based on genetic variant forms of AhR with

different affinities for the agent. For instance, discrete strains of mice have different variants of AhR; C57BL/6 being very responsive, BALB/c being mid responsive and DBA/2 strain mice being the least responsive. Interestingly, the human AhR is a low-affinity receptor analogous to the AhR in DBA/2 strain mice. Several recent studies have described that activation of the AhR enhances polarisation of Th17 cells *in vitro*. However, all studies to date have used the high affinity AhR mouse strain C57BL/6.We have, therefore, investigated whether the class of AhR in different strains of mice affects optimal *in vitro* polarisation of Th17 cells.

Materials and methods: Following magnetic bead isolation, $CD4^+$ cells (>95% pure) from C57BL/6, BALB/c and DBA/2 mice were polarised *in vitro* using interleukin (IL)-6, IL-1β and transforming growth factor-β in medium containing a natural AhR agonist (tryptophan). Successful polarisation was determined by production of IL-17 measured by RT PCR and ELISA. To assess the contribution of AhR activation during Th17 polarisation; cells were cultured in the presence or absence of an AhR antagonist (CH-223191; 3 μM).

Results: Th17 polarisation was achieved for all three mouse strains, with the highest levels of IL-17 protein and mRNA expression recorded for C57BL/6 tissue. However, levels achieved for C57BL/6 mice were lower than those reported by other authors. Following inhibition of the AhR using the antagonist, all mouse strains displayed at least a 50% reduction in Th17 polarisation but interestingly, levels of IL-17 mRNA and protein were particularly reduced (>80%) in the low affinity AhR DBA/2 strain mice.

Conclusions: These data suggest that AhR activation is essential for optimal Th17 polarisation in all mouse strains investigated and that considerations of AhR affinity do not apply when considering the influence of a natural agonist on Th17 polarisation.

P0530

The Shc family protein adaptor, Rai, acts as a negative regulator of Th17 cell development

C. Ulivieri,* M. T. Savino,* B. Ortensi,† L. Emmi,‡ G. Pelicci,† M. M. D'elios§ & C. T. Baldari*

**Evolutionary Biology, University of Siena, Siena, Italy, †Experimental Oncology, European Institute of Oncology, Milano, Italy, ‡Lupus Clinic, Policlinico di Careggi AOUC, Firenze, Italy, §Internal Medicine, University of Florence, Firenze, Italy*

Purpose/Objective: Rai acts as a negative regulator of antigen receptor signaling in T and B cells. $Rai^{-/-}$ mice develop lupus-like autoimmunity associated to the spontaneous activation of self-reactive lymphocytes. Here we have addressed the potential role of Rai in the development of the proinflammatory Th1 and Th17 subsets.

Materials and methods: Lymph node T cells or naïve T cells were isolated from wild-type and $Rai^{-/-}$ mice and their cytokine profile wasdetermined by ELISPOT and qRT-PCR both as such and after stimulation *in vitro* with immobilized anti-CD3 mAb in the presence or absence of polarizing cytokines. The expression of rai was measured in PBL from SLE patients and healthy donors by qRT-PCR.

Results: We show that $Rai^{-/-}$ mice display a spontaneous Th1/Th17 bias. *In vitro* polarization experiments demonstrate that rai deficiency favours the development and expansion of Th17, but not Th1, cells, indicating that Rai modulates TCR signaling to antagonize the pathways driving naïve $CD4^+$ T cell differentiation to the Th17 lineage. Th1 and Th17 cell infiltrates were found in the kidneys of $Rai^{-/-}$ mice, providing evidence that Rai deficiency contributes to the development of lupus nephritis not only by enhancing lymphocyte activation but also by promoting the development and expansion of proinflammatory effector T cells. Interestingly, T cells from SLE patients were found to have a defect in Rai expression, suggesting a role for Rai in disease pathogenesis.

Conclusions: In conclusion, we have identified Rai as a negative regulator of Th17 cell differentiation and expansion in the mouse and found evidence of an impairment of Rai expression in PBL from SLE patients, where a Th1/Th17 bias has been clearly documented, which suggests that it might subserve a similar function in humans. Given the causal role of Th17 cells in a number of autoimmune disorders, such as multiple sclerosis and rheumatoid arthritis, these data suggest that Rai may play a function in preventing autoimmunity beyond lupus nephritis.

P0531

The signalling strength of Phosphatidylinositol-3-kinase (PI3K) pathway regulates T helper subsets and plays a central suppressive role in autoimmunity

D. Ielo, M. Zayoud, K. El Malki, A. Heinen, C. Hackenbruck, S. Reißig, F. Wanke, A. Waisman & F. C. Kurschus

Molecular Medicine, University Medical Center of the Johannes Gutenberg, University of Mainz Institu, Mainz, Germany

Purpose/Objective: Recent works have shown the importance of Phospohayidylinositol-3-kinase (PI3K) on T helper cell commitment. Using distinct genetic means we show that the intensity of the PI3K signal generate T helper cells type 1, T helper cells type 17 and induced regulatory T cells subsets.

When thePI3Ks signaling pathwayis constitutively over-expressed on T cells; mice do not develop any signs of induced Experimental Autoimmune Encephalomyelitis (EAE) and of induced colitis.We show then, a new role of the PI3Ks signalthat plays a central role in induction of tolerance on autoimmunity via IL-22 and IFNγ.

Materials and methods: $CD4^+$ CD62LT cells oniTreg, Th1 cells, and Th17 cells: LNs and SPs from WT mice, PD-1 KO, CD4creP110ind mice were harvested and naiveT cells were sorted using Magnetic Beads columns. The cells were cultured from 1 to 7 days under different conditions.

Induction and assessment of EAE: Active EAE was induced by immunization with 50 μg of MOG35*55 peptide emulsified in CFA. Mice also received 200 ng of PTi.p. on the day of immunization and two days later. Clinical assessment of EAE was performed according to the standard criteria: from 0 to 6 based on the level of the sickness.

Results: We demonstrate that different concentration of the CD28 stimulus and/or the lack of the PD-1 receptor inhibits the production of IL-17A under TH17 condition, impairs the generation of iTregs and enhances the production of IFNγ under TH1.

We further demonstrate that TGFβ reduces the PI3K signalling strengthrestoring the production of cytokines under different conditions, altered by the higher PI3Ks pathway. Mice that over express PI3Ks, do not develop any signs of EAE and aretotally resistant to induced colitis transfer model on RAG1 KO model; the level of GM-CSF and IL-17A is not affected but the production of IFN$\gamma$and IL-22 is dramatically enhanced.

Using neutralizing antibodies for IFNγ and IL-22 we proved that either EAE and colitis can be both rescued in the transgenic model to a comparable level of the WT.

Conclusions: Here we show the master role of PI3Ks on $CD4^+$ T helper cells commitment; the major role of this cascade in influencing the cytokines production.

An high activity of PI3Ks leads to a TH1 outcome, a middle activity to TH17 anda low activity to Tregs.

The high production of IL-22 and IFNγ protect the mouse from EAE and colitis unveiling a complete new role of PI3Ks cascade on induction of tolerance and identify IL-22 as a new potential target in autoimmunity

P0532

The transcription factor Blimp-1 is a critical regulator of IL-10 expression by T helper 1 cells

C. Neumann,* F. Heinrich,* J. Ahlers,* S. Rutz,† N. Mockel-Tenbrinck‡ & A. Scheffold*

Cellular Immunology, German Rheumatism Research Centre Berlin, Berlin, Germany, †Department of Immunology, Genentech, San Francisco, CA, USA, ‡Miltenyi Biotec, Research and Development, Bergisch-Gladbach, Germany

Purpose/Objective: Expression of the anti-inflammatory cytokine IL-10 by pro-inflammatory T helper 1 cells (Th1) is a crucial mechanism for Th1 self-regulation and the containment of inflammatory immune responses. To identify potential transcription factors that are involved in the regulation of IL-10, we highly purified IL-10 secreting and non-secreting Th1 cells and screened their gene expression profile for new candidates.

Materials and methods: Sorted murine naïve CD4 T cells were activated *in vitro* under Th1 polarizing conditions and subjected to cytokine secretion assay on day 5 following re-stimulation with PMA/Iono. Subsequently, IL-10 secreting and non-secreting T cells were highly purified via FACS sorting and analysed using an Affymetrix GeneChip® array for the expression of candidate transcription factors.

Results: We found that Blimp-1 was selectively over-expressed by IL-10 producing Th1 cells. Blimp-1 deficiency in *in vitro* as well as *in vivo* differentiated Th1 cells completely abolished IL-10 expression. In turn ectopic expression of Blimp-1 strongly induced IL-10 production by Th1 cells. Importantly over-expression of c-Maf, which also segregated with IL-10 secretion in our screen, could not rescue the IL-10 deficiency in Blimp-$1^{-/-}$ Th1 cells, although c-Maf over-expression was sufficient to induce IL-10 as well as Blimp-1 expression in wild-type T cells. Furthermore c-Maf expression levels were not altered in Blimp-1 deficient Th1 cells as well as after Blimp-1 over-expression, suggesting that Blimp-1 rather than c-Maf limits IL-10 expression. In addition, stability studies with sorted IL-10 producing Th1 cells revealed that also IL-10 re-expression highly correlated with Blimp-1 expression in contrast to c-Maf.

Conclusions: Taken together our data identify Blimp-1 as a critical transcription factor for IL-10 expression by Th1 cells and introduce an attractive target for therapeutic manipulation of this pivotal immunoregulatory mechanism.

P0533

Toll-like receptor 9 ligand promotes vaccine potency by enhancing Follicular Helper T cell development

S. Chakarov

Centre de Physiopathologie de Toulouse Purpan, INSERM UMR1043, Toulouse, France

Purpose/Objective: Protein sub-unit vaccines promote long-term immunity through the production of high-affinity B cell memory. To be effective, vaccine priming must induce antigen-specific Follicular Helper T cells (Tfh) that control plasma cell production and memory B cell development in secondary lymphoid tissue. Thus, understanding the mechanisms of Tfh cells and how to manipulate them could have a lot of impact for vaccine design.

It was shown that soluble TLR9 ligand can be used as adjuvant for a protein antigen *in vivo* by enhancing the T-dependent antibody response. This effect require TLR signaling in dendritic cells (DC). Thus, it is clear that TLR9 ligand can promote antibody responses, there is little understanding of the rules governing how TLR9 signaling contribute to antibody responses *in vivo*. Moreover, whether complementation ofexisting vaccine with TLR9 ligand enhances adjuvancity is still unknown.

Materials and methods: We took advantage of the well-characterized T and B immune responses of C57BL/6 mice to I-Eα protein and its immunodominant MHC class II epitope using Eα52-68-I-Ab pMHCII tetramers and Flow cytometry approaches to monitor the dynamics of antigen-specific B and T cell resposnes after protein vaccination. Furthermore, using this antigen model, we can also track antigen presentation and the nature of presenting DC that appear in draining lymph nodes from immunized animals. Using this protein vaccination, we investigated the impact of CpG addition in the adjuvanticity and on antigen-specific immune response.

Results: We show that addition to vaccine adjuvant of TLR9 ligand, CpG, enhances the antigen-specific B cell responses after protein vaccination *in vivo*. In particular, this effect correlates with an increase of antigen-specific Tfh cell. Furthermore, we observed that cDC recruited in the draining LN in CpG-primed condition secrete more IL-6, a cytokine necessary for Tfh cell differentiation *in vivo*, and are more prone to induce Tfh cell differentiation directly *ex vivo* when compared to DC from primed animals without CpG. In contrast, conventional DC bearing pMHCII on their surface which are recruited in the draining LN are less abundant in CpG-primed condition. In addition, we also showed that pDC do not capture and present Ag but participate in this bias towards Tfh cell differentiation by secreting IL-6.

Conclusions: Our results suggest that TLR9 ligand through DC imprints the specialized program of antigen-specific effector Tfh function needed to promote high affinity B cell immunity *in vivo* and could serve as a basis for manipulating the formulation of the next generation of protein vaccines.

P0534

Towards identification of gene regulatory network resulting in human TH17 differentiation

S. Tripathi,* S. Tuomela,* V. Salo,* Z. Chen,* K. Laurila,† B. Gupta,* T. Äijö,† H. Lähdesmäki,† B. Stockinger‡ & R. Lahesmaa‡

Molecular Immunology Group, Turku Centre for Biotechnology, Turku, Finland, †Department of Information and Computer Science, Aalto University School of Science, Helsinki, Finland, ‡Division of Molecular Immunology, Medical Research Council National Institute for Medical Research, London, UK

Purpose/Objective: The aim of our study is to identify key regulatory networks of the early human Th17 cell differentiation process. This will be achieved through combination of genome wide and computational methods exploiting the strategy we recently used to report fundamentally new insights into human Th2 cell differentiation (Elo et al., Immunity, 2010).

Materials and methods: $CD4^+$ T cells isolated from human umbilical cord blood were used to generate Th17 cells. To generate Th17 cells, cells were activated via cross linking T cell receptor (anti-$CD3^+$ anti-CD28) and polarization was stimulated with combination of TGF- β, IL-6, IL1β, anti-IL4, and anti-IFN-γ. Polarization of Th17 cell differentiation was confirmed by measuring the expression of several Th17 specific genes such as IL17A, IL17F, RORC, and CCR6. For transcriptional profiling, samples were collected at 0, 0.5, 1, 2, 4, 6, 12, 24, 48, and 72 h time points of culture. Total RNA was processed and hybridized on Illumina Sentrix HumanHT-12 Expression BeadChip, version 3.The microarray data analysis was done using Bioconductor package beadarray.Expression of selected genes was validated by RT-PCR, western blot, and FACS analysis.

Results: We, for the first time, report genome-wide gene expression profiling during early stages of human Th17 cell differentiation. We observed that gene expression pattern at the very early stage of human Th17 differentiation is highly dynamic. Further, we validated the selected genes at the protein level and analyzed their expression in Th1,

Th2 and iTreg T helper subsets.We found that ATP1B1, CXCR5, KDSR, and IL2RB are selectively regulated in Th17 condition during the early priming towards Th17 phenotype. On the other hand, CD52, VDR and CTSL1 were highly expressed also in response to initiation of some of the other T helper programmes. Our study provides an overview of genes and pathways regulated in response to induction of Th17 differentiation in humans and identifies several candidates which potentially play role in modulation of Th17 responses.
Conclusions: This is the first transcriptional profiling study on early Th17 differentiation process, provides the starting point for constructing the gene regulatory network and identifying new candidates possibly regulating the Th17 differentiation in human.

Upstream stimulating factors mediated regulation of RORgammaT expression in human Th17 lymphocytes

J. Dastych,* M. Ratajewski,† A. Walczak-Drzewiecka* & A. Salkowska*
**Laboratory of Cellular Immunology, Institute of Medical Biology of PAS, Lodz, Poland, †Laboratory of Transcriptional Regulation, Institute of Medical Biology of PAS, Lodz, Poland*

Purpose/Objective: One of the two alternative products of RORC gene is RORγT, the orphan nuclear receptor that regulates the development of Th17 cells.Increased expression of RORγT is a hallmark of Th17 differentiation. We investigated the transcriptional regulation of RORγT in human lymphocytes to gain further insights into the process of Th17 differentiation.

Materials and methods: RORγT promoter analysis was performed with luciferase based constructs in Jurkat, HeLaand HepG2 cells.Screening for transcription factors regulating RORγT was performed by cotransfection ofRORγT promoter reporter constructs and expression vectors coding transcription factors into HeLa cells.Chromatin immunopreciptation and electrophoretic mobility shift assays were performed employing Jurkat T cells. Gene expression was assessed with real time PCR. Th17 cells were obtained from naïve $CD4^+$ T cells isolated from PBMCs cultured for 5 days under Th17 polarizing conditions. Concentration of IL-17 in supernatants was determined by ELISA.siRNA experiments were performed using nucleofection of lymphocytes with duplexes of Stealth siRNA. Statistical analysis was performed using one-way ANOVA, followed by Tukey's *post hoc* test.
Results: While nonlymphatic human cells exclusively expressed RORγ, Jurkat lymphocytes predominantly expressed RORγT. Analysis of human RORγT promoter activity with 5' deletion and *in situ* mutagenesis analysis, chromatin immunoprecipitation and overexpression of selected transcription factors, revealed that USF-1 and USF-2 are critical for RORγT expression in Jurkat lymphocytes. USFs expression was upregulated upon differentiation of Th17 cells *in vitro* and siRNA mediated knockout of USFs expression resulted in significant decrease in expression of RORγT in Jurkat and in Th17 cells.
Conclusions: We demonstrate the role of the USF-1 and USF-2 transcription factors in regulating the expression of RORγT in human lymphocytes.Thus, USFs are important for the molecular mechanisms of Th17 differentiation, and possible changes in the expression of USFs might be of interest for inflammatory conditions with a Th17 component.

Evaluation of genetic diversity of IGHG in 11 Lepus species

A. Pinheiro,[*,†,‡] **P. C. Alves,**[*,†] **C. Gortázar**[‡] **& P. J. Esteves**[*,§]
[*]*Centro de Investigação em Biodiversidade e Recursos Genéticos, Universidade do Porto, Vairão, Portugal,* [†]*Departamento de Biologia, Universidade do Porto, Porto, Portugal,* [‡]*Instituto de Investigación en Recursos Cinegéticos IREC, CSIC-UCLM-JCCM, Ciudad Real, Espanha*

Purpose/Objective: The European rabbit is unique in several immunological aspects, one of which being the possession of only one IGHG. Rabbit IgG has been extensively studied and its allelic variation characterized in detail since the early days of immunogenetics. However, the information available for this molecule in the Leporids is scarce, being limited to a few species hinge and CH2 sequences. In this study we sequenced the complete *IGHG* exons for 11 *Lepus* species. (382).
Materials and methods: The four IgG exons, CH1, hinge region, CH2 and CH3, were PCR amplified and sequenced for 11 extant Lepus species: L. americanus, L. californicus, L. callotis, L. capensis, L. castroviejoi, L. corsicanus, L. europaeus, L. granatensis, L. timidus, L. townsendii and L. saxatilis. Six European rabbits were also sequenced. The primers were designed on European rabbit IGHG available sequences. (332).
Results: 32 specific nucleotide differences were observed between European rabbit and hares (Lepus sp.) IgG genes corresponding to 19 aminoacid modifications. Within hares 50 SNP were found, that translate to 26 aminoacid changes. Specific aminoacids were detected for *L. americanus, L. callotis, L. californicus, L. capensis, L. europaeus, L. saxatillis and L. townsendii*. The greatest nucleotide and aminoacidic variability is found on the CH2 and CH3 domain. No variability was found among the studied 11 hare species hinge region.
Conclusions: The studied hare species share a great sequence homology for IGHG. However, specific residues were observed for 7 *Lepus* species, mostly on the CH2 and CH3 domain but also on CH1. These could be related to resistance against specific pathogens. The hinge region is highly variable among species and IgG subclasses. Surprisingly, all 11 *Lepus* species studied share the same genetic hinge, suggesting that some selective pressure is maintaining the hinge motif in the *Lepus* taxon.

P0537
Signatures of positive selection in mammalian interleukins

F. Neves, J. Abrantes & P. J. Esteves
CIBIO/UP- Centro de Investigação em Biodiversidade e Recursos Genéticos, n.a., Vila do Conde, Portugal

Purpose/Objective: Due to the host-pathogen co-evolution, the immune system and its genes are constantly evolving being under pressure and selection for adaptation, where advantageous mutations are highly favoured and deleterious mutations are quickly eliminated. Interleukins (ILs) have been identified as some of the genes of the immune system under positive selection in different mammals. Nevertheless, most studies do not specify the selected codons. Thus, we have searched for signatures of positive selection in mammalian ILs by using different codon-based maximum-likelihood (ML) approaches.
Materials and methods: Sequences of mammalian ILs used in the analyses were retrieved from GenBank (http://www.ncbi.nlm.nih.gov/), Ensembl (http://useast.ensembl.org/index.html) and UniProt (http://www.uniprot.org/). Each interleukin was aligned using ClustalW implemented in the software program BioEdit version 7.1.3 and adjusted manually. To detect signatures of positive selection in individual codons of mammalian ILs, d_N/d_S ratios were compared using two ML frameworks, the HyPhy package implemented in the Data Monkey Web Server (http://www.datamonkey.org/) and CODEML implemented in PAML version 4.
Results: Signatures of positive selection were found in IL1A and B, IL2, IL4-IL10, IL12A and B, IL14-IL17A and C, IL18, IL20-IL22, IL25, IL26, IL27B, IL31, IL34, IL36A and G. Codons under positive selection identified by, at least, two ML methods varied between 1 and 15, being IL6 the interleukin with higher percentage of positive selected sites (2.28%, 15 codons) followed by IL7 (2.04%, 11 codons). No codons were detected in IL13, 17B and F, IL19, IL23, IL24, IL27A and IL29.
Conclusions: Through protein-coding sequences comparison we are able to identify proteins under positive selection. Several studies have shown that genes related with immunity are among those proteins, including ILs. In ILs, codons located in regions where these proteins interact with their receptors are prone to be positively selected in order to influence signalling intensity. Also, signatures of positive selection may be related with escaping mechanisms from antagonistic parasite-encoded proteins to maintain the ILs functions in the immune response.

Altered calcium signalling in B and T cells from Systemic Lupus Erythematosus patients is related to STIM1 expression

J. O. Pers,* T. Fali,* O. Mignen,† M. Burgos,† S. Jousse,* A. Saraux,* C. Jamin* & Y. Renaudineau*

**Immunology, Brest University Medical School Hospital, Brest, France,*
†Inserm U1078, Brest University Medical School Hospital, Brest, France

Purpose/Objective: The *calcium* sensor *STIM1* in lymphocytes is an essential mediator of the calcium influx that acts as a second messenger in response to activation and proliferation. Although mutations in STIM1 cause complex immunodeficiencies, the role of STIM1 in the T and B cell autoreactivity process during autoimmune diseases is currently unknown.

Materials and methods: Using thapsigargin (Tg), an inhibitor of calcium pump of the endoplasmic reticulum (ER), elevations of cytosolic calcium from the ER and activation of the store-operated calcium entry (SOCE) were evaluated in T and B cells from patients with systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), primary Sjögren's syndrome (pSS), and healthy controls (HC). Concomitantly, STIM1 expression was evaluated by flow cytometry in T and B cell subsets.

Results: Higher constitutive calcium entry and increased Tg-mediated extracellular calcium entry, but not ER calcium entry, were observed in T and B cells from SLE patients compared with controls. No significant differences could be observed in SOCE/ORAI molecules by RT-qPCR. However, STIM1 expression was quantitatively different according to the disease. SLE T cells express more STIM1 than HC and pSS patients, whilst RA T cells express lower level. SLE B cells express higher STIM1 molecules than pSS B cells, whereas HC and RA B cells express similar low levels. In SLE B cells, STIM1 is overexpressed in all B cell subpopulations with highest levels detected in autoreactive transitional B cells (MFI 9.5 ± 2.3 in SLE versus 1.5 ± 0.7 in HC, $P > 0.001$). Interestingly, STIM1 level is strongly correlated with the constitutive calcium entry and the extracellular calcium influx (both, $P < 0.01$). In contrast, activity of the disease and autoantibody production were not correlated. Finally, CpG and anti-IgM co-stimulations are as efective as CpG and anti-CD40 stimulations to induce STIM1 expression in normal B cells as well as cell cycle progression in a B cell line.

Conclusions: In conclusion, these findings suggest that differential STIM1 expression may be an important determinant in the SLE autoreactivity process.

A time resolved analysis of nc/mRNA and protein expression throughout Th cell activation

M. von Bergen,* K. Reiche,* N. Hösler,† M. Rockstroh,* F. Horn,† J. Hackermüller* & J. Tomm*
**Proteomics, Helmholtz Centre for Environmental Research, Leipzig, Germany, †Institute for Clinical Immunology, University of Leipzig, Leipzig, Germany*

Purpose/Objective: Activation and differentiation of immune cells are crucial for an efficient and controlled immune response. To be able to secrete cytokines, naïve T helper-cells need to get in contact with antigen presenting cells (APC) to become activated and differentiate into the different T helper-cell subsets responsible for the different cytokines.These processes are controlled by a combination of transcriptional and translational regulatory mechanisms. In terms of transcriptional control non coding RNAs have been proven recently to be crucial first for epigenetic effects but also for transcription and translation. The effects can be assessed first by RNA seq and second by proteomic approaches to control for the effects of regulatory processes. Therefore we combined here RNAseq and proteomics to reveal the regulatory and effective mechanisms in T cell activation and differentiation into Th1 cells.
Materials and methods: For analysis of RNAs cells were lysed in Trizol and RNA was extracted out of the aqueous phase followed by tiling arrays and transcriptome sequencing. Proteins were extracted from the phenolic phase of the Trizol extraction and analysed via GeLC-MS/MS.
Results: We identified ~22.000 transcriptionally active regions (TARs) in the genome which are differentially expressed throughout this process and fall into diverse coding and non-coding transcript categories.Out of 10 buffy coats 2445 proteins were unambiguously identified in at least five of 10 buffy coats. Among the 409 proteins regulated over the activation time course were known transcription factors like STAT1, NF-kB and others, which are known to be involved in cellular differentiation of immune cells.
Conclusions: The combination of transcriptome and proteome data allow identification of new ncRNAs as well as deciphering the influence of non-coding sequences on the abundance of relevant factors in T cell activation.

CD8aa TCRab intraepithelial lymphocytes: a unique distinct T cell lineage

S. Mayans, D. Stepniak, S. Palida, R. Skinnakazu, B. Arlian, H. Cheroutre & F. Lambolez
Developmental Immunology, La Jolla institute for Allergy and Immunology, La Jolla, USA

Purpose/Objective: We aimed to define the thymic development and MHC restriction of CD8aa TCRab intraepithelial lymphocytes (IEL) of the small intestine.
Materials and methods: We cloned TCR genes isolated from naturally arising CD8aa TCRab IEL and retrovirally express these TCRs in bone marrow (BM) chimera.
Results: First, we successfully sequenced and cloned three TCRab isolated from single cells and then expressed them retrovirally in Rag KO BM chimera. Analysis of the chimera showed that all three TCR clones gave rise to T cells. The T cell that developed were CD4- CD8b- or CD8aa TCRab cells and phenotypically identical to CD8aa TCRab IEL isolated from un-manipulated wild type mice. In addition, they were preferentially found in the gut. In order to define the MHC restriction of these particular TCRs, BM chimeras in various MHC-deficient backgrounds were generated. Subsequent analysis of the chimera for the presence of CD8aa TCRab IEL demonstrated that they are dependent either on KbDb MHC I or on b2m-dependent MHC I molecules aside from KbDb.
Conclusions: Our results show for the first time that TCRs originally cloned from CD8aa TCRab IELs can only give rise to this identical T cell lineage but not conventional CD4 and CD8ab T cells. In addition, this implies that the CDR3 from the TCR sequence will exclusively allow the selection of this unique T cell population most likely through an instructive model. Finally, CD8aa TCRab IELs can also harbor clones selected on different MHC molecules.

P0541
Characterization of the development and function of thymic Hassall's corpuscles

M. Laan,* X. Wang,* R. Bichele,* K. Kisand,* H. S. Scott† & P. Peterson*
Molecular Pathology, University of Tartu, Tartu, Estonia, †Department of Molecular Pathology, The Centre for Cancer Biology & The School of Medicine, The School of Molecular and* **Biomedical Science, The Institute of Medical and Veterinary Science & University of Adelaide, Adelaide, SA, Australia

Purpose/Objective: Thymic Hassall's corpuscles (HCs) are enigmatic tissue structures with poorly defined origin and function. Since recent studies have indicated a role for the Autoimmune Regulator (Aire) in HC development, the aim of this study was to clarify whether HCs are derived from the $Aire^+$ medullary thymic epithelial cells (mTECs), and whether the unique features of $Aire^+$ mTECs to express and present tissue specific antigens (TSA) to the developing thymocytes, are preserved at the HC-stage of mTEC development.
Materials and methods: Two different Aire-reporter mouse models (Aire-LacZ and Aire-GFP) as well as Aire KO mice were used to elucidate the relations between Aire and HCs. Also, FACS-based cell sorting followed by quantitative PCR was used in order to define gene expression profiles of different mTEC populations.
Results: In the Aire-reporter mice the majority of HCs stained also positive for LacZ or GFP whereas in the Aire KO mice the numbers of HCs were severely reduced. The post-Aire developmental stages of mTEC development were characterized by pronounced downregulation of MHC class II and CD80, and of most of the Aire-dependent and Aire-independent TSAs, with the exception of keratinocyte-specific genes. In the final stage of maturation, the mTECs lost their nuclei to become HCs and specifically expressed certain keratinocyte-specific autoantigens, such as desmogleins (DGs) 1 and 3.
Conclusions: HCs comprise a post-Aire mTEC population which specifically expresses keratinocyte-specific antigens. Via cross-presentation of these TSAs by APCs to the developing thymocytes, HCs may contribute to tolerance induction against these pemphigus vulgaris-related antigens.

Purpose/Objective: V(D) J recombination is a process catalyzed by Recombination Activation Genes-1 and -2 in B-lymphocyte progenitors to assemble the variable (V) region genes of the immunoglobulin heavy and light chain polypeptides. In mammals, the establishment of

a sufficiently complex primary Ig repertoire is essential for life-long immunity against foreign pathogens. Current knowledge indicates that IgH V-gene diversification results from single successful VDJ recombination events. Recent reports have challenged this model showing occurrence both in humans and mice of secondary IgH rearrangements. Importantly, this process has been so far described in transgenic mouse models expressing non-functional IgH chains or in the context of autoimmunity, raising the question of its physiological relevance. This project thus aims to precisely estimate the contribution of secondary IgH rearrangements to the establishment of a normal antibody repertoire.

Materials and methods: A unique mouse strain generated by nuclear reprogramming of an intestinal IgA plasma cell expressing a non-autoreactive BCR was employed, which allows a rapid and easy tracking of B-cells undergoing secondary IgH rearrangements.

Results: B-cell progenitors in cloned IgA mice are expected to express the same pre-rearranged IgH V gene. By phenotype analysis we observed that over 20% of peripheral mature B-cells in IgA heterozygous mice expressed IgM on the cell surface, suggesting the occurrence of secondary IgH rearrangements in a substantial number of developing B cells. Sequencing of IgA rearrangements in sorted IgM^+ B cells of $IgA^{H/+}$ mice revealed that both V_H replacement and direct V_H-to-J_H joining contributed to the disruption of the original V_H rearrangement, thereby triggering novel rearrangements on the second (germline) IgH chromosome. Sequence analysis of CDR3 regions suggested that secondary IgH rearrangements likely occurred in pro-B cells as they carried *n* nucleotides introduced by terminal deoxynucleotidyl transferase (TdT). Interestingly, V-gene analysis in B cells undergoing secondary IgH rearrangements, revealed a strong bias for V-genes adjacent to the pre-rearranged V_H gene as recombination substrates.

Conclusions: Altogether these results provide evidence for a major contribution of secondary IgH rearrangements to the diversification of the primary antibody repertoire under conditions of normal B-cell development.

Differential induction of TH1-17 and TH-9 cytokines in human naïve t helper cells by B7h- and B7.1-mediated costimulation

C. Gigliotti, R. Mesturini, M. F. Soluri, A. Woldetsadik, A. Chiocchetti & U. Dianzani

Department of Health Sciences, Interdisciplinary Research Center of Autoimmune Diseases (IRCAD), 'A. Avogadro' University of Eastern Piedmont, Novara, Italy

Purpose/Objective: ICOS and CD28 are expressed by T cells and are involved in costimulation of cytokine production in T helper (TH) cells. ICOS binds B7h expressed by several cell types, whereas CD28 binds B7.1 and B7.2 expressed by antigen presenting cells (APC). This work compared the activity of recombinant B7h-Fc and B7.1-Fc in induction of TH17 and TH9 cytokine secretion in human naïve TH cells.

Materials and methods: Purified naïve TH cells were activated with anti-CD3 mAb in the presence of either B7h-Fc or B7.1-Fc plus different combinations of rIL-1β, rIL-6, rIL-21, rIL-23, rTGF-b1, and rIL-4. Secretion of IL-17A, IL-17F, IL-17A/F, IL-10, and IL-9 was assessed by ELISA in the supernatants. Levels of the IL-26 mRNA were evaluated by Real-time PCR in the cell lysate.

Results: Results showed that, in the presence of $rTGF\text{-}b1^+$ rIL-1b (a TH17 polarizing condition), B7h-Fc was more effective than B7.1-Fc in inducing IL-17A and IL-10, whereas B7.1-Fc was more effective in inducing IL-17F and IL-26. These different patterns were supported by further addition of rIL-6, rIL-21, and rIL-23 in the culture medium. In the presence of $rTGF\text{-}b1^+$ rIL-4 (a TH9 polarizing condition), B7.1-Fc induced high levels of IL-9 that was instead barely detectable using B7h-Fc. Upon dual costimulation with both B7h-Fc and B7.1-Fc, secretion of IL-17A and IL-17F was similar to that induced by B7.1 alone, with predominance of IL-17F, but secretion of high levels of IL-10 mimicked that induced by B7h-Fc alone; secretion of IL-9 displayed intermediate levels between those induced by B7.1 alone and B7h-Fc alone.

Conclusions: These data showed that B7h and B7.1 have different effects on secretion of TH17 and TH9 cytokines in naïve TH cells, and that the effect of contemporary use of both costimuli is not the simple sum of the effects exerted by each of them.

Flipping of lipids by a putative transporter is essential for B-cell development and function

M. Yabas,* C. E. Teh,* S. Frankenreiter,* D. Lal,* B. Whittle,† D. T. Andrews,† E. M. Kucharska,* S. Broer,‡ C. C. Goodnow* & A. Enders*

**Immunology Department, The John Curtin School of Medical Research, The Australian National University, Canberra, SA, Australia, †Australian Phenomics Facility, The John Curtin School of Medical Research, The Australian National University, Canberra, SA, Australia, ‡Division of Biomedical Science and Biochemistry, Research School of Biology The Australian National University, Canberra, SA, Australia*

Purpose/Objective: B cells with their ability to secrete a wide array of antibodies against various invading pathogens play a central role in the generation of humoral immunity. The development of B cells takes place in the bone marrow of most mammals in a highly regulated process that depends on cell intrinsic and extrinsic factors such as signaling through the precursor-B cell receptor (pre-BCR) and, at least in the mouse, the Interleukin-7 receptor (IL-7R), and the activation of transcription factors. However, the role of the composition of the cell membranes on the development of B cells is still poorly understood. Here we describe a new ENU-induced X-linked B cell deficiency syndrome in mice caused by a mutation in *Atp11c*, a previously uncharacterized member of the P4-ATPase family thought to serve as flippases that catalyze aminophospholipid transport from the exoplasmic to the cytoplasmic leaflet of cell membranes.

Materials and methods: Analysis of mice with an ENU-induced point mutation in *Atp11c* by flow cytometry and genetic crosses as well as *in vitro* assays to determine the uptake of aminophospholipids in cells from mutant and control animals.

Results: We show that ATP11C deficient mice have a near complete absence of B cells in the blood due to a severe block at the transition from the pro-B to pre-B cell stage of B cell development in the bone marrow. This block could partially be rescued by the introduction of a transgenic B cell receptor whereas elevated levels of Interleukin-7 or enforced expression of Bcl-2 showed only a minimal increase in peripheral B cell numbers. Similarly, in the spleen the number of B cell was also greatly reduced except for normal numbers of marginal zone B cells. This correlated with a reduced internalization of fluorescently labeled phosphatidylserine in developing pro-B cells but not in other developmental stages of B cells or different cell types in the bone marrow and spleen. Interestingly, despite the reduced B cell numbers the response to T-independent antigen was normal but both the primary and memory antibody response to T-dependent antigens was greatly reduced with the most severe reduction seen in the germinal centre-dependent response to the hapten azo-benzen-arsonate.

Conclusions: The results demonstrate that the phospholipid transporter ATP11C is crucial for early B cell development and antibody production, and reveal an intimate and novel connection between phospholipid transport and B lymphocyte development and function. Our results also provide a new candidate gene for the many currently unclassified human primary immune deficiencies.

P0545

HDAC7 plays a significant role in IL7 signalling during the Pro-B/Pre-B transition of B cell development

M. MacKenzie, M. Anderson & S. Matthews
Immunology, University of Dundee Medical Research Institute, Dundee, UK

Purpose/Objective: In many cellular systems Histone Deacetylases (HDACs) play important roles in the regulation of cell differentiation, proliferation and survival. HDACs regulate chromatin structure and thus gene transcription by reversing histone lysine acetylation. As such they been identified as key players in the development of the immune system with evidence suggesting HDAC7 acts as a gene expression switch regulating T cell development and function while HDAC9 increases regulatory T cell function by interacting with the transcription factor FOXP3. A role for HDACs in B cell development and function is poorly characterised and where our interest lies.
Materials and methods: We have bred an HDAC7 floxed/floxed mouse with a *vav*-cre transgenic mouse in order to delete HDAC7 from all haematopoietic cells including B cells. To investigate a role for HDAC7 in B cell development we analysed the phenotype of lymphoid tissues in WT and KO mice (Spleen, Lymph Nodes and Thymus) using flow cytometry and qPCR.
Results: Using flow cytometry we identified a significant reduction in size of these tissues due to a large reduction in cellular content of B cells and T cells. To investigate the B cell phenotype further we looked in the bone marrow again identifying a significant reduction of Pre-B, immature and mature B cells. A small but significant increase in Pro-B cell number suggested a partial block in development between the Pro-B and Pre-B stage of development. This is a critical point during B Cell development where IL7 signalling drives expression of the pre-BCR complex. The pre-BCR complex in turn induces specific intracellular signals that drive the transcription of genes relevant for the proliferation, survival and expansion of developing B cells. In addition, defects in the expression of IL-7Ra chain in HDAC7$^{-/-}$ pro-B cells, as well as down stream effects such as RAG1/2 expression and IgM expression may account for the observed B cell phenotype in our mice.
Conclusions: These data suggest a key role for HDAC7 in controlling B cell development and further highlights the importance of HDACs within the adaptive immune system.

P0546

IL-7Ra plays a critical role in the development of B cells

D. T. Patton,* A. Plumb,* J. Seo* & N. Abraham†
**Microbiology and Immunology, Life Sciences Insitute, Vancouver, Canada, †Microbiology and Immunology and Zoology, Life Sciences Insitute, Vancouver, BC, Canada*

Purpose/Objective: IL-7 is a critical cytokine throughout lymphocyte biology and controls the development of T and B cells from lymphocyte precursors in the thymus and bone marrow. The molecular signalling events downstream of the IL-7Rα are not fully characterised. Y449 is critical for the development and function of T cells; the role of this motif has not been investigated in B cells, and due to the clear role of IL-7Rα in B cell development, we decided to evaluate the role of IL-7Rα^{Y449} motif in B cell development.
Materials and methods: We used flow cytometry to examine a knock-in mouse possessing a point tyrosine to phenylalanine mutation at position 449 (IL7Rα^{449F} mice) within the cytoplasmic YxxM SH2-binding motif of IL-7Rα, as well as IL-7 over-expressing, TSLPR$^{-/-}$ and IL-7Rα$^{-/-}$ mice.
Results: Signalling downstream of IL-7Rα^{Y449} is critical during early B cell development, as numbers of B cells in the bone marrow of IL-7Ra$^{-/-}$ mice and IL-7Ra^{449F} were reduced at pro-B and pre-B cell stages, suggesting that Y449 is the major signalling residue downstream of the receptor in bone-marrow B cell development. IL-7Rα also controls B cell development in the spleen, as IL-7Rα^{449F} mice have a partial and IL-7Rα$^{-/-}$ mice a near-total block at T1-T2 transition. However, IL-7Rα^{449F} was required for follicular, but not marginal zone B cell populations. Over-expression of IL-7 had the opposite effect on follicular B cells, increasing their numbers, but had no effect on marginal zone B cells. Any role for TSLP was ruled out, as TSLPR$^{-/-}$mice had an identical B cell phenotype to wild-type mice. Experiments using bone-marrow chimera suggested that the defect seen in pre-B cells was due to defective IL-7Rα signalling within the B cell, whereas the splenic defect was due to defective IL-7Rα signalling in non-B cells, as WT and IL-7Rα^{449F} B cells showed an identical phenotype in a mixed environment and did not express IL-7Ra nor signal through pSTAT5 in response to IL-7.
Conclusions: IL-7 plays a key role in the development of B cells from the earliest stages, however signalling downstream of IL-7Rα Y449 is only required at the pro-B and pre-B cell stages in the bone marrow. However, in the spleen, follicular, but not marginal zone B cells are critically dependent on IL-7Rα signalling levels and are controlled by IL-7Ra signalling in an as-yet unidentified manner extrinsic to the B cell compartment.

P0547

Inhibition of glycogen synthase kinase-3 regulates T cell development *in vitro*

H. Schroeder, M. Janas & M. Turner
Lymphocyte Signaling and Development, Babraham Institute, Cambridge, UK

Purpose/Objective: The development of functional non-autoreactive T cells requires receptor-mediated transition through multiple checkpoints in the thymus. Double negative 3 (DN3) thymocytes are selected for the presence of a rearranged TCR beta chain in a process termed beta-selection which requires signalling via the preTCR and Notch1. Pre-selection DN3 are referred to as DN3a and express low levels of CD27 and CD98, while post selection DN3 (which are TCRbeta positive) express higher levels of CD27 and CD98. Additional signalling from CXCL12 ensures optimal proliferative expansion of DN3 thymocytes. Signal integration by these receptors converges on core pathways such as the Phosphatidylinositol-3-kinase (PI3K) pathway. Glycogen Synthase Kinase 3 (GSK3) is generally thought to be negatively regulated by the PI3K pathways.
Materials and methods: Murine DN3a were FACS sorted as negative for CD4/CD8/CD44/CD11b/CD19/NK1.1/Gr-1/$\gamma\delta$TCR/Ter119 and CD25highCD98low. FACS sorted DN3a were cultured with OP9 or OP9-Delta Like 1 stromal cells or in wells that had been coated with 10 μg/ml of recombinant mouse Delta Like 4. In the stromal cell-free cultures DN3a cells were cultured in the presence or absence of recombinant murine CXCL12 and IL-7. In some experiments the GSK3 inhibitor CHIR99021 was added with the DN3a cells from the start of culture. After up to 96 h of culture numbers of gated lymphocytes were determined and analysed by FACS.
Results: We have shown that a GSK3-inhibiting drug, CHIR9902,1 promotes the proliferative expansion of DN3a cultured with recombinant Delta Like 4 and CXCL12. Here we show that developmental progression of DN3a is promoted by CHIR99021. Furthermore, inclusion of CHIR99021 allowed differentiation in the absence of preTCR- or Notch1-mediated signalling. Inactivation of GSK3 using CHIR99021 appears to antagonize IL-7-mediated inhibition of development at the DN stage. In addition to the effect on T cell development, CHIR99021 increased IL-7 dependent proliferation and caused enhanced cell recovery in these experiments.
Conclusions: These experiments indicate a potentially important role for inactivation of GSK3 during the process of beta-selection. A stromal free culture system that promotes beta-selection may offer a

new drug discovery platform for screening regulators of proliferation, differentiation and apoptosis.

Matrix attachment regions flanking the IgH intronic Eμ enhancer are important cis- and trans-regulators of somatic hypermutations

E. Pinaud, M. Marquet, S. Bender, P. Rouaud, A. Garot, Y. Denizot & M. Cogné
CNRS Unité Mixte de Recherche 7276, Controle de la Réponse Immune B et des Lymphoproliferations, Limoges, France

Purpose/Objective: The immunoglobulin heavy chain (IgH) intronic enhancer region (Eμ) is a combination of both an enhancer core element (220 bp) and two 310−350-bp flanking scaffold/matrix attachment regions (S/MARs herein named $MARs_{E\mu}$) that were first defined by nuclear matrix-binding assays *in vitro*. The Eμ core enhancer region is critical for efficient V-D-J recombination at early stages of B cell development. Strikingly, the physiological role of $MARs_{E\mu}$ is still unclear even if several nuclear factors have been found to bind to this region: a B cell transcription factor named BRIGHT/Arid3a; AT rich binding proteins expressed in T cells and in B cell progenitors (SATB2); and also a negative regulatory factor named NF-μNR whose expression decreases at late stages of B cell development when cells express high levels of Ig heavy chains.
Materials and methods: We generated a mouse model carrying an endogenous deletion of MARs and performed a detailed analysis of its consequences on B cell development.
Results: We found that, unlike the core Eμ element, the absence of MARs did not affect B cell development but led to a significant decrease in somatic hypermutations in Peyer's patch germinal centre B cells. In the intronic region downstream IgH J segments, the mutation frequency was also significantly reduced in the corresponding region of the Ig Kappa locus.
Conclusions: Our data revealed that IgH $MARs_{E\mu}$ regions are critical regulatory elements that participate in efficient recruitment of SHM machinery to Ig loci target sequences. In germinal centre B cells, we postulate that $MARs_{E\mu}$ also act *in trans* to recruit Ig Kappa loci and contribute spatially to the SHM process.

P0549

Progenitor deprivation provokes acute T cell lymphoblastic leukemia

V. Martins* & H. R. Rodewald†
**Institute of Immunology, University Hospital of Ulm, Ulm, Germany, †Division of Cellular Immunology, German Cancer Research Center, Heidelberg, Germany*

Purpose/Objective: Continuous thymus function is thought to depend on a steady supply of T cell progenitors from the bone marrow. To address the fate of a thymus in the complete absence of developmentally competent bone marrow progenitors, we have transplanted normal wild-type thymus into *Rag2$^{-/-}$gc$^{-/-}$KitW/Wv* mice.
Materials and methods: Compound mutant *Rag2$^{-/-}$gc$^{-/-}$KitW/Wv* mice lack competitive hematopoietic stem cells (HSC) and are devoid of T cell progenitors. Using this strain as recipient for wild-type thymus grafts,.
Results: we unexpectedly find that thymocytes persist and that T lymphocytes continue to be produced and exported for several months. Sequencing of the expressed alpha and beta TCR loci in progenitor-deprived thymus grafts shows that the TCR repertoire is still diverse. The analyses of single mutants as recipients for the thymus transplants indicate that *gc*-mediated signals alone play a key role in the competition between thymus-resident and bone marrow-derived progenitors. Hence, the turnover of each generation of thymocytes is not only based on short life span but is also driven via expulsion of resident thymocytes by fresh progenitors entering the thymus.However, a frequent consequence of progenitor-independent thymus autonomous function is the development of T cell acute lymphoblastic leukemia (T-ALL).Recipient mice developed hepatosplenomegaly and full-blown signs of T-ALL. Blast cells in bone marrow, blood and spleen had cell surface phenotypes reminiscent of T-ALL in humans, the tumors were transplantable and were clonal, based on the analysis of the TCR rearrangements. These murine T-ALLs bore mutations in the heterodimerization and PEST domains of *Notch1*. *Rag1* and *Rag2* mRNA continued to be expressed in the leukemic cells but Rag expression was not required for leukemogenesis.
Conclusions: We propose that competition between old and new progenitors in the thymus provides a quality control mechanism that ensures that young outcompete old progenitors, and that abrogation of this competition results in thymus-intrinsic T cell development, followed by the development of leukemia.

P0550

Spatio-temporal regulation of Notch ligand expression defines functional microenvironments in the human thymus: implications in the TCR Alpha Beta versus TCR Gamma Delta T-cell fate decision

M. J. Garcia-leon,* J. L. De La Pompa,† J. C. Ferreres Piñas,‡ M. Garrido Pontnou‡ & M. L. Toribio García*
**Cellular Biology and Immunology, Centro de Biología Molecular Severo Ochoa, CSIC-UAM, Madrid, Spain, †Cardiovascular Developmental Biology, Centro Nacional de Investigaciones Carciovasculares, CNIC, Madrid, Spain, ‡Hospital Universitario Vall d'Hebron, Banco de Tejidos Fetales, Barcelona, Spain*

Purpose/Objective: Interaction of Notch receptors with Notch ligands (DLL1, DLL4, JAG1, JAG2) expressed on the thymic microenvironment (TME) is essential to support T-cell development. DLL4 is the essential ligand that drives T-cell specification, but little is known about the ligands involved is subsequent differentiation of pre-T cells into either TCR$\alpha\beta$ or TCR$\gamma\delta$ cells. As T-cell development implies the active movement of developing thymocytes throughout distinct thymic regions, we ought to determine whether a differential distribution of Notch ligands at defined anatomical regions could endow discrete intrathymic niches with specific developmental functions once T-cell specification has been induced by DLL4.
Materials and methods: We analysed the spatio-temporal regulation of Notch ligand expression in the human thymus by immunohistochemistry and confocal microscopy. The characterization of particular TME niches defined by Notch ligands *in vivo* provided the framework to approach the specific functions of those ligands in the TCR$\alpha\beta$ versus TCR$\gamma\delta$ cell fate of human pre-T cells using the OP9 co-culture system.
Results: We found that distinct Notch ligands are confined to defined histological regions and stromal cell types, and this distribution changes along thymus ontogeny. The four ligands are expressed at high levels in the postnatal thymus (PNT) at the cortico-medullary junction (CMJ) and thymic medulla. In contrast, JAG1 and DLL4 are essentially undetectable in the PNT cortex, although DLL4 is expressed on cortical thymic epithelial cells (cTECs) in the human embryonic thymus (<19 weeks). Instead of DLL4, JAG2 is the most prominent ligand expressed by cTECs in the PNT, although low DLL1 expression levels are also found.

Functional assays show that *a*ll ligands allow the development of TCR$\alpha\beta$ and TCR$\gamma\delta$ cells. JAG2 almost exclusively triggers the generation of TCR$\gamma\delta$ cells, which however expressed an immature phenotype. In contrast, JAG1 impairs TCR$\gamma\delta$ fate, thus balancing TCR$\alpha\beta$ and TCR$\gamma\delta$ cell fates. Additionally, JAG1 drive TCR$\gamma\delta$ cells mainly to the conventional phenotype.

Conclusions: Specific TME niches are defined by Notch ligand expression during human thymopoiesis. This finding together our functional data highlight the importance that spatio-temporal regulation of Notch ligand expression may have *in vivo* to control the TCR$\alpha\beta$ versus TCR$\beta\gamma\delta$ cell fate and differentiation.

P0551
Stage- and ligand-specific regulation of dendritic cell development by Notch signalling in the human thymus

M. L. Toribio, M. J. García-León & E. Martín-Gayo
Cell Biology and Immunology, Centro de Biología Molecular Severo Ochoa, Madrid, Spain

Purpose/Objective: Early thymic progenitors (ETPs) are multipotent precursors that can generate plasmacytoid and conventional dendritic cell (pDCs and cDCs), in addition to T-cells, both *in vitro* and *in vivo*. Given that DCs are normal residents in the steady-state thymus, it is believed that at least part of thymic DCs are generated *in situ*. How ETPs escape from intrathymic signals provided by Notch ligands and avoid T-cell fate specification to generate DCs has not been established; neither the developmental relationship between the two DC thymic lineages, nor the developmental cues that determine the alternative pDC and cDC cell fates are known.
Materials and methods: To assess these questions, we used an *in vitro* DC differentiation assay, based on the co-culture of human ETPs or DC-primed intrathymic progenitors onto OP9 stromal cells expressing different Notch ligands, together with gene expression analyses.
Results: We show here that both DC subtypes are generated from human ETPs through intermediate pDC/cDC progenitors that can be identified also *in vivo*. Such thymic intermediates display phenotypic and genetic myeloid-associated features and have lost T-cell potential. According to the current view that Notch signaling induced by Delta-like-1 ligand (DLL1) binding impairs non-T cell development, we found that DLL1-induced signaling hampered the generation of intermediate pDC/cDC progenitors from ETPs. In contrast, Jagged-1 (JAG1) was permissive. However, once generated, DC progenitors were dependent on survival signals provided by either DLL1 or JAG1, which also favour their differentiation into either pDCs or cDCs. Indeed, DLL1 promoted cDC but did not affect pDC differentiation from pDC/cDC precursors, while differentiation of both DC subtypes was promoted by JAG1-mediated signaling.
Conclusions: Our results provide evidence that Notch signaling controls the development of intrathymic DCs in a stage- and ligand-specific manner and suggest that the spatial regulation of JAG1 versus DLL1 expression in the human thymus could provide specific niches supporting the final fate of ETPs and thereafter of pDC/cDC common progenitors.

P0552
TC21 provides survival signals during negative selection

A. Martínez Riaño & B. Alarcón
Cell Biology and Immunology, Centro de Biología Molecular Severo Ochoa, Madrid, Spain

Purpose/Objective: During thymic development the TCR expressed by immature thymocytes is affinity-proofread according to its interaction with Mayor Histocompatibility Complex (MHC) loaded with self-peptides presented by thymic antigen presenting cells (APC). If affinity of the rearranging TCRs for self-peptide/MHC is too high, thymocytes enter in a program of apoptosis that eliminates potentially harmful autoreactive T cells. TC21 is a GTPase of the Ras-related (RRas) subfamily which interacts with the TCR and is important for tonic TCR signalling and survival of mature T cells. The aim of this work was to study the role of TC21 during thymic development.
Materials and methods: We used C57BL/6 TC21-deficient and WT mice non transgenic and transgenic for AND TCR receptor with H-$2^{k/b}$ and H-$2^{b/b}$ haplotypes. Classical and non-classical Ras GTPases expression in thymic subpopulations was measured by absolute and relative qPCR. Different markers of thymic development were studied by flow cytometry. Tunnel immunofluorescence was used to quantify apoptotic thymocytes. Activation of several signalling pathways was studied by Immunoblot upon TCR stimulation with different ligand concentrations and time-points.
Results: The absence of TC21 in AND TCR transgenic (Tg) mice expressing the I-Ek haplotype, in which the TCR-MHC interaction is of higher affinity, provokes a blockade at the DP stage with no virtually SP4 generated. These thymocytes have upregulated the expression of Nur77 and Annexin V, indicating that the DP blockade is caused by an exacerbated negative selection. Although apparently there are no differences in the phenotype of non-transgenic mice, a Tunnel assay shows more apoptotic thymocytes in TC21 KO thymuses. Furthermore, TC21-deficient AND Tg thymocytes have increased sensitivity to apoptosis induced by stimulation with antigen-loaded dendritic cells *in vitro*. In this system, TC21-deficient thymocytes show impaired phosphorylation of Akt, suggesting that TC21 is required for the activation of a TCR-dependent phosphoinositide 3-kinase (PI3K) pathway in the thymus.
Conclusions: TC21 plays an important role during negative selection by modulating TCR-induced pro-survival signals.

P0553
The impact of DNA and RNA alterations of Ikaros (IKZF1) transcription factor on protein expression and localization

D. Cerna,* V. Kanderova,* J. Volejnikova,* V. Budinsky,† T. Brdicka,‡ T. Kalina§ & E. Fronkova§
**Childhood leukemie investigation Praque (CLIP), 2nd School of Medicine Charles University and University Hospital Motol, Prague, Czech Republic, †Department of Immunology, 2nd School of Medicine Charles University and University Hospital Motol, Prague, Czech Republic, ‡Laboratory of Molecular Imunology, Academy of Sciences of the Czech Republic – Institute of Molecular Genetics, Prague, Czech Republic, §Childhood leukemie investigation Praque (CLIP), 2nd School of Medicine Charles Universtiy and University Hospital Motol, Prague, Czech Republic*

Purpose/Objective: Ikaros is a key regulator of lymphocyte development. Multiple IKZF1 isoforms arise via alternative splicing, including functional IK1, IK2 isoforms and short isoforms lacking DNA-binding capacity (IK4, IK6, IK8) that are predicted to act as inhibitors of IKZF1 function. Recently, it was shown that gene deletions are the main cause of short isoforms expression in acute lymphoblastic leukemia (ALL). In a cohort of 206 children with ALL we found 14 cases (7%) with deletions of at least one exon of IKZF1 that were not always reflected in altered gene expression. Conversely, 5/206 (2%) cases without deletion expressed Ik6 isoform. Both types of alterations predicted poor prognosis. Data on the impact of IKZF1 gene alterations on protein expression are still inconsistent.
Materials and methods: We examined IKZF1 protein expression by Western blot and localization by confocal microscopy in cases with different types of IKZF1 alterations.
Results: In sorted normal B, T cells and monocytes, IKZF1 was located in the nucleus showing a punctate pattern. Interestingly, during mitosis, IKZF1 protein was completely shifted to cytoplasm. In 7 ALL cell lines without genomic deletion preferentially expressing IK1/IK2 mRNA and protein the vast majority of protein was localized in the nucleus. In case with monoallelic DNA deletion of exon 4–7 causing Ik6 mRNA expression we only detected Ik6 mRNA while Western blot showed Ik6 together with Ik1. Protein was localized partly in the cytoplasm and partly in the nucleus. This contradicts the general

consensus on cytoplasmic localization in IK6 expressing cells.In a cell line with monoallelic deletion of exons 4−8 we detected only long isoform Ik1 that was likely to originate from the second allele. The protein was mostly present in nucleus.Surprisingly, in two cell lines with monoallelic deletion of exon 1−7 we found only Ik6 mRNA that was confirmed by Western blot although protein expression was weak. Protein was localized in the nucleus with a smaller proportion present in the cytoplasm. The mechanism of this expression pattern has still to be clarified.

Conclusions: Our data showed that the incomplete correlation between IKZF1 alterations at DNA and RNA level further increases at the protein level, which is the key determinant of IKZF1 role in malignant transformation.

The Influence of Lck on thymic selection thresholds and peripheral T Cell activation

K. Allikmets & R. Zamoyska
Institute of Immunology and Infection Research, University of Edinburgh, Edinburgh, UK

Purpose/Objective: Selection of the T cell repertoire in the thymus is governed by the need to create a repertoire of peripheral T cells that can respond to any foreign antigen in the context of self-MHC, while enforcing central tolerance to self-antigens. The affinity of the selection window has been shown to be very narrow. Perturbations in signalling molecules that reduce the affinity of thymic selection can lead to the production of a peripheral repertoire with increased autoimmunity, as has been shown for mutations in the Zap-70 kinase.

$p56^{lck}$ (Lck) is the most proximal tyrosine kinase required for effective TCR triggering upon TCR engagement by peptide:MHC, upstream of Zap-70. We asked how altering the expression of Lck influenced selection of thymic T cells and activation of peripheral T cells in two mouse models in which expression of Lck is altered.

Materials and methods: Lck^{ind} mice have conditional expression of Lck under the control of a tetracycline inducible transgene. Lck^{ind} mice have high expression of Lck in the thymus but lower -10 to 20% of wild-type (WT) − expression of Lck in the periphery. Lck^{VA} mice express Lck constitutively from a T cell specific transgene and have very low expression of Lck (~5% of WT) in both the thymus and periphery. Cells were analysed by FACS and Western Blot.

Results: Peripheral Lck^{ind} T cells have higher activation thresholds, requiring approximately fivefold more antigen, than WT cells to be triggered. In contrast, Lck^{VA} mice have comparable activation thresholds to WT cells. We asked whether this difference in sensitivity of peripheral T cells from these two lines was a consequence of the amount of Lck available for thymic selection.

Lck^{VA} mice display altered TCR expression pattern in the thymus during development compared to WT and Lck^{ind}. On a TCR transgenic background Lck^{VA} mice also show lower expression of TCR on peripheral T cells.

Conclusions: The level of Lck available to T cells in the thymus influences thymic selection and subsequently affects TCR expression and the behaviour of peripheral T cells.

The role of pTalpha isoforms in alpha beta T cell development

C. L. A. Grandjean, J. Mahtani-Patching, D. J. Pang & D. J. Pennington
Centre of Immunology, Blizard Institute, London, UK

Purpose/Objective: Mature $\alpha\beta$ T cells, that express a heterodimeric $\alpha\beta$ T cell receptor (TCR$\alpha\beta$), develop in the thymus from a common lymphoid progenitor and are indispensable components of a healthy immune system, displaying a range of functions (being cytotoxic, regulatory, or providing 'help') and sites of migration (to tissues such as gut versus secondary lymphoid organs). Early in thymic development, in order to successfully traverse an important developmental checkpoint, immature thymocytes up-regulate a pre-TCR complex that is composed of a rearranged TCRβ chain, the invariant pTα chain, and various CD3 signalling molecules. The availability of two alternatively-spliced pTα isoforms ($pT\alpha^a$ and $pT\alpha^b$) provide the cell with the choice between two distinct preTCR complexes ($preTCR^a$ and $preTCR^b$). However, the truncated form; $pT\alpha^b$, has been frequently omitted from studies or described as non-functional despite previous work suggesting the opposite. Our recent work has demonstrated that despite lacking an extracellular Ig-loop that was previously implicated in pre-TCR signalling, $pT\alpha^b$ could successfully drive early T cell development. The aim of this study was to ascertain a role to both pTα isoforms in T cell development.

Materials and methods: BAC-transgenic animals expressing only full-length pTα ($pT\alpha^a$) were generated. Subsequently, $\alpha\beta$ T cell subsets in thymuses, lymph nodes and gut of transgenic animals and controls were analyzed by flow cytometry. Positive selection at the DP stage was investigated by staining intracellular phosphorylated ERK following cross-linking of TCR$\alpha\beta$.

Results: Preliminary data suggest that $pT\alpha^a$ alone is sufficient for the development of conventional $\alpha\beta$ T cells ($CD8^+$ and $CD4^+$ T cells), but does not seem to rescue a particular population of gut T cells referred to as unconventional $TCR\alpha\beta^{(+)}$ $CD8\alpha\alpha^{(+)}$ intraepithelial lymphocytes (IELs). Furthermore, our data show a favored development of SP thymocytes ($CD4^+$ or $CD8^+$) and different levels of phosphorylated ERK in DP thymocytes ($CD4^+$ $CD8^+$) of transgenic animals.

Conclusions: Contrary to previous belief, our work showed that $pT\alpha^a$ and $pT\alpha^b$ isoforms do not have redundant functions in $\alpha\beta$ T cells development. Additionally, the data reveal a hitherto unrecognized role for pTα in the positive selection of $\alpha\beta$ T cells at the $CD4^+$ $CD8^+$ 'DP' stage.

The role of the ileal Peyer's patches and the bone marrow in B cell development of swine

M. Sinkora, K. Stepanova & J. Sinkorova
Department of Immunology and Gnotobiology, Institute of Microbiology v.v.i. Academy of Sciences of the Czech Republic, Novy Hradek, Czech Republic

Purpose/Objective: Pigs are traditionally categorized into group of animals that use Gut Associated Lymphoid Tissues (GALT) for generation of B cell repertoire. This group include chicken that use bursa of Fabricius, rabbit that use sacculus rotundus (or appendix), and other ungulates including swine that use Ileal Peyer's Patches (IPP). Since bursectomy results in B cell deficiency, we wondered if resection of the IPP of piglets would have a similar effect.

Materials and methods: Flow cytometry and molecular immunology methods were used to compare IPP from resected, surgical shams and untreated germ-free piglets, all of which were later colonized with a defined commensal flora. A similar approach was used for analyses of flow cytometry sorted cell populations from the bone marrow.

Results: Studies disprove categorization of swine (and probably other ungulates) into group of animals that use GALT for generation of B cell repertoire. It has been shown that IPP are not a significant source of B cells, are not required for maintenance of the systemic B cell pool and are not a site of primary B cell lymphogenesis because resection of IPP does not have any effect to development of systemic B cells. On the other hand, colonization of IPP caused a shift from the fetal type of lymphocyte distribution to the adult type that is characteristic by prevalence of mature effector lymphocytes. Comparison of germ-free

with colonized pigs proves that lymphocyte development in IPP is dependent on colonization. According to finding that IPP are a secondary lymphoid tissue, we have extended reported studies by analyses of RAG, TdT, VpreB expression and the presence of DJ_H, VDJ_H, VJ_L rearrangements and signal joint circles (SJC) in the genom of flow cytometry sorted cell populations from the bone marrow. The results clearly show that porcine B cells are developed in the bone marrow throughout entire life.

Conclusions: The results indicate that porcine IPP are not required for systemic B cell generation or maintenance, but are secondary lymphoid tissue that appear important in immune responses to colonizing bacteria. On the other hand, the bone marrow is fully capable of B cell lymphogenesis and remains active throughout entire life. This work was supported by grants P502/10/0038 and P502/12/0110 from the Czech Science Foundation, and a grant ME09089 from the MSMT.

P0558
The role of the tyrosine kinase receptor RET in T cell development and function

A. R. M. Almeida, D. Fonseca-Pereira, S. Arroz-Madeira, H. Ribeiro & H. Veiga-Fernandes
Immunobiology Unit, Instituto de Medicina Molecular, Lisbon, Portugal

Purpose/Objective: The neuronal growth factor family includes the glial cell-line derived neurotrophic factor (GDNF) ligands (GFLs), which signal through the RET tyrosine kinase receptor. Importantly, *Ret* expression in T lymphocytes has been reported both in mouse and human, and while a role for RET ligands in thymocytes has been suggested the function of RET in mature T lymphocytes remains elusive. Using cellular and genetic approaches, we are investigating the expression and function of RET in T cell development and function.

Materials and methods: Materials and methods are briefly described within the results section.

Results: Our results confirm the expression of *Ret* and of the co-receptors *Gfra1* and *Gfra2* by developing thymocytes and mature $CD4^+$ and $CD8^+$ T cells. In contrast to previously suggested, our results using *Gfra1*$^{-/-}$, *Gfra2*$^{-/-}$ and *Ret*$^{-/-}$ embryos show that embryonic T cell development is not affected. Adult T cell development was also unaffected in *Ret*$^{-/-}$ FL chimeras or in *Ret*$^{fl/fl}$ animals bred to *CD2Cre* mice, excluding a role for RET-mediated signals in T cell development. This finding allowed us to use T cells from these animals and investigate the role of RET in peripheral T cell homeostasis and function. Importantly, gene expression analysis revealed that *Ret* is developmentally regulated being absent in naïve T cells but present in activated/memory phenotype T cells, thus suggesting a role in the establishment of memory T cell pools or in the effector function of T cells. The analysis of the peripheral *Ret*$^{-/-}$ T cell pools ruled out a major role for RET-mediated signals in peripheral T cell homeostasis, as steady-state subpopulation structure was unperturbed. We have thus focused our studies on T cell effector function. We found fast up-regulation of *Ret* and co-receptors upon *in vitro* activation of T cells and we have observed an impact of RET-absence in *in vitro* polarization cultures, with higher differentiation of IL-10 producing $CD4^+$ T cells in TH2 polarization conditions. In order to translate these findings into *in vivo* settings, we have treated WT or Ret$^{fl/fl}$xCD2Cre with anti-CD3 as this treatment results in IL17-dependent gut inflammation under the control of IL10-producing regulatory T cells. Our initial results confirm our hypothesis and suggest that RET-mediated signals modulate the regulatory arm of $CD4^+$ T cell responses, resulting in diminished IL17 production in the absence of RET.

Conclusions: We conclude that RET-dependent signalling is not involved in T cell development but is most likely playing a role in IL10-dependent regulatory function of $CD4^+$ T cells.

P0560
Thymic block in T cell development in rheumatoid arthritis

M. Rossol,* A. Schulz,† A. Schatz,† U. Meusch,† C. Baerwald† & U. Wagner†
**Translational Centre for Regenerative Medicine, University of Leipzig, Leipzig, Germany, †Department of Internal Medicine Rheumatology, University of Leipzig, Leipzig, Germany*

Purpose/Objective: Background. Several lines of evidence show, that the T cell compartment of RA patients is characterized by premature immunosenescence and a disturbed homeostasis. Latent cytomegalovirus (CMV) infection has been shown to contribute to homeostatic exhaustion of $CD4^+$ T cells in RA. Aim of the study was to analyze if the reduced frequency of naïve $CD4^+$ T cells in the peripheral blood of RA patients is due to a reduced bone marrow output of progenitors cells.

Materials and methods: Methods. Mononuclear cells of the peripheral blood of 33 RA patients and 33 age-matched healthy controls (median age 63 years) were analyzed by flow cytometry. RA patients were all $ACPA^+$ and RF^+, and 50% were SE-$DR4^+$. An additional healthy cohort ($n = 60$) was recruited to analyze the influence of age on various parameters.

Results: Results. The frequency of the pre-thymic lymphoid progenitor ($CD34^+$ /Lin-/CD24-/$CD10^+$) as well as the frequency of recent thymic emmigrants (RTEs, $CD4^+$ /$CD45Ra^+$/$CD31^+$) negatively correlates with age in healthy controls. Additionally, the lymphoid progenitor frequency positively correlates with the frequency of RTEs.

The frequency of the lymphoid progenitor is increased in RA patients compared to healthy controls (41 cells per 1E07 PBMC versus 28 cells per 1E07 PBMC, $P = 0.0063$). However, the thymic output, characterized by the frequency of RTEs, is decreased in RA patients (32.0% versus 44.1%, $P = 0.003$). In RA patients, the lymphoid progenitor frequency does not correlate with the frequency of RTEs.

The increased frequency of the lymphoid progenitor in RA is not influenced by CrP levels, tender/swollen joint count, the presence of SE-DR4 and DAS28 score. However, CMV Ig^+ patients have increased frequencies of the pre-thymic lymphoid progenitor compared to CMV Ig- RA patients (50 cells per 1E07 PBMC versus 32 cells per 1E07 PBMC, $P = 0.03$).

Conclusions: Conclusion. The thymic output of $CD31^+$ recent thymic emigrants is influenced by the availability of pre-thymic lymphoid progenitor cells in healthy controls. The frequency of the pre-thymic lymphoid progenitor is increased in RA compared to healthy controls, while the thymic output of $CD31^+$ RTEs is reduced. We hypothesize, therefore, that insufficient thymic T cell genesis is the underlying cause of the disturbed T cell homeostasis in this disease, and might also contribute to the pathogenesis of the disease.

P0561

TNF superfamily members have different roles in thymic epithelial microenvironment

R. Bichele, K. Kisand, P. Peterson & M. Laan

Department of General and Molecular Pathology, University of Tartu, Tartu, Estonia

Purpose/Objective: Thymic epithelial cells (TECs) play a key role in the thymic selection of T-cells due to their ability to express a wide variety of tissue restricted antigens (TRAs) as well as thymic chemokines that guide immature T-cells throughout their maturation. TRAs are expressed by mature $MHCII^+CD80^+$ medullary thymic epithelial cells (mTECs), at which stage they also express Autoimmune Regulator (Aire), a transcription factor shown to be responsible for the expression of a large number of TRAs. However, the signals that drive epithelial maturation and chemokine expression remain largely unknown. Previous studies have shown that RANK-RANKL signaling is necessary for producing $Aire^+$ mature mTECs. We aimed to further study the effects of tumor necrosis factor superfamily (TNFSF) members RANKL, CD40L, LIGHT, TNF-alpha and lymphotoxin beta (LT-beta) on thymic epithelium maturation along with chemokine expression in murine fetal thymus organ culture (FTOC).

Materials and methods: Thymic lobes of embryonic day 16.5 mice were removed and cultured *ex vivo* for 6 days in the presence of 2′-deoxyguanosine. Thereafter the lymphocyte-depleted lobes were stimulated with selected TNFSF members for 48 h. Material was collected and analyzed for changes in gene expression using quantitative real-time PCR.

Results: RANKL on its own was sufficient for maintaining the expression of Aire and TRAs in *ex vivo* organ culture depleted of $CD45^+$ cells. Out of the TNFSF members tested RANKL was also the only one able to induce Aire and TRA expression. LIGHT and CD40L alone did not seem to have any effect on the expression of either TRAs or chemokines. However, RANKL and especially LT-beta and TNF-alpha potently induced the expression of several chemokines including the CCR7 ligands CCL19 and CCL21.

Conclusions: Our results demonstrate how distinct intrathymic signals are responsible for different aspects of thymic function. Only RANKL seems to regulate Aire and TRA expression while thymic chemokines share a broader selection of inducers, including TNF-alpha and LT-beta in addition to RANKL. We show that these TNFSF members work cooperatively on different aspects of creating a proper thymic microenvironment.

Poster Session: Lymphocyte Signalling Mechanisms

P0562
CD46 glycosylation controls its expression and function in human T cells

S. Ni Choileain & A. L. Astier
MRC Centre for Inflammation Research, University of Edinburgh, Edinburgh, UK

Purpose/Objective: T cell development, differentiation and activation modulate the glycosylation profile of glycoproteins on T cells, and levels of glycosylation of several glycoproteins have been shown to control T cell responses. CD46, a complement regulator, acts as a costimulatory molecule for human T cells and induces Tr1 differentiation, a subset of regulatory T cells characterized by large amounts of IL-10 secretion. CD46 ectodomain contains 3 N-glycosylation and multiple O-glycosylation sites. Proteolytic cleavage of CD46 occurs upon T cell activation and has been shown to be important to regulate T cell activation and cytokine production. Herein, we determined whether CD46 glycosylation was important for its processing and function.
Materials and methods: $CD4^+$ T cells, purified from blood, were first activated by anti-CD3/CD46 antibodies in presence or absence of N- and O-glycosylation inhibitors. CD46 expression was determined. In order to assess whether glycosylation of CD46 was important for its functions, we also expressed the different N-glycosylated mutants of CD46 (arginine replaced by a glutamine, as previously published and kindly provided by Dr. JP Atkinson), the O-mutant (region rich in O-glycosylation sites deleted), or the corresponding wild-type isoform, in primary human T cells, and compared the level of CD46 expression, proliferation and cytokine production upon CD46 costimulation.
Results: T cell culture with broad-spectrum inhibitors of N- or O-glycosylation demonstrates contrasting roles of N- and O- glycosylation in CD46 downregulation upon CD46 costimulation. Moreover, expression of the different N- and O- glycosylated mutants has differential effects on CD46 downregulation and T cell function, with antagonistic roles on T cell proliferation and IL-10 production.
Conclusions: Our novel data demonstrate that the level of CD46 glycosylation determines its shedding from the surface upon its activation, which is, in turn, important to control T cell activation. These data also highlight once more the importance of glycans in the control of the immune response.

P0563
Characterization of THEMIS as a new member of the TCR signalosome

W. Paster,* C. Brockmeyer,† G. Fu,‡ A. Kabat,* C. Wuelfing,§ N. Gascoigne‡ & O. Acuto*
**Sir William Dunn School of Pathology, University of Oxford, Oxford, UK, †Department of Molecular & Cell Biology, University of California, Berkeley, CA, USA, ‡Department of Immunology, The Scripps Research Institute, La Jolla, USA, §Department of Immunology, UT Southwestern Medical Center, Dallas, TX, USA*

Purpose/Objective: Stimulation of the T cell antigen receptor (TCR) induces formation of phosphorylation-dependent signalling networks, ultimately leading to T cell proliferation and differentiation. Composition and dynamics of the TCR signalosome are still incompletely understood. Others and we have recently identified Thymocyte-expressed molecule involved in selection (THEMIS), as a novel regulator in thymocyte positive selection. The exact role of THEMIS in signalling, especially in mature peripheral T cells, has remained poorly characterized and controversial. Here we set out to study the role of THEMIS in proximal TCR signalling in more detail.
Materials and methods: Work on human T cells was carried out in the Jurkat leukemia T-cell line and in primary human CD4 T cells isolated from peripheral blood. Lentiviral vectors were used for overexpression and knockdown of THEMIS. Tyr-phosphorylation sites were identified on in-vitro phosphorylated recombinant THEMIS by mass spectrometry. THEMIS synapse recruitment was studied by live-cell imaging of GFP-reporters in MHC class II restricted 5C.C7 TCR transgenic mouse T cells.
Results: In the present study we show that THEMIS is a new member of the TCR-proximal signalosome. THEMIS acts as a positive regulator of TCR-induced IL-2 gene expression, via modulation of the MAP kinase ERK and the transcription factor NFAT. TCR ligation leads to rapid Tyr-phosphorylation and recruitment of THEMIS to the immunological synapse via the transmembrane adapter Linker for activation of T cells (LAT). We demonstrate that Lck is the upstream kinase for THEMIS and map potential Tyr-phosphorylation sites. LAT recruitment is essential for THEMIS phosphorylation and is mediated via the adapter molecule growth factor receptor-bound protein 2 (GRB2). GRB2 binds constitutively to a highly conserved proline-rich region (PRR1) at the C-terminus of THEMIS. We can show that GRB2 association to PRR1 is indispensible for THEMIS Tyr-phosphorylation and function *in vitro* and importantly for thymocyte development *in vivo*.
Conclusions: Taken together, our study firmly establishes THEMIS as a regulator of proximal TCR signalling and further shows that correct positioning of THEMIS in the LAT-signalosome via GRB2 is crucial for thymocyte development.

P0564
Characterization of Trojan: a novel leukocyte protein

P. Petrov, T. Uchida & O. Vainio
Medical Microbiology Nad Immunology, University of Oulu, Oulu, Finland

Purpose/Objective: Aiming to identify molecules involved in T cell development, we have cloned and characterized a novel avian cell surface protein called 'Trojan' from embryonic thymocyte cDNA library. From our previous results we expect Trojan to have anti-apoptotic and/or proliferative role for lymphocytes. Our current objectives are to investigate its function, its signalling mechanism and characterize the novel protein family it belongs to.
Materials and methods: Trojan characterization. Perform sequence analysis, investigate Trojan expression by RT-PCR and flowcytometry.

Functional analysis. Cells from a T cell line are exposed to different apoptosis inducers (UV light, 5-FU, anisomycin, etc..) and any changes in Trojan expression are measured by flow cytometry. Levels of apoptosis are assessed by Annexin V and 7AAD, while cellular proliferation by CFSE dye loading.

Signalling analysis. Cells are loaded with the tandem Fluo-4 and Fura Red calcium indicators and stimulated with polystyrene beads coated with Trojan-specific antibodies. Elevation in intracellular calcium is measured by flow cytometry.

Protein family characterization. Bioinformatics sequence analyses of the family members are carried out.
Results: Trojan is a transmembrane protein, predicted to have a CCP domain, two Fibronectin type III domains and a short cytoplasmic tail with two possible serine phosporylation sites. Trojan is expressed specifically in lymphoid tissues, while on thymocytes its expression pattern is similar to that of IL-7Rα and the anti-apoptotic Bcl-2.

Upon apoptosis induction in cultured cells, Trojan expression generally rises on the surface of surviving cells and gradually decreases towards its normal levels as cells proliferate.

Stimulation through Trojan has yielded controversial results. We are aiming to mimic cell-cell and ligand-receptor interactions in order to conclude whether Trojan transmits intracellular signalling.

Trojan gene is found in the publicly available databases, where the adjacent two genes encode for hypothetical Trojan-like proteins. One family member is predicted as a receptor type protein tyrosine phosphatase while the other as a membrane protein having pairs of CCP and FN3 domains.

Conclusions: In the presented study we characterize Trojan: a novel cell surface molecule. Trojan has a similar expression during T cell development as IL-7Rα and Bcl-2: two molecules known to be important for thymocyte survival and proliferation. Such similar expression, supported by our current functional analyses, makes Trojan an attractive candidate of having an anti-apoptotic or proliferative role.

P0565

Cord blood leptin levels of healthy neonates are associated with IFN-g production by cord blood T-cells

I. Panagoulias,* G. Raptis† & A. Mouzaki*

**Division of Hematology, Department of Internal Medicine, University of Patras, Patras, Greece, †Department of Child Health, Royal Oldham Hospital, Oldham, UK*

Purpose/Objective: Leptin is a hormone synthesized by adipocytes and other tissues, including the placenta, and it regulates food intake and energy expenditure, reproductive and immune functions. The pro-Th1 immunomodulatory effects of leptin have been linked to enhanced susceptibility to autoimmune or inflammatory diseases, mainly in experimental models. Our goal in this study is to investigate the role of leptin in neonatal immunity.

Materials and methods: We measured serum leptin and cytokine (IFN-g, TNF-a, IL-2, IL-4, IL-10, IL-12) levels in cord blood (cb) of 510 healthy neonates, 14 small for gestational age (SGA), 312 appropriately grown for gestational age (AGA) and 184 large for gestational age (LGA). To investigate whether leptin can independently influence cytokine gene expression by cb T-cells and monocytes (Mc), we cultured cb T-cells or Mc, isolated from randomly selected AGA neonates or adult peripheral blood, with leptin.

Results: Median serum leptin concentration in the whole sample was 11 ng/ml. In 11.2% neonates (1 SGA, 32 AGA, 24 LGA), leptin levels were >90th percentile (median 39 ng/ml). In 33.3% of those (3.72% of total sample) with the highest leptin levels (median 46 ng/ml), significantly elevated levels of serum IFN-g were also found (mean 27.11 pg/ml, range 17.5–38.5 pg/ml). In neonates with leptin levels ~50th percentile (median 12 ng/ml) or <10th percentile (median 1 ng/ml), serum IFN-g levels were negligible. All other cytokines measured, were < the assays' detection limits. Leptin can influence cytokine gene expression by cb T-cells and monocytes. Addition of leptin in cb-T-cells and Mc cultures resulted in upregulation of IL-2, IFN-g and IL-4 gene expression in cb and adult T-cells and IL-10 expression mainly in cb-Mc. Significantly higher expression of IFN-g occurred in female cb-T-cells cultured with leptin, compared with male cb-T-cells.

The figure above represents a proposed model of leptin regulation of cytokine production by cord blood T-cells and monocytes.

Conclusions: In conclusion, the concurrent presence of high concentrations in both leptin and IFN-g in cb of healthy infants, and leptin's ability to directly upregulate cytokine gene expression in cb T and Mc cells, indicate that abnormally high leptin levels can independently influence the immune system of healthy newborns, and may mediate gender differences in the development of a Th1 polarized immune response.

P0566

Cytohesins regulate static adhesion, MAP kinase signaling, and T cell receptor internalization in T cells through a GEF-dependent manner

F. Tolksdorf, M. Rieck, N. Novak, T. Quast, J. Grell & W. Kolanus

Department of Molecular Immune and Cell Biology, Life and Medical Sciences Institute, Bonn, Germany

Purpose/Objective: Members of the cytohesin protein family of guanine nucleotide exchange factors for ARF-GTPases were found to play important roles in immune cell biology, since these proteins are involved in LFA-1-mediated cell adhesion and migration, as well as in MAP kinase signaling during T cell activation. However the exact functions of the individual cytohesins and their precise localizations in the various T cell signaling pathways remain unclear.

Materials and methods: The role of cytohesins during T cell activation was addressed by assessing their contributions to e.g. static or dynamic adhesion, the regulation of TCR internalization, IL-2 production and analysis of MAP kinase signaling.To this end, we employed two recently identified small molecular cytohesin inhibitory compounds (Secin16, Secin144), the specificity of which was proven via surface plasmon resonance affinity measurements and fluorescence-based nucleotide exchange assays.

Results: Analysis of cytohesin activity on the TCR internalization revealed a specific and novel role of cytohesin 3. The overexpression of cytohesin 3, but not of cytohesin-1 or -4, reduced the ligand-dependent and ndependent TCR internalization in a GEF-dependent manner. Furthermore, using the chemical cytohesin inhibitors Secin 16 and Secin 144 for analyses of cell adhesion, MAP kinase signaling, IL-2 production, we observed differential effects. Although Secin16 and Secin 144 both bind to the Sec7 domain of cytohesin 1, only Secin 16 inhibited the nucleotide exchange of the cytohesin Sec7 domain towards ARF 1 *in vitro*. Interestingly, both compounds impaired IL-2 production in stimulated T cells, as well as their adhesion to ICAM-1.On the other hand, we found that the dynamic adhesion of T cell in laminar flow conditions was only inhibited by Secin 144 and was thus GEF-independent, whereas the phosphorylation of ERK 1/2was only impaired by Secin16 and thus GEF dependent.

Conclusions: Therefore we conclude that cytohesin-mediated signaling mechanisms are important for T cell functions, e.g. adhesion, IL-2 production, MAP kinase signaling and T cell receptor internalization, which are GEF-dependent or independent, respectively.

P0568

Differential polarisation of Csk between naïve and antigen-experienced CD8$^+$ T cells

J. G. Borger,* A. Filby† & R. Zamoyska*

**Institute of Immunology and Infection Research, University of Edinburgh, Edinburgh, UK, †Flow Cytometry Laboratory London Research Institute, Cancer Research UK, London, UK*

Purpose/Objective: In CD8$^+$ T cells, engagement of the T cell receptor (TCR) with agonist peptide:MHC molecules causes dynamic redistribution to the immunological synapse of surface molecules including the CD8 co-receptor. CD8 associates with the Src-family kinase (SFK) Lck, which in turn initiates the rapid tyrosine phosphorylation events that drive cellular activation. Compared to naïve T cells, antigen (Ag)-experienced CD8$^+$ T cells make shorter contacts with antigen presenting cells, are less dependent on costimulation, and are triggered by lower concentrations of antigen, yet the molecular basis of this more rapid response of Ag-experienced T cells is not fully understood. Here we show differences in co-localisation of the SFK and their negative regulator, Csk, between naïve and Ag-experienced CD8$^+$ T cells.

Materials and methods: Ag-experienced CD8$^+$ T cells were generated by incubation of naïve F5 TCR Tg CD8$^+$ T cells in 10nM cognate

peptide, NP68, for 3 days and then rested for 4 days in IL-2$^+$ IL-7. Naive and Ag-experienced F5 CD8$^+$ T cells were stimulated with TCR$^+$CD8 cross-linking for 5mins, then fixed in 4% PFA and permeabilised in Triton X-100 for double staining of pTyr, Lck, LckpTyr^{505} and Fyn with Csk. Cells were imaged by 4-colour confocal microscopy and analysed by Volocity and ImageJ software.
Results: In naïve CD8$^+$ T cells there was pronounced co-localisation of the SFK and Csk at the immunological synapse, while in Ag-experienced cells, although more Lck molecules redistrbuted to the proximal pole of the cells, Csk displayed a bipolar distribution. Interestingly, the SFK Fyn, shared a similar bipolar distribution as Csk in Ag-experienced CD8$^+$ T cells. Furthermore, in Ag-experienced but not naïve CD8$^+$ T cells, a proportion of Csk was sequestered within a cytosolic structure.
Conclusions: The data show that there is differential redistribution of a key negative regulator away from the site of TCR engagement in Ag-experienced compared to naïve CD8$^+$ T cells, which might be associated to the more rapid responses of memory cells upon re-exposure to antigen.

P0569

Differentially expressed genes in MiHA-specific CD8$^+$ T cells upon co-inhibitory receptor-mediated T cell dysfunction after allogeneic stem cell transplantation

W. J. Norde,* F. Maas,* T. Mutis,† M. Griffioen,‡ R. van der Voort* & H. Dolstra*
**Laboratory of Hematology, Department of Laboratory Medicine, Radboud University Medical Centre, Nijmegen, The Netherlands, †Department of Clinical Chemistry and Hematology, Utrecht University Medical Centre, Utrecht, The Netherlands, ‡Department of Hematology, Leiden University Medical Centrer, Leiden, The Netherlands*

Purpose/Objective: Allogeneic stem cell transplantation (alloSCT) can cure hematological malignancies by inducing alloreactive T cell responses targeting minor histocompatibility antigens (MiHA) expressed on malignant cells. Despite induction of robust MiHA-specific T cell responses and long-term persistence of alloreactive memory T cells specific for the tumor, often these T cells fail to respond efficiently to tumor relapse. Previously, we demonstrated the involvement of the coinhibitory receptors programmed death-1 (PD-1) and B and T lymphocyte attenuator (BTLA) in suppressing MiHA-specific CD8$^+$ T cell immunity. Signalling via these and other receptors have rendered the alloreactive T cells dysfunctional. The aim of this study is to identify which key intracellular mediators are involved in the exhaustion of MiHA-specific T cells.
Materials and methods: To characterize diferences between functional versus impaired MiHA-specific memory CD8$^+$ T cells, we have isolated cells by flow cytometry assisted cell sorting. These samples were either from 10 patients in remission (functional) or from 10 patients which developed relapse, despite initial immune responses (impaired). Next, we compared gene expression profiles between these groups on a dedicated qPCR platform. Genes investigated were selected after an explorative microarray analysis and literature search.
Results: By comparing gene expression profiles of MiHA-specific T cells from patients in remission versus patients whom experienced relapse, we found interesting differences. As expected, co-inhibitory molecules were differentially expressed between these two groups. Furthermore, we found differences in effector molecules such as Granzyme B and perforin. Interestingly, we found a higher expression of the transcription factor FOXO3 in MiHA-specific memory CD8$^+$ T cells of relapsed patients. FOXO3 is a pro-apoptotic transcription factor, and has been implicated in T cell memory formation. These factors provide a possible link to co-inhibitory receptor-mediated T cell impairment, and therefore the role of FOXO3 in this process will be investigated.
Conclusions: We have identified interesting differentially expressed genes, by comparing gene expression profiles from MiHA-specific T cells from relapsed versus patients in remission. These include co-inhibitory molecules, T cell effector proteins, and interestingly, the transcription factor FOXO3. Therefore, the role of FOXO3 in immune responses after alloSCT needs to be investigated, and may provide a rationale to prevent of reverse T cell functional impairment of MiHA-specific memory CD8$^+$ T cells.

P0570

Distinct signalling patterns and functional responses to CD2 and CD28 co-stimulation of human primary T cells

K. Moltu, S. Skånland, T. Berge & K. Taskén
Centre for Molecular Medicine Norway Nordic EMBL Partnership and Biotechnology Centre, University of Oslo, Oslo, Norway

Purpose/Objective: T-cell activation depends on stimulation of the T-cell receptor (TCR) via interactions with peptide/ MHC molecules on antigen-presenting cells (APCs) together with additional signals from co-receptors. Co-receptor ligation modulates the intracellular signalling pathways that regulate T-cell fate and lack of co-stimulation results in non-responsiveness or T-cell anergy. Studies have demonstrated that CD28 is the principal co-stimulatory receptor for T-cell activation, but multiple molecules on the T cell have been described to deliver co-stimulatory signals. CD2 functions as an adhesion molecule, but cross-linking of CD2 also serves as an efficient co-stimulus in T cells and CD28 and CD2 have been considered largely redundant based on studies with null mutant mice. We are currently investigating the differences in CD2 versus CD28 co-stimulation on downstream signalling events in human primary T cells.
Materials and methods: Using phospho-specific flow cytometry in combination with fluorescent cell barcoding, we are mapping both proximal and distal T-cell signalling events under various co-stimulatory conditions. Peptide array technology enables characterisation of the interactions between the Lck/Fyn SH3-domains and CD2/CD28.
Results: CD2 and CD28 co-stimulation trigger overlapping but distinct signalling pathways in human primary T cells. Phospho-specific flow cytometry analysis revealed that stimulation of CD28 is required for the activation of NF-κB while stimulation through CD2 appears to give stronger signalling responses in more TCR-proximal proteins such as SLP-76. Furthermore, CD2 and CD28 co-stimulation result in different cytokine responses. Both CD2 and CD28 associate with the Src family tyrosine kinases Lck and Fyn via proline-rich sequences contained within their cytoplasmic domains. To investigate the molecular mechanisms that give rise to the distinct signalling responses observed after CD2 and CD28 co-stimulation, we are dissecting the protein interactions between the co-receptors and Lck/Fyn.
Conclusions: Our study describes distinct differences, both qualitatively and quantitatively, in the co-stimulatory capacities of CD2 and CD28.

P0572

Identification of enzymes that dephosphorylate Ser39 of PTP-PEST in CD3/CD28-mediated phosphorylation

H. Palmer, S. Motohashi & A. Maruyama
Life Science, Rikkyo (St Paul's) University, Tokyo, Japan

Purpose/Objective: Protein tyrosine phosphatase-PEST (PTP-PEST), encoded by the *PTPN12* gene, is a protein tyrosine phosphatase associated with T cell signaling. Previous studies have associated PTP-PEST with TCR regulation, however, the specific role has not been fully elucidated. PTP-PEST has two phosphorylation sites; Ser39 and Ser435, the former of which is the major site that negatively regulates

the PTP activity. So far we have demonstrated that Ser39 phosphorylation is induced in CD3/CD28 costimulated Jurkat T cells, predominantly through the PKC-θ. However, molecules involved in the dephosphorylation observed after 10 min stimulation, have not yet been established. We identified PP1α as a PTP-PEST binding protein that associates with the dephosphorylation of Ser39, and postulate the possible participation of PP1-isoenzymes to be involved in the dephosphorylation of CD3/CD28-costimulated Jurkat T cells. In this study, we aim to determine the Ser39 dephosphorylating enzymes in CD3/CD28-costimulated Jurkat T cells, focusing on PP1 isoenzymes.
Materials and methods: Jurkat T cells expressing exogenous PTP-PEST pretreated with and without PP1-specific inhibitors were stimulated by anti-CD3/anti-CD28 mAbs, and the phosphorylation of PTP-PEST at Ser39 was evaluated by Western blotting with phosphor-Ser39-specific antibody. HEK 293 cells expressing exogenous PTP-PEST and PP1 isoenzymes were treated with TPA and Ser39 phosphorylation was determined by Western blotting.
Results: Ser39 was phosphorylated by CD3/CD28-costimulation, and dephosphorylation observed after 10 min stimulation in Jurkat T cells. Cells treated with PP1-specific inhibitors had pronounced CD3/CD28-mediated Ser39 phosphorylation, compared with untreated cells. TPA-mediated Ser39 phosphorylation was diminished by PP1α, PP1β and PP1γ1, suggesting that PP1 isoenzymes contributed Ser39 dephosphorylation in Jurkat T cells.
Conclusions: Ser39 of PTP-PEST was phosphorylated by CD3/CD28-mediated signaling, and subsequently dephosphorylated. Here we identified PP1 as major dephosphorylating enzymes of Ser39, however, the isoenzyme specificity is presently under investigation.

P0573
Importance of growth factor receptor-bound protein 2 (Grb-2) binding to CD28 in mediating NF-kB activation in T cells

Y. Thaker & C. Rudd
Pathology, University of Cambridge, Cambridge, UK

Purpose/Objective: The full activation of T-cells is achieved via concomitant engagement of CD3/TCR and CD28 molecules on T-cells (1, 2). While the role of the co-receptor CD28 in T-cells is well established, the nature of their interdependence in the NF-kB activation is poorly understood (2). Whether TcR/CD3 and CD28 operate as separate entities, or need to cooperate for NF-kB activation is not well established.
Materials and methods: CD28 deficient (i.e. *Cd28*$^{-/-}$) primary T-cells and Jurkat T-cells were used to monitor NF-kB activation using dual luciferase assay and electro-mobility shift assay supplemented with flow cytometry and western data. Role of cytoplasmic domain of CD28 was investigated using site specific knock-in mouse model or CD28 deficient cells reconstituted with mutant (N193Q) CD28 that abrogated Grb2 binding. Further, Grb2 expression was specifically knocked down using siRNA.
Results: We previously showed that CD28 binds to the growth factor receptor-bound protein 2 (Grb-2) via the YMNM motif (3,4). Here, we show, using *Cd28*$^{-/-}$ primary T-cells and Jurkat T-cells, that substantial NF-kB activation can be achieved by CD28 ligation alone in the absence of antigen receptor ligation. Further, using a site specific mutant in the CD28 domain at YMN-QM that disrupts Grb-2 binding to cytoplasmic domain, we showed that this interaction is critically needed for NF-kB activation. Similarly, siRNA knockdown of Grb-2 expression prevented NF-kB activation as shown by luciferase and EMSA assays. The additional role of CD28-Grb-2 interaction with downstream adapter molecules for NF-kB activation will be discussed.
Conclusions: Co-stimulatory molecule CD28 forms an essential component of NF-kB activation during T cell activation. CD28 mediated NF-kB activity is dependent upon its binding to Grb2 and does not essentially requires T-cell receptor co-engagement.

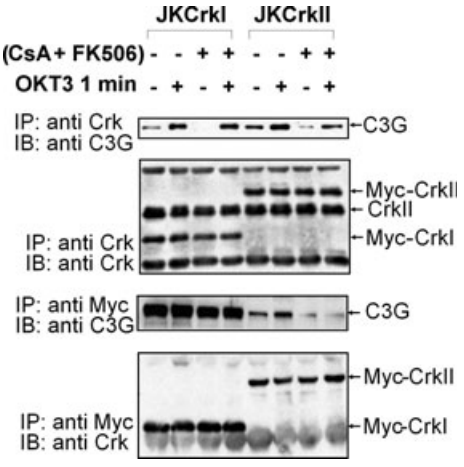
Inhibition of peptidyl prolyl cis-trans isomerases decreases CrkII association with its functional binding partner in leukemic T cell

P. R. Nath, G. Dong & N. Isakov
Department of Microbiology and Immunology, Ben Gurion University of The Negev, Beer-Sheva, Israel

Purpose/Objective: Cell growth and differentiation are strictly controlled processes mediated by effector molecules, which are regulated by posttranslational chemical modifications. Adaptor proteins are critical players in these processes, thanks to their ability to simultaneously interact with two or more effector molecules and orchestrate the assembly of signaling complexes downstream of activated surface receptors. Among these adaptor proteins, CrkII is ubiquitously expressed, involved in multiple receptor-linked signaling pathways, and involved also in signal transduction downstream of activated T cell antigen receptors. Peptidyl prolyl cis-trans isomereses (PPIases) are widely distributed proteins and has recently emerged as important molecular timers in the dynamic regulation of biological processes. We aimed to determine whether CrkII can serve as an *in vivo* substrate for PPIases and whether inhibitors of PPIases can alter CrkII-dependent T cell activation responses.
Materials and methods: CrkII-based binding studies using PPIases-inhibitors treated or untreated T cells, a FRET-based assay, immunofluorescence assay by confocal microscopy and studies of the effect of the inhibitors on CrkII-dependent T cell functions, including cell adhesion and migration.
Results: Treatment of Jurkat T cells with the inhibitors decreased the ability of CrkII-SH3N domain to associate with binding partners. In parallel, this treatment altered the proportions of *cis* versus *trans* forms of CrkII, as indicated by FRET studies. Finally, CrkII overexpression-induced increase of Jurkat T cell adherence and migration was significantly inhibited by pretreatment with PPIases-inhibitors.



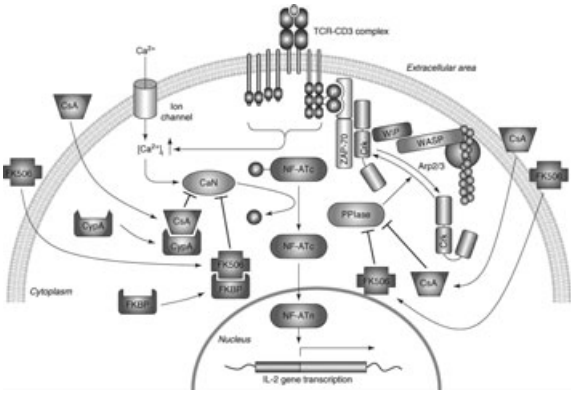


Figure 1. Intervention of distinct signaling pathways in activated T lymphocytes by Cyclosporine A (CsA) and FK506.

Conclusions: Our results suggest that CrkII can serve as an *in vivo* substrate for PPIases in Jurkat T cells. Inhibition of CrkII association with binding proteins by PPIases-inhibitors may represent one additional mechanism of PPIases-mediated inhibition of T cell activation, which potentially synergizes with the negative effect of PPIases-inhibitors on the calcineurin-NF-AT signaling pathway.

Integration of activating and inhibitory immune-receptor signaling by regulated Vav1 phosphorylation

C. Watzl,* D. Urlaub,* S. Mesecke,† H. Busch† & R. Eils†
**Immunology, Leibniz Institute for Occupational Research, Dortmund, Germany, †Division of Theoretical Bioinformatics, German Cancer Research Center, Heidelberg, Germany*

Purpose/Objective: Natural Killer (NK) cells are important immune effector cells whose activation is carefully regulated by the interplay of activating and inhibitory receptors signals. Triggering of activating receptors leads to activation of Src family kinases and Vav1 phosphorylation, whereas inhibitory receptors dephosphorylate Vav1 via the phosphatase SHP-1.
Materials and methods: Here we use mathematical modeling confirmed by experimental data to gain insight into this integration of positive and negative signals on a molecular level.
Results: Based on published signaling events a simplified model of the receptor proximal events of NK cell activation was generated. Six putative signaling modules that could influence the activation can be included into the model. Our experiments showed that increased triggering of activating receptors lead to a rapid switch-like increase in Vav1 phosphorylation. Similarly, titrating the engagement of inhibitory receptors resulted in switch-like dephosphorylation of Vav1. NK cell cytotoxic activity correlates with phosphorylation of Vav1. Comparing experimental results with predictions derived from the family of mathematical models shows that an association of Src-family kinases with activating receptors is essential to create such a physiologic response. Interestingly, other concepts of immune receptor signaling such as phosphatase segregation and kinase auto-phosphorylation were not necessary in our mathematical model.
Conclusions: Our data support a central role for Vav1 in the decision making process of NK cells and provide a novel insight into the molecular details of the integration of positive and negative signals during lymphocyte activation.

P0576

Interplay between receptors of the adaptive and innate immune systems in human B-cells

G. Sarmay, D. Szili, E. Toth, M. Simon & Z. Herincs
Department of Immunology, Eotvos Lorand University, Budapest, Hungary

Purpose/Objective: Development of B-cells is regulated by the antigen binding receptors (BCR) and a bunch of other receptors positively or negatively influencing the cells' fate. The innate receptor, TLR9 is located on intracellular membranes (endosomes) and may use BCR as a shuttle to deliver its ligand, hypomethylated CpG rich DNA sequences. The B-cell activating factor, BAFF mediates survival signals for B-cells thus support antigen driven development. The communication between signaling pathways mediated by BCR, TLR9 and BAFF receptor (BAFFR) is not clarified yet. Efficient co-signaling may lower the activation threshold of B cells, leading to the development of B-cells with low affinity BCR that are potentially autoreactive. Our aim was to identify crucial molecules responsible for the cross-talk between signaling pathways thus playing role in breaking the tolerance.
Materials and methods: For the parallel determination of the relative levels of phosphorylation of mitogen activated protein kinases (MAPKs) and other serine/threonine kinases human phospho-MAPK array kit was used. We confirmed and further studied the results by Western blot technique and phospho-flow analysis. Cell proliferation was measured by CFSE staining of B cells; the results were evaluated by flow cytometry. Cytokine secretion was tested by Flow-Cytomix kit.
Results: We have found that TLR9 ligation induces p38, JNK and MSK2 activation in synergy with the BCR induced signals. Upstream of MAPK, the MAPKKK7/Tak1 is synergistically activated via BCR and TLR9 but not by BAFF. BCR-induced Erk1 phosphorylation is slightly enhanced both by TLR9 and BAFFR mediated signals, while TLR9 and BAFFR do not cooperate at this level. Downstream on the pathway, the BCR-induced CREB phosphorylation is enhanced both by CpG DNA and by BAFF, while IκB phosphorylation is synergistically induced by TLR9 and BAFF or BCR, respectively. Functional assays have shown that BCR and TLR9 mediated collaborative signals significantly stimulate B-cell proliferation that can be diminished by Tak1 inhibitor. Furthermore, BCR and TLR9 mediated signals synergistically operate in inducing secretion of IL-6 and IL-10; and this effect is also blocked by specific inhibitor of Tak1.
Conclusions: Our results suggest that Tak1 playscentral role in the interplay between BCR and TLR9 mediated signalling and in regulation ofB-cells' function.

P0577

Jak3 enables T cell migration towards chemokines via Cofilin-1 and RhoA

X. Ambriz Peña,* H. Zamudio Meza,* R. Olguín Alor,* C. Mier Aguilar,* E. Carbajal Franco,* G. Aleman Muench,* M. Macías Silva,† I. Meza Gómez Palacio,‡ E. García Zepeda* & G. Soldevila*
**Departamento de Inmunología, Instituto de Investigaciones Biomédicas UNAM, Mexico City, Mexico, †Departamento Biología Celular, Instituto de Fisiología Celular UNAM, Mexico City, Mexico, ‡Departamento de Biomedicina Molecular, Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional, Mexico City, Mexico*

Purpose/Objective: Jak3 is involved in the CXCR4- and CCR7-dependent T cell migration. As cytoskeletal dynamics are essential to allow migration, we investigated the impact of Jak3 deficiency in CXCR4 and CCR7 mediated cytoskeleton reorganization involved in this process.
Materials and methods: Lymph node T cells from C57BL/6 mice or human PBMCs were treated or not with the Jak3 specific inhibitor WHI-P131 or Pertussis toxin (PTX). In addition, parallel experiments

were performed using splenic T cells of Jak3$^{-/-}$ or Jak3$^{+/+}$ mice. Cells were stimulated with the chemokine CXCL12 (human cells) or CCL21 (murine cells) at different time points. Cell shape changes and polymerized actin in response to chemokines were analyzed by time-lapse microscopy or flow cytometry, respectively. Western blot analysis was performed to analyze cofilin phosphorylation kinetics. RhoA activation was analyzed by fluorescent microscopy staining of RhoA-GTP.

Results: Time-lapse analysis showed that WHI-P131-treated cells display impaired motility and deficient uropod formation towards chemokines. Secondly, actin polymerization was impaired in the absence of Jak3 activation in response to CXCL12 and CCL21, in both pharmacologically inhibited and Jak3$^{-/-}$ T cells. This correlates with the cofilin phosphorylation kinetics observed in WHI-P131-treated and non-treated cells. Non-treated cells have a peak of activation (dephosphorylation) at 30 s post stimulation and returns to the basal level at 300 s, while in WHI-P131-treated-cells cofilin activation continues increasing after 30 s up to 300 s. In addition, confocal microscopy revealed that RhoA-GTP was significantly diminished in WHI-P131-treated-cells.

Conclusions: We have demonstrated the involvement of Jak3 in the actin dynamics in response to chemokines. Time-lapse and confocal microscopy analysis suggests a link between Jak3 and RhoA for uropod formation. Moreover, F-actin reduction may be a consequence of active cofilin levels post stimulation. In summary, our results provide strong evidence that T cells require Jak3 to achieve appropriate actin dynamics, cofilin kinetics and RhoA activation and translocation in response to CXCL12 and CCL21. Work supported by PAPIIT, DGAPA, UNAM.

P0578
Modulating p56Lck signalling in T-cells by a chimeric peptide derived from two independent Herpesvirus saimiri Tip motifs

J. P. Vernot, A. M. Perdomo, L. A. Pérez & D. F. Martínez
Depto. Ciencias Fisiológicas Grupo de Fisiología Celular y Molecular, Universidad Nacional de Colombia Facultad de Medicina, Bogotá, Colombia

Purpose/Objective: To study the effect of the Lck binding domain CSKH from Herpesvirus samiri Tip protein in human and Aotus T-cell signalling and activation. To test the proper delivery of this motif to lipid rafts by using an hydrophobic sequence motif from the Tip protein.

Materials and methods: Peptides, including the hydrophobic Tip sequence (hTip), the Tip Lck-binding motifs (CSKH) and the chimera (hTip-CSKH), were synthesised by solid phase synthesis. Human and Aotus PBMC were cultured for 1 h in the absence or presence of different peptide concentrations, and stimulated or not with PHA-P or PMA. Proliferation was assayed by [methyl-3H]-thymidine incorporation. Immunodetection was performed with anti-Lck, anti-phosphotyrosine, anti-p-ERK1/2, anti-ERK1/2, anti-Fyn, anti-β-Actin and anti-Flotillin-2. Rafts were isolated by sucrose density gradients. Surface marker expression was evaluated with anti-CD3; anti-CD25 and anti-TCRα/β antibodies.

Results: Here we have shown thathTip-CSKH can induce an increased proliferation rate in either unstimulated or stimulated conditions (PHA-P). This effect was dose-dependent and was not observed with control peptides.hTip-CSKH modifies the Lck electrophoretic pattern and phosphorylation state, simulating the changes induced by polyclonal T-cell receptor stimulation. Nevertheless, phosphorylation kinetics was increased with the chimeric peptide. Furthermore, treatment with this peptide complements the partial signal induced by phorbol esters, confirming its specific effect on T-cell receptor signalling. hTip-CSKH was present high density lipid rafts, as it would be expected for an Lck activating molecule. By treating cells with this short sequence we did not observe any downmodulation of cell surface marker expression, as occurs with transfection of the whole Tip molecule. Also, it was shown that Tip effect is specific for Lck activation, with no activation of Fyn.

Conclusions: This approach let us to conclude that Tip's CSKH motif can modulate specifically T-cell receptor pathways by targeting Lck. This could be the basis for designing specific T-cell immunomodulating compounds directed to target molecules present in lipid rafts. This approach would be also useful for some diseases in which rafts are involved during signaling.

OX40L engagement induces a reverse signalling in human B cells

A. Cortini, U. Ellinghaus, C. L. Pinder & T. J. Vyse
Department of Medical & Molecular Genetics, King's College London, London, UK

Purpose/Objective: The tumour necrosis factor superfamily member 4 gene, which encodes for the co-stimulatory molecule OX40 ligand, has been previously identified in our lab as a susceptibility gene in SLE. It is well known that the engagement of OX40 through OX40L provides a co-stimulatory signal promoting division, survival and clonal expansion of effector and memory T-cells; in contrast, very little is known about OX40L intracellular signalling and the role that this could play in autoimmunity. In this study we want to investigate the OX40L reverse signalling pathway, in particular its effects in human B-cells.

Materials and methods: A soluble OX40 fusion protein (OX40-FP) was produced by cloning the extracellular domain of OX40 into a vector in which a C-terminal double-tag was integrated by oligonucleotide cloning. Binding of OX40-FP was assessed by competition assay using an antibody to OX40L. OX40-FP was used to trigger OX40L in human B cells stimulated with F(ab')2 anti-IgM and CD40L and to perform a tandem affinity purification of potential OX40L binding partners.

Results: EBV transformed B cells (EBV-B cells) expressing OX40L were used to test whether the OX40-FP binds OX40L. The specificity of the binding was shown by a decrease in OX40-FP binding on EBV B cells pre-treated with increasing amount of an antibody to OX40L. We found that B cells treated with OX40-FP showed less proliferation ($P < 0.05$). Furthermore we observed a higher production of IgG in B cells activated through OX40L engagement compared to control cells. We could not observe any difference in Ca^{++} mobilization in cells pre-treated with OX40-FP. Potential OX40L binding partners were isolated by stimulating EBV-B cells with OX40-FP and immune-precipitating the OX40-OX40L complex using the two tags of the OX40-FP. Performing an SDS-page followed by silver staining we could show the binding of several different proteins to our complex.

Conclusions: Using a recombinant OX40 protein as a molecular tool we have been able to show how engagement of OX40L initiates reverse signalling in human B-cells leading to less proliferation and increase of IgG production. Moreover, the design of our OX40-FP allowed us to start to investigate the molecular basis of OX40L reverse signalling. Several proteins have been already purified and are being characterized by liquid chromatography-tandem mass spectrometry.

P0580
Physiopathology of TCR/CD3: genomic induction in CD3gamma deficient cells

M. S. Mazariegos, B. Garcillan, M. Muñoz-Ruiz & J. R. Regueiro
Facultad Medicina Universidad Complutense, Microbiologia I, Madrid, Spain

Purpose/Objective: The final objective of this project is the analysis by means of the technique of microarrays in order to evaluate the geno-

mic induction in transformed T lymphocytes which are CD3gamma deficient ($\gamma^{-/-}$) after stimulating with anti-CD3 antibodies, comparing these results with the ones obtained in normal lymphocytes ($\gamma^{+/+}$).
Materials and methods: Comparative flow cytometry, Western-blot, oligonucleotide microarray.
Results: It was proved that it is possible to stimulate transformed T cells (*Herpesvirus saimiri*) despite of their high basal activation level. We have checked this stimulation analyzing early functional parameters (CD69 and CD25 induction, calcium flux induction) and late ones (phosphorylation pattern). After anti-CD3 stimulation of the cells (both $\gamma^{+/+}$ and $\gamma^{-/-}$), cDNA was hybridized against a chip and afterwards, gene expression estimates were calculated.
Conclusions: There is a different gene expression pattern between CD3gamma deficient and sufficient transformed T cells. There are many genes which are differently induced (upwards or downwards) and this difference is attributable to CD3gamma chain.

P0581
Protein kinase D2 integrates antigen receptor, diacylglycerol and Protein Kinase C mediated signals to fine tune cytokine production in T cells

M. N. Navarro, C. Feijoo-Carnero, L. V. Sinclair, D. Martin, J. Goebel & D. A. Cantrell
Cell Signalling and Immunology, University of Dundee, Dundee, UK

Purpose/Objective: Protein kinase Ds are a conserved family of serine/threonine kinases. PKD2 is the predominant PKD isoform expressed in lymphocytes, and it is selectively phosphorylated and activated in response to T cell receptor (TCR)-induced generation of diacylglycerol and stimulation of PKC. Our aim is to explore the role of PKD2 in T cells.
Materials and methods: To analyse the role of PKD2 in T cells we have generated PKD2 null mice and mice deficient in PKD2 enzymatic activity ('knockin' mutation of phosphorylation sites essential for PKD2 catalytic activity), and we have backcrossed them in to TCR-transgenic mice (P14 and OTI).
Results: Mice that lack PKD2 or have wild type PKD2 alleles substituted with PKD2 mutant alleles that cannot be phosphorylated by PKC produce peripheral T cells that have the transcriptional profile of normal naïve T cells. However, these cells have defects in antigen receptor induced proliferation and they are unable to correctly reprogram their transcriptome in response to TCR engagement. The role of PKD2 in mediating the TCR induced transcriptional program is selective but includes the control of key cytokines and chemokines, like interleukin 2 and interferon gamma, known to be essential for T cell effector function. PKD2 thus has a restricted but vital role in antigen receptor signal transduction. PKD2 is required for the effector function of cytotoxic T cells. The present study presents a quantitative analysis of PKD2 deficient cytotoxic T cell phosphoproteome using high resolution quantitative mass spectrometry as a screening tool for putative PKD2 substrates.
Conclusions: PKD2 activity is required for maximal TCR-induced clonal expansion and differentiation into CD8 effector T cell. PKD2 is involved in diverse processes that control expression of essential pro-inflammatory cytokines. PKD2 has a global impact in the T cell phosphoproteome, revealing both direct and indirect pathways controlled by PKD2 catalytic activity.

P0582
Regulation of ERM (Ezrin/Radixin/Moesin)-activity during LFA-1-mediated T cell migration

K. Fehlner & M. Laschinger
Chirurgische Klinik und Poliklinik, Klinikum rechts der Isar – TUM, München, Germany

Purpose/Objective: T cell migration requires adhesion at the cell-front and de-adhesion at the back, controlled by interaction of active LFA-1 with its ligand ICAM-1 and dissociation upon LFA-1 de-activation. Rearrangement of the cytoskeleton regulates cell migration intracellularly. ERM (Ezrin/Radixin/Moesin)-proteins act as linker between the membrane and the cytoskeleton. We were interested in the role of ERM-proteins in mediating de-adhesion of migrating T cells by signal-transduction from LFA-1 to the cytoskeleton.
Materials and methods: We investigated the localization of ERM-proteins in primary murine T cells migrating on ICAM-1 by confocal microscopy and their interaction with LFA-1 by immunoprecipitation. We compared expression of phosphorylated ERM-proteins in migrated T cells expressing wildtype or constitutively active LFA-1. We screened for phosphatases regulating ERM activity. In order to investigate the role of identified phosphatases during T cell migration we chemically interfered with their activity in naïve T cells and analyzed LFA-1 mediated T cell migration by live-cell imaging *in vitro*, and homing experiments to lymph node and spleen *in vivo*.
Results: We found ERM-proteins being co-localized with LFA-1 at the site of de-adhesion, the back end of migrating cells, but not directly interacting with LFA-1. The equilibrium between active and inactive ERM-proteins was shifted towards the active, phosphorylated form in T cells expressing constitutively high affinity LFA-1 and showing a defective de-adhesion. This indicates that increased ERM-phosphorylation might correlate with defective T cell migration. We identified the protein phosphatase PP1 to interact with LFA-1 in T cells and PP1/PP2A to specifically dephosphorylate ERM-proteins. Blocking PP1/PP2A-activity in T cells impaired T cell migration *in vitro* and *in vivo*. Namely, T cells did not actively migrate across endothelial cells *in vitro*, and were not able to enter the lymph node T cell zone or the white pulp of the spleen *in vivo*.
Conclusions: We identified PP1 as binding partner of LFA-1 in T cells and demonstrate that PP1/PP2A specifically dephosphorylate ERM-proteins. Our data provide evidence for the importance of ERM-activity-regulation by PP1/PP2A, downstream of LFA-1, during T cell migration.

P0583
Regulation of T cell activation mediated by modification and localization of the Src family kinase Lck

P. Eckerstorfer,* W. Paster,* L. Zimmermann,† A. Sonnleitner,‡ G. J. Schütz† & H. Stockinger*
**Molecular Immunology Unit, Institute for Hygiene and Applied Immunology, Medical University of Vienna, Vienna, Austria, †Institute of Applied Physics, Vienna University of Technology, Vienna, Austria, ‡Center for Biomedical Nanotechnology, Upper Austrian Research GmbH, Linz, Austria*

Purpose/Objective: p56Lck, the T cell specific non-receptor protein tyrosine kinase, plays a key role in signaling from the T cell antigen receptor (TCR). According to common 'textbook' knowledge, Lck is supposed to undergo structural changes from a closed inactive to an open active conformation upon TCR engagement. However, previously we could show by biochemical assays and live-FRET imaging that regulation of Lck upon TCR stimulation is rather mediated by other mechanisms, presumably reorganization of localization or domain displacement of intramolecular interactions by ligands than acute structural changes of the molecule.

Materials and methods: A variety of mutated and truncated Lck molecules were generated and C-terminally tagged with a monomeric enhanced green fluorescence protein (mEGFP). These constructs were retrovirally transduced into Lck-deficient JCaM1.6 Jurkat T cells and used for biochemical and microscopy experiments.
Results: We investigated the determinants mediating binding of Lck to the inner leaflet of the plasma membrane, and also determined the ratio between cytoplasmatic and membrane-bound Lck molecules in stimulated and non-stimulated T cells. By using a mEGFP-tagged Lck biosensor and a non-invasive single molecule imaging approach we were able to determine the exact lifetime of Lck in the plasma membrane. Moreover, we found by live-FRET imaging and single molecule analysis Lck molecules forming dimers and higher order structures. Biochemical methods showed that the N-terminal membrane anchor is mediating this intermolecular interaction of Lck.
Conclusions: Together, these advanced imaging studies of Lck in the live cell context provide a novel picture of the function and regulation of this key kinase in signaling via TCR.

Supported by the GEN-AU Program of the Austrian Federal Ministry of Science and Research, the PhD program Cell Communication in Health and Disease, and the EUROCORES EUROMEMBRANE_project I00300 LIPIDPROD of the Austrian Science Fund.

SLAM family mediated cyotoxicity in NK cells depends on PLCγ1 and PLCγ2

M. Brown & T. J. Wilson
Sir William Dunn School of Pathology, University of Oxford, Oxford, UK

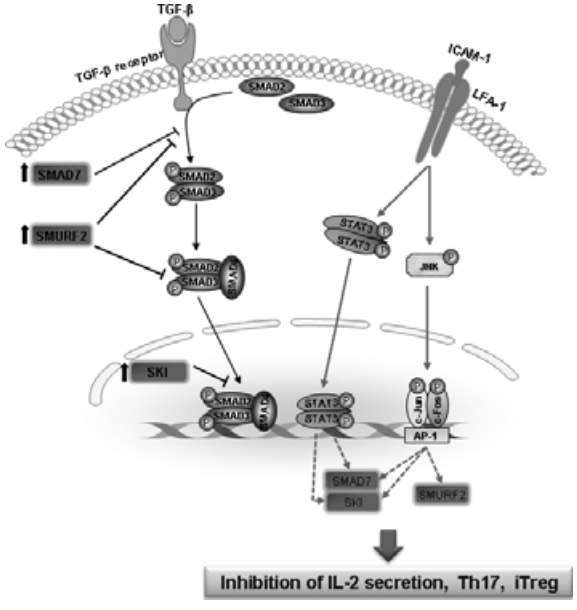
Purpose/Objective: The mechanism of signal transduction by receptors containing Immunoreceptor Tyrosine-based Switch Motifs in the CD2/SLAM family is of interest particularly because of the disease association with X-linked proliferative disease and autoimmunity, and potential exploitation in treating cancer. Two related intracellular SH2 domain containing adaptor proteins, SAP and EAT-2 bind the tyrosine motifs. Transmission of activating signals through SAP involves simultaneous, non competitive binding to cytoplasmic tails of SLAM family receptors and SH3 domains of signalling proteins. EAT-2 also has an activating role downstream of SLAM family receptors, which is dependent on phosphorylation of a C-terminal tyrosine motif. The purpose of this study was to determine the direct binding partners for the C-terminal tyrosine motif in EAT-2 and test the functional relevance of the biochemical data.
Materials and methods: We have used a biochemical approach involving mass spectrometry and surface plasmon resonance and carried out functional experiments in an NK cell line using shRNA.
Results: We identify interactions between EAT-2 and PLCγ1 and PLCγ2 likely to be important for regulation of signal transduction by SLAM family receptors. Functional data have provided insight into the relative importance of adaptors, EAT-2 and SAP and enzymes, PLCγ1 and PLCγ2 for SLAM family mediated cytotoxicity in a human NK cell line.
Conclusions: SLAM family mediated cyotoxicity in NK cells depends on PLCγ1 and PLCγ2. Correlation between dependence of a SLAM family receptor, CRACC on EAT-2 and PLCγ is consistent with a direct interaction between them.

P0585

T-cells stimulated via LFA-1/ICAM-1 are programmed to become refractory to TGF-ß signalling: Implications for local inflammatory response

N. K. Verma E. Dempsey & D. Kelleher
Clinical Medicine, Trinity College Dublin, Dublin, Ireland

Purpose/Objective: The β_2 integrin LFA-1 plays a key role in lymphocyte motility, but the downstream gene regulation by this adhesion molecule remains largely unknown. The aim of this study was to investigate changes in gene expression caused by the LFA-1 interaction with its ligand ICAM-1, and subsequent functional consequences in T-cells.
Materials and methods: Peripheral blood lymphocyte T-cells from healthy volunteers and the human T-cell line Hut78 were used. Differential gene expression in T-cells was identified by cDNA microarrays combined with gene ontology and Ingenuity Pathway Analysis. Standard molecular, biochemical and microscopic techniques were employed.
Results: The LFA-1/ICAM-1 interaction induced a genetic signature associated with reduced TGF-β responsiveness *via* up-regulation of SKI, SMURF2 and SMAD7 genes and proteins. The expression of these TGF-β inhibitory proteins was dependent on STAT3 and/or JNK activation. Increased expression of SMAD7 and SMURF2 in LFA-1/ICAM-1 cross-linked T-cells resulted in impaired TGF-β-mediated phosphorylation of SMAD2 and suppression of IL-2 secretion. Expression of SKI caused resistance to TGF-β-mediated suppression of IL-2, but SMAD2 phosphorylation was unaffected. Blocking LFA-1 by neutralizing antibody or specific knockdown of TGF-β inhibitory molecules by siRNA substantially restored LFA-1/ICAM-1-mediated alteration in TGF-β signalling. LFA-1/ICAM-1 stimulated T-cells were refractory to TGF-β-mediated induction of FOXP3$^+$ Treg and RORγt$^+$ Th17 differentiation.



Conclusions: This study reveals a complex molecular programme that links gene transcription induced by LFA-1/ICAM-1 interaction to impairment of TGF-β signal transduction in T-cells. Given a crucial role of the immunosuppressive cytokine TGF-β in the induction and maintenance of immunologic tolerance, these new findings form a basis of future translational research for human diseases and for designing of immunotherapies.

P0586

The absence of individual NFAT family members ameliorates experimental autoimmune encephalomyelitis, an animal model of multiple sclerosis

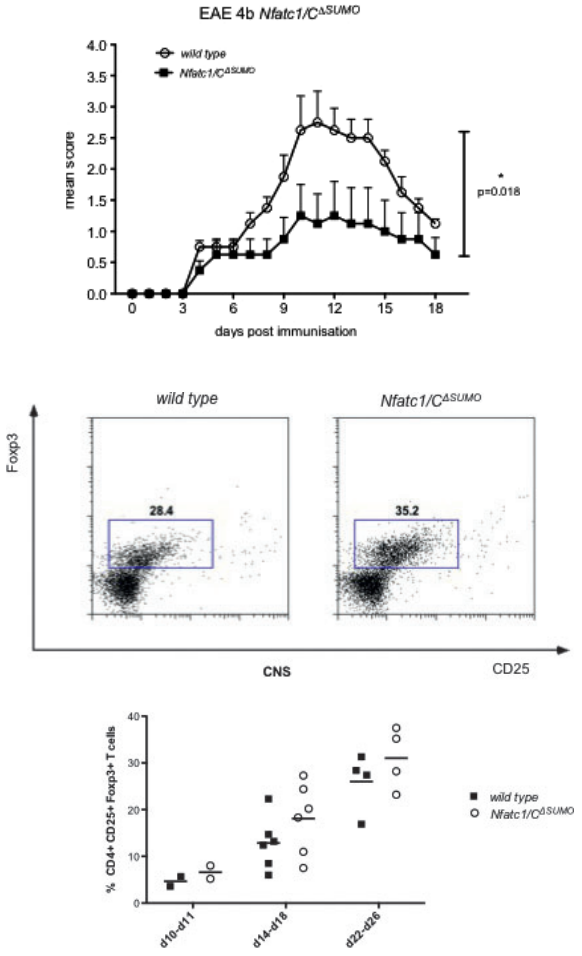
L. Dietz,* F. Frommer-Hezel,† M. Buttmann‡ & F. Berberich-Siebelt§

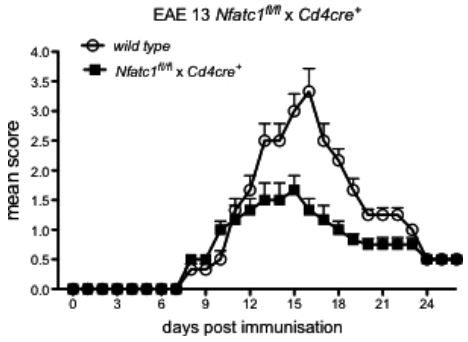
**Department of Molecular Pathology, Institute of Pathology, University of Würzburg, Würzburg, Germany, †Institute for Molecular Medicine, University Medical Center of the Johannes Gutenberg University of Mainz, Mainz, Germany, ‡Department of Neurology, University of Würzburg, Würzburg, Germany, §Department of Molecular Pathology, Instiute of Pathology, University of Würzburg, Würzburg, Germany*

Purpose/Objective: Multiple sclerosis (MS) is an autoimmune disease, where after inflammatory disruption of the blood brain barrier immune cells infiltrate the CNS and cause axonal damage and demyelination within the CNS. T helper cells, in particular Th1 and Th17, are important mediators during this progress and are antagonized by regulatory T cells (Treg). Members of the transcription factor family 'Nuclear Factors of Activated T cells' (NFAT) are induced in response to TCR stimulation and act as pleiotropic regulators of T cell function.

Materials and methods: To investigate the role of single NFAT factors in the pathophysiology of multiple sclerosis we used several NFAT deficient mice in the animal model of this disease (EAE).

Results: So far we could show that not only the deficiency of NFATc1 or NFATc2, but also the absence of the C-terminal (specific) sumoylation of NFATc1 reduces the clinical severity of EAE. Regardless





of a comparable influence on the disease, the reasons are distinct: T cells from *Nfatc1/C*$^{\Delta SUMO}$ mice produce significantly more IL-2 *in vitro* and *in vivo*, especially under Th1 driving conditions, while cultured Th1 and Th17 express less IFNγ and IL-17, respectively. Consistently, the MOG_{35-55}-induced EAE with *Nfatc1/C*$^{\Delta SUMO}$ mice revealed an ameliorated clinical disease severity compared to *wild type* (*wt*) controls with a robust IL-2- driven increase in Tregs and a reduction in effector lymphokine producing T helper cells. In case of the T cell specific loss of NFATc1 (*Nfatc1*$^{fl/fl}$ × *Cd4cre*$^{+}$ mice) the clinical score was diminished due to impaired effector functions of $CD4^+$ T cells lacking all NFATc1 isoforms. This was demonstrated by lower levels of IFNγ and IL-17 producers in the CNS of *Nfatc1*$^{fl/fl}$ × *Cd4cre*$^{+}$ mice compared to *wt* siblings. Unexpectedly, also the *Nfatc2*$^{-/-}$ mice showed a protection against experimental autoimmune encephalomyelitis. The deficiency of NFATc2 results in a striking defect of $CD4^+$ T cells in producing IFNγ, which might be ascribed to the known enhanced immune responses with Th2-like characteristics of *Nfatc2*$^{-/-}$ mice.

Conclusions: In summary, we could show that individual NFAT factors and their isoforms/modifications play a distinct role in the pathogenesis of MS. Therefore, targeting or modulating specific NFAT factors could be a future therapeutic approach to inhibit undesired or boost desirable NFAT functions in the respective human disease context.

The ITIM receptor CD31 is recruited to the immunological synapse to act as a negative co-receptor of the TCR

M. Clement,* G. Fornasa,* M. Leprieur,* K. Guedj,* M. Morvan,* J. Khallou-Laschet,* A. T. Gaston,* C. Hivroz,† A. Nicoletti* & G. Caligiuri*

**Inserm U698, team 4, Paris, France, †Institue Curie Inserm U932, Section Recherche Pavillon Pasteur, Paris, France*

Purpose/Objective: CD31 is a homophilic ITIM receptor expressed by endothelial cells, platelets and leukocytes, that comprises 6 Ig-like extracellular domains. Trans-homophilic engagement of the distal domain drives: 1- Clusterization of CD31 molecules at the cell surface via cis-homophilic interaction of a juxtamembrane extracellular peptide sequence 2- ITIMs phosphorylation that activates of SHP-2. CD31 is cleaved following TCR stimulation. Although the membrane-proximal portion, containing the sequence of clusterization, remains expressed after the cleavage, the trans-homophilic domain is lost. We therefore reasoned that CD31 cleavage occurs at the level of the immunological synapse, where otherwise its trans-homophilic engagement by the interacting antigen-presenting cells would prevent effective activation.

Materials and methods: We studied the localization and integrity of CD31 molecules on Jurkat T cells during immunological synapse formation and assessed the role of CD31 on T cell activation by using $CD31^-$Jurkat $CD4^+$ T cells or a peptide able to trigger the signaling

downstream of a cleaved CD31. Immunological synapses were generated by crosslinking the MHC II of RAJI (Activated B cells) with a superantigen to the TCR of Jurkat T cells. Recruitment of CD31 to the synapse and the downstream signaling of the TCR were analyzed by fluorescence microscopy. Calcium mobilization, CD69 expression and IL-2 production were quantified by cytometry.

Results: We found that the CD31 molecule is consistently recruited to the synapse.In the pSMAC area the CD31 molecule is intact and co-localizes with ICAM1, while a cleaved form clusterizes with the TCR complex in the cSMAC. The lack of the trans-homophilic membrane-distal Ig domain of CD31, lost with the cleavage, favors synapse formation as demonstrated by cytometric analysis of the Jurkat-RAJI conjugates. Rescue of the ITIM signaling downstream the truncated CD31, with the CD31 peptide, inhibits conjugate formation, calcium mobilization, IL-2 production and CD69 expression, MTOC docking, clusterization of the TCR complex and recruitment of pZAP70 at the immunological synapse via an increased recruitment of pSHP2.

Conclusions: We concluded that CD31 acts as an important co-inhibitory receptor involved in the regulation of adaptive immune responses by negatively affecting the formation of the immunological synapse.

P0588

The PI 3-kinase/Akt signalling axis regulates integrin-mediated lymphocyte adhesion and motility

H. S. Lek,* V. L. Morrison,* M. Conneely,† D. McGloin,† A. MacIntyre,‡ M. MacPherson,* A. R. Prescott,‡ D. A. Cantrell‡ & S. C. Fagerholm*

**Division of Cancer Research, University of Dundee Medical Research Institute, Dundee, UK, †Electronic Engineering and Physics Division, University of Dundee, Dundee, UK, ‡Cell Signalling and Immunology, University of Dundee College of Life Sciences, Dundee, UK*

Purpose/Objective: In the immune system, integrin-mediated adhesion is important for lymphocyte homing, activation and effector functions. The PI3-kinase pathway has been previously implicated in the regulation of lymphocyte homing. We have now investigated the roles of PI3-kinase and two downstream kinases, PDK1 and Akt in integrin-mediated functions in lymphocytes.

Materials and methods: Splenic B cells and effector T cells generated from wild-type mice were treated with PI 3-kinase inhibitors (LY-29004 and GDC-0941) and Akt inhibitors (Akt VIII inhibitor and MK-2206). PDK1-deficient cells were generated using Cre/Lox methodology with Tamoxifen treatment. Cell adhesion to ICAM-1 ligands was assessed using solid-phase assay with or without introduction of shear flow. TIRF microscopy was used to observe 2D motility and Atomic Force Microscopy was used to assess strength of integrin-ligand unbinding force.

Results: Effector T cells have high PI 3-kinase/Akt activity, and the pre-treatment of these cells with PI 3-kinase inhibitors significantly reduced effector T cell adhesion to ICAM-1. This suggests a role for PI3-kinase in regulating aLb2 integrin-mediated adhesion. Both PDK1-deficient effector T cells and Akt inhibitors-treated effector T cells showed reduced adhesion to ICAM-1. Akt inhibitor-treated effector T cells exhibited significantly reduced ability in 2D motility on ICAM-1 than untreated cells. Measurements using Atomic Force Microscopy also showed that the force required for unbinding of integrin-ligand interactions was significantly lower for Akt inhibitor-treated effector T cells than untreated cells. However, Akt inhibition does not affect effector T cells adhesion to ICAM-1 under shear flow. In both unstimulated and BCR-stimulated naïve murine B cells, PI 3-kinase and Akt inhibitors significantly reduced binding to integrin ligands. Additionally, Akt inhibitors reduced SDF-1-induced B cell adhesion to ICAM-1 under shear flow. In contrast, integrin-mediated adhesion of $CD4^+$ T cells was not affected by Akt inhibition either under static and shear flow conditions.

Conclusions: With these results, we propose that the PI 3K/PDK1/Akt signalling axis plays a role in the regulation of lymphocyte integrin function and homing, but the adhesion of different lymphocyte subsets (naïve B cells and effector T cells) are differently dependent on Akt.

P0589

The role of protein tyrosine phosphatase PTPN22 in T cell signaling

S. Sood, R. J. Brownlie & R. Zamoyska

Immunology, Immunology & Infection Research, Edinburgh, UK

Purpose/Objective: A dynamic balance between tyrosine phosphorylation and dephosphorylation is crucial for the maintenance of homeostasis and proper regulation of immune system. A large number of protein tyrosine phosphatases (PTPs) are known to regulate signaling through the T cell receptor (TCR). The protein tyrosine phosphatase PTPN22 (also called PEP/LYP) is a negative regulator of T-cell activation. An allelic variant of PTPN22, a missense C1858T ($PTPN22^{R620W}$) single nucleotide polymorphism, is associated with multiple autoimmune diseases in humans. Studies conducted with human cells indicated that this mutation was a gain of function leading to decreased TCR signaling. By contrast, studies conducted in a comparable knock in mouse model, $PTPN22^{R619W}$, suggested this variant was a loss of function, as the $PTPN22^{R619W}$ protein was more prone to calpain mediated degradation. Thus the $PTPN22^{R619W}$ mouse was phenotypically similar to the PTPN22 KO mice and both showed an increase in T effector/memory cells. Whether the allelic variant is a loss- or gain-of function still needs to be resolved. In order to address this question we have examined the role of $PTPN22^{R619W}$ *in vitro* and *in vivo* using retroviral and lentiviral transduction.

Materials and methods: Lentivirus and retrovirus expression constructs were derived by subcloning full length wild type *Ptpn22* (619R) or mutant *Ptpn22* (619W) cDNAs containing C- terminal One-Strep tag and an EGFP reporter gene. $PTPN22^{-/-}$ T cells and bone marrow cells were transduced *in vitro* by retroviral generated supernatant. FACS analysis was conducted to confirm the expression of PTPN22 and functional assays performed on transduced cells.

Results: naïve T cells were recovered from Rag-KO chimeras reconstituted with $PTPN22^{-/-}$ bone marrow transduced with vector alone, $PTPN22^{WT}$ and $PTPN22^{R619W}$ retroviral constructs. Preliminary studies indicate that retroviral expression of either construct reduced T cell activation compared to $PTPN22^{-/-}$ T cells. WT PTPN22 appeared to be more suppressive of T cell responses than variant $PTPN22^{R619W}$.

Conclusions: Our data point to the variant $PTPN22^{R619W}$ as being a partial loss of function allele. Further studies are underway to clarify how the WT and mutant alleles influence T cell signaling.

P0590

TRAIL receptor co-stimulation inhibits human T cell proliferation by preventing proximal T cell receptor signalling

C. Lehnert, K. M. Debatin & G. Strauß

Department of Pediatrics and Adolescent Medicine, University Medical Center, Ulm, Germany

Purpose/Objective: Death receptors are originally characterized as apoptosis inducers but are now increasingly recognized as surface receptors with additional functions depending on cell type, stimulation, and cellular environment. Activation of TRAIL receptors e.g. can either induce apoptosis or proliferation in tumor cells depending on the tumor phenotype. In this study, we want to elucidate the role of TRAIL receptor co-stimulation during T cell activation.

Materials and methods: To analyze the effect of TRAIL receptor co-stimulation on T cells, CFSE-labeled human T cells from buffy coats of healthy donors were stimulated with anti-CD3 and -CD28 antibodies in the absence or presence of recombinant human TRAIL. T cells were analyzed for proliferative capacity, expression of activation markers, and cytokine secretion. In order to define the effects of TRAIL receptor co-stimulation on T cell signal transduction, tyrosine phosphorylation, MAP kinase and caspase activation, and nuclear translocation of transcription factors were analyzed.

Results: CD3/CD28 triggered activation of T cells is inhibited by TRAIL receptor co-stimulation in a dose-dependent manner. This effect is dependent on TCR activation, since no inhibition of T cell proliferation is observed after activation with PMA and Ionomycin. Inhibition of T cell proliferation by TRAIL receptor co-stimulation can not be reverted by IL-2 and is only achieved by immobilized TRAIL. TCR and TRAIL receptor stimulation leads to decreased expression of activation markers CD25, CD69, CD71, CD95, and HLA-DR compared to TCR stimulation alone. The secretion of cytokines IL-2, IFN-γ, TNF-α, IL-5, and IL-13 is efficiently suppressed after TRAIL receptor co-stimulation. T cell activation in the presence of TRAIL receptor triggering efficiently inhibits the phosphorylation of tyrosine and MAP kinases and blocks nuclear translocation of transcription factors NFAT, NFκB, and AP-1.

Conclusions: Co-stimulation of TRAIL receptors in T cell activation specifically inhibits TCR mediated T cell proliferation and activation by blocking the induction of TCR proximal pathways such as tyrosine phosphorylation, MAP kinase activation, and translocation of transcription factors. Althogether, we could show that TRAIL receptors not only act as death receptors, but have an important function in immunoregulationof T cells.

Cell depletion and regulatory T cell in thymus of alloxan-induced diabetic mice

C. Francelin,* J. S. Ribeiro,* R. Thomé,* R. di Gangi,* T. Alves da Costa,* L. A. Peroni† & L. Verinaud*
*Department of Structural and Functional Biology/Unicamp, Biology Institute, Campinas, Brazil, †VBP Biotechnology, Immuny Monoclonal Antibodies, Campinas, Brazil

Purpose/Objective: In this work we investigated cell death in CD3+ cells, expression of apoptotic proteins and the presence of regulatory T cell in thymus of alloxan-induced diabetic mice.
Materials and methods: Expression *in situ* of apoptotic and anti-apoptotic proteins was detected through immunohistochemical stain protocol and gene expression of apoptotic proteins was detected by real time polymerase chain reaction technique. To evaluate apoptotic cells, was performed Tunel stain *in situ* and flow cytometry for Annexin-V in total thymus cellularity. Regulatory T cells were observed by flow cytometry using FoxP3 Staining kit from E-Bioscence.
Results: It is possible to observe that thymus from aloxan-induced diabetic mice presents an increase of apoptotic cells when compared to non-diabetic animals. Cell death in diabetic thymus probable is higher due to an increase in apoptotic protein levels as loss of survival cytokines expression, such IL-2. Diabetic thymus also presents alterations in expression of apoptotic molecules genes. Also, was observed an altered pattern in the regulatory T cell population in atrophic thymus.
Conclusions: Atrophic thymus from diabetic mouse presents a deep commitment in thymocyte population which is activated for cell death and to express a regulatory phenotype.

Ethical approval: All experiments were approved by the internal ethical committee (CEUA #2312-1).

Central memory CD8 T cells regulate hematopoietic stem cell function

M. A. Nolte,* C. I. Brandao* & A. M. De Bruin†
*Sanquin Research, Hematopoiesis, Amsterdam, The Netherlands, †AMC, Exp. Immunology, Amsterdam, Netherlands

Purpose/Objective: After immune activation, effector T cells, including virus-specific CD8 T cells, are known to migrate to the bone marrow (BM), but their function at this site is unknown. Since BM T cells are known to have a positive influence on engraftment of hematopoietic stem cells (HSCs) upon allogeneic transplantation, we here test the hypothesis that T cells present in the BM can directly influence the function of hematopoietic stem cells (HSCs).
Materials and methods: Highly purified HSCs from murine or human origin were cocultured together with different subsets of BM T cells to determine their capacity to adjust the function of the HSCs.
Results: We found that murine BM T cells can enhance the differentiation capapcity of HSCs as well as their ability to self-renew. This feature is specific for BM CD8 central memory T (T_{CM}) cells, since other T cell subsets are not able to affect HSCs. Moreover, depletion of CD8 T_{CM} cells from the total BM T cell pool abrogates their impact on HSC differentiation and self-renewal. *In vitro* studies revealed that BM CD8 T_{CM} cells do not affect quiescence of HSCs, but do enhance their proliferative capacity. We also found that supernatant from stimulated and non-stimulated CD8 T_{CM} cells is sufficient to increase HSCs numbers *in vitro*. Competitive transplantation assays performed in irradiated mice showed that HSCs cultured with CD8 T_{CM} cell-derived supernatant perform much better in multilineage reconstitution than medium-treated HSCs. Finally, we could demonstrate that adoptive transfer of BM CD8 T_{CM} cells is sufficient to restore the function of HSCs in T cell-deficient mice. Preliminary data indicate that these findings are also relevant for the human situation, since we found that autologous BM T cells can increase the numbers of human HSCs, as well as their differentiation capacity *in vitro*.
Conclusions: Overall, these findings demonstrate that T cells have an important function in the BM and that especially CD8 T_{CM} cells can directly influence HSC homeostasis. We postulate that this feedback mechanism of the immune system on the hematopoietic process in the BM is particularly relevant during viral infection, as the efficient migration of virus-specific CD8 T cells to the BM could well benefit the replenishment of the HSC/progenitor cell compartment and restoration of blood cell numbers that got lost upon infection.

P0594

Characterization of T cells in the distal lung A Hutton, JA Warner and C Pickard, Faculty of Medicine, University of Southampton

A. Hutton, J. Warner & C. Pickard
Clinical and Experimental Sciences, University of Southampton, Southampton, UK

Purpose/Objective: To investigate the CD4+ve and CD8+ve T cell populations in the distal lung of patients with COPD.
Materials and methods: Tissue was obtained from patients undergoing resection for carcinoma at Southampton General Hospital.Patients were classified as no evidence of airways obstruction (FEV1/FVC = 0.78 ± 0.02) or as mild/moderate COPD (FEV1/FVC = 0.57 ± 0.02). T cells were isolated from the distal lung by mechanical and enzymatic disruption followed by red cell lysis. Resultant cells were stained for CD3, CD4 and CD8 and analyzed via flow cytometry. Dead and apoptotic cells were excluded from analysis following 7-AAD and Annexin V staining.
Results: We found substantial numbers of CD4+ve T cells in the distal lung of patients with (median = 40.7% of total CD3+ve cells) and without (median = 36.4% of total CD3+ve cells) COPD. The proportion of CD8+ve cells in the two groups was also similar with a median of 43.1% in the no COPD group and 38.8% in the COPD group. We found no relationship between the proportion of CD4+ve or CD8+ve cells and patient lung function. There were also substantial numbers of CD3+ve, CD4-ve, CD8-ve cells in both groups (median 6.3% for no COPD and 7% for the COPD patients) and CD3+ve, CD4+ve CD8+ve cells (median 5.2% for no COPD and 4.5% for the COPD patients).
Conclusions: A substantial percentage of the CD3+ve cells isolated from the distal lung were CD4+ve with a similar percentage of CD8+ve cells. We could also identify populations of double positive and double negative cells. We found no evidence that any of the populations were altered in mild/moderate COPD. There was no relationship between number of CD4+ve or CD8+ve cells and lung function. Our future research will aim to explore the antigen specificity of these T cells; in particular examining carbonyl modified self-proteins as potentially stimulatory antigens.Thus we are aiming to investigate a possible autoimmune aspect to COPD.

P0595

Characterization of the renal CD4(+) T-cell response in experimental autoimmune glomerulonephritis

S. Hünemörder,* J. Holzer,* H. J. Paust,† U. Panzer,† H. Hopfer‡ & H. W. Mittrücker*

*Institute for Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, †Internal Medicine III, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ‡Institute for Pathology, University Hospital Basel, Basel, Switzerland

Purpose/Objective: Anti-glomerular basement membrane glomerulonephritis results from an autoimmune reaction against the Goodpasture antigen, the non-collagenous domain of the alpha3 chain of type 4 collagen (alpha3IV-NC1). The production of autoantibodies and their deposition along the basement membrane of glomeruli and pulmonary alveoli are central to pathogenesis of disease. However, there is also increasing evidence from clinical and experimental data for a contribution of T cells to disease development.

Materials and methods: We use the mouse model of experimental autoimmune glomerulonephritis (EAG) to analyze the role of T cells in renal destruction.

Results: Following immunization with recombinant alpha3IV-NC1, DBA/1 mice display a pathogenesis that reflects all hallmarks of human anti-glomerular basement membrane glomerulonephritis. We observe an initial alpha3IV-NC1-specific IgG response with deposition of autoantibodies along the glomerular basement membrane and progressive proteinuria. In this stage, the kidney shows only marginal signs of inflammation. After 9–13 weeks, mice develop severe signs of glomerulonephritis including crescent formation as well as massive tubulointerstitial damage with accumulation of T cells and macrophages. Renal inflammation eventually results in a severe loss of kidney function accompanied by massive edema formation. CD4+ T lymphocytes isolated from the kidneys of end stage EAG mice display a highly activated phenotype and produce TNFalpha, IFNgamma and IL-17A upon polyclonal *in vitro* stimulation. Using highly sensitive FACS-based techniques, we can also detect renal CD4+ T cells that produced cytokines in response to stimulation with alpha3IVNC1.

Conclusions: From our data, we conclude that renal accumulation of autoreactive T cells might play a role in the progression from mild renal inflammation to severe glomerulonephritis with cell-mediated destruction of glomerular structures and severe tubulointerstitial inflammation.

P0596

Functional properties of resident B cells in arterial walls of human atherosclerotic patients

M. Hamze,* C. Desmetz,* C. Guzman,* P. Roger,† M. L. Berthe,‡ N. Boulle,‡ P. Brancherau,§ E. Picard,§ C. Tolza* & P. Guglielmi*

*Faculty of Pharmacy, CIPD-Centre de pharmacologie et d'innovation dans le diabète, Montpellier, France, †Centre Hospitalier Universitaire-CHRU Nîmes, laboratoire d'anatomie pathologique, Nîmes, France, ‡Centre Hospitalier Universitaire-CHRU Nîmes, Laboratoire de Biologie Cellulaire et Hormonale, Montpellier, France, §Centre Hospitalier Universitaire-CHRU Nîmes, Service de chirurgie vasculaire, Nîmes, France

Purpose/Objective: Animal models suggest that B cells may have contradictory protective or pro-atherogenic effects. To further understand the pathophysiology of human atheroma, we analyzed B lymphocytes present in vascular lesions.

Materials and methods: Ig repertoires were analyzed by RT-PCR on whole tissue extracts from carotid endarterectomy samples of 13 patients using adapted V and C primers. Cytokine, surface marker and transcription factor mRNA expression was studied on adventitial lymphocytes isolated by laser capture micro dissection (LCM).

Results: In adventitia, B lymphocytes constituted diffuse infiltrates or formed small cell clusters adjacent to plaques and BCR sequence analysis revealed that individual samples contained each a limited number of B cell clones. Functional $\alpha 1$, $\alpha 2$, $\gamma 1$ and $\gamma 2$ mRNAs comprised the majority of adventitial Ig H chain mRNAs. In some samples, IgA was expressed as the only H chain isotype. IgM was absent in many adventitias. Most L chain transcripts were of the λ type. V regions of all γ, α and one micro transcripts were hyper mutated and used recurrent VDJ associations. Moreover, a number of genetically distinct VH and VL regions evolved to eventually code for identical CDRs. Expression of the cytidine deaminase AID was detected in several arterial wall samples, in keeping with the observation of a local H chain class switch. Using CDR3 sequences as clonotypic markers, we found that plaque and adventitia repertoires were different and that some B cells were trafficking between adventitia and draining lymph nodes. Most resident B lymphocytes could be described as CD20 negative plasmablasts. However, they lacked markers of terminal differentiation to plasma cell (CD138 and Blimp-1). LCM isolated adventitial B lymphocytes had an activated phenotype: they expressed IL-6, GM-CSF and TNF-α whereas IL-2, IL-4, IL-10, M-CSF and IFN-γ were not detected.

Conclusions: In atherosclerosis, arterial wall B cells are mainly mature B2 lymphocytes and thus differ from B1 cells responsible for the systemic production of protective antibodies. CDR3 convergence, AID expression, clonal H chain switch and an inverted λ/κ ratio of L chain usage witness for a local and antigen-driven maturation that selects oligoclonal adventitial B lymphocytes able to act on inflammation and disease progression directly or by promoting polarization of other immune cells.

P0597

Gliadin- or secalin-primed $CD4^+$ $CD62L^-$ CD44high T cells as sensors of dietary gluten – practical application of a mouse model of gluten-sensitive enteropathy

T. L. Freitag,* J. Loponen,† M. Messing,* L. C. Andersson,‡ T. Sontag-Strohm,† P. Saavalainen,§ D. Schuppan,¶ H. Salovaara† & S. Meri*

*Haartman Institute, Bacteriology and Immunology, University of Helsinki, Finland, †Food and Environmental Sciences, University of Helsinki, Finland, ‡Haartman Institute, Pathology, University of Helsinki, Finland, §Haartman Institute, Medical Genetics, University of Helsinki, Finland, ¶Medicine I, University of Mainz, Mainz, Germany

Purpose/Objective: We recently described a model of gluten-sensitive enteropathy, based on the adoptive transfer of gliadin-sensitized $CD4^+$ CD45RBlow $CD25^-$ T cells (FACS-sorted) into $Rag1^{-/-}$ mice. Here, we asked whether a different memory T cell population, $CD4^+$ $CD62L^-$ CD44high T cells, would be equally potent in the induction of enteropathy. We also tested in this disease model the immunostimulatory and inflammatory effects of germinated rye sourdough, a food product from a baking system characterized by extensive prolamin hydrolysis (Loponen J *et al.*, J Agric Food Chem 2009).

Materials and methods: In modification of a published protocol (Freitag TL *et al.*, Gut 2009), $Rag1^{-/-}$ or nude mice were injected with column-prepared, splenic $CD4^+$ $CD62L^-$ CD44high T cells from wheat gliadin- (or rye secalin-) immunized wildtype donor mice. Recipient mice were then challenged with diets containing different doses of gliadin (or secalin), different doses of either germinated or native rye sourdough (10 or 50 g/kg diet), or gluten-free control diet. Prolamin content of mouse diets was reassessed by R5 ELISA.

Results: $Rag1^{-/-}$ recipients of gliadin- (or secalin-) sensitized $CD4^+$ $CD62L^-$ CD44high T cells lost more body weight and suffered from significant exacerbation of histological duodenitis when challenged with diets containing 2.5 g gliadin (or secalin)/kg diet versus

gluten-free diet. Secretion of IFNg by splenocytes in response to secalin restimulation was also increased. In nude mice, serum anti-secalin IgG and IgG2c titers (ELISA) were strongly reduced in the 50 g/kg germinated versus native rye sourdough group. However, we found no difference in body weight development, histological duodenitis scores or splenocyte cytokine secretion between 2 groups of $Rag1^{-/-}$ mice challenged with 50 g/kg germinated versus native rye sourdough.
Conclusions: Column prepared, gliadin- (or secalin-) sensitized $CD4^+$ $CD62L^-$ CD44high memory T cells are effective in the induction of gluten-sensitive enteropathy in lymphopenic mice. Hydrolysis of secalin in germinated-rye sourdoughs remains incomplete. While B cell epitopes appear to be destroyed more efficiently, secalin peptides retain T cell stimulatory capacity. Our results caution against the use of antibody-based prolamin detection methods when testing the safety of processed cereal food products for celiac patients.

P0598

Identification and characterization of CD4+Helios+Foxp3- memory-like T cell population in Peyer's Patches

A. Visekruna, A. Hellhund, M. Kespohl, S. Riechel & U. Steinhoff
Institute for Medical Microbiology and Hygiene, Mucosal Immunology, Marburg, Germany

Purpose/Objective: The concept of immunological memory has been well recognized for protective immunity to pathogens, however, much less is known about food-specific memory T cells. Tolerance to food antigens affects the responsiveness of the local immune system in the intestinal mucosa itself, but is also manifested by the suppression of immune reactions to subsequent systemic antigen challenge, a phenomenon known as oral tolerance. Most aspects of oral tolerance are dependent on $CD4^+$ T cell immune responses including clonal deletion, clonal anergy and induction of regulatory T (Treg) cells. The question remains whether T cells are able to generate potentially dangerous memory responses following oral uptake of innocuous dietary antigens.
Materials and methods: Adoptive transfer of $CD4^+$ T cells: $CD4^+$ T cells were purified from OT-II mice and were transferred i.p. into C57BL/6 mice. Tolerance induction: Oral and intestinal tolerance was induced by supplementing drinking water with 2 mg/ml OVA. Intracellular cytokine staining (ICS) and flow cytometry: Single cell suspensions were obtained from various organs. The stained cells were analyzed by flow cytometry.
Results: In this study, we show that soluble dietary antigens induced high frequencies of $CD4^+Helios^+$ $CD44^+$ memory T cells in Peyer's Patches (PP). These cells were present in both WT mice and germ-free mice representing the most abundant T cell population in this organ. Apart from the Helios expression, they did not share substantial functional similarities with Treg cells. Although many activation/memory markers were expressed on $CD4^+Helios^+Foxp3^-$ T cells, the immunomodulatory environment within PP led to silencing of IL-7R signalling in this T cell population.
Conclusions: Despite the large extent of antigenic exposure, the intestinal immune system has the unique propensity to evoke hyporesponsiveness to innocuous food antigens. Although the priming of naïve T cells might take place at various sites in the gut, we here demonstrate that the storage of potentially dangerous food-specific $CD4^+$ T cells occurs mainly in PP, where the downregulation of IL-7R signalling provides their dormant and apoptotic behaviour.

P0599

IL-18 regulates effector cells of both the innate and adaptive immune response in models of lung inflammation

S. C. Piper, N. H. E. Davis, D. C. Corkill, G. J. Ferguson, M. A. Sleeman, D. K. Finch & E. Briend
Medimmune, RIA Biology, Cambridge, UK

Purpose/Objective: Interleukin-18 has been shown to prime a number of cell types enhancing their response to exogenous and endogenous signals. The ability of IL-18 to induce IFNg production by T cells and NK cells when used in the presence of IL-12 has been well characterised and associates IL-18 with the development of TH1 and CD8 responses. Conversely, a number of studies have suggested that IL-18 could enhance IL-4 and IgE production when in the presence of TH2 promoting signals. We describe a set of *in vivo* experiments to further address the role of IL-18 on effectors of the innate and adaptive immune response in the lung.
Materials and methods: The cellular infiltrate and mediators being present in the lung of mice were characterised in 2 mouse models using IL-18KO mice or a neutralising anti-IL-18 antibody. Firstly, we assessed lung inflammation 24 h after an intranasal LPS challenge. Secondly, we performed subcutaneous immunisation of ovalbumin (OVA) in complete Freund's adjuvant followed by six aerosolised OVA challenges 3 weeks later. This model aimed to assess the contribution of IL-18 to TH1 and TH2-driven lung responses.
Results: In the acute LPS challenge model abrogation of IL-18 signalling resulted in a significant decrease in the total number of cells present in the broncho-alveolar lavage, neutrophils being the main leukocyte population affected. In the OVA lung inflammation model a significant reduction in the number of eosinophils infiltrating the lung was observed in IL-18KO mice with no significant change to the recruitment of neutrophils or T cells. Surprisingly, when antigen-specific responses were analysed using Pentamer staining, an increased frequency of OVA-specific CD8 cells was observed in IL-18KO mice compared to wild type mice. This was associated with an increased production of IFNg upon *ex-vivo* re-stimulation of lung T cells.
Conclusions: In an acute model, we showed that IL-18 plays a role in early inflammatory events leading to lung neutrophilia associated with an LPS challenge. In addition, IL-18 also affects antigen-specific T cell responses as exemplified by the decreased TH2-driven eosinophilia observed in IL-18KO mice. These preliminary findings highlight the complexity of the role of IL-18 which is dependent on the context in which it is released.

Light, xenobiotics and AHR activation in Lupus patients

G. Gorochov,* K. Dorgham,† A. Mathian,* C. Parizot,‡ H. Yssel,§ M. Larsen,* L. Arnaud,¶ C. Frances & Z. Amoura***
**INSERM UMRS 945, Université Paris 6, Paris, France, †INSERM, UMRS 945, Paris, France, ‡Hôpital Pitié-Salpêtrière AP-HP, Immunology, Paris, France, §INSERM, U454, Montpellier, France, ¶Hôpital Pitié-Salpêtrière AP-HP, Medecine 2, Paris, France, **Hôpital Tenon AP-HP, Dermatology, Paris, France*

Purpose/Objective: Sun exposure or the ingestion of certain medications are typical triggering factors in the development of autoimmune disease flares. Systemic Lupus Erythematosis (SLE) is often cited as the prototypical potentially photo- or medication-induced autoimmune disease. The immunopathologic effect resulting from exposure to these two seemingly different triggering factors remains, to date, unknown.
Materials and methods: Intracellular IL-17 and IL-22 was detected, gated on CD4+ T lymphocytes, using FACS analysis of PBMC stimulated 18 h with anti-CD3 and anti-CD28 antibodies. Quantitative RT-PCR was applied to unstimulated PBMC and lesional skin of SLE

patients, using primers specific for IL-17, IL-22, Cyp1a1, CD3 or §-actin. Several drugs implicated in the induction of SLE were screened, in their native forms and after UV exposition, for their abilities to activate the Aryl Hydrocarbon Receptor (AHR) and induce Cyp1a1 mRNA expression. Propranolol and its UV-induced derivatives were studied by mass spectrometry. Th17 differentiation was performed on CD4+ cord blood cells using anti-CD3 and anti-CD28 antibodies in the presence of IL6, IL1b and TGFb. Cytokines were evaluated using a bead-based assay (Luminex) and ELISA.
Results: We confirm that during SLE flares the circulating Th17 subpopulation is amplified. This augmentation is not typically found in other systemic auto-immune diseases such as primary Sjögren syndrome or in 'primary' antiphospholipid syndrome. The aryl hydrocarbon receptor (AHR) plays a central role in Th17 differentiation. We found that SLE patients are hyper-responsive to AHR ligands and show characteristic signs of AHR activation in their skin lesions that strongly correlate with lesional interleukin-22 levels. Finally, we show that the photo-induced degradation products of certain medications are equally capable of activating AHR *in vitro*.
Conclusions: Taken together these results allow us to reconcile the patho-physiologic effects of medications and UV light by relating the two mechanisms to local activation of Th17 cells.

P0601
Lymph node dissection – understanding the immunological function of lymph nodes

M. Buettner & U. Bode
Hannover Medical School, Functional and Applied Anatomy, Hannover, Germany

Purpose/Objective: Lymph nodes (LN) are one of the important sites in the body where immune responses to pathogenic antigens are initiated. This immunological function induced by cells within the LN is an extensive area of research. To clarify the general function of LN, to identify cell populations within the lymphatic system and to describe the regeneration of the lymph vessels, the experimental surgical technique of LN dissection was established in various animal models.
Materials and methods: For dissection of the mesenteric LN (mLN) the abdomen was opened and the gut was taken out so that the mLN were seen. The mLN were excised carefully in order not to injure the superior mesenteric artery lying behind, whereas the connection of the lymph vessels and small blood vessels to the LN was disturbed. Afterwards the gut was replaced in the abdomen and the abdomen was closed.
Results: To analyze the different cell subsets of the incoming lymph in detail LN were dissected. Furthermore, LN were identified as the place where the induction of an antigen-specific response occurs and more significantly where this immune response is regulated. During bacterial infection, LN, as a filter of the lymph system, play a life-saving role. In addition, LN are essential for the induction of tolerance against harmless antigens, because in LN-resected animals tolerance could not be induced.
Conclusions: The technique of LN dissection is an excellent and simple method to identify the important role of LN in immune responses, tolerance and infection.

P0602
RGS-1 in intestinal T cell trafficking and responsiveness

L. Deban,* D. L. Gibbons,† L. Abeler-Dörner,† T. Raine,‡ I. Y. Hwang,§ A. Jandke,* M. Wencker,* P. M. Irving,¶ J. H. Kehrl§ & A. C. Hayday†
**Cancer Research UK, Immunosurveillance Lab, London, UK, †Peter Gorer Department of Immunobiology, King's College London, London, UK, ‡Department of Pathology, University of Cambridge, Cambridge, UK, §National Institute of Allergy and Infectious Diseases, B-Cell Molecular Immunology Section, Bethesda, MD, USA, ¶National Institute for Health Research, Biomedical Research Centre, London, UK*

Purpose/Objective: Few clear mechanisms have been defined by which the regulation of gut T cell responses may be distinguished from systemic T cell regulation. In addition, how lymphocytes selectively respond to, or ignore, chemotactic signals in the gut is very poorly understood. Regulator of G protein signalling 1 (RGS1) might be a key regulator of T cell trafficking in the gut based on its conspicuously high expression in gut-associated T cells.
Materials and methods: We have evaluated the role of RGS1 in human and mouse T cell migration using transfected and knock-out cells, respectively. The colitogenic potential of RGS1-deficient T cells was evaluated in $CD4^+$ $CD45RB^{Hi}$ T cell transfer model of colitis.
Results: We have shown that RGS1 is elevated (50–100-fold) in human (and mouse) gut T cells compared to peripheral T cells. Consistent with its capacity to regulate the $G\alpha_i$ subunit of GPCRs, RGS1 inhibited the activity of specific chemokine receptors, reducing human and mouse T cell migration to selected cytokines, e.g. CCL19, CXCL12, but not to gut-homing chemokines, CCL25 and CCL20. In addition, RGS1 levels are further elevated in T cells derived from inflamed gut and the colitogenic potential of RGS1-deficient T cells was significantly reduced, Interestingly, GWAS strongly implicate the RGS1 locus in celiac disease, multiple sclerosis and Type I diabetes. RGS1 is also highly expressed by regulatory T cells. We therefore explored further its regulation of T cell responsiveness, finding that RGS1-deficient cells make exaggerated cytokine responses upon activation *in vitro* and *in vivo*.
Conclusions: Our data suggest that RGS1 ordinarily represses T cell egress from the gut, possibly to sustain local immunoprotection and/or immunoregulation vis-a'-vis commensals. Ongoing work aims to further discern to what degree this non-redundant regulation of IEL by RGS1 contributes to the unique state of rapidly responsive body-surface lymphocytes, as well as to what degree differential expression of other RGS molecules regulates intraepithelial T cell subsets with implications for diseases in different tissues. In sum, RGS1 emerges as a novel, site-specific T cell regulator that may prove an effective clinical target, complementing the intense pharmacological targeting of chemokine receptors.

P0603
Role of T-cells in cardiac ischemia-reperfusion injury

D. Mathes*, U. Hofmann,† C. Pachel,* B. Vogel,* J. Weirather* & S. Frantz†
**Department of Internal Medicine I, University Hospital Würzburg, Würzburg, Germany, †Department of Internal Medicine I, University Hospital Würzburg CHFC Würzburg, Würzburg, Germany*

Purpose/Objective: The extent of injury after acute myocardial infarction is determined by duration of ischemia. However, after coronary flow restoration, the myocardium is additionally damaged by reperfusion. This so-called reperfusion injury is partially mediated by recruitment of inflammatory cells. Yet, the role and activation patterns of T-cells (TCs) after myocardial reperfusion have not been established.
Materials and methods: The left coronary artery was surgically occluded in male mice for 30 min (ischemia), followed by 3, 6, 18

or 24 h of reperfusion. FACS analysis and immunohistochemistry were performed to characterize the time course of inflammatory cell infiltration during reperfusion in WT mice. After 24 h of reperfusion, WT, CD4KO, CD8KO and OTII mice underwent Evans Blue/TTC-staining to determine the infarct size in relation to the area at risk. As control, mice underwent a sham operation procedure (sham).
Results: Significantly more CD3+ TCs infiltrated the mouse myocardium after 30 min ischemia and 24 h of reperfusion in comparison to sham. CD4+ TCs (47%) and CD8+ TCs (30%) are the predominant subsets among all $CD45^+$ $CD3^+$ leukocytes recruited to the myocardium during the entire reperfusion period. NK TCs (12%) and gd TCs (5%), but not B lymphocytes could be detected. Evans Blue/TTC-staining demonstrated that CD4 KO and OTII mice, but not CD8 KO mice were partially protected. The reduction in infarct size in OT II mice indicates that antigen recognition is relevant for the harmful effect of CD4+ TCs on ischemia-reperfusion injury.
Conclusions: We could demonstrate that, besides innate immune cells, there is considerable infiltration of TCs into infarcted myocardium after ischemia-reperfusion. CD4+, but not CD8+ TCs contribute to myocardial ischemia-reperfusion injury, obviously after activation by recognition of self-antigens.

P0604
Th17/Tc17 recruitment and positioning in the human hepatic inflammation

Y. H. Oo,* E. Liaskou,* D. R. Withers,† E. Humphrey,* S. G. Hubscher,* P. Klenerman‡ & D. H. Adams*
**Centre for Liver Research & NIHR BRU, University of Birmingham, Birmingham, UK, †MRC centre for immune regulation, University of Birmingham, Birmingham, UK, ‡Peter Medawar Building for Pathogen Research, University of Oxford, Oxford, UK*

Purpose/Objective: IL-17 secreting CD4 (Th17) and CD8 (Tc17) are distinct lineages of T lymphocytes implicating autoimmunity, bacterial infections in murine models and human diseases. They are implicated in several inflammatory, autoimmune and viral liver diseases and also in progression of hepatocellular carcinoma. However little is known about human Th17 & Tc17 cells molecular recruitment mechanism and positioning in the inflamed human liver.
Materials and methods: Human liver infiltrating (LI) lymphocytes were freshly isolated from explanted liver tissues. LI-Th17&Tc17 cells frequencies, phenotype, chemokine receptors, integrin expression and cytokine secretion assessed *ex-vivo* by flow cytometry. Frequency and distribution in tissue determined using dual immunohistochemistry and confocal microscopy. Recruitment was studied *in-vitro* using IFN-g stimulated hepatic sinusoidal endothelium cells (HSEC) in flow based adhesion assays. Positioning around bile duct was investigated by chemotasis. Chemokine expression and secretion from bile duct was assessed by immunohistochemistry and ELISA.
Results: Inflamed human liver contains a higher proportion of LI-IL-17 cells comprising 3% of T cells infiltrate with associated neutrophils. LI-Th17&Tc17 express RORc, IL-23 receptor and secrete IL-17, IL-22, TNF and IFN-g. $RORc^+$ liver infiltrating $IL17^+$ cells did not co-express $Foxp3^+$. Liver infiltrating Th17 and Tc17 express chemokine receptors CXCR3, CCR6 and integrin LFA-1, VLA-4. Human peripheral blood Th17/Tc17 cells were recruited via inflamed HSEC by CXCR3, ICAM-1, VCAM-1, and VAP-1 dependent mechanisms. IL-17 receptor is expressed on HSEC and IL-17 treatment up-regulates adhesion molecules and chemokines on HSEC creating a paracrine loop to promote further recruitment. Th17 cells were located close to inflamed bile ducts that express the CCR6 ligand, CCL20. Human cholangiocytes stimulated with TNF-α and IL-17 secreted CCL20 and induces CCR6-dependent migration of human Th17 cells.
Conclusions: Th17 and Tc17 cells are recruited via hepatic sinusoidal endothelium using CXCR3, integrin and VAP-1 dependent mechanisms. IL-17 secreted by infiltrating cells has paracrine effects on endothelium leading to enhanced Th17 recruitment. Their subsequent positioning near bile ducts is dependent on cholangiocyte-secreted CCL20.

P0605
The function of the chemokine receptor CXCR6 in the T-cell response against Listeria monocytogenes

K. Heesch,* F. Raczkowski,* V. Schumacher,* U. Panzer† & H. W. Mittrücker*
**Department of Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, †III. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Purpose/Objective: The chemokine receptor CXCR6 recognizes the chemokine CXCL16 which is expressed in a transmembrane form by sinosoidale enothelium cells and in a secreted form by activated dendritic cells. CXCR6 is expressed on NK cells and NKT cells as well as activated CD8 T cells and CD4 Th1 cells. CXCR6 controls accumulation and survival of NKT cells in the liver. However, the function of CXCR6 in conventional T cells is less well understood.
Materials and methods: Here, we use the Listeria monocytogenes infection model to characterize the role of CXCR6 in the regulation of CD8 T cell responses.
Results: Expression studies revealed that particularly in the liver a large fraction of conventional CD4 and CD8 T cells expressed CXCR6. The chemokine receptor was further upregulated on activated CD4 and CD8 T cells during listeria infection. Expression of CXCR6 on listeria-specific T cells was a late event and regulated independently from IFNg expression. Following infection, CXCR6-deficient mice showed similar listeria titers in spleen and reduced titers in liver. Analysis of T-cell responses in CXCR6-deficient mice, revealed only minor changes in frequencies of listeria-specific CD4 and CD8 T cells in spleen as well as in liver. T cells from infected wild type and CXCR6-deficient mice also showed comparable cytokine profiles following *in vitro* restimulation. Listeria-specific T cell responses were also analysed with a competitive T-cell transfer assay. This approach revealed an altered tissue distribution of CXCR6-deficient CD8 T cells, with reduced frequencies in blood, lymph nodes and liver at late time points post infection. At early time points, T cell frequencies were reduced only in the blood. Interestingly, transferred CXCR6-deficient CD8 T cells showed diminished proliferation at these time early points.
Conclusions: In summary, CXCR6 controls tissue distribution of CD8 T cells but has only limited impact on the acquired CD8 T cells response against L. monocytogenes infection.

P0606
The role of the small GTPase Arl4d in CD8 T cell immune function

J. Kaczmarek, C. Metzger & L. Diehl
Institutes of molecular Medicine and experimental Immunology, Molecular Medicine, Bonn, Germany

Purpose/Objective: The liver is known to induce tolerance rather than immunity. Liver sinusoidal endothelial cells (LSEC) can induce a non-responsive state in naïve CD8 T cells after antigen-specific stimulation. The ADP-ribosylationfactor/ARF-likeprotein (ARF/Arl) family regulates membrane traffic and organelle structure. Arl4d is localized to the plasma membrane and can recruit cytohesin-2/ARNO, where it modulates actin remodeling. We found Arl4d to be overexpressed in LSEC-stimulated CD8 T cells compared to dendritic cell (DC) stimulated T cells in gene expression profiling. Therefore, we further investigated the role of Arl4d in CD8 T cell function.
Materials and methods: Naive CD8 T cells were cocultured with antigen-loaded LSEC or DC. We analysed the kinetics of Alr4d mRNA

and protein expression by real-time PCR and Western Blot, respectively. To investigate the function of Arl4d in CD8 T cells, we used Arl4d$^{-/-}$ mice. CD8 T cells were isolated from the spleen by MACS Cell Separation, which were further stimulated with a-CD3/CD28 antibodies. IL-2 production was analysed by ELISA.

Results: Using real-time PCR and Western blot we could confirm overexpression of Arl4d in CD8 T cells during tolerance stimulation by LSEC *in vitro*. Conversely, Alr4d mRNA was down-regulated in DC-stimulated CD8 T cells. We further found that Arl4d$^{-/-}$ mice do not display overt changes in their lymphoid compartment. Furthermore, we showed that Arl4d is involved in regulating IL-2 production by naïve CD8 T cells. Arl4d$^{-/-}$ CD8 T cells produced significantly more IL-2 than Arl4d$^{+/+}$ CD8 T cells upon TCR stimulation.

Conclusions: Arl4d expression is highly induced during CD8 T cell stimulation by LSEC. In Alr4d$^{-/-}$ mice the lymphoid compartment is not changed and thus Arl4d does not seem to be involved in lymphocyte development. More interestingly, we found Alr4d to be involved in the production of IL-2. As the amount of IL-2 produced by naïve CD8 T cells during antigen-specific interaction with LSEC is an important factor for the induction of non-responsive CD8 T cells, the action of Arl4d may be central to dampen IL-2 production and for subsequent abrogation of immediate effector function in naïve CD8 T cells.

TNFa acts as a Chemokine to attract CD4+ T cells to rheumatoid joints

K. Schubert,* M. Rossol,* U. Meusch,* A. Schulz,* R. Scholz,† C. Baerwald* & U. Wagner*

**Department of Internal Medicine/Rheumatology, University of Leipzig, Leipzig, Germany, †Department of Orthopedics, University of Leipzig, Leipzig, Germany*

Purpose/Objective: The cytokine TNFα plays a central role in the pathogenesis of rheumatoid arthritis (RA), but its disease-specific effector mechanisms have not been fully elucidated. Aim of the study was the investigation of the role of TNFα in T cell accumulation and migration in synovitic joints of RA patients and the identification of a surface marker which allows discrimination of tissue infiltrating CD4+ T cells from non-infiltrating CD4+ T cells.

Materials and methods: Vital tissue sections from rheumatoid synovium were generated using a horizontally oscillating microtom, and were co-incubated with fluorescence-labelled CD4+ T cells. Migration was detected by fluorescence and confocal microscopy. Migrating T cells were recovered from the tissue using enzymatic digestion and phenotypically analyzed by FACS. Chemokinesis of CD4+ T cells from RA patients and healthy donors in response to TNFα were analyzed in transwell experiments.

Results: CD4+ T cells from RA patients migrated into the tissue sections in significantly higher numbers than CD4+ T cells from healthy controls. Migrating CD4+ T cells differed from non-migrating ones in their increased expression of TNFR1. Furthermore, TNFR1 is expressed on a fraction of circulating CD4+ T cells from RA patients, but not from healthy controls. In a Chemotaxis migration assay, it could be shown that TNFα directly acts as a chemokine for peripheral blood CD4+ T cells from RA patients, but not for CD4+ T cells from healthy controls. Accordingly, blockade of either TNFα or of TNFR1 nearly abrogated *in vitro* T cell migration in synovial tissue.

Conclusions: Taken together, the results indicate, that the interaction of TNFα with TNFR1 is pivotal for T cell migration in synovial tissue *in vitro*, and thereby suggests a relevant role for the cytokine for *in vivo* T cell trafficking to rheumatoid joints.

Poster session: Lymphoid Organogenesis

P0608
Differential regulation of small intestinal and colonic lymphoid tissue development by IL-23 and regulatory T cells

D. S. Donaldson & N. A. Mabbott
The Roslin Institute, Neurobiology, Edinburgh, UK

Purpose/Objective: Isolated lymphoid follicles (ILF) are single B cell follicles found throughout the intestines that develop postnatally and represent a dynamic way in which gut lymphoid system responds to environmental challenges. ILF develop in the colon of transgenic mice lacking genes essential for lymphoid tissue development including small intestinal (SI-) ILF and are less dependent on the intestinal microbiota for their development than SI-ILF. In order to further characterise these differences, the development and maturation of large intestinal (LI-) ILF have been studied in a number of models.
Materials and methods: ILF and mature ILF (mILF) were characterised using wholemount immunofluorescence in mice treated with LTβR-Ig *in utero*. ILF status was also assessed in germ-free mice, IL-23p19$^{-/-}$ mice and mice treated with anti-IL-17, anti-IL-22 or anti-CD25.
Results: LI-ILF develop earlier than SI-ILF, with higher numbers of LI-ILF observed at 2 weeks after birth. Only the colon contained mILF at this timepoint. In germ-free mice, LI-ILF was present and contained mILF in the absence of bacterial stimulation. In contrast to SI-ILF, which increased following colonisation of germ-free mice, LI-ILF were reduced. Interestingly, IL-23p19^{+} cells are enriched in LI-ILF and IL-23p19$^{-/-}$ mice have a reduced number of LI-ILF despite similar numbers of SI-ILF. This phenotype was also present in mice lacking Peyer's patches that had been reconstituted with IL-23p19$^{-/-}$ bone marrow.Antibody neutralisation of IL-22 or IL-17A partially reduced colonic ILF; however neither of these fully recapitulated the phenotype of IL-23p19$^{-/-}$ mice.Foxp3^{+} regulatory T cells (Treg) are also enriched in ILF of both the small intestine and colon and depletion of CD25^{+} Treg increased ILF and mILF in both the ileum and colon.
Conclusions: These results suggest that the homeostatic balance reached with the microbiota through development of ILF in the small and large intestines is differentially regulated by intrinsic factors specific to each microenvironment.The specific regulation of colonic ILF development by IL-23 may have implications in colonic pathology.

P0609
Lymph node transplantation and its immunological significance in animal models

U. Bode & M. Buettner
Hannover Medical School, Institute of Functional and Applied Anatomy, Hannover, Germany

Purpose/Objective: Lymph nodes (LN) are distributed all over the body and whatever the site consist of the same cell populations. However, there are great differences between LN from different draining areas. For example, in mesenteric LN, homing molecules, e.g. CCR9 and a4b7 integrin, were induced and cytokines, e.g. IL-4, were produced on higher levels compared to peripheral LN.
Materials and methods: To study the immunological functions of mLN and pLN, we established a surgical technique, removing the mLN and transplanting a pLN or another mLN into the mesentery. Briefly, mice were anesthetized and the abdomen opened. The gut was taken out so that the mLN were seen. The mLN were removed carefully not injuring the blood vessels lying behind, whereas the connection of the lymph vessels to the LN was disturbed. Previously excised mLN or pLN from a donor animal were transplanted into this vacant area. After this the gut was replaced carefully in the abdomen and the abdomen closed.
Results: We analyzed the regeneration of the transplanted LN (LNtx).To identify the regeneration of LNtx a kinetic study was performed and the architecture of the LNtx was analyzed. Over a period of 8 weeks a fully regenerated LN developed with connections to lymph and blood vessels. All vessels were shown to be functional, transporting lymph fluid or lymphocytes into the transplanted LN. Furthermore, we could clearly show that lymphocytes from the donor LN disappeared from the LNtx and lymphocytes from the recipient repopulated the transplanted LN. In addition, DC from the draining area migrated from the gut via the afferent lymphatics into the LNtx. Furthermore, using transgenic mice which express the GFP gene in all cells, we showed for the first time that stromal cells remained in the tissue during regeneration. Stromal cells are non-hematopoietic cells, which form the skeletal backbone of the LN by forming a network and extracellular matrix components.
Conclusions: The role of stromal cells as a central cell population within the LN has to be elucidated. In addition, all cell types (stromal cells, lymphocytes and DC) involved in the induction of an immune responses or tolerance concerning foreign Ag or self Ag have to be studied in combination with each other. This could be done by transplanting LN into different draining areas. Therefore, LN transplantation is an important method to examine all these questions.

P0610
M1 inflammatory macrophages act as lymphoid tissue inducer cells in atherosclerosis-associated lymphoid neogenesis

K. Guedj, J. Khallou-Laschet, M. Morvan, A. Gaston, M. Clément, M. Marchand, G. Fornasa, G. Caligiuri & A. Nicoletti
Inserm U698, Immunopathology and immunomodulation of cardiovascular diseases, Paris, France

Purpose/Objective: Atherosclerosis is a chronic inflammatory disorder that is characterized by the formation of tertiary lymphoid structures (TLO) within the adventitial layer. However, the cellular and molecular mechanisms orchestrating TLO formation are still to be investigated. Smooth muscle cells (SMC), that constitute the medial layer of the aorta, have been implicated as chemokine-expressing cells, allowing the formation of TLO. Yet the inducer signal that is locally generated and that confers to SMC their organizer potential is still to be understood. Several lines of evidence suggest that it could be mediated by signaling through TNF- and LT$-receptors, as it is the case during the formation of secondary lymphoid organs.

Herein, we hypothesized that macrophages infiltrated in the plaque could trigger the LT$R/TNFR signaling in vascular SMC, which in turn are responsible for the formation of atherosclerosis-related TLO in the adventitia.
Materials and methods: We analyzed by RT-qPCR the expression of chemokines by mouse primary SMC stimulated by macrophage supernatants and by recombinant LT-α and TNF-α, and their concentration was assessed by ELISA. Matrigel scaffolds loaded with SMC stimulated or not with macrophage supernatant were implanted sub-cutaneously in mice and analyzed by flow cytometry and immunohistochemistry 15 days later.
Results: We found that M1, but not M2 *in vitro*-polarized macrophages induced the expression of TNF-α and LT-α. Moreover, stimulation of SMC with M1-conditioned medium induced the expression of CCL19, CCL20 and CXCL16 chemokines. Importantly, our results showing that stimulation of SMC with rLT-α and rTNF-α induced the same expression profile suggested that M1 macrophages could be responsible for the LT$R/TNFR-mediated triggering of chemokine expression in SMC. This was corroborated with the increased concentration of the three chemokines in the supernatant of rLT-α/rTNF-α-stimulated SMC as compared to unstimulated cells.

Finally, scaffolds loaded with *ex vivo* stimulated SMC presented inflammatory infiltrates that were organized in follicles composed of T and B lymphocytes.
Conclusions: Together, these results suggest that M1 macrophages infiltrated within atherosclerotic lesions are able to trigger the expression of CCL19, CCL20 and CXCL16 by vascular SMC through LT$R/TNFR signalling, allowing the formation of aortic TLO.

P0611
MAdCAM-1 independent lymphocyte homing to GALT of Nkx2.3$^{-/-}$ mice

Z. Kellermayer, M. Mihalj & P. Balogh
Department of Immunology and Biotechnology, University of Pécs, Pécs, Hungary

Purpose/Objective: Nkx2-3 transcription factor is involved in the regulation of mucosal addressin cell adhesion molecule-1 (MAdCAM-1) expression, and its sequence variants have been identified as susceptibility trait for inflammatory bowel diseases. Although mice lacking Nkx2.3 transcription factor have no endothelial MAdCAM-1, Peyer's patches (PP) and mesenteric lymph nodes (mLN) still develop. As the homing of lymphocytes to gut-associated lymphoid tissues (GALT) is dependent on the high endothelial venules (HEV) displaying MAdCAM-1, we investigated the molecular components of homing to the GALT in Nkx2.3$^{-/-}$ mice.
Materials and methods: The phenotypic features of PP HEVs (PNAd and MAdCAM-1 addressins, production of CCL21 and CXCL13 chemokines) in Nkx2-3 and wild-type BALB/c mice were studied by immunofluorescence. The kinetics of homing to GALT was tested by adoptive cell transfer using CFSE-labeled or GFP/MHC alloantigen-marked donor lymphocytes, followed by flow cytometry or tissue immunofluorescence. The expression of mRNA for addressin proteins and the posttranslational glycosylation enzymes was determined by qPCR. The involvement of MAdCAM-1 or PNAd adressins in the GALT homing was studied *in vivo* using antibody-mediated blockade.
Results: PPs and mLNs of mutant mice showed an enhanced staining for luminal MECA79 epitope against PNAd sulfoglycoepitope, and also increased production of mRNA for several PNAd backbone proteins and modifying enzymes. Adoptively transferred lymphocytes could effectively home to PNAd-positive GALT HEVs, which process could be blocked by MECA-79 anti-PNAd mAb injection, but not with anti-MAdCAM-1 mAb. Although the gut and GALT in Nkx2.3 deficient mice at neonatal age contain MAdCAM-1-positive vessels, in the gut mucosa with organized lymphoid tissues HEVs gradually replace MAdCAM-1 with PNAd, whereas in the non-lymphoid segments of intestinal vasculature the loss of MAdCAM-1 is not coupled with the induction of PNAd.
Conclusions: Together these data indicate that in the absence of endothelial MAdCAM-1 in Nkx2.3$^{-/-}$ mice PNAd controls homing to GALT, thus HEV function is maintained, although with different adhesion molecule expression patterns.

P0612
Presence of lymphoid tissue organizer cells in human tonsil

A. Prados Martín,* P. J. Martinez-González,* R. Munoz-Fernández,† E. Leno-Durán* & E. G. Olivares*
**Centro de Investigaciones Biomédicas, University of Granada, Granada, Spain, †Inst. de Parasitología y Biomedicina 'López-Neyra' (CSIC), Armilla, Spain*

Purpose/Objective: Stromal cells from secondary lymphoid organs (SLO) are a heterogeneous population of non-hematopoietic cells. These cells improve survival and differentiation of lymphocytes, are involved in peripheral tolerance and produce the segregation of T and B lymphocytes in different lymphoid areas. In adult SLO, three main types of stromal cells have been identified: follicular reticular cells (FRC) located in the T zone, follicular dendritic cells (FDC) in lymphoid follicles and marginal reticular cells (MRC) detected in the peripheral zone of the lymphoid tissue. During embryonic development, these stromal populations derived from a common precursor called lymphoid tissue organizer (LTo) cells. Our objective was to obtain lymphoid stromal cells from human tonsil and to study the presence of the above mentioned populations.
Materials and methods: Human lymphoid stromal cell lines were isolated from human tonsil using EMEM culture medium with a low concentration of fetal calf serum (3%). Tonsil samples were obtained from patients (3–10 years old) who underwent tonsillectomy for recurrent tonsillitis. Cell phenotype was studied by RT-PCR, flow citometry and histochemistry. Cell lines were differentiated after incubating with the corresponding media.
Results: Human Tonsil Stromal Cells (hTSC) showed to be a homogeneous population that expressed podoplanin and mesenchymal markers (CD10, CD29 and CD73), without contamination by endothelial cells or leukocytes (CD31 and CD45 negative). Moreover, hTSC expressed TRANCE (MRC marker), CXCL13 (MRC and FDC marker), CCL19 and CCL21 (FRC markers), but they were negative for CD21 and CD35 (FDC markers). This phenotype was compatible either with a MRC and FDC mixture, or with LTo cells. The possibility of a different cell types mixture was rejected since hTSC clones also expressed TRANCE, CCL19 and CCL21, but not CD21, CD35 and CXCL13. Finally, hTSC expressed markers associated with mesenchymal stem cells (STRO-1 and CD271) and embryonic stem cells (OCT-3/4 and NANOG). Under appropriate differentiation conditions, they showed adipogenic, chondrogenic and osteogenic potential.
Conclusions: Our results show the presence of LTo-like cells in human tonsil. These cells exhibited a high plasticity, and can be differentiated *in vitro* into other mesenchymal cell types.

P0614
TGF-beta (TGFb) negatively regulates the establishment of the thymic medulla

M. Hauri,* G. Hollander† & S. Ziegler*
**Benaroya Research Institute, Immunology, Seattle, WA, USA, †Paediatrics, University of Oxford, Oxford, UK*

Purpose/Objective: Thymic epithelial cells (TEC) are an essential component of the thymic microenvironment. They provide the structural and functional requirements for efficient T cell development. Stochastic rearrangement of the T cell receptor during T cell development necessitates mechanisms to harness potentially auto-reactive T cell clones. Connected with their unique capacity to express peripheral tissue antigens [a.k.a. promiscuous gene expression (pGE)] medullary (m) TEC drive the elimination of auto-reactive T cells clones or foster their development into regulatory T cells. Thus, inborn or acquired numerical or functional mTEC deficiency is linked with autoimmunity. Insight into processes regulating mTEC proliferation and maturation may therefore provide novel directions for therapeutic interventions to improve thymic function.
Materials and methods: We use murine models of TEC-specific inactivation of molecules involved in TGF-beta-signaling and downstream targets to identify the contribution of this pathway to TEC development *in vivo* and *in vitro*.
Results: Genetic abolition of TGFb-signaling specifically in TEC enhances their proliferative potential as well as their terminal differentiation. The ensuing surge in total and mature mTEC is associated with significant increases in both pGE and production of regulatory T cells. In addition, *in vitro* experiments show that TGFb directly modulates alternative NFkB-signaling in TEC. The TGFb target gene c-myc is essential for maintaining the proliferative

but not the differentiation potential of mTEC. In view of a potential therapeutic application of these findings, we show that systemic administration of a small molecule inhibitor of TGFb-signaling alone or in conjunction with Keratinocyte Growth Factor (KGF) results in significant expansion and maturation of mTEC and enhances the thymopoietic effects of KGF.
Conclusions: TGFb negatively impacts the post-natal formation of the thymic medulla in a TEC-autonomous manner and involves the modulation of alternative NFkB signaling. Down-regulation of c-myc expression by TGFb limits the expansion but not the differentiation of mTEC. Our findings that short-term inhibition of TGFb-signaling positively affects the mTEC compartment have implications for therapies aimed at improving thymic function.

WNT/CTNNB1 pathway inhibition guides the human thymic involution process

S. Ferrando-Martinez,* R. S. de Pablo-Bernal,† M. A. Muñoz-Fernandez,* M. R. van den Brink,‡ J. Grillari,§ E. Ruiz-Mateos† & M. Leal†
**Gregorio Marañon University Hospital, Laboratory of Molecular Immuno-Biology, Madrid, Spain, †Biomedicine Institute of Sevilla, Laboratory of Immunovirology, Sevilla, Spain, ‡Department of Immunology and Medicine, Sloan Kettering Institute, New York City, NY, USA, §Department of Biotechnology, BOKU, University of Natural Resources and Applied Life SciencesVienna, Austria*

Purpose/Objective: To analyze mRNA and microRNA expression differences between elderly and young human thymuses.
Materials and methods: Four elderly human thymuses (70 years old) and four young thymuses (younger than 10 months) were obtained from individuals undergoing cardiac surgery. mRNA and microRNA differential expression levels were analyzed by microarrays. Expression levels from selected genes was confirmed by quantitative PCR using thymus samples from neonates, 50-years old and 70-years old individuals, all of them obtained from cardiac surgery interventions.
Results: The mRNA analysis showed a great increase in the WNT pathway inhibitors. Results were confirmed by quantitative PCR. Results showed that WNT inhibitors are being mostly produced by non-adipocytic cells. Moreover, both non-adipocytic cells and adipocytes showed a significant increase in adipocyte-differentiation transcription factors mRNA expression levels. The micro-RNA analysis showed changes in miRNAs related with human ageing, stress-related thymic involution, epithelial to mesenchymal transition and control of the WNT pathway. WNT pathway inhibition is compatible with the main processes observed in human thymus: 1) arrest of thymocyte maturation, 2) loss of the cortico-medular structure of thymic epithelial cells and 3) replacement of the epithelial mesh to adipose tissue.
Conclusions: Our results strongly suggest that WNT/CTNNB1 pathway inhibition could be one of the main mechanisms of the human thymic involution process. To stablish this mechanisms is necessary to identify therapeutical targets aiming to slow or even increase thymic function in both, elderly individuals and pathologies associated with lymphopenia and immunological impairment.

P0618
Influence of sphingolipids on lymphoma cell proliferation and survival

C. Bode & M. H. Gräler
Charité, University Medical School, Molecular Cancer Research Centre, Berlin, Germany

Purpose/Objective: Lipids are important structural membrane components that determine membrane stability and fluidity. Some lipid metabolites also act as signalling molecules by binding and activating specific G protein-coupled receptors on the cell surface, or as cofactors and adapter molecules within cells. Here we evaluated the impact of sphingolipids on lymphoma cell proliferation.
Materials and methods: Different germinal-center-like (GC) and activated-B-cell-like (ABC) diffuse large B cell lymphoma (DLBCL) cell lines were incubated with the naturally occurring D-erythro-Sph (Sph), its unnatural synthetic stereoisomer L-threo-Sph (Lt-Sph), the phosphorylated metabolite sphingosine 1-phosphate (S1P), and its close relative sphingosylphosphorylcholine (SPC).
Results: Of this group of lipids, only Sph and Lt-Sph negatively influenced the proliferation of DLBCL cell lines in a concentration-dependent manner, with Sph having a greater impact than Lt-Sph on GC-, but not ABC-DLBCL proliferation. Since ABC-DLBCL were shown to be significantly more dependent on protein kinase C (PKC) signalling than GC-DLBCL, we investigated the influence of Sph and Lt-Sph on PKC activation. Correspondent results not only confirmed PKC inhibition by Sph, but also revealed a similar activity of its synthetic stereoisomer Lt-Sph. Our data suggest that both Sph and Lt-Sph act as PKC inhibitors by binding to the regulatory C1-domain and competing with endogenous PKC activators like phosphatidylserine (PS). Indeed exogenous application of PS to ABC-DLBCL partially rescued the anti-proliferative effect of Lt-Sph, but not Sph, while it had no effect on GC-DLBCL. Annexin-V and propidium iodide staining with subsequent flow cytometric analysis of cell populations demonstrated cell death, partially induced by apoptosis, and impaired proliferation by a G1-phase cell cycle arrest as the predominant reasons for the observed Sph- and Lt-Sph-induced anti-proliferative effect. Electron microscopy analysis of DLBCL cell lines suggested autophagy as an additional PKC-independent mechanism of Sph.
Conclusions: Thus a cellular increase of Sph potentially interferes with lymphoma growth by inducing cell cycle arrest and cell death via PKC inhibition and autophagy.

P0620
Malignant lymphoma B cells induce dysfunctional cytotoxic T cells

T. Hilmenyuk, C. Riether, S. Hoepner, C. Schürch & A. F. Ochsenbein
Department of Clinical Research, University of Bern, Bern, Switzerland

Purpose/Objective: B cell Non-Hodgkin lymphoma (NHL) is the fifth most common cancer in humans. In several types of cancers, cytotoxic T lymphocytes (CTLs) are commonly found to be dysfunctional and exhausted. However, little is known about how malignant cells modulate the effector function of CTLs. Therefore, we aimed to identify and characterise the mechanism of CTL dysfunction in a murine model of NHL.
Materials and methods: To investigate CTL dysfunction, we used Eμ-Myc transgenic mice that constitutively express the myc oncogene in the immunoglobulin gene locus under the potent Igh locus enhancer (Eμ) on C57BL/6 background. These animals develop B cell lymphoma. We analysed the expression pattern of three inhibitory receptors and absolute numbers of T cell subsets. Furthermore, IFN-γ and TNF-α production from host T cells and adoptively transferred naïve $CD8^+$ TCR transgenic (p14) T cells specific for the gp-33 antigen of lymphocytic choriomeningitis virus (LCMV) in lymphoma-bearing mice were analysed after LCMV infection. The direct impact of malignant B cells on CTL proliferation, apoptosis and cytotoxicity was investigated in co-culture and transwell experiments. Finally, to characterise the soluble factor responsible for T cell dysfunction, supernatants from malignant B cells were fractionated by filter size exclusion and proliferation assays were performed.
Results: Numbers of $CD8^+$ and $CD4^+$ T cells of lymphoma-bearing mice and their ability to secrete IFN-γ and TNF-α were significantly reduced. Activation of specific p14 CTL with LCMV was impaired in lymphoma bearing mice resulting in a reduced cytokine production. The impaired CTL function could be reversed after transfer into secondary C57BL/6 recipients.

Supernatants of lymphoma B cells directly inhibited the proliferation of CTLs *in vitro*, induced apoptosis and reduced the cytokine production of CTLs. Fractionation of cell supernatants revealed that the suppressive factor is <3kDa.
Conclusions: These data demonstrate that dysfunction of CTLs in our NHL model is mediated by a soluble lipid or small metabolite of less than 3kDa secreted by lymphoma cells. Further investigation will focus on the identification of this soluble mediator involved in suppression of CTL function. Finally, these results may provide a therapeutic strategy to enhance immunogenicity against lymphoma.

P0621
MIF expression in leukemic cells

M. Georgouli & I. Athanassakis
Biology, University of Crete, Herkclion, Greece

Purpose/Objective: Invariant chain (Ii) or CD74 is a non-polymorphic glycoprotein whose initial role in antigen presentation was recognized two decades ago. Apart from its role as a chaperone dedicated to MHC-II molecules, CD74 is known to be a high-affinity receptor for Macrophage Migration Inhibitory (MIF).The aim of the present study was to define the roles of CD74 and MIF in the immunological surveillance escape process. To this direction, the leukemia cell lines HL-60, Raji, K562 as well as primary pre-B leukemic cells were used, whereas HeLa cells, lacking MHC-II molecules and Ii, were used as control cells. In order to clarify MIF's involvement in endosomal pathway, we examine along with secretion profile of MIF.
Materials and methods: Flow cytometry analysis was used to define expression of HLA-DR, CD74, HLA-DM, HLA-DO and MIF in HL-60, Raji, K562, HeLa and primary leukemic cells. Isolated mRNAs were submitted to RT-PCR experiments using CD74 specific primers. Regulation of CD74 and MIF expression by IFN-γ used as inducer was tested in K562 and HL-60 cell lines by flow cytometry analysis. The secretion of MIF in a free or exosomes-engaged form was evaluated by Elisa experiments.
Results: Flow cytometry analysis detected high levels of expression of MIF and CD74 at the membrane of all leukemic cells tested, whereas IFN-γ increased MIF expression and induced secretion of MIF in exosome-engaged forms.
Conclusions: The unexpected expression of MIF in leukemia cells and the detection of CD74 both intracellularly and membrane bound provides a novel mechanism for escape from immunological surveillance. CD74 seemed to possess a key-role in this pathway and react with MIF synergistically. Future studies determining the precise role of the CD74-MIF complex will allow understanding the involvement of MIF in the antigen presentation process.

Regulated release of ATP by Yac lymphoma cells

J. Becher, S. Nader, J. Nicola, W. Danquah, F. Koch-Nolte & F. Haag
Institute of Immunology, University Medical Centre Hamburg-Eppendorf, Hamburg, Germany

Purpose/Objective: Extracellular ATP (eATP) concentrations are elevated in many tumors. By acting on purinergic receptors, eATP and its breakdown products exert multiple effects on tumors, including the transmission of survival signals, modulating the sensitivity to chemotherapeutic drugs, and positively or negatively influencing the anti-tumor immune response. Among other receptors, eATP acts on the P2X7 receptor, which is expressed by many cells of the immune system. While accumulation of eATP was thought to result mainly from necrotic tissue damage, awareness is increasing that many cell types actively secrete ATP in a regulated fashion. We used the Yac mouse T cell lymphoma to investigate whether lymphoma cells share this ability.
Materials and methods: Intracellular and extracellular ATP concentrations were measured in a luminometer using luciferase/luciferin. Dye uptake and Erk-phosphorylation were determined by flow cytometry.
Results: We first investigated whether TCR/CD3 signalling caused ATP release. Incubation of Yac cells with anti-CD3/CD28 antibodies decreased the concentration of intracellular ATP. Concomitant activation of P2X7 augmented this effect, and typically induced cells to release more than half of their intracellular ATP content. Surprisingly, we found that activation of P2X7 caused ATP release even in the absence of TCR signalling. Yac cells responded in multiple ways to activation of P2X7, including the shedding of cell surface CD62L and the externalisation of phosphatidylserine to the outer leaflet of the cell membrane – a characteristic of cells entering a preapoptotic stage. We also detected P2X7-dependant pore formation by monitoring the uptake of fluorescent dyes. We speculated that ATP might be released through the same pores that permit dye entry. However, preliminary pharmacological evidence suggests that ATP release and dye uptake occur by separate mechanisms. Stimulation by eATP strongly induced phosphorylation of the MAP kinases Erk1/2 in Yac cells, a pathway known to transmit anti-apoptotic survival signals to the cell.
Conclusions: In conclusion, our studies show that Yac lymphoma cells actively secrete substantial amounts of ATP into the extracellular environment in response to extracellular signals, including P2X7 activation. This released ATP may amplify P2X7 signalling or act on other purinoreceptors to modulate tumor growth and the anti-tumor immune response.

P0623

Autoreactive-memory CD8+ T cells are unable to induce Type 1 diabetes

P. Thebault, S. Lesage & N. Labrecque
Maisonneuve Rosemont Hospital Research Center, Microbiology and immunology, Montreal, QC, Canada

Purpose/Objective: Autoimmune destruction of insulin-secreting beta-cells of the pancreas is responsible for the development of type 1 diabetes (T1D) and is mediated by self-reactive T cells that have escaped tolerance mechanisms. During the immune response to infectious agent, foreign antigen (Ag-specific naïve T cells undergo massive proliferation and differentiate into effector T cells that are responsible for the elimination of the pathogen. Following, Ag clearance, most of the effector T cells die while a few further (5−10%) differentiate into memory T (Tm) cells. Despite the implication of T cells in the development of T1D, few studies have investigated the role of memory T cells so far. Our goal is to evaluate the role of autoreactive Tm cells in the induction of autoimmune diabetes in a transgenic mouse model.
Materials and methods: To do this, we transferred different doses (5.10^4−3.10^6) of OT-I CD8+ Tm cells specific for ovalbulmin (OVA) in transgenic mice expressing OVA under the control of rat insulin (RIP-MOVA).
Results: Surprisingly, none of the different doses of Tm cells does not induce diabetes in recipient mice. In parallel, we observed that injection of 3.10^6 cells naïve OT-I allows the induction of diabetes. Following these results, we wanted to understand why Tm cells are unable to induce diabetes. First, we tested the localization of Tm cells transferred and we observed that these cells will migrate to the lymph pancreatic, therefore their location does not seem to be the problem. Secondly, we tested the activation of OT-I Tm cells compared to naïve OT-I cells *in vivo*. Interestingly, we observed that Tm cells are less activated than naïve T cells in pancreatic lymph nodes of RIP-mOVA, suggesting that Tm cells are more sensitive to the regulation by regulatory T cells than naïve T cells.
Conclusions: This comparative study of the functionality of two types of T cells in the context of diabetes could provide a better understanding of the mechanisms regulating the response of memory T cells.

P0624

CD4 memory T cells are resistant to the induction of tolerance *in vivo* despite poor survival following reactivation

M. MacLeod,* A. David,† F. Crawford,† P. Garside,‡ J. Kappler† & P. Marrack†
**Glasgow University, Institute of Infection Immunity and Inflammation, Glasgow, UK, †National Jewish Health, Howard Hughes Medical Institute and the Integrated Department of Immunology, Denver, CO, USA, ‡Institute of Infection Immunity and Inflammation, University of Glasgow, Glasgow, UK*

Purpose/Objective: Autoimmune diseases, such as rheumatoid arthritis, occur when an individual's immune system responds to their own organs, causing tissue damage and inflammation. A greater understanding of how to control the immune cells that can drive autoimmunity will provide the means to design targeted and rational therapeutics. Autoimmune diseases are, in the main, diagnosed following initiation of the disease. Any therapy that aims to tolerise autoreactive T cells must, therefore, target activated and memory cells rather than naïve T cells. Memory T cells can respond to low doses of antigen and costimulation, potentially allowing them to be activated by signals that successfully tolerise naïve T cells. While much is known about the means and mechanisms of tolerance in naïve CD4 T cells, there is little appreciation of whether and how memory CD4 T cells respond to tolerisation signals.
Materials and methods: We have used MHC class II tetramers and *in vivo* readouts of T cell effector functions to track and analyse the responses of endogenous CD4 T cells exposed to tolerisation signals *in vivo*.
Results: Antigen specific memory CD4 T cells proliferate in response to, and survive following, exposure to soluble peptide delivered in the absence of adjuvant. The subsequently generated memory cells express normal levels of chemokine and cytokine receptors such as CXCR5, CCR7 and CD127, suggesting that their migration and survival are unaltered by the tolerisation signal. Upon further activation *in vivo*, these memory cells divide normal but have a reduced ability to survive with increased caspase activation and reduced levels of Bcl2. Importantly, memory cells that have received a tolerisation signal are still able to provide an accelerated helper response for B cells resulting in the generation of antigen specific class switched antibody early in the response.
Conclusions: Memory cells respond to and re-enter the memory pool following exposure to a classical tolerisation signal. However, while these cells are not tolerant in terms of their proliferative or helper responses, their survival is limited following reactivation, suggesting a disconnect between T cell activation and survival.

P0625

CD69 and CD49b regulate the establishment and maintenance of T helper cell memory

K. Tokoyoda,* A. Hanazawa,† K. Shinoda,† A. Radbruch* & T. Nakayama†
**German Rheumatism Research Centre Berlin, Leibniz institute, Berlin, Germany, †Chiba University, Immunology, Chiba, Japan*

Purpose/Objective: Memory CD4 T cells play a key role in immunological memory. We have demonstrated that professional memory CD4 T cells reside and rest in the bone marrow (BM) adhering IL-7-expressing stromal niches. However, the cellular and molecular mechanisms of their establishment and maintenance in the BM remain unclear. We here show how effector CD4 T cells transmigrate to the BM and memory CD4 T cells adhere to their survival niches, mediated by CD69 and CD49b.
Materials and methods: To clarify the roles of CD69 and CD49b in the generation and maintenance of memory CD4 T cells in the BM, we transferred CD69 or CD49b-deficient or -blocked effector CD4 T cells into normal mice and evaluated their migaration ability to the BM, as well as the phenotypic or functional analyses of CD69 or CD49b-deficient CD4 T cells. Moreover, to understand the cellular mechanisms for establishment of memory cells in the BM, we performed the localization analyses of CD4 T cells in the effector or memory phase of an immune response.
Results: The loss or inhibition of CD69 or CD49b induced the defective migration of memory precursors into the BM. The inhibition of CD49b also reduced memory CD4 T cell numbers. Also, the localization analyses clarified the cell dynamics of memory precursors through CD69 and CD49b in the BM.
Conclusions: We here show that CD69 and CD49b regulate the establishment of memory CD4 T cells in the BM and also that CD49b supports the maintenance of memory cells. Furthermore, to mature into memory cells, memory precursors have to transmigrate into sinusoids and move onto survival niches for memory cells in the marrow of bones using CD69 and CD49b.

Demethylation at the IFNG gene promoter and CNS-1 correlates with cytokine memory for IFN-gamma in human CD4+ T lymphocytes

J. Dong,* H. D. Chang,* C. Ivascu,† Y. Qian,‡ S. Rezai,§ A. Okhrimenko,* F. Annunziato,¶ A. Radbruch* & A. Thiel**
*German Rheumatism Research Centre Berlin, Cell Biology, Berlin, Germany, †Epigenomics AG, Biomarker Services, Berlin, Germany, ‡Berlin-Brandenburg Regenerative Center for Therapies, Regenerative Immunology and Aging, Berlin, Germany, §Sapienza Università di Roma, Dipartimento di Clinica e Terapia Medica Applicata Sezione di Reumatologia, Rome, Italy, ¶Center of Research Transfer High Education DENOTHE, University of Florence, Firenze, Italy, **Berlin-Brandenburg Regenerative Center for Therapies Berlin, Regenerative Immunology and Aging, Berlin, Germany*

Purpose/Objective: Cytokine memory for IFN-gamma by effector/memory Th1 cells plays a key role in both protective and pathological immune responses. To understand the epigenetic mechanism determining the ontogeny of effector/memory Th1 cells characterized by stable effector functions, we analyzed DNA methylation changes in the *IFNG* gene during Th1 differentiation of naïve human $CD4^+$ T cells, and we investigated how and at which stage these cells develope cytokine memory for IFN-gamma.
Materials and methods: *Ex vivo* $CD4^+$ and $CD8^+$ T cell subsets and NK cell subsets were isolated from healthy donors. For Th1 differentiation, naïve $CD4^+$ T cells were primed under Th1 conditions with allogenic monocyte-derived DCs or anti-CD3/CD28. *Ex vivo* or differented IFN-gamma-producing Th cells were isolated using cytokine capture assay and FACS. For *IFNG* reactivation, cells were stimulated with PMA/iono, fixed, permeablized and stained for intracellular IFN-gamma. DNA methylation analyses were performed using bisulfate-specific PCR sequencing, clone sequencing, and pyrosequencing. Cell cycle status was assessed by BrdU incorporation.
Results: We identified a T cell-specific methylation pattern at the promoter and CNS-1 of *IFNG* in *ex vivo* effector/memory Th1 cells. During Th1 differentiation, demethylation occurred at these two regions independently of cell proliferation and DNA synthesis. Early IFN-gamma-producers acquired 'permissive' levels of demethylation and developed into effector/memory cells undergoing progressive demethylation at these regions when induced by IL-12. Methylation levels of the promoter and CNS-1 in memory $CD4^+$ T cells of peripheral blood in RA patients correlated inversely with reduced frequencies of IFNG-gamma-producers, coincident with recruitment of effector/memory Th1 cellls to the site of inflammation.
Conclusions: TCR signaling and Th1 instructive signals induce dynamic demethylation of *IFNG* and the latter further stablizes *IFNG* expression during the transition from effector to effector/memory Th1 cells. Analyzing methylation status of *IFNG* may serve as a novel method for evaluating the distribution and/or re-distribution of effector/memory Th1 cells.

P0627

Differences in CD_4 and CD8 memory T-cell populations in Dutch children after vaccination with various pertussis vaccines

L. de Rond,* R. M. Schure,* K. Öztürk,* I. van Twillert,* M. Carollo,† F. Mascart,‡ C. Ausiello,† K. Smits,‡ C. van Els* & A. M. Buisman*
National Institute for Public Health and the Environment, Centre for Infectious Disease Control Netherlands, Bilthoven, The Netherlands, †Department of Infectious Parasitic and Immune-mediated Diseases, Instituto Superiore di Sanità, Rome, Italy, ‡Université Libre de Bruxelles, Laboratory for Vaccinology and Mucosal Immunity, Brussels, Belgium

Purpose/Objective: Whooping cough remains a worldwide problem despite vaccination. Since cellular immunity plays a role in long-term protection, we studied pertussis-specific T-cell responses. We compared T-cell memory responses in 4-years old children, who have been primed during infancy with either the whole cell pertussis (wP)- or the acellular pertussis (aP) vaccineand have been boosted with an aP vaccine at 4 years of age.
Materials and methods: PBMCs were isolated from 4-year old children and stimulated with the pertussis-vaccine antigens for 5 days. T-cells were phenotypically characterized by cell-staining for CFSE, CD4, CD3, CD45RA, CCR7, IFN-γ, TNF-α and dead cell discrimination. Cytokine responses were determined in culture supernatants by using fluorescent bead-based immunoassays.
Results: Three years after vaccination, at 4 years of age, T-cell cytokine responses were persistently high and T-cell proliferation ($CFSE^{dim}$) had increased in aP- compared to wP-vaccinated children. Pertussis-specific CD4 central memory T-cells ($CCR7^+$ $CD45RA^-$) were elevated just slightly, whereas clearly more effector memory cells ($CCR7^-CD45RA^-$) were induced in aP-vaccinated children compared to those vaccinated with wP. Upon stimulation with pertussis antigens CD8 T-cells reacted in a similar way as CD4 T-cells, except that about 15% exhausted T-cells were present in all samples. After a preschool aP booster vaccination, both T-cell effector memory CD4 and CD8 T-cells were enhanced in wP-vaccinated children, but not in aP vaccinated children.
Conclusions: Infant vaccinations with four high-dose aP vaccines result in high pertussis-specific CD4 and CD8 Tcell responses that persist in children until 4 years of age. After a preschool booster the already high T cell responses in aP vaccinated children did not increase in contrast to wP vaccinated children. Therefore, studies into changes in vaccine dosage and timing of aP pertussis (booster) vaccinations are needed.

P0628

Different populations of influenza antigen presenting cells in lungs regulate the proliferation and cytokine patterns of influenza specific memory T cells

K. O. Grönvik & R. Feinstein
National Veterinary Institute (SVA), Virology Immunobiology and Parasitology, Uppsala, Sweden

Purpose/Objective: To study phenotype, function and localization of influenza virus antigen presenting cells and virus specific memory T cells.
Materials and methods: Balb/c and C57BL/6 mice were infected intranasally with 10^4 $TCID_{50}$ of H_1N_1 PR8 influenza virus strain and 3 months later by a secondary infection via the same route with a 100 times higher dose of homologous influenza virus. At 3–6 months post last infection the mice were sacrificed and T cells were isolated from lymphoid organs and lungs. Influenza infected antigen presenting cells, APCs, were obtained from lymphoid organs and lungs of syngeneic mice infected intranasally for 36 h with 10^6 $TCID_{50}$ of H_1N_1 PR8 influenza virus. Viral RNA in organs was detected by RT-PCR analysis. Cells were purified by immunoaffinity with MiniMacs or with flow cytometry and responding T cells from influenza memory mice were co-cultured *in vitro* with different populations of influenza infected APCs.
Results: At 36 h post infection PCR analysis showed viral RNA in the lungs and in mediastinal lymph nodes but not in spleen or in inguinal lymph nodes. Intranasal challenge of memory mice with influenza virus rapidly induced IFN-γ containing memory T cells in lungs and spleen. Stimulation with influenza infected lymphoid APCs resulted in poor proliferation and cytokine production of the T cells *in vitro*. Dendritic cells and granulocytes in the lung down regulated proliferation of memory $CD4^+$ T helper cell *in vitro* while retaining a high production of pro-inflammatory IFN-γ and IL-17. The inhibited proliferation was enhanced by removal of $CD4^+$ $CD25^+$ regulatory T

cells from the responding $CD4^+$T cells. Furthermore influenza infected APCs in the lung promoted a strong $CD4^+$ T helper cell independent immune response of influenza specific $CD8^+$ memory T cells *in vitro*..
Conclusions: Intranasal infection of mice with influenza virus induces $CD4^+$ $CD25^+$ regulatory T cells and localizes different populations of influenza infected APCs in the lungs and its regional lymph nodes that can regulate the immune response of influenza specific memory T cells differently *in vitro*.

P0629
Effects of doxorubicin on bone marrow stroma and survival of long-lived plasma cells

H. Ingelman-Sundberg,* C. Ritzmo,† S. Eksborg† & A. Nilsson*
**Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, †Karolinska University Hospital, Child Cancer Research Unit, Stockholm, Sweden*

Purpose/Objective: Children treated with chemotherapy for leukemia loose antibodies they acquired from the childhood vaccination program, and the number of bone marrow plasma cells, crucial for maintenance of protective titers, is diminished. In addition, re-immunization is impaired at least up to a year after cessation of therapy. The bone marrow stroma is pivotal for homing and long-term survival of plasma cells, and consequently for vaccination memory. We hypothesize that cytotoxic drugs disrupt the plasma cell survival niche, due to stromal cell death and reduced production of cytokines, leading to impaired ability to support plasma cell homing and survival, and insufficient long-term antibody titers after vaccination.
Materials and methods: The commonly used chemotherapeutic agent Doxorubicin was used as model drug. The human derived stromal cell lines HS-5 and HS-27 were exposed to the same concentration of Doxorubicin as in plasma of pediatric ALL patients. Plasma cells were differentiated *in vitro* using peripheral blood from healthy donors.
Results: Semi-quantitative measurement showed significant uptake in the nuclei, and impairment of production of the known survival factors Interleukin-6, CXCL-12 and B-cell activating factor (BAFF) has been found. Preliminary data imply that stromal cell lines are able to increase plasma cell secretion of IgG, and further investigation will reveal weather the negative effects of Doxorubicin on stromal cells interfere with this ability.
Conclusions: We hope that our results will add important clues to how cytotoxic treatment can have long-term effects on immunity, and consequently why vaccination is not always possible after leukemia treatment.

P0630
Human memory B cell response and its age-dependence after tick-borne encephalitis virus vaccination

J. Aberle,* K. Stiasny,* M. Kundi† & F. X. Heinz†
**Department of Virology, Medical University of Vienna, Vienna, Austria, †Medical University of Vienna, Center for Public health, Vienna, Austria*

Purpose/Objective: The ability of the immune system to respond to antigenic stimulation decreases with advanced age which leads to reduced protective effects of vaccination and increased morbidity due to infectious diseases. To date, there is little information about the frequency and functional integrity of memory B cells generated during old age.

We have conducted a prospective analysis of the quantities and functionalities of antigen-specific B cell responses and its association with the functional helper $CD4^+$T cell responses. The ability of naïve B cells from old and young humans to establish functional memory was examined following primary and booster vaccination with an inactivated-virus vaccine against tick-borne encephalitis.
Materials and methods: For this purpose, we quantified TBEV-specific IgG, neutralizing antibody titers and TBEV-specific memory B cells using an ELISA-based limiting dilution analysis in 12 young (20−31 years) and 21 older (60−80 years) healthy individuals.
Results: Our data show that the number of antigen-specific memory B cells generated during primary vaccination was ~3-fold lower in old than in young individuals. The maintenance and booster responsiveness of these memory B cells was not compromised, as evidenced by similar increases in specific memory B cell frequencies upon revaccination in old and young vaccinees. In contrast, the Ab response mediated per memory B cell after revaccination was dramatically diminished in the elderly. Also, antigen-specific IL-2-positive $CD4^+$T cell responses were strongly reduced in the elderly and displayed an excellent correlation with Ab titers.
Conclusions: The data suggest that the dramatically lower antibody response in the elderly could only partially be accounted for by the reduced B cell numbers and was strongly correlated with profound functional defects in CD4 help.

P0631
Identification of resting bone marrow memory T cells in humans

J. Dong, A. Okhrimenko, A. Serra, K. Westendorf, O. Sercan, M. McGrath, H. D. Chang & A. Radbruch
**German Rheumatism Research Centre Berlin, Cell Biology, Berlin, Germany*

Purpose/Objective: Memory T cells play a critical role in immunological memory responses, in that they mediate more effective protection during pathogen rechallenge. We have previously shown that murine memory $CD4^+$ T cells characterized by expression of Ly-6C preferentially reside and rest in the bone marrow (BM). Here we aimed to address whether human resting memory T cells also reside and rest in the BM, and we dissect the functional properties of memory T cells isolated from the BM and the periphery.
Materials and methods: Mononuclear cells were isolated from paired blood and BM samples from healthy individuals. Phenotypic analysis and cytokine profile of distinct memory T-cell subets were assessed by flow cytometry. Proliferation and cell cycle status were analyzed using Ki-67 and PI staining, respectively. Signature molecules for resting memory T cells and signaling pathways required for the maintenance of bone marrow memory T cells will be identified by transcriptome analysis. Antigen specificity will be assessed by activation of memory T-cell subsets with a panel of antigens of interest. Mobilization of antigen-specific memory T cells to the periphery will be performed by systemic re-immunisation of healthy donors with tetanus toxoid.
Results: Distinct CD69-expressing $CD8^+$ $CD45RA^-$ and $CD4^+$ $CD45RA^-$ T cells can be detected in the bone marrow but not in the peripheral blood. CCR7 expression was decreased on bone marrow $CD69^+$ $CD4^+$ $CD45RA^-$ and $CD69^+$ $CD8^+$ $CD45RA^-$ T-cells. Ki-67 staining indicated that T cells from the bone marrow proliferated less than those from the peripheral blood.
Conclusions: In steady state, human bone marrow consists of CD69-expressing $CD8^+$ $CD45RA^-$ and $CD4^+$ $CD45RA^-$ T cells. Compared to peripheral memory-phenotype T cells, bone marrow memory-phenotype T cells reduce their homing capacity to the secondary lymphoid organs by downregulating CCR7 expression, and rest in terms of proliferation. Future work will identify signature molecules for resting memory T cells and their functional properties.

P0634

The role of CMV in development of the human T cell memory repertoire and the influence of co-infection with EBV

A. Pachnio, J. Begum, E. Perks, A. Leese, R. Abbott, A. Rickinson & P. Moss

School of Cancer Sciences, University of Birmingham, Birmingham, UK

Purpose/Objective: 70% of people acquire cytomegalovirus (CMV)-infection by adulthood. Usually asymptomatic it can cause severe complications in immune suppressed. The virus establishes latency with episodes of reactivation. In healthy donors the immune system controls this, but a large proportion of the T cell compartment is dedicated to CMV and virus specific T cells accumulate leading to impaired control of other infections. The aim of this study was to investigate changes CMV-infection induces in the T cell repertoire of young healthy donors, how stable the immune response against this virus is over time and how it is influenced by co-infection with other viruses e.g. Epstein-Barr virus (EBV). For this purpose we started a large prospective study of a student cohort.

Materials and methods: Blood samples were taken at time of entry into medical school and yearly thereafter, Plasma and PBMCs were isolated and cryostored. Serostatus for CMV and EBV was determined by ELISA or VCA-test. Using multicolour flow cytometry the overall T-cell repertoire, frequencies and phenotype of virus specific T-cells were analysed. EBV viral load in PBMC was determined by qPCR.

Results: Four donor groups were identified: CMV^-/EBV^- (17%), CMV-/EBV+ (44%), CMV+/EBV^- (10%) and CMV+/EBV+ (29%). The group with dual infection showed a marked reduction in the CD4:CD8 T cell ratio. Comparing the overall T cell repertoire no differences were seen between virus naïve donors and those infected with EBV only. Single infection with CMV caused profound changes in both CD4 and CD8 T cell repertoire. A large reduction in the expression of costimulatory molecules CD27 and CD28 * 15% and 5% on CD4+, 25% and 17% on CD8+ T cells and homing marker CD62L (16% for CD4+ and 18% for CD8+ T cells) was observed, also a marked increase in the frequency of differentiated CD57+ T cells. Concerning memory T cell subsests CMV infection induced a significant reduction in the frequency of naïve T cells and a marked increase of effector memory cells. These changes were less pronounced in CMV+/EBV+ individuals. Frequencies of EBV-specific T cells were lower in those who are co-infected with CMV.

Conclusions: Already at a young age CMV infection shapes the immune repertoire dramatically. Changes seem to be more pronounced in individuals that were infected with CMV only compared to those who were co-infected with EBV.

Poster Session: NKT and γ T Cells

P0636
$CD56^+$ $CD3^+$ T cells in relation to infection in normal subjects and kidney transplant patients

M. Almehmadi,* A. Hammad,† S. Howarth,† B. R. Flangan‡ & S. T. Christmas‡
*I G H, University of Liverpool, Liverpool, UK, †Transplant Unit, The Royal Liverpool University Hospital, liverpool, UK, ‡CIMI, University of Liverpool, Liverpool, UK

Purpose/Objective: $CD3^+$ $CD56^+$ cells are a small subset of T cells of unknown function but with cytotoxic capacity following activation *in vitro*. In preliminary work we found that levels were higher in normal subjects positive for cytomegalovirus (CMV) than in CMV- subjects. Kidney transplant patients are particularly prone to reactivation of CMV infection which as well as causing acute disease may play a role in triggering the rejection process. Aims; This work aims to study $CD3^+$ $CD56^+$ T cells and their response to CMV and other pathogens, and their possible role in triggering the immune system toward the transplanted organ.
Materials and methods: Phenotypic studies of several markers of $CD56^+$ $CD3^+$ in normal CMV^+ and CMV- subjects were done to investigate the lineage of these cells by FACS analysis and whether they are increased in CMV infection. Any differences in numbers, phenotype or function in transplant patients with or without CMV infection were analysed.
Results: as have been found in our preliminary study, $CD3^+$ $CD56^+$ are higher in CMV^+ in both healthy and patients PBMC than CMV-. Moreover, CD62L, CD161 and CD28 are higher in CMV- healthy and patients PBMC than CMV^+ healthy and patientsPBMC. CD161 is known to be an inhibitory function in NK cells which may also serve the same role in NKT cells. CD62L is a memory and effector marker found in naïve cells, and their low expression on NKT indicates previous stimulation of these cells. On other hand, the costimulatory molecule CD28 is less in CMV^+ than CMV- which could be lost after these cells being activated.
Conclusions: Conclusion and results are written on the Results Box

P0638
Column-free isolation of untouched human gamma-delta T cells from PBMC in 45 min

N. Tabatabaei-Zavareh, T. A. Le Fevre, T. E. Thomas & M. A. Fairhurst
Research and Development, STEMCELL Technologies Inc., Vancouver, BC, Canada

Purpose/Objective: T cells expressing the γδ T cell receptor (γδ TCR) make up a minor subset of human circulating T cells (1–10%). γδ T cells are distinct from αβ T cells in that they exhibit limited combinatorial diversity of the TCR and recognize non-peptide antigens independent of HLA molecules. γδ T cells exert innate effector functions including rapid release of cytokines and killing of target cells without prior antigen exposure. Adaptive immune responses such as memory functions have also been attributed to γδ T cells. Typically, elaborate purification protocols such as FACS-based cell sorting or expansion in culture are needed to obtain enough γδ T cells for subsequent studies. Here, we describe an immunomagnetic, column-free negative selection method (EasySep™) to isolate untouched γδ T cells from fresh or previously frozen peripheral blood mononuclear cells (PBMC).
Materials and methods: Briefly, non-γδ T cells are labeled and cross-linked to dextran-coated magnetic particles using bispecific tetrameric antibody complexes. γδ T cells were then separated from unwanted labeled cells by placing the tube in an EasySep™ magnet and pouring off unlabeled cells into a new tube. The enrichment procedure may also be performed using the automated cell separator, RoboSep™. Functionality of the enriched cells was tested by evaluation of cytokine production in response to aminobisphosphonate (zoledronate) pretreated monocytes.
Results: Starting with 3 ± 2% $CD3^+$ γδTCR^+ T cells in PBMC, purities of 94 ± 3% (n = 20) were achieved using EasySep™. Similar purities were observed using RoboSep™. The isolated γδ T cells produced interferon-gamma (IFN-γ) when activated with zoledronate-pretreated monocytes.
Conclusions: γδ T cells have potential therapeutic applications in cancer and infectious diseases. This rapid method for the isolation of γδ T cells will assist in the study of γδ T cell biology and the development of γδ T cell-based immunotherapies.

P0639
Direct Identification of Rat iNKT Cells Reveals Remarkable Similarities to Human iNKT Cells and a profound deficiency in LEW Rats

T. Herrmann,* D. Paletta,* L. Starick,* I. Müller,* D. B. Sant'Angelo,† E. Pyz* & E. Monzon-Casanova*
Medicine, Institute for Virology and Immunobiology, Würzburg, Germany, †Department of Pediatrics, Child Health Institute of New Jersey, New Brunswick, NJ, USA

Purpose/Objective: Human iNKT cells differ from that of mice in terms of frequency (about 0.5% of intrahepatic T cells compared to 50% in C57BL/6 mice), surface phenotype (some CD8aa positive in humans but not in mouse) and *in vitro* expandability (very easy in humans but not in mouse). iNKT cells of rats, which serve as model for many human diseases, have not yet been directly identified, although genetic as well as functional studies (CD1d dependent a-GalCer response) have indicated their existence. Aim of this study is phenotypical and functional characterization of rat iNKT cells.
Materials and methods: First generation of rat CD1d dimers which allow direct rat iNKT cell identification. Identification of *AV14AJ18* rearrangements of different *AV14* genes (type I versus Type II) by sequencing of RT-PCR products in different organs. Phenotypical rat iNKT cells by immuno-flow cytometry including intracellular PLZF staining and and functional characterization by cytokine assays.
Results: RatCD1d dimers were found to be mandatory for direct identification of iNKT cells in the rat and allowed first time identification of these cells. Rat iNKT cells expressed PLZF and were CD4 positive, double negative and to a very low frequency CD8aa positive. Cells were found to produce IL-4 and IFNg by intracellular staining, ELISPOT and ELISA. The surface phenotype and the very low frequency of iNKT cells(1.05% ±0.52 (SD) of all intrahepatic T cells) found in F344 rats resembled features of human iNKT cells. F344 rat iNKT cells resembled human iNKT cells also in their robust *in vitro* expansion. In contrast, in LEW inbred rats, which are often used as model for organ-specific autoimmune diseases, iNKT cells were near or below the detection limit. Interestingly, the usage of members of the rat *AV14* gene family differed between F344 and LEW inbred rats. Differences in the CD1d binding properties of several members of this gene family are currently analyzed *in vitro*.
Conclusions: The resemblance of F344 inbred rat iNKT cells to human iNKT cells and the availability of the iNKT cell-deficient LEW rat strain makes the rat a promising animal model for the study of iNKT cell-based therapies and of iNKT cell biology.

P0640

Evolution of Vg9Vd2 T cells

M. M. Karunakaran,* L. Starick,* T. W. Goebel† & T. Herrmann*
**Institute for Virology and Immunobiology, Medicine, Würzburg, Germany,* †*Department of Veterinary Sciences, University of Munich Institute for Animal Physiology, Munich, Germany*

Purpose/Objective: The hallmark of Vgamma9Vdelta2 (Vγ9Vδ2) T cells is expression of Vγ9JP and Vδ2 containing TCR chain with reactivity for pyrophosphate containing metabolites (phosphoantigens) of host and microbial isoprenoid synthesis such as IPP and HMBPP. Rodents lack Vγ9 and Vδ2 like genes and so far it is generally perceived that phosphoantigen-recognizing Vγ9Vδ2 T cells are restricted to higher primates. Aim of this study is to test for existence of Vγ9Vδ2 T cells and phosphoantigen-reactivity in other mammalian taxa and to use this knowledge for analysis of molecular basis of antigen recognition by Vγ9Vδ2 T cells and their phosphoantigen-mediated activation.
Materials and methods: RNA extracted from PBMCs of alpaca and horse lymphocytes were used for cDNA synthesis, which was later used for Reverse transcriptase PCR. BovineMacrophage Cell line (BoMac) was used as the source of genomic DNA. Genomic DNA and cDNA was used for amplification of Vγ9 and Vδ2 like genes and PCR products were cloned into TA vector and analyzed by sequencing.
Results: Analysis of public data bases revealed fragments of Vγ9 and Vδ2 like genes in all eutherian subgroups (Afrotheria, Xenarthra, Euarchontoglires and Laurasiatheria) suggesting common emergence of Vγ9 and Vδ2 genes and placental mammals. So far we identified full length Vγ9 and Vδ2 like sequences including RSS in six species namely, 1.Horse 2.Cow 3.Alpaca 4.Sloth 5.Bottlenose dolphin 6.Grey mouse lemur. The first three were further analyzed by (RT)-PCR and sequencing. Horse and cow genome showed Ig domain disrupting mutations and stop codons, respectively. But RT-PCR of alpaca (*vicugna pacos*) blood mononuclear cells revealed Vγ9JP and Vδ2 comprising rearrangements spliced to the respective C domains. This suggests the capacity to express Vγ9Vδ2 TCR. Analysis of alpaca blood cells for phosphoantigen-reactivity and attempts to clone, express and analyze function of the presumed alpaca Vγ9Vδ2 TCRs are in progress as well as analysis of co-evolution with members of the buytrophilin-family.
Conclusions: Vγ9 and Vδ2 TCR emerged with eutherian evolution. Analysis of in frame Vγ9JP and Vδ2 containing TCR-chains suggests existence of functional Vγ9Vδ2 T cells in alpaca – a new world camelid – and offers the opportunity to study function and evolution of this cell population.

P0641

HLA class I molecules in tumor B cells: stress antigens for Vdelta3 gamma-delta TCR?

R. Marlin,* S. Netzer,* V. Pitard,* S. Daburon,* C. Harly,* J. F. Moreau,† J. L. Taupin† & J. Dechanet-Merville*
**Immunology, CNRS UMR 5164, Bordeaux, France,* †*Immunology and Immunogenetic Laboratory C. H. U., CNRS UMR 5164, Bordeaux, France*

Purpose/Objective: Non-Vδ2 $\gamma\delta$ T cells represent the vast majority of $\gamma\delta$ T cells in epitheliums and tissues. These subsets show high TCR diversity, and most of the antigenic ligands of non-Vδ2 $\gamma\delta$ TCR remained unidentified. Our previous studies evidenced an expansion of non-Vδ2 $\gamma\delta$ T cells in Cytomegalovirus (HCMV) infected individuals. $\gamma\delta$ T cell clones isolated from these patients show dual reactivity against tumor cell lines and HCMV infected cells suggesting recognition of stress self antigens. The aim of this study was to identify antigens recognized by Vδ3 $\gamma\delta$ T cells.
Materials and methods: In order to determine the cell targets expressing antigenic ligands of Vδ3 $\gamma\delta$ TCR, we generated Vγ9Vδ3 TCR transductants derived from an HCMV-reactive $\gamma\delta$ T cell clone. Target cell lines were co-cultured with Vγ9Vδ3 TCR transductants or the original clone and TCR activation was measured by flow cytometry using CD69 / CD107a markers. Highest activating cells were used to immunize mice and hybridomas supernatants were screened for blocking Vγ9Vδ3 TCR activation. Analyses were performed using selected antibodies to identify antigens recognized by the TCR.
Results: Among 50 tumor cell lines tested, only three $CD20^+$ /$CD38^+$ tumor B cell lines specifically activated Vγ9Vδ3 TCR transductants. Several mAbs (LSM-01 to 06) abrogating the anti-B cell reactivity of Vγ9Vδ3 TCR transductants and original clone were generated. They ubiquitously stained different cell lines except HLA class I-deficient ones. Recognition of HLA-I by LSM mAbs was confirmed by immunoprecipitation experiments, and their reactivity towards HLA class I alleles established using HLA-typing Luminex technology. Alignments of HLA sequences revealed a shared epitope for all LSM mAbs in the α-2 domain of HLA-I proteins. The silencing of β-2-microglobulin in B cell targets abrogated Vγ9Vδ3 TCR reactivity. Interestingly, original clone expressed HLA-inhibitory receptors suggesting a regulation of TCR signal in physiologic context. Blocking these receptors dramatically increased the Vγ9Vδ3 $\gamma\delta$ T clone reactivity against B cell targets.
Conclusions: Taken as a whole, our results identify HLA-I molecules as potential stress antigens recognized by a Vγ9Vδ3 TCR. Dual reactive clones and the TCR they express constitute interesting tools to identify stress antigens of $\gamma\delta$ TCRs, which is critical to consider $\gamma\delta$ T cell activation for therapy purposes.

P0642

IL-17 production by gamma delta T cells contributes to the clearance of persistent bacterial renal infection

S. Teteris & C. Kurts
Institutes of Molecular Medicine and Experimental Immunology, Rheinische Friedrich Wilhelms University, Bonn, Germany

Purpose/Objective: The innate immune system and particularly polymorphonuclear neutrophilic granulocytes (PMNs) are the first responders to, and are responsible for, the clearance of bacterial infections. IL-17 has been established as one of the key cytokines in pathways of PMN recruitment and activation. In addition to the well-known Th17 cells, another major producer of IL-17 are the innate-like leukocyte gamma delta ($\gamma\delta$) T cells. Here we investigate the role played by $\gamma\delta$ T cells in the clearance of renal bacterial infections in pyelonephritis.
Materials and methods: The clinical uropathogenic *E. coli* isolate 536 (UPEC 536) was instilled into the bladder of anaesthetised C57Bl/6 mice using a catheter. Mice were infected again 3 h later to induce an ascending renal infection. Kidneys were excised and digested with DNAse/Collagenase and the inflammatory infiltrate analysed by flow cytometry. The level of kidney infection was determined by plating dilutions of the renal digest onto CPS ID plates and counting colonies.
Results: Kidney infection with *E. coli* was maximal 3 h after the second infection, with the numbers of *E. coli* present dropping 1000-fold over the following 72 h. Infiltration of the renal tissue by PMNs peaked at day 2 post-infection and decreased sharply as the bacteria were cleared. However, PMN numbers rose again if the bacteria were not cleared and a chronic infection was established. Notably although $\gamma\delta$ T cells were extremely rare in the normal kidney, their numbers increased significantly from fourfold at 72 h post-infection up to 12-fold at day 7 post-infection. Furthermore the numbers of $\gamma\delta$ T cells remained slightly elevated in mice that had cleared the infection as compared to healthy mice. When the cytokine profile of the $\gamma\delta$ T cells was investigated they produced IL-17 rather than IFNγ (27.3% versus 2.4% respectively). Additionally $\gamma\delta$ T cells predominately produced IL-

17A alone (17.6%) rather than IL-17A and IL-17F (3.9%) or IL-17F alone (4.4%).
Conclusions: Bacterial renal infection or pyelonephritis induces the infiltration of $\gamma\delta$ T cells into the renal parenchyma where they express IL-17A. The expression of IL-17 by $\gamma\delta$ T cells later in renal infection may be responsible for amplification of the innate immune response, enabling optimal recruitment and activation of PMNs and clearance of persistent renal infections.

P0644
Implication of gamma delta T cells in the immune response against murine CMV

M. Capone, S. Netzer, A. Villacreces, M. Juzan, V. Praloran, J. F. Moreau & J. Dechanet-Merville
CNRS, immunology, Bordeaux, France

Purpose/Objective: We previously showed that $\gamma\delta$ T cells participate to CMV riddance in humans: 1- CMV-infection is associated with activation and expansion of circulating $\gamma\delta$ T cells, 2- CMV-induced $\gamma\delta$ T cells control CMV multiplication through Interferon γ release *in vitro* and 3- $\gamma\delta$ T cell expansion is concomitant to the resolution of viremia in immune-compromised individuals. Further understanding of $\gamma\delta$ T cell-mediated control of CMV requires the development of a reliable animal model. The aim of the present study was then to determine whether murine $\gamma\delta$ T cells are involved in the control of mouse CMV (MCMV).
Materials and methods: C57BL/6 mice deficient for $\gamma\delta$ and/or $\alpha\beta$ T cells were infected with MCMV in order to compare their sensitivity towards MCMV as well as the viral load in different organs.
Results: We showed that whichever subpopulation is sufficient to confer protection of mice against MCMV. DNA copy numbers of MCMV increased substantially with time in all organs tested from CD3$\varepsilon^{-/-}$ infected mice until they died. At that time however, viral loads were much lower in TCR$\alpha^{-/-}$ mice when compared to CD3$\varepsilon^{-/-}$ mice. Finally, reconstitution of $\gamma\delta$ T-cell development in CD3$\varepsilon^{-/-}$ mice using bone marrows from TCR$\alpha^{-/-}$ mice confers protection against MCMV.
Conclusions: Altogether these results indicate that murine $\gamma\delta$ T cells are involved in the control of MCMV uncovering an interesting model to dissect the anti-viral functions of this enigmatic unconventional T cells. They also suggest that $\gamma\delta$ T cells could compensate for the absence of $\alpha\beta$ T cells in the fight against CMV, a property that could be of particular relevance in immune-suppressive contexts where $\alpha\beta$ T cells are more specifically compromised.

P0645
iNKT cell crosstalk with dendritic cells in the splenic marginal zone drives CCL17 production in a STAT6-dependent manner

V. Semmling,* I. L. King,† M. Tighe,† K. Mohrs,† N. Veerapen,‡ G. Besra,‡ C. Kurts,* M. Mohrs† & E. A. Leadbetter†
**Institutes of molecular Medicine and experimental Immunology, University Hospital, Bonn, Germany, †Department of Immunology Trudeau Institute, Saranac Lake, NY, USA, ‡Immunology, University of Birmingham, Birmingham, UK*

Purpose/Objective: CD8$^+$ T cell activation is a tightly regulated process that requires a range of signals provided by mature dendritic cells (DCs). For DCs to be able to provide these stimulatory signals, they first need to be activated in a process called DC licensing, which can be performed by invariant NKT (iNKT) cells. Chemokines and their receptors seem to be important mediators of the cellular interactions required for cognate help. We could previously show, that induction of the chemokine CCL17 is a part of NKT cell-mediated DC licensing, but how iNKT cells mediate this event *in situ* remains elusive.
Materials and methods: CCL17 expression was analysed by flow cytometry and qRT-PCR. iNKT cell visualization was performed by a confocal imaging approach using CD1d tetramers to identify the location of endogenous iNKT cells *in situ*.
Results: We now show that DC-derived CCL17 is induced by NKT cell-derived IL-4 in a STAT6-dependent manner. Using a new method to unambiguously localize the endogenous splenic iNKT cell population, we demonstrate that upon administration of microbial and synthetic glycolipid antigens, iNKT cells rapidly accumulate in the splenic marginal zone where they produce IL-4 in a highly compartmentalized fashion. iNKT cell activation requires marginal zone DCs and acts reciprocally to upregulate CCR7 and mobilize this antigen-presenting subset to the splenic T cell zone for interaction with CD8$^+$ T cells.
Conclusions: These new insights into intrasplenic immune cross-talk demonstrate a critical role for both Type 2 cytokine signaling and cognate interactions in the iNKT cell-dependent DC licensing program.

P0646
Interleukin 17 responses induced in mice by chemical allergens: a functional role for ydeltaT cells

M. D. Hayes,* B. Hunt,† A. Hayday,† I. Kimber* & R. J. Dearman*
**Faculty of Life Sciences, University of Manchester, Manchester, UK, †London Research Institute, Cancer Research UK, London, UK*

Purpose/Objective: The interleukin (IL)-17 cytokine family, expressed by T helper 17 cells, plays pivotal roles in adaptive immune responses. They have been implicated in autoimmune and allergic diseases as well having roles in bacterial and fungal clearance. Importantly, several innate sources of these cytokines have also been described, including $\gamma\delta$ T cells. Interestingly, IL-17 producing $\gamma\delta$ T cells have been shown to be important in the development of adaptive Th17 responses during experimental autoimmune encephalomyelitis. We have questioned whether IL-17 influences the development of sensitisation to low molecular weight chemical allergens.
Materials and methods: BALB/c strain mice were exposed topically to the contact allergen 2,4-dinitrochlorobenzene (DNCB), the respiratory allergen trimellitic anhydride (TMA), or to vehicle alone. At selected time points single cell suspensions of draining lymph nodes were cultured and analysed for cytokine secretion (ELISA) or for mRNA following enrichment/depletion using magnetic beads.
Results: A single exposure to either allergen resulted in transient up-regulation of IL-17 from $\gamma\delta$ T cells in the draining lymph node. Maximal levels of secretion were observed at 6 and 48 h following exposure to DNCB and TMA, respectively. After repeated exposure under conditions where DNCB and TMA stimulate polarised Th1 and Th2 cytokine phenotypes, respectively, IL-17 production by DNCB-activated cells was shown by complement depletion to reside in the CD4$^+$ population only. In subsequent experiments, responses were explored in $\gamma\delta$ T cell KO mice and C57BL6 wild type (WT) controls. A similar pattern of IL-17 production to that provoked in BALB/c strain mice was seen in the WT mice following prolonged exposure to DNCB. However, in the $\gamma\delta$ T cell KO mice the adaptive Th17 response was completely abrogated.
Conclusions: These data suggest strongly that the lack of IL-17 production by $\gamma\delta$ T cells during the acute (innate) response affects the subsequent adaptive Th17 response to chemical contact allergens.

P0647

Interleukin-7 selectively promotes expansion and functional properties of mouse and human IL-17-producing gamma/delta T cells

M. L. Michel,* D. J. Pang,† S. Y. Haque,‡ A. J. Potocnik,§ D. J. Pennington† & A. C. Hayday‡
*Immunosurveillance, Cancer Research UK, London, UK, †Barts and The London School of Medicine, The Blizard Institute Queen Mary University of London, London, UK, ‡Immunobiology, King's College of London, London, UK, §Molecular Immunology, MRC National Institute for Medical Research, London, UK

Purpose/Objective: IL-17-producing CD27$^-$ $\gamma\delta$ cells ($\gamma\delta^{27-}$ cells) are widely viewed as innate immune cells making critical contributions to host protection and autoimmunity. However, factors that promote them over interferon-γ-producing $\gamma\delta^{27+}$ cells are poorly elucidated. Moreover, although human IL-17-producing $\gamma\delta$ cells are commonly implicated in inflammation, the cells themselves have proved difficult to isolate and characterise.
Materials and methods: Therefore, in our study, we investigated *in vitro* and *in vivo* the role of cytokines on the proliferation and the functional properties of mouse and human IL-17-producing $\gamma\delta$ cells.
Results: Our data show that murine CD44^{high} $\gamma\delta^{27-}$ cells and thymocytes are rapidly and substantially expanded by IL-7 *in vitro* and *in vivo*, notably in the context of imiquimod-induced inflammation. This is not the case for IFN-γ-producing ($\gamma\delta27^+$) cells. This is in large part attributable to the capacity of IL-7 to activate STAT3 selectively in $\gamma\delta^{27-}$ cells. IL-7 also permits IL-17-producing $\gamma\delta$ cells to respond to TCR agonists rather than to be killed by them, thus re-emphasizing the cells' adaptive as well as innate potentials. This cytokine facilitates notably strong responses, such as cytotoxicity, of $\gamma\delta^{27-}$ cells to TCR stimulation. Likewise, IL-7 and TCR agonists jointly drive the substantive expansion of IL-17 producing human $\gamma\delta$ cells.
Conclusions: Hence, IL-7 is a profound, conserved, and selective regulator of IL-17-producing $\gamma\delta$ cells, with both biological and clinical implications.

P0648

NKT cells aggravate the development of abdominal aortic aneurysms

G. van Puijvelde P. van Osch, I. Bot, A. C. Foks, M. ter Borg, K. L. L. Habets, T. J. C. van Berkel & J. Kuiper
Biopharmaceutics, Leiden Amsterdam Center for Drug Research/Leiden University, Leiden, The Netherlands

Purpose/Objective: An abdominal aortic aneurysm (AAA) is a dilatation of the abdominal aorta and is mostly undiscovered until it ruptures leading to serious complications and mostly to death. Development of AAA is associated with an accumulation of inflammatory cells in the lesions such as NKT cells. The exact contribution of these cells in AAA formation remains unclear. The goal of this study was to investigate the role of NKT cells in angiotensin II (AngII) induced AAA formation.
Materials and methods: To investigate the influence of AngII on NKT cell activation, an NKT cell hybridoma and splenocytes from LDLr$^{-/-}$ mice were incubated with AngII in combination with α-GalCer. Additionally, to determine the role of NKT cells in AAA formation, LDLr$^{-/-}$ and LDLr$^{-/-}$CD1d$^{-/-}$ mice were fed a Western-type diet prior to infusion with AngII.
Results: *In vitro*, AngII amplified the α-GalCer induced activation of NKT cells observed by increased production of IL-2 by the NKT cell hybridoma and increased IFN-γ production by splenocytes. Additionally, *in vivo*, AngII infusion induced an increased expression of the activation marker CD25 on NKT cells. During the *in vivo* aneurysm experiment, 5 out of 12 LDLr$^{-/-}$ mice died due to rupture of the aorta while in the LDLr$^{-/-}$CD1d$^{-/-}$ group 0 out of 11 mice died. A clear significant difference in severity of AAA was observed in the surviving mice. In seven out of 11 LDLr$^{-/-}$CD1d$^{-/-}$ mice no AAA lesions were found compared with only one out of 12 LDLr$^{-/-}$ mice.
Conclusions: These data show that NKT cells aggravate the development of AAA and induce aortic ruptures in an AngII-based AAA model possibly due to a direct effect of AngII on NKT cells. These results provide new opportunities to intervene in the development of aneurysms.

P0649

NKT cells play a role in an experimental model of adenine-induced renal injury

C. Aguiar,* A. Castoldi,† M. Correa-Costa,† E. L. Naka,* M. A. Cenedeze,* M. T. Amano,† T. T. Braga,† N. O. S. Camara† & A. Pacheco-Silva*
Medicine, Federal University of São Paulo, São Paulo, Brazil, †Biological Sciences, University of São Paulo, São Paulo, Brazil

Purpose/Objective: Diseases that affect the renal tubulointerstitial compartment are numerous and varied. The pathogenesis of kidney diseases involves the participation of various elements of the immune response. NKT cells constitute a distinct population of lymphocytes characterized by reactivity to glycolipids presented by CD1d molecules. The aim of our study was to analyze the role of NKT cells in an experimental model of adenine-induced tubulointerstitial nephritis.
Materials and methods: We used wild type C57BL/6j mice and Jα18 KO and CD1d KO mice (8–10 weeks old). A diet containing 0.25% adenine was given *ad libitum* to the animals for 10 days. Control animals were fed a standard diet. A second group of wild type (WT) animals was injected once with agonists of NKT cells, αGalCer or Sulfatide, and the adenine dietwas started at the same day. All groups were euthanized on the 10th day after adenine diet feeding. Blood and kidney samples were collected for analysis of renal function, gene expression, histology and immunohistochemistry. Data were presented as mean ± SD and ANOVA was used to compare groups.
Results: Jα18 KO and CD1d KO mice which were fed adenine diet had a significant increase in gene expression of KIM-1 and TNF-α in renal tissue compared to WT adenine fed mice. There was also a significant increase in renal interstitial fibrosis in Jα18 KO mice of the adenine group compared to WT mice of the same group. αGalCer and Sulfatide administration reduced serum creatinine levels in adenine fed WT mice. Similarly, a reduction of IL-6 and TNF-α gene expression was also observed after αGalCer and Sulfatide administration. Most importantly, there was a significant decrease of interstitial fibrosis and staining for FSP-1 and α-SMA following αGalCer and Sulfatide injection and adenine feeding compared to WT mice of adenine group.
Conclusions: Taken together, these data indicate that NKT cells participate in the process of adenine-induced renal injury by attenuating it. The absence of NKT cells leads to a deterioration of renal function and its activation is capable of improving kidney function in adenine-fed WT mice.

P0650

NOD mice contain an elevated frequency of iNKT17 cells that exacerbate diabetes

Y. Simoni,* A. S. Gautron,* L. Beaudoin,* L. C. Bui,† X. Coumoul,† M. L. Michel,‡ M. Leite-de-Moraes,‡ G. Eberl§ & A. Lehuen*
Inserm, U986, Paris, France, †Inserm, UMR-S747, Paris, France, ‡CNRS, 8147, Paris, France, §Pasteur CNRS, URA 1961, Paris, France

Purpose/Objective: Invariant natural killer T (iNKT) cells are a distinct lineage of innate-like T lymphocytes and converging studies in mouse models have demonstrated the protective role of iNKT cells in

the development of type 1 diabetes. Recently, a new subset of iNKT cells, producing high levels of the pro-inflammatory cytokine IL-17, has been identified (iNKT17 cells). Since this cytokine has been implicated in several autoimmune diseases, we have analyzed iNKT17 cell frequency, absolute number and phenotypes in the pancreas and lymphoid organs in non-obese diabetic (NOD) mice.
Materials and methods: iNKT17 cells frequency in lymph nodes and in the pancreas was determinated by flow cytometry mice. Local activation of this cells was determined by qPCR. The role of iNKT17 cells in the development of diabetes was investigated using transfer experiments.
Results: NOD mice exhibit a higher frequency and absolute number of iNKT17 cells in the lymphoid organs as compared to C57BL/6 mice. iNKT17 cells infiltrate the pancreas of NOD mice where they express IL-17 mRNA. Contrary to the protective role of $CD4^+$ iNKT cells, $CD4^-$ iNKT cells containing iNKT17 cells enhance the incidence of diabetes. Treatment with blocking an anti-IL-17 antibody prevents the exacerbation of the disease.
Conclusions: This study reveals that different iNKT cell subsets play distinct roles in the regulation of type 1 diabetes. iNKT17 cells that are abundant in NOD mice, exacerbate diabetes development. Further investigations are underway to analyze iNKT17 cell activation in the pancreas.

P0651
Porcine gammadelta T lymphocytes differ in level of TCRgamma-delta expression

K. Stepanova* **& M. Sinkora†**
**Department of Immunology and Gnotobiology, Faculty of Science Charles University in Prague, Institute of Microbiology v.v.i. Academy of Sciences of the Czech Republic, Novy Hradek, Czech Republic, † Department of Immunology and Gnotobiology, Institute of Microbiology v.v.i. Academy of Sciences of the Czech Republic, Novy Hradek, Czech Republic*

Purpose/Objective: Our studies showed that natural expression of T cell receptor (TCR) $\gamma\delta$ on fresh porcine T lymphocytes occurs in two densities: low and high. These two subsets have different distribution of CD2/CD8 subsets of porcine $\gamma\delta$ T cells. It is known that different CD2/CD8 $\gamma\delta$ T cell subsets are differentially located in various tissues and they likely have different functional characteristic. However, there is no report showing whether the CD2/CD8 subsets represent separate and independent lineages or if they represent subsequently developing subsets.
Materials and methods: Flow cytometry and cell sorting; cell cultures and stimulation *in vitro*; PCR amplification and CDR3 spectratyping.
Results: Natural expression of T cell receptor (TCR) $\gamma\delta$ on fresh porcine T lymphocytes occurs in two densities: low and high. These two subsets are differentially distributed among CD2/CD8 $\gamma\delta$ T cells: while $TCRgd^{lo}$ T cells are preferentially $CD2^+$ $CD8^+$, $TCR\gamma\delta^{hi}$ T cells are mostly $CD2^{\tilde{N}}CD8^{\tilde{N}}$. Sorting and cultivation experiments revealed that $TCR\gamma\delta^{hi}$ T cells can generate $TCR\gamma\delta^{lo}$ T cells in cultures but never oppositely. Most intense down-regulation of $TCR\gamma\delta$ can be observed in $CD2^{\tilde{N}}CD8^{\tilde{N}}$ subset. Moreover, stimulation by PMA or IL-2 can enhance the down-regulation of $TCR\gamma\delta$. However, while IL-2 has clearly highest impact on $CD2^{\tilde{N}}CD8^{\tilde{N}}$ $\gamma\delta$ T cells, PMA preferentially influence $CD2^+$ $CD8^+$ subset. It has been also shown that $CD2^{\tilde{N}}CD8^{\tilde{N}}$ $\gamma\delta$ T cells are unable to generate other CD2/CD8 subsets while $CD2^+$ $CD8^{\tilde{N}}$ and $CD2^+$ $CD8^+$ can acquire or lost CD8 molecule respectively. In accordance, there is significantly more cycling $CD2^+$ $CD8^{\tilde{N}}$ and $CD2^+$ $CD8^+$ than $CD2^{\tilde{N}}CD8^{\tilde{N}}$ $\gamma\delta$ T cells after IL-2 *in vitro* stimulation. Interestingly, although IL-2 clearly stimulates all three CD2/CD8 subpopulations, while $CD2^+$ $CD8^{\tilde{N}}$ and $CD2^+$ $CD8^+$ almost do not express CD25, $CD2^{\tilde{N}}CD8^{\tilde{N}}$ $\gamma\delta$ T cells respond by significant increase in CD25 expression. These results collectively indicate that CD2 expression most probably determine two lineages of $\gamma\delta$ T cells that differ in many functional, phenotype and behavioral aspect: (1) $CD2^{\tilde{N}}CD8^{\tilde{N}}$ and (2) $CD2^+$ $CD8^{\tilde{N}}$ and $CD2^+$ $CD8^+$ $\gamma\delta$ T cells.
Conclusions: This work was supported by grants P502/12/0110 and P502/10/0038 from Czech Science Foundation, GA UK 151-43-251119 and MSMT ME09089.

Regulatory network of T regulatory cells (Tregs) and NKT cells in environmental diseases

A. Bulog,* V. Micovic* & I. Mrakovcic-Sutic†
**Department of Public Health, Medical Faculty, Medical School, Univercity of Rijeka, Rijeka, Croatia, †Department of Physiology and Immunology, Medical Faculty, Univercity of Rijeka, Rijeka, Croatia*

Purpose/Objective: Objectives: The occurrence of environmental diseases has been increasing more than 30% for the last few decades and these illnesses are an onerous burden both to the individual and to the public health. These diseases include all disturbances caused by environmental, as well as behavioral factors. Environmental factors represent the group of changeable outdoor and indoor environments, while behavioral influences involve the augmentation in immunizations as a result of frequent infections, non regular use of antibiotics, diminished physical activities and decreased outdoor staying. The augmentation of NKT cells is associated with antitumor and allergic immune response, chronic inflammatory conditions, viral infection and autoimmune diseases. Moderation of immune response by Tregs is characterized with specific T-cell proliferation, following with decreased secretion of T-helper 1 and T-helper 2-type cytokines.
Materials and methods: Our hypothesis about regulatory network of Tregs and NKT cells was studied by flow cytometry, analyzing the characteristics of human Tregs and NKT cells, by phenotypic analysis of peripheral blood lymphatic cells of inhabitants leaving near gasoline industry, compared to people from rural areas, as well as by cytotoxicity assay against tumor cell line (human NK-sensitive line K562) to determine the functions ofcytotoxic T lymphocytes and natural killer (NK) cells, which have a crucial role in innate immunity.
Results: Our data have shown that inhabitants living near industrial area have significantly increased percentage of NKT and Tregs in comparation with those from rural fields, which may interplay with the function of immune system and percentage of allergic diseases. Interestingly, all exposed individuals have significant diminished values of NK-mediated cytotoxicity against human NK-sensitive target in comparation with people from rural area.
Conclusions: It has been proposed that NKT cells perform an important subpopulation of cells which can play both roles: as effectors and as regulatory cells in a wide range of disease settings. We can talk about the new kind of cells: NKT-reg cells. NKT-reg cells monitoring may lead to important early diagnosis and/or prognosis of environmental diseases.

TCR requirements for gamma delta T cell development

N. Sumaria,* D. J. Pang,* J. F. Neves,* K. V. Stoenchev,* B. Silva-Santos† & D. J. Pennington*
**Centre for Immunology and Infectious Disease, Blizard Institute, London, UK, †Faculdade de Medicina, Instituto de Medicina Molecular, Lisbon, Portugal*

Purpose/Objective: Gamma delta ($\gamma\delta$) T cells play important roles in immune responses against pathogens and tumours which seem to

strongly correlate with the secretion of cytokines such as IFNγ and IL-17A. Recent evidence suggests that $\gamma\delta$ cells are predominantly pre-committed to certain effector fates during thymic development; T cell receptor (TCR)-agonists favouring the development of IFNγ-producing $\gamma\delta$ cells (that are variously identified by CD27, CD122 and NK1.1), whereas the absence of ligand interactions was suggested to generate IL-17A-producing $\gamma\delta$ cells (identified as CD27$^{(-)}$, but expressing CCR6). The aim of this study was to determine the role of the TCR and TCR signalling in the development of $\gamma\delta$ T cell subsets and in the adoption of effector fates in the thymus.
Materials and methods: Integrating all the markers described above including CD24 and CD25, we used flow cytometry to establish a gating strategy to identify IFNγ-secretors and IL-17A-secretors in the lymph nodes and thymus of C57BL/6 (BL/6) mice. Subsequently, we sorted various $\gamma\delta$ subsets and put them into different culture systems including fetal thymic organ cultures (FTOC) as well as on to OP9-DL1 stromal cell line to analyse $\gamma\delta$ cell development and the adoption of different effector functions under different conditions. These conditions included inducing TCR signalling by cross-linking with an activating antibody or in a ligand-independent manner by generating a TCR that was incapable of binding a ligand.
Results: Our results demonstrate that at least four distinct subsets of $\gamma\delta$ T cells can be identified in both the periphery and the thymus of BL/6 mice. These subsets display distinct cytokine-secreting and proliferative potential as well as variable TCR usage. Our data *in vitro* demonstrate a $\gamma\delta$ developmental sequence where CD27$^{(-)}$ IL-17A-secreting $\gamma\delta$ T cells are generated from CD27$^{(+)}$ precursors. In addition, we find that TCR signalling induced by cross-linking with an activating antibody or in a ligand-independent manner does not favour the development of IL-17A-secreting $\gamma\delta$ T cells. Furthermore, we observed differences in downstream signalling events between the $\gamma\delta$ subsets analysed.
Conclusions: We conclude that effector fate of $\gamma\delta$ subsets is not likely to correlate with ligand-dependent versus ligand-independent signalling but instead appears to correlate with quantitative and/or qualitative differences in TCR signalling.

P0654
The impact of Skint genes on peripheral gammadelta T cell function

A. Jandke, R. Hart & A. Hayday
Immunosurveillance Laboratory, Cancer Research UK, London, UK

Purpose/Objective: Skint1 expressed by thymic epithelial cells is essential for the selective development of murine dendritic epidermal T cells (DETCs), which express an identical Vγ5Vδ1 T cell receptor (TCR). Mice lacking V$\gamma5^+$ V$\delta1^+$ DETCs display dysregulated cutaneous inflammation and an increased susceptibility to carcinogenesis. The function of Skint1 on keratinocytes is unknown and it has yet to be determined whether Skint1 is a ligand for the Vγ5Vδ1 TCR. A recent study demonstrated a sustained interaction between Vγ5Vδ1 TCRs localised in the termini of immobilised DETC dendrites and an unknown ligand expressed on keratinocytes, which resulted in constitutive signalling downstream of the TCR [and the formation of phosphotyrosine-rich aggregates located on projections (PALPs)]. We are investigating the contribution of Skint1 to this steady state interaction, the role of Skint2 in the selection of DETCs and other $\gamma\delta$ T cell repertoires e.g. uterine intraepithelial T cells and the regulation of-Skint1 and Skint2 in response to skin stresses.
Materials and methods: To investigate the role of Skint1, we used confocal microscopy to compare the number of PALPs in strains of FVB mice differentially expressing Skint1 and/or the Vγ5Vδ1 TCR, before and after skin stress. Skint mRNA levels were analysed by RT-PCR. To investigate the role of Skint2, we disrupted Skint2 gene functions by replacing it with a fluorescent reporter.
Results: DETCs from mice in which Skint1 (and therefore also V$\gamma5^+$ V$\delta1^+$ DETCs) was absent and DETCs from Vγ5V$\delta1^{-/-}$ mice, had fewer PALPs than DETCs from wild-type mice and mice transgenic for Skint1. Following application of low concentrations of TPA to WT mice, Skint1 mRNA levels in the epidermis decreased and the DETCs resembled those from mice lacking Skint1.
Conclusions: Hence Skint1 has a profound effect on the peripheral status of DETCs. The results of further experiments looking at the effect of low concentration TPA on Skint1 transgenic mice (in which the Skint1 mRNA levels remain constant) and the role of Skint1 in keratinocytes specifically will be reported, as will the progress resulting from experiments using the Skint2 knockout and reporter mice.

The role of $\gamma\delta$ T cells in *Porphyromonas gingivalis*-induced periodontal disease

J. Lenzo, N. M. O'Brien-Simpson, V. Tam & E. C. Reynolds
Melbourne Dental School, The University of Melbourne Oral Health CRC, Melbourne, Vic., Australia

Purpose/Objective: $\gamma\delta$ T cells are a rare population of T lymphocytes found in most tissues that play an important but poorly defined role in protective immunity to infection. $\gamma\delta$ T cells appear to have both

proinflammatory and regulatory functions, acting as a bridge between the innate and adaptive immune response as well as down modulating the inflammatory response once an infection is cleared. Chronic periodontitis is an inflammatory disease of the supportive tissues of the teeth leading to resorption of alveolar bone and eventual tooth loss. The disease is a major public health problem in all societies and is estimated to effect 5−20% of any population. Recent studies are now strongly indicating that chronic periodontitis effects systemic health and is a major risk factor for diseases such as coronary heart disease, pancreatic cancer, diabetes and rheumatoid arthritis. Whilst several bacterial species are strongly associated with disease, *Porphyromonas gingivalis* has been implicated as a major etiological agent.

Materials and methods: We investigated the role $\gamma\delta$ T cells have in chronic periodontitis using the mouse bone loss model, ELISA and ELISPOT assays. We also isolated $\gamma\delta$ T cells (autoMACS assay) and determeined their activation state and secretion of IL-17 and IFNγ by flow cytometry and ELISPOT.

Results: In a mouse model of periodontitis the absence of $\gamma\delta$ T cells (TCR$\delta^{-/-}$ mice) resulted in significantly ($P < 0.05$) less *P. gingivalis* induce bone loss compared to wild type controls. In the *P. gingivalis*-inoculated TCR$\delta^{-/-}$ mice there was a *P. gingivalis*-specific antibody and $\alpha\beta$ T cell response albeit weaker than *P. gingivalis*-inoculated control. In the *P. gingivalis*-inoculated TCR$\delta^{-/-}$ mice there was a weak and equal IL-4 and IFNγ $\alpha\beta$ T cell response, whereas in the *P. gingivalis*-inoculated control mice a IFNγ $\alpha\beta$ T cell response was dominant. Furthermore *P. gingivalis* whole cells and lipids were found to up regulate CD69 and CD25 expression on $\gamma\delta$ T cells and induce IL-17 and IFNγ secretion.

Conclusions: Our study strongly indicates that $\gamma\delta$ T cells play a major role in periodontitis and that they are directly activated by *P. gingivalis* and its lipids, resulting in the secretion of pro-inflammatory cytokines which may contribute to disease pathology

Thymus and major histocompatibility complex class II-dependent CD8alpha/beta$^+$ T cell receptor gamma/delta intestinal intraepithelial lymphocytes in mice

Y. Emoto,* I. Yoshizawa,† S. H. E. Kaufmann† & M. Emoto*
**Department of Laboratory Sciences, Gunma University Graduate School of Health Sciences, Maebashi Gunma, Japan, †Department of Immunology, Max Planck Institute for Infection Biology, Berlin, Germany*

Purpose/Objective: In the mouse, intestinal epithelial layers constitute a rich source of T cell receptor (TCR) γ/δ cells and the vast majority of TCRγ/δ intestinal intraepithelial lymphocytes (iIEL) surface express CD8α, but lack CD8β. In the present study, we examined whether functional TCRγ/δ cells expressing both CD8α and CD8β exist in the small intestine and whether the development of this cell population is controled by major histocompatibility complex (MHC) class I or MHC class II.

Materials and methods: We examined whether TCRγ/δ cells expressing both CD8α and CD8β exist in the small intestine by flow cytometry and whether the development of this cell population is controlled by MHC class I or MHC class II using various mouse strains including MHC class I or class II-deficient mice. Moreover, we also examined whether this cell population expresses functional activities such as interferon (IFN)-γ-secreting activity and cytolytic activity.

Results: We identified intestinal TCRγ/δ cells expressing both CD8α and CD8β in some mice. These CD8α/β^+ TCRγ/δ iIEL emerge in C57BL/6 (H-2^b) mice independently from age and bacterial colonization, although their abundance varied among individual animals. CD8α/β^+ TCRγ/δ cells were restricted to the intestine and virtually absent in other organs. CD8α/β^+ TCRγ/δ iIEL were rare in adult and neonatally thymectomized C57BL/6 mice. Substantial numbers of CD8α/β^+ TCRγ/δ iIEL were found in mice deficient for β2-microglobulin (H-2^b), whereas they were rare in mice deficient for MHC class II (H-2^b) and also in C57BL/10 (H-2^b), SVJ129 (H-2^b), BALB/c (H-2^d), C3H/HeJ (H-2^d), DBA/2 (H-2^d), CBA (H-2^k), SJL (H-2^s) and FVB (H-2^q) mice. Profound IFN-γ-secretion and target cell lysis were found in iIEL from C57BL/6 mice comprising unconventional CD8α/β^+ TCRγ/δ iIEL as compared to C57BL/6 mice lacking these cells. Purified CD8α/β^+ TCRγ/δ iIEL from C57BL/6 mice expressed elevated cytolytic activities and IFN-γ after TCRγ/δ engagement.

Conclusions: Our findings suggest that emergence of CD8α/β^+ TCRγ/δ iIEL with functional activities is controlled by thymic epithelial cells and by MHC class II-related molecules distinct from H-2^b.

Transcriptional and epigenetic signatures of pro-inflammatory gamma-delta T cell subsets

K. Serre, N. Schmolka, J. Ribot, A. Gomes & B. Silva-Santos
Instituto de Medicina Molecular, Unidade de Imunologia Molecular, Lisbon, Portugal

Purpose/Objective: Interferon-gamma (IFN-γ) and interleukin-17 (IL-17) are critical pro-inflammatory cytokines which play protective roles during host defense against infections, but also, pathogenic roles such as during autoimmunity.

Gamma-Delta ($\gamma\delta$) T cells are major early sources of IFN-γ and IL-17. We identified two murine subsets of $\gamma\delta$ T cells that segregate with CD27 expression and display mutually exclusive capacities to make IFN-γ or IL-17. These phenotypically and functionally distinct populations differentiate already within the thymus and colonize peripheral lymphoid organs.

Our objective is to get insights into the molecular basis of the developmental pre-programming that controls the emergence of these discrete cytokine-producing $\gamma\delta$ T cell subsets.

Materials and methods: The acquisition of selective effector functions relies on specific molecular programs that tightly control the chromatin structure (at an epigenetic level) and transcriptional activity of a combination of genes. Thus, here we have undertaken:

- an unbiased approach to analyze active histone H3 marks (methylation at K4)

- a candidate gene approach to evaluate the expression of key transcription factors

This led to mapping the key transcription factor and cytokine expressions, as well as active histone (H3K4me2) marks in FACS-sorted CD27$^+$ and CD27- $\gamma\delta$ T cells from naïve C57Bl/6 mice.

Results: - Active histone H3K4 methylation marks in type 17 genes are differentially distributed between CD27$^+$ and CD27- $\gamma\delta$ T cells and ensure a striking restriction of *Il17* expression to CD27- $\gamma\delta$ T cells. By contrast, type 1 gene loci are epigenetically poised in both subsets.

- Key type 1 and type 17 transcription factors (including Tbox21, Eomes, Runx3, or RORc, RORα) are expressed at similar levels in both CD27$^+$ and CD27- $\gamma\delta$ T cell subsets derived from the thymus. By contrast, CD27$^+$ and CD27- $\gamma\delta$ T cells derived from secondary lymphoid organs show significant differential expression of the type 17 genes.

- Upon 48h *in vitro* re-stimulation, in the presence of cytokines, CD27- $\gamma\delta$ T cells become able to secrete both IL-17 and IFN-γ, while, CD27$^+$ $\gamma\delta$ T cells only produce IFN-γ.

Conclusions: Our results provide novel insight into the mechanisms that control the programming and plasticity of functional $\gamma\delta$ T cell subsets.

B7-CD28 and CD40-CD40L blockade leads to hypo-responsiveness of effector T cells but allows for activation of Foxp3-expressing regulatory T cells

I. Vogel,* B. Verbinnen,† S. W. Van Gool* & J. L. Ceuppens*
*Experimental Immunology, Catholic University of Leuven, Leuven, Belgium, †Experimental Laboratory Immunology, Catholic University of Leuven, Leuven, Belgium

Purpose/Objective: Costimulatory signals are required for efficient priming and activation of naïve T cells, while it is less clear how they contribute to induction of regulatory T cell (Treg) activity. We previously reported that the simultaneous and prolonged blockade of B7-CD28 interaction and of the CD40L-CD40 interaction *in vivo* efficiently suppresses allogeneic T cell activation after transfer of spleen cells to an allogeneic host. This protection was characterized by an initial rise in Foxp3$^+$ cells (without *de novo* induction), followed by disappearance of host reactive cells.
Materials and methods: To further investigate the effects of costimulatory blockade on Treg cells, we used an *in vitro* model of CD4 cell activation with allogeneic splenocytes. In order to faithfully track Foxp3-expressing cells, we used cells from Foxp3-GFP transgenic mice. The CD28-CD80/CD86 and the CD40-CD40L pathways were blocked using CTLA-4Ig and MR1 (anti-CD40L mAb), respectively.
Results: We show that blocking B7 molecules (using CTLA4-Ig) together with CD40L (using anti-CD40L mAb) prevents effector T cell activation and proliferation. Moreover, we observed a relative increase in Foxp3 expression in cultures with costimulation deficient conditions, which does not result from *de novo* induction of Foxp3 but rather from proliferation of Treg cells and their ability to survive in an environment with limited IL-2 availability. Furthermore, we show that cells cultured in the presence of costimulation blockade are hyporesponsive upon re-stimulation unless Foxp3 expressing cells are removed. Under costimulation deficient conditions activated Foxp3 expressing Treg cells are further able to prevent T cell proliferation *in vitro* in the absence of costimulation blockade more efficiently than freshly isolated Treg cells.
Conclusions: Together these results suggest that Treg cells are less dependent on CD40L and B7 signaling concerning activation, survival and proliferation. As a consequence, they become functionally dominant over effector T cells in a situation of costimulation blockade.

P0662

Clinical significance of NKT and Treg cells in autoimmune thyroid disease during pregnancy

I. Mrakovcic-Sutic,* T. Bogovic-Crncic,† A. Bulog‡ & V. Micovic‡
*Department of Physiology and Immunology, Medical Faculty, Univercity of Rijeka, Rijeka, Croatia, †Department of Nuclear Medicine, Medical Faculty, Clinical Hospital Centre Rijeka Croatia, Univercity of Rijeka, Rijeka, Croatia, ‡Department of Public Health Medical School, Medical Faculty, Univercity of Rijeka, Rijeka, Croatia

Purpose/Objective: NKT cells represent a unique sublineage of innate lymphocytes, that share the properties of natural killer cells and conventional T cells. Autoimmune thyroid dysfunction (ATD), which comprises two main clinical entities: Graves' disease and Hashimoto thyroiditis, often affect women of reproductive age. In a healthy pregnancy predominant is Th2 over Th1 immunity, which explains the improvement of autoimmune disease during pregnancy, while after birth due to changes in Th1/Th2 ratios often leads to deterioration of ATD. NKT and Tregs seem to play an important part in mediating maternal tolerance to fetus. Although many researches have been done in the field ofthyroid autoimmunity, very few studies investigated the role of innate immunity in AITD during human pregnancy and in the postpartal period.
Materials and methods: We investigated the presence of ATD in pregnant and postpartum period in women with hormonal status determination, the titer of thyroid antibodies and auto antibodies and compared them with healthy pregnant women and subjects' postpartum and not pregnant women. After intracellular and surface staining using flow cytometry, we analyzed the phenotype and cytolytic potential of isolated peripheral blood mononuclear cells of pregnant women and postpartum women, and not pregnant women.
Results: Total in 25% of pregnant women and 41.5% of postpartum women have demonstrated the presence of thyroid autoimmunity. The cells of innate immunity: NKT and Tregs are elevated in healthy pregnancies and in pregnancies with hypo-and hyperthyroidism, as well as postpartum in all experimental groups. NKT cells are reduced in pregnant women with positive antibodies indicating a decrease in NKT cell protective effect of pregnancy under the action of antibodies. Total perforin was decreased in healthy women, but higher in patients with positive antibodies, hypo-and hyperthyroidism and postpartum indicating the increased cytolytic potential of these cells in autoimmune process.
Conclusions: Pregnancy and the postpartum period influence the function of the thyroid gland. In the presence of thyroid autoimmunity changes are more pronounced, especially postpartum. Apart from pregnancy and postpartum period influence the course of ATD and thyroid autoimmunity affects thyroid function in pregnancy and the postpartum period.

Constitutively active STAT3 in T-cells induces a distinct tolerogenic program

K. G. Schmetterer,* A. Neunkirchner,* D. Haiderer,* J. Leitner,† P. Steinberger† & W. F. Pickl*
*Christian Doppler Laboratory for Immunomodulation, Institute of Immunology, Medical University of Vienna, Vienna, Austria, †Institute of Immunology, Medical University of Vienna, Vienna, Austria

Purpose/Objective: The signal transducer and activator of transcription 3 (STAT3) is a key integrator of signals provided by a multitude of cytokines and factors. Yet, the role of STAT3 in T-cells is not well established. Current research indicates Th17-inducing but also tolerogenic roles. We assessed the effects of STAT3 activation in human T-cells.
Materials and methods: A constitutively active mutant of STAT3 (STAT3C) was generated and cloned into an IRES-GFP harboring retroviral vector. Upon transduction into peripheral blood CD4$^+$ T-cells we analyzed phenotype, cytokine secretion, proliferation and suppressive potential in response to qualitatively different stimuli.
Results: STAT3C$^+$ T-cells showed clear-cut transgene expression and phenotypically displayed an effector T-cell phenotype regarding the assessed characteristic regulatory T-cell markers CD25, CD39, CD127 and CTLA-4. Following anti-CD3 stimulation in concert with costimulatory signals via either CD80-CD28 or CD58-CD2, STAT3C$^+$ T-cells were hyporesponsive and displayed a distinct cytokine profile. This included a significant reduction of IL-2, IL-13, IFN-γ and TNF-α secretion and a fourfold increase in IL-10 production. In co-cultures with CD4$^+$ responder T-cells, STAT3C$^+$ T-cells showed no suppressive capacity in response to CD80 co-stimulation but significant suppressive capacity following CD58 co-stimulation. Suppression was contact-dependent but independent of IL-10 and TGF-β. Preliminary microarray data suggest that STAT3C$^+$ T-cells up-regulate a distinct set of immunoregulatory genes.

Conclusions: Our data provide a clear-cut relation between activation of STAT3 and the acquisition of an anti-inflammatory cytokine profile and suppressive function. Consequently, the main function of STAT3 in T-cells seems to be the regulation of tolerogenic processes.

P0664
Deficiency of glycoprotein A repetitions predominant in T cells predisposes to severe colitis

A. O. Samokhin, C. Schnabel, H. Schulze-Koops & A. Skapenko
Medizinische Klinik und Poliklinik IV, University of Munich, München, Germany

Purpose/Objective: Glycoprotein A repetitions predominant (GARP) is a transmembrane protein with an extracellular region composed primarily of 20 leucine-rich repeats. It belongs to orphan Toll-like receptors and is expressed in different cells and organs during embryogenesis. Recently, it has been shown that GARP expression is highly upregulated in human activated natural regulatory CD4 T cells (nTreg). The function of this protein is still unknown, although some studies suggest that GARP might be necessary for the activation of TGF-§ in Tregs upon TCR stimulation.
Materials and methods: To evaluate the function of GARP in Tregs we generated mice lacking GARP in T cells using a Cre-Lox conditional gene targeting approach. Flow cytometry was used to estimate the phenotypical changes in mice deficient for GARP in T cells. The dextran sodium sulfate (DSS) model of colitis was used to assess the role of GARP in a suppressive function of Tregs in inflammatory conditions.
Results: The conditional deletion of GARP resulted in decreased frequencies of CD4 T cells in the blood, spleen and lymph nodes, whereas frequencies of $CD69^+$ /$CD4^+$ cells were increased. Analysis of the small intestine revealed increased numbers of CD4 T cells and a shift in the ratio of TCRab/TCRgd T cells towards TCRab in the lamina propria and the intraepithelial layer. Frequencies of $Foxp3^+$ CD4 T cells were slightly increased in the spleen, mesenteric and inguinal lymph nodes, whereas in the gut their frequencies were significantly decreased. Mice with conditional deletion of GARP developed more severe colitis assessed by clinical and histological scores. Treatment of GARP-deficient mice with nTregs from wild type mice before induction of colitis resulted in amelioration of disease activity, whereas GARP-deficient nTregs failed to improve.
Conclusions: These data demonstrate that selective knock out of GARP in T cells alters CD4 T cell subset distribution and results in higher susceptibility to colitis. This might be related to the decreased ability of Tregs to migrate into the gut.

P0665
Diacylglycerol kinase alpha is essential for regulatory T cell induction

D. Soutar,* M. Martínez-Moreno,* A. Ávila-Flores,* X. Zhong,† G. Koretzky‡ & I. Mérida*
**Department of Immunology and Oncology, Centro Nacional de Biotecnología, Madrid, Spain, †Department of Pediatrics, Duke University Medical Center, Durham, NC, USA, ‡Abramson Family Cancer Research Institute, University of Pennsylvania School of Medicine, Signal Transduction Program, Philadelphia, PA, USA*

Purpose/Objective: T cell receptor triggering in T cells leads to generation of diacylglycerol (DAG), a lipid second messenger that mediates activation of the RasGRP1/Ras/Erk pathway. Diacylglycerol kinase alpha (DGKα) catalyzes DAG conversion to phosphatidic acid (PA), and negatively regulates this pathway during $CD4^+$ T cell activation. Activated $CD4^+$ T cells then differentiate further into distinct populations. The fate of naïve T helper (Th) cells as effector or regulatory cells is linked to activation signal intensity and regulated by mTOR. We analyzed the role of DGKα in Treg cells and the impact of DGKα deficiency in T effector versus Treg cell determination.
Materials and methods: To study the implication of DGKα in induced Treg cell (iTreg) differentiation, $CD4^+$ $CD25^-$ naïve T cells were stimulated with anti-$CD3^+$ anti-CD28 antibodies and treated with TGFβ and IL2, followed by confirmation of Treg induction by flow cytometry analysis of FOXP3 expression. DGKα expression was determined by Western blot analysis with specific antibodies. To understand the impact of DGKα deficiency in Treg cells, we compared the proportion of iTreg as well as of natural Treg cells in DGK$\alpha^{-/-}$ and wild type mice.
Results: We found that at difference from T effector cells, iTreg express high DGKα levels. Sustained DGKα expression is important for maintenance of the regulatory phenotype, as FOXP3 induction is greatly impaired in DGK$\alpha^{-/-}$ compared to WT mice.
Conclusions: Our results suggest that sustained DGKα expression is important for attenuation of the TCR signals needed for differentiation of Th cell populations. Enhanced activation of the Ras/ERK/mTOR pathways in DGK$\alpha^{-/-}$ mice prevents iTreg cell differentiation. The contribution of DGKα to T effector versus Treg differentiation will be discussed.

Purpose/Objective: In the past few years, regulatory T cells (Treg) have emerged as important players of the immune system. Impaired function of Treg cells leads to several autoimmune diseases. In addition, they are involved in regulating immune homeostasis and the immune response to infections, tumors and tissue transplants. Therefore, a better understanding of Treg cell function and development is crucial. Previously, we and others performed gene expression profiles of Treg cells under a variety of conditions and locations. But, so far, only limited data exist on the proteome level. Thus, we addressed the proteome of Treg cells in an unbiased differential quantitative mass spectrometry approach.
Materials and methods: Proteins from sorted murine Treg cells and conventional $CD4^+$ T cells were differentially labeled with stable-isotopes, joint together and relative protein abundance was measured by differential quantitative mass spectrometry. To increase the power, four independent replicates were performed and the results were statistically analyzed.
Results: Mass spectroscopy identified and quantified more than 4000 proteins of which 165 were significantly differentially expressed in Treg cells as compared to conventional $CD4^+$ T cells. In depth analysis of the obtained proteome data and corresponding genomic data sets revealed an overall strong correlation between protein and RNA expression. For example, some of the Treg specific genes like Foxp3, IL2rβ, GITR or neuroplin-1 were highly over-expressed on both protein and RNA level. In addition, we identified several novel proteins which were under- or over-represented on the protein level as compared to the RNA level.
Conclusions: In gereral protein expression follows RNA but some interesting exceptions occur. We are now in the course of investigating the role of targets in Treg function and development.

DSS-induced colitis is attenuated in GPx1 KO mouse by regulation of treg function

H. R. Kim,* S. M. Lee,* J. Y. Seoh* & J. H. Kie†
*Department of microbiology, Ewha Womans University Graduate School of Medicine, Seoul, Korea, †Department of Pathology, National Health Insurance Cooperation Ilsan Hospital, Koyang, Korea

Purpose/Objective: Reactive oxygen species (ROS) have been considered harmful to tissues and as mediators of inflammation at the injury sites for a long time. However, in recent, many findings about other functions of ROS are reported. The effects of ROS such as suppression of autoimmune disease and allergen-induced inflammation have been studied by using knock-out systems for ROS-related molecules. Moreover, regulatory T cell (Treg) effects to various diseases including autoimmune and inflammatory diseases depending on own activity. Therefore, we tried to identify the relation of Treg function with ROS in chemical induced inflammation through glutathione peroxidase 1 knock-out (GPx1 KO) system.
Materials and methods: C57BL/6 WT mice and GPx1 KO mice were used for entire experiments. Colitis was induced by 3% dextran sulfate sodium salt (DSS) and the colons were excised. We detected losses of weight, colon lengths by macroscopic anatomy and histological scores by hematoxylin & eosin staining. Treg functional tests were performed by CFSE labeling and cell proliferation assay. Some cytokines in culture supernatants of mice splenocytes were detected by cytometric bead array.
Results: First of all, losses of weight were founded in not GPx1 KO mice but B6 WT mice by DSS. And then, macroscopic inspection clearly showed colon shortening in DSS-WT mice and NAC injected DSS-GPx1 KO mice. In histological data, colon tissues of DSS-Gpx1 KO mice had normal structure whereas those of DSS-WT mice showed abnormal lesions such as ulcer, inflammation and early adenocarcinoma. Furthermore, suppressive activity of regulatory T cell was diminished in DSS-WT mice and it had correlation with cytokine distribution.
Conclusions: These data indicate that ROS accumulation in GPx1 KO mice activates regulatory T cells and DSS-induced colitis is controlled by Treg depending on own activity.

Feasibility of using regulatory T cells as an 'off the shelf' cellular reagent

E. Mavin, A. M. Dickinson & X. N. Wang
Haematological Sciences, Institute of Cellular Medicine, Newcastle upon Tyne, UK

Purpose/Objective: Treg offer a potential therapeutic modality for the prevention and/or treatment of autoimmune disorders and protection of adverse effect following allogeneic transplantation. Several clinical trials using freshly isolated or *ex vivo* expanded Treg have shown promising therapeutic benefit creating an opportunity for cryopreserved Treg to be used as an 'off the shelf' cellular reagent either in the clinic or for research purposes. This study aimed to investigate whether Treg retain their suppressive properties after cryopreservation.
Materials and methods: $CD4^+$ $CD25^{hi}Foxp3^+$ Treg were isolated from LRS cones followed by *ex vivo* expansion in the presence of anti-CD3/CD28 beads, rapamycin and IL-2. In comparison to non-cryopreserved Treg, the suppressive properties of cryopreserved Treg were assessed for their ability to modulate the alloreactive immune responses of $CD8^+$ T cells, including activation, proliferation, cytokine production and prevention of cutaneous graft-versus-host reactions, using flow cytometry, ^3H incorporation, CBA and a skin explant assay.
Results: Large number of Treg with high suppressive potency was obtained. Foxp3 expression and suppressive function of Treg remained stable for over 5 weeks in *ex vivo* expansion culture. The inhibition rate of alloreactive $CD8^+$ T cell proliferation was 77% and 79% for Treg with or without cryopreservation respectively. Early activation marker CD69 was suppressed by 71% and 76% and late activation marker CD25 expression was suppressed by 83% and 84% for freshly expanded and cryopreserved Treg respectively. The potency of Treg suppression in IFNγ production by alloreactive $CD8^+$ cells was comparable regardless of cryopreservation. Furthermore, cryopreserved Treg retained their protective effect on alloreactive $CD8^+$ T cell mediated target tissue destruction in an *in vitro* human GVHD skin explant model.
Conclusions: No significant difference was observed between the suppressive properties of Treg with or without cryopreservation, when they were used to modulate allogeneic moDC stimulated $CD8^+$ T cells immune responses, suggesting that Treg suppressive functions are not affected by cryopreservation and could potentially be developed as an 'off the shelf' cellular reagent.

$Foxp3^+$ follicular regulatory T cells control the germinal centre response

M. A. Linterman,* W. Pierson,† S. K. Lee,‡ A. Kallies,§ S. Kawamoto,¶ S. Fagarasan,** A. Liston,† C. G. Vinuesa‡ & K. G. C. Smith*
*Department of Medicine, Cambridge Institute for Medical Research, Cambridge, UK, †Department of Experimental Medicine, University of Leuven/VIB, Leuven, Belgium, ‡Pathogens and Immunity, The Australian National University, Canberra, SA, Australia, §Molecular Immunology, The Walter and Eliza Hall Institute of Medical Research, Melbourne, Vic., Australia, ¶Molecular Immunology, RIKEN Research Center for Allergy and Immunology, Yokohama, Japan, **Mucosal Immunity, RIKEN Research Center for Allergy and Immunology, Yokohama, Japan*

Purpose/Objective: T Follicular helper (Tfh) cells provide growth and survival signals to germinal centre B cells as they undergo the process of somatic hypermutation and selection that results in affinity maturation. Tight control of the Tfh population is vital to maintain self-tolerance and ensure that self-reactivity does not arise from the germinal centre. Here, we describe a population of $Foxp3^+$ $Bcl6^+$ $CD4^+$ T cells that also share cell surface markers with Tfh cells and constitute 10–25% of the $CXCR5^{high}PD\text{-}1^{high}CD4^+$ T cell population found in splenic germinal centres after immunisation.
Materials and methods: We immunized wild-type, $Foxp3^{GFP}$, $Foxp3^{DTR}$, *Sh2d1a*$^{-/-}$, *Cd28*$^{-/-}$ and *Bcl6*$^{-/-}$ mice, or mixed bone marrow chimeras of these genotypes, to investigate the phenotype of follicular regulatory T (Tfr) cells, to determine whether they derive from Treg or Tfh precursors, what cues are required for their differentiation and ascertain what their role is in the germinal centre response.
Results: Follicular regulatory T (Tfr) cells share phenotypic characteristics with both Tfh and conventional $Foxp3^+$ regulatory T cells (Tregs) yet are distinct from either. Similar to Tfh cells, Tfr cell development depends on the expression of Bcl-6, the transcriptional regulator of the Tfh subset, furthermore their maintenance requires SAP-mediated cognate interactions with B cells. This shared differentiation pathway suggests that Tfr cells may arise from Tfh cells that have switched on Foxp3; however Tfr cells originate from $Foxp3^+$ precursors and not naïve T cells or Tfh cells.This demonstrates that Tregs can co-opt the Tfh differentiation pathway to migrate into the germinal center, where they can participate in the response. Tfr cells are suppressive *in vitro* and limit Tfh and germinal centre numbers *in vivo*. In the absence of Tfr cells, there is an outgrowth of non-antigen-specific B cells in germinal centres leading to a reduced number of antigen-specific germinal centre B cells.

Conclusions: Our results indicate that Foxp3$^+$ Tregs can utilise the Tfh differentiation pathway to produce a population of specialised suppressor cells that control the size and composition of the germinal centre response.

P0670

Foxp3$^+$ regulatory T cells in the inflamed CNS are insensitive to IL-6-driven IL-17 production

R. O'Connor,* S. A. Jones† & S. M. Anderton*

**Centre for Inflammation Research QMRI, University of Edinburgh, Edinburgh, UK, †Deprtment of Infection Immunity & Biochemistry, The School of Medicine, University of Cardiff, Cardiff, UK*

Purpose/Objective: Foxp3$^+$ T regulatory cells (Treg) can be induced to produce IL-17 by *in vitro* exposure to pro-inflammatory cytokines drawing into question their functional stability at sites of inflammation We sought to assess the capacity of Treg from an inflammatory site produce IL-17 in response to IL-6.

Materials and methods: Purified Foxp3$^+$ Treg from the inflamed central nervous system (CNS) of mice with experimental autoimmune encephalomyelitis and splenic Treg were stimulated *in vitro* in the presence of IL-6 and their capacity for IL-17 production determined.

Results: Unlike their splenic counterparts, CNS-Treg resisted conversion to IL-17 production when exposed to IL-6. The highly activated phenotype of CNS-Treg includes elevated expression of the Th1-associated molecules CXCR3 and T-bet, but reduced expression of the IL-6 receptor α chain (CD126) and the signalling chain gp130. We found a lack of IL-6 receptor on all CNS CD4$^+$ T cells, which was reflected by an absence of both classical and *trans* IL-6-signalling in CNS CD4$^+$ cells, compared to their splenic counterparts.

Conclusions: Lack of responsiveness to IL-6 stabilizes the regulatory phenotype of activated Treg at sites of autoimmune inflammation. Increased knowledge of cytokine receptor expression profiles will help predict the responsiveness of different T cell subsets to inflammatory environments.

Functional change of regulatory T cells during an experimental infection with sparganum (plerocercoid of Spirometra mansoni)

H. R. Kim,* S. M. Lee,* J. H. Kie,† H. J. Yang‡ & J. Y. Seoh*

**Department of microbiology, Ewha Womans University Graduate School of Medicine, Seoul, Korea, †Department of Pathology, National Health Insurance Cooperation Ilsan Hospital, Koyang, Korea, ‡Department of Parasitology, Ewha Womans University Graduate School of Medicine, Seoul, Korea*

Purpose/Objective: Regulatory T cells (Tregs) are important in the regulation of immune response, but how Treg function is actually regulated *in vivo* is still not well known. In order to understand how Treg function is regulated during a parasite infection, we investigated the functional activity of CD4$^+$ CD25$^+$ Tregs as well as the frequency and number of CD4$^+$ CD25$^+$ FoxP3$^+$ Tregs in the spleens of mice experimentally infected with sparganum (plerocercoid of *Spirometra mansoni*) for 3 weeks..

Materials and methods: Male BALB/c mice were infected with 2 spargana and were sacrificed at day 3, week 1, 2, and 3 for the functional study of spleen CD4$^+$ CD25$^+$ Tregs, CD4$^+$ CD25$^-$ effector T cells (Teffs), and CD4$^-$ antigen-presenting cells (APCs), by using CFSE dilution assay. When necessary, crude extracts (CE) or excretory-secretory products (ESP) of sparganum were added for the study of host-parasite interaction. Cytokine-producing capability of the splenocytes was investigated by restimulation assay *in vitro* and measurement of cytokine levels in the supernatants by cytometric bead array, in order to study the pattern of immune response of the mice to the parasite. Specific antibody to spargana was measured in the sera by ELISA, as an objective parameter of adaptive immune response to the parasite.

Results: Treg function fluctuated during the parasite infection, being upregulated at day 3, downregulated until week 2, and thereafter upregulated again in week 3. The capabilities of the splenocytes to produce IL-2, IFN-g and IL-17a were decreased, while those of IL-4 and IL-10 were increased along the time course of the parasite infection. Meanwhile, IL-6 producing capability was increased to reach a peak at week 2, and thereafter was decreased to the baseline level. As a regulatory mechanism, we found Tregs proliferated well *in vitro*, in the presence of IL-2, and in particular to weak stimulating signals better than CD4$^+$ CD25$^-$ Teffs. We also found that the CE decreased, whereas the ESP of sparganum increased the suppressive function of Tregs, suggesting that sparganum products were involved in the triggering and regulation of immune response in the acute and chronic phases, respectively.

Conclusions: Taken together, Tregs are central in the immune homeostasis *in vivo* maintained by host-parasite interaction during the parasite infection.

Functional roles for defective PI3K signaling and differing co-stimulatory activity of APCs in T-Cell plasticity

E. Etemire,*,† M. Krull,‡ P. Reichardt‡ & M. Gunzer§,¶

**Institute for Molecular and Clinical Immunology, Otto von Guericke University, Magdeburg, Germany, †Department of Immunology, Institute for Experimental Immunology and Imaging, University Hospital Essen Germany, University of Duisburg-Essen, Essen, Germany, ‡Department of Immunology, Institute for Molecular and Clinical Immunology, Otto von Guericke University, Magdeburg, Germany, §Institute for Molecular and Clinical Immunology, Otto von Guericke University, Magdeburg, Germany, ¶Department of Immunology, Institute for Experimental Immunology and Imaging, University Hospital Essen, University of Duisburg-Essen, Essen, Germany*

Purpose/Objective: The activation of naïve CD4$^+$ T-cells by naïve peptide loaded B cells (TofB) leads to the production of T cells with a CD62-L high phenotype and regulatory properties (Treg) *in vivo* and *in vitro*. This is in contrast with the functional outcome following activation of T-cells with dendritic cells serving as APC (TofDC). We sought to investigate the underlying molecular mechanisms governing this differential regulation of CD62-L and the induction of a regulatory phenotype.

Materials and methods: 8–12 weeks old OT-2 and DO11.10 were sources of naïve CD4 T-cells specific for a peptide of chicken ovalbumin. Balb/c and C57/Bl6 mice were used as sources of DC and naïve B-cells. Splenic T and B-cells were negatively enriched using the MACS system. DC were obtained from bone marrow precursors differentiated with GM-CSF and IL4 or GM-CSF alone and treated with LPS when further functional maturation should be induced.

Results: Inhibition of PI3K/Akt and mTOR signaling led to increased CD62-L expression in the TofDC. Signal profiling of the differentially activated T-cells revealed a specific defect in the PI3K signaling pathway. In the TofB, we identified an attenuated phosphorylation of the hydrophobic motif of Akt occurring at the time of divergence in CD62-L kinetics between TofB and TofDC. T-cells triggered with immature DCs which are known to tolerize T-cells also induced an attenuated Akt profile in addition to a high CD62-L phenotype, which were both indistinguishable from the effects seen in TofB. Under certain conditions, it was also possible to induce regulatory behavior in T-cells triggered with matured DCs via fine tuning of the P13K but not the mTOR pathway.

Conclusions: Thus, the regulation of CD62-L involves bothPI3K/Akt and mTOR signaling; however the PI3K/Akt axis seems to be singularly responsible for the induction of a regulatory phenotype.The applica-

tion of this knowledge might be useful for tuning immune responses i.e. for inducing Treg production in cases of exaggerated immune responses or vice-versa.

HLA-C KIR-ligand allotype differentially induces the expansion of alloreactive CD8$^+$ KIR2D$^+$ T lymphocytes *in vivo* and *in vitro*

A. Minguela Puras,* L. Gimeno,* S. Soriano,† M. A. Cánovas,† J. A. Campillo,† M. R. López-Álvarez,† J. M. Bolarin,† R. M. Blanco-García,† M. V. Bernardo,† B. Las Heras-Ferre,† I. Legaz,† A. Mrowiec,† E. M. Plaza,‡ M. Muro† & M. R. Álvarez-López†
Immunology, University Hospiatl Virgen de la Arrixaca, Santo Angel-Murcia, Spain, †Immunology, University Hospiatl Virgen de la Arrixaca, Murcia, Spain, ‡Regional Blood Donation Centre, Murcia, Spain

Purpose/Objective: Results from our group have shown better early liver allograft acceptance associated with *in vivo* expansion of CD8$^+$ KIR2D$^+$ T cells. Apparently, HLA-C differentially influences the expansion of CD8$^+$ KIR2D$^+$ T cells with C1C1 and C1C2 but not C2C2 HLA-C KIR-ligand allotypes showing clear expansions 1 year after transplantation. The purposes of this study was to confirm in an *in vitro* model the differential expansion of CD8$^+$ KIR2D$^+$ responder T cells according to their HLA-C KIR-ligand allotype, and characterize the functional profile of expanded cells.
Materials and methods: Three different set of allogenic cultures were carried out in parallel using PBLs from healthy individuals. C1/C2-heterozygous stimulator cells were used to stimulate C1C1, C1C2 and C2C2 responder cells during 20-days. The cytotoxic capability of CD3$^+$ CD8$^+$ KIR2D$^+$ expanded cells was tested using the CD107a degranulation assay and a LSR-II flow cytometry (B. Dickinson).
Results: CD8$^+$ KIR2D- T-cells showed similar expansion for all HLA-C KIR-ligand allotypes. In contrast, C2C2-allotype showed significantly lower expansion of CD8$^+$ KIR2D$^+$ T cell than C1-allotypes.CD8$^+$ KIR2DL1/S1$^+$ T cells expanded by 39, 20 and 5.8 for C1C1, C1C2 and C2C2, respectively ($P < 0.05$). CD8$^+$ KIR2DL2/L3/S2$^+$ T cells expanded by 36, 21 and 12 for C1C1, C1C2 and C2C2, respectively ($P < 0.05$). Degranulation capability of *in vitro* CD8$^+$ KIR2D$^+$ expanded cells was decreased compared to CD8$^+$ KIR2D- (22.6% for KIR2DL1/S1$^+$ and 24.6% KIR2DL2/L3/S2$^+$ and 46.5% for KIR-).
Conclusions: Our results are consistent with the *in vivo* observation of CD8$^+$ KIR2D$^+$ T cells expansion and its dependence on the liver recipient HLA-C allotype. Deeply analysis of these cells should be done in order to determinate its role in the alloresponse as possible regulatory cells.

Funding: This work was supported by Mutua Madrile—a Fundation (AP74392010) and FFIS (FFIS/CM10/007). L. Gimeno was support by ISCIII and FFIS (CA09/00099).

Human regulatory T cell subpopulation heterogeneity at single-cell level in homeostatic conditions and during graft-versus-host disease

L. Rogge,* S. Dong,* S. Maiella,* A. Xhaard,† Y. Pang,* L. Wenandy,* C. Becavin,‡ A. Benecke,‡ E. Bianchi* & G. Socié†
Immunology, Institut Pasteur, Paris, France, †Hematology, Saint-Louis Hospital, Paris, France, ‡Institut des Hautes Etudes Scientifiques, Systems Epigenomics, Bures-sur-Yvette, France

Purpose/Objective: CD4$^+$ FOXP3$^+$ regulatory T cells (Treg) are of critical importance for the control of immune homeostasis and the maintenance of tolerance. While Treg were initially considered a homogeneous and stable population, recent studies have identified multiple Treg subpopulations and their potential plasticity. Understanding of the heterogeneity and potential for lineage reprogramming of Treg to effector T cells with pro-inflammatory functions is key for advancing Treg therapy into the clinics.
Materials and methods: We have explored the heterogeneity and functional diversity of human Treg using multi-parameter single-cell analysis techniques in healthy donors and in patients developing acute graft-versus-host disease (aGVHD) after allogeneic hematopoietic stem cell transplantation (alloHSCT).
Results: Our single-cell analysis of the human Treg compartment revealed a pattern of highly variegated gene expression that has not been appreciated by the analysis of bulk populations or by flow cytometry. We found that IFN-γ or IL-17A-secreting CD4$^+$ FOXP3$^+$ Treg are characterized by an overlap of gene expression signatures of Th1 or Th17 cells and of Treg within the same cell. Of note, a substantial fraction of cytokine-producing Treg express *IKZF2* indicating thymic origin. Similar to FOXP3$^-$ CD4$^+$ effector T cells, the mosaic-like expression of transcription factors, signaling molecules and homing receptors can endow individual Treg with specific functions and migratory properties.

Analysis of Treg homeostasis in the severely inflammatory and lymphopenic environment in patients after alloHSCT at the time of engraftment did not provide evidence for lineage reprogramming of CD4$^+$ FOXP3$^+$ T cells. Although we observed a strongly skewed Treg compartment in patients developing aGVHD compared to the control group, the overall frequency of CD4$^+$ FOXP3$^+$ T cells and the suppressive activity of Treg isolated from aGVHD patients were preserved.
Conclusions: Our results show that the human Treg compartment displays a similar level of complexity and functional heterogeneity as conventional CD4$^+$ effector T cells. Furthermore, we found that altered homeostasis of functionally distinct Treg subpopulations, rather than the total number of Treg, is associated with acute GVHD.

P0675

ICOS-ICOSL regulates the generation and function of CD4$^+$ Treg in a CTLA-4 dependent manner

J. Zheng,* P. L. Chan,* Y. Liu,* G. Qin,* Z. Xiang,* K. T. Lam,* D. B. Lewis,† Y. L. Lau* & W. Tu*
Department of Paediatrics, The University of Hong Kong, Hong Kong, China, †Division of Immunology and Allergy, Stanford University, Stanford, CA, USA

Purpose/Objective: Inducible co-stimulator (ICOS, CD278) is a member of CD28/Cytotoxic T-lymphocyte Antigen-4 (CTLA-4, CD152) family and broadly expressed in activated CD4$^+$ T cells or induced regulatory CD4$^+$ T cells (CD4$^+$ Treg). The biology function of ICOS is mediated by the interaction between ICOS and its ligand (ICOSL, CD275). Here we investigate the role of ICOS-ICOSL in the generation and function of CD4$^+$ Treg and its underlying mechanisms.
Materials and methods: In our previous work, we established a cost-effective system to generate a novel human allo-antigen specific CD4$^+$ Treg by co-culturing their naïve precursors with allogeneic CD40-activated B cells *in vitro*. This induced CD4$^+$ Treg expressed high level of both ICOS and CTLA-4 on its surface. In this work, ICOS-Ig fusion protein and endocytosis inhibitors E64 and pepastatin A were applied to clarify the effects of ICOS-ICOSL and its correlation with the expression of CTLA-4.
Results: We found that blocking ICOS-ICOSL pathway impaired the induction and expansion of CD4$^+$ Treg activated by allogeneic CD40-activated B cells. Moreover, CD4$^+$ Treg induced with the supplement of ICOS-Ig exhibited decreased suppressive capacity on allo-responses. According to the molecular mechanisms, ICOS-ICOSL pathway signal was found to up-regulate the surface expression of CTLA-4 by both increasing the endocytosis and decreasing the exocytosis of CD4$^+$ Treg.

Conclusions: These data demonstrates the beneficial role of ICOS-ICOSL pathway in the generation of $CD4^+$ Treg through the interactions between co-stimulators (ICOS and CTLA-4) expressed in $CD4^+$ Treg.

P0676
Impaired homeostasis and function of circulating regulatory T cells in patients with coronary artery disease

L. Hasib,* L. Jonasson,* K. Backteman† & J. Ernerudth†
**Division of Cardiovascular Research, Department of Medical and Health Sciences, Univesity Linköping, Linköping, Sweden, †Division of Clinical Immunology, Department of Clinical and Experimentale Medicine, Univesity Linköping, Linköping, Sweden*

Purpose/Objective: Regulatory T cells (Tregs) are believed to be protective in atherosclerosis. Normally, numbers of naïve (*n*) Tregs decline with age while memory (m) Tregs are maintained or even increased in elderly. Studies of total Tregs in patients with coronary artery disease (CAD) have yielded contradictory results.

In the present study, we investigated whether CAD patients exhibited an impaired function and homeostasis of Tregs.

Materials and methods: We included 25 patients with stable CAD (all statin-treated) and 25 controls. Phenotypic analysis of Tregs using CD3, CD4, CD25, FoxP3, CTLA4 and Helios markers was performed *in vivo* by flow cytometry applying different gating strategies. Sorting of Tregs was performed using CD4, CD25, CD127 and CD45RA. Afterwards, nTregs and mTregs were analysed for FoxP3. In suppression assays, nTregs and mTregs were cocultured with T responder cells at ratios of 1:1, 1:4 and 1:10 for 18 h. Proliferation of responder cells was evaluated as well as cytokine secretion (IFN-γ, TNF, IL-2, IL-10) insupernatants.

Results: The frequencies of total Tregs *in vivo* ($CD3^+$ $CD4^+$ $CD25^{high}$, $CD3^+$ $CD4^+$ $CD25^{dim}$ and $CD3^+$ $CD4^{dim}CD25^{high}$) were similar in patients and controls. However, the proportion of nTregs ($CD4^+$ $CD25^{high}CD45RA^+$ or $CD4^+$ $CD25^+$ $CD127^-/^{low}CD45RA^+$) was significantly lower in patients, while the proportion of mTregs did not differ. The expression of activation markers CTLA-4 and Helios was higher on mTregs than nTregs but without any differences between patients and controls. However, the ability of both nTregs and mTregs to inhibit responder cell proliferation was significantly reduced in patients. The capacity of nTregs to inhibit the secretion of IFN-γ and TNF was also significantly decreased in patients and the capacity of both Treg fractions to induce secretion of IL-10 was significantly reduced in patients.

Conclusions: Using different gating strategies total Tregs was similar in patients and controls, however a significant reduction of nTregs in CAD patients was found. These results indicate an altered Treg homeostasis. Moreover, the function of both nTregs and mTreg was markedly impaired in patients. Although the clinical relevance remains to be elucidated, the data highlight the presence of immune dysfunction and immunosenescence in CAD patients.

P0677
Induction of $CD4^+$ regulatory T cells by soluble HLA-G isoforms

M. E. Gianolini,* C. Magnani,* J. LeMaoult,† E. D. Carosella,† R. Rizzo,‡ M. G. Roncarolo§ & S. Gregori§
**Division of Regenerative Medicine Stem Cells and Gene Therapy, San Raffaele Telethon Institute for Gene Therapy, Milano, Italy, †Service de Recherches en Hemato-Immunologie, Institut Universitaire d'Hematologie, Hopital Saint Louis, Paris, France, ‡Section of Microbiology, Department of Experimental and Diagnostic Medicine, University of Ferrara, Ferrara, Italy, §Department of Regenerative Medicine Stem Cells and Gene Therapy, San Raffaele Telethon Institute for Gene Therapy (HSR-TIGET), Milano, Italy*

Purpose/Objective: The non-classical HLA class I molecule HLA-G was initially shown to play a major role in feto-maternal tolerance. Since this discovery, it has been established that HLA-G is a tolerogenic molecule, which participates to the control of the immune response. HLA-G inhibits a wide array of immune cells and has long-term immune-modulatory effects since it can induce the generation of suppressor/regulatory cells. We recently demonstrated that tolerogenic DC, termed DC-10, promote the differentiation of Tr1 cells via the IL10-dependent membrane bound HLA-G1/ILT4 pathway. The role of membrane-bound HLA-G1 in promoting Tr1 cells *via* DC-10, raise the question whether soluble shed HLA-G1 or HLA-G5 can promote Tr1 cell differentiation.

Materials and methods: Human naïve $CD4^+$ T cells were stimulated via anti-CD3 mAbs cross-linked on artificial APC consisting in murine L-cells co-transfected with human CD32, CD80, and CD58 in the presence of shed sHLA-G1 or HLA-G5 alone or in combination with IL-10. As control, we used Th0 and Tr1 cells differentiated with artificial APC alone or in the presence of IL-10 and IFN-a, respectively.

Results: We showed that repetitive stimulation of human naïve $CD4^+$ T cells in the presence of shed HLA-G1 or HLA-G5, alone or in combination with IL-10, induced the differentiation of a population of $CD4^+$ T cells that are phenotypically different from both Th0 and Tr1 cells. T cells differentiated with soluble HLA-Gs secrete lower levels of IFN-g and IL-2 as compared to Th0 cells. Interestingly, HLA-G-induced T cells secrete low amounts of IL-10, which is slightly increased when IL-10 is present in culture, but never reach the levels produced by Tr1 cells. Despite the ability to proliferate upon polyclonal activation, HLA-G-induced T cells suppress the proliferation of autologous $CD4^+$ T cells *in vitro*.

Conclusions: We showed that activation of human $CD4^+$ T cells in the presence of both soluble shed HLA-G1 or HLA-G5, alone or in combination with IL-10, promotes the induction of a population of suppressor $CD4^+$ T cells, which are distinct from Tr1 cells.

P0678
Induction of IL-35 in human T cells upon co-stimulation via CD43 and PD-1

M. Modak, M. Seyerl, R. Aigner, P. Cejka, O. Majdic, G. Zlabinger & J. Stöckl
Center for Pathophysiology Infectiology and Immunology, Institute of Immunology, Vienna, Austria

Purpose/Objective: IL-35, an IL-12 family member, is a heterodimer of EBV induced gene 3 (EBI3) and p35. IL-35 has been characterised as an inhibitory cytokine and is extensively studied in mouse models. Recently, our group has shown the induction of IL-35 producing human regulatory T cells by human rhinovirus treated dendritic cells (R-DC) via up-regulation of B7H1 (CD274) and sialoadhesin (CD169). Thus, a combined set of co-stimulatory signals for T cells seems to be critical to induce IL-35. We therefore investigated the underlying molecular mechanisms involved on T cell side for the

induction of IL-35. In addition, we have also investigated the mechanism of action of IL-35 on human T cells.
Materials and methods: For the induction of IL-35, T cells isolated from human peripheral blood, were stimulated with a panel of plate-bound monoclonal antibodies (mAbs) against putative accessory T cell surface receptors.The IL-35 induction was analyzed by qPCR, intracellular staining and by using newly established ELISA. T cell cytokines were also measured. The inhibitory effect of R-DC induced IL-35 was also tested on T cells activated in presence or absence of antigen presenting cells (APC).
Results: Among the various combinations tested, T cells stimulated with plate-bound anti-PD-1 mAb (CD279) in combination with CD43mAb and CD3 mAb − OKT3 was identified to most potently induce IL-35, whereas the other T cell activation pathways failed to do so. T cells activated via $CD3^+$ $CD43^+$ PD-1 co-signaling showed a diminished proliferative response compared to cells stimulated via $CD3^+$ CD43. However, the T cell signature cytokine profile (IL-2, IL-4, IL-10, IL-17, IL-22, IFN-γ) remained unaltered upon stimulation via $CD3^+$ $CD43^+$ PD-1, compared to other activation protocols. Furthermore, the R-DC induced IL-35 exhibited the inhibitory effect only when T cells were activated in the presence of DCs.
Conclusions: Thus, suggesting that the presence of APC is rather essential for IL-35 mediated inhibition. From our data, human T cell stimulation via $CD3^+$ $CD43^+$ PD-1 seems to be a specific pathway to induce IL-35 production, that is not accompanied by re-organisation in the T cell signature cytokine profile and a novel pathway for the induction of immune inhibitory T cells.

P0679
Innate immune sensing by human regulatory T cells − role of TLR2 and relevance to autoimmunity in multiple sclerosis

M. H. Nyirenda,* T. Constantin-Teodosiu,† J. Crooks,* G. Podda,* A. Bar-Or,‡ G. X. Zhang,§ C. S. Constantinescu* & B. Gran*
**Division of Clinical Neurology, University of Nottingham, Nottingham, UK, †School of Biomedical Sciences, University of Nottingham, Nottingham, UK, ‡Neuroimmunology Unit, McGill University, Montreal, QC, Canada, §Department of Neurology, Thomas Jefferson University, Philadelphia, PA, USA*

Purpose/Objective: We and others previously reported that TLR2 is more highly expressed on human $CD4^+$ $FOXP3^+$ $CD25^{hi}$ regulatory T cells (Tregs) and that activation of TLR1/2 heterodimers reduces Treg suppressive activity. We also found that TLR2 activation induces human Tregs to a Th-17-like phenotype and that similar to previour reports in the mouse, it can also induce human T helper precursors to Th17 differentiation. The objective of this study was to compare the modulation of $CD4^+$ Tregs by TLR2 agonists in people with and without multiple sclerosis (MS), an inflammatory demyelinating disease of the central nervous system in which defects of Treg function have been reported.
Materials and methods: For suppression assays, we used co-cultures of effector/responder T cells and Tregs purified using either CD25/CD127 or CD25/CD45RA sorting strategies (Miyara et al., Immunity 2009). These are APC-free cultures (Nyirenda et al., J Immunol 2011). Cells were cultured for 3−5 days in the presence or absence of TLR1/2 (Pam3Cys) or TLR2/6 agonists (Pam2Cys or FSL-1) and proliferation determined by incorporation of tritiated thymidine. For T-cell polarisation assays, CD4-enriched T cells were cultured in the presence or absence of a Th17 differentiation cocktail (IL-1, IL-16, TGF-beta, IL-23, anti-IFNgamma, and anti-IL-4) or the above mentioned TLR2 agonists. Intracellular expression of cytokine was measured by flow cytometry and cytokine secretion by ELISA or cytometric bead arrays.
Results: In a pilot study of 10 patients with MS and matched healthy controls, we found that the suppressive functions of $CD4^+$ $CD25^{hi}CD127^{neg}FOXP3^+$ Tregs as well as $CD45RA^+FOXP3^{lo}$ (naïve Tregs) and $CD45RA^-FOXP3^{hi}$ (effector Tregs) Treg subsets from MS patients were more susceptible to TLR2-induced reduction of suppressive function and expression of Th17 cytokines than those derived from healthy controls. Blocking IL-6 with a neutralising Ab reversed TLR2-induced loss of suppressive function and conversely, stimulation of $CD4^+$ T cells with Pam3Cys enhanced the expression of IL-6 and pSTAT3 in cultured T cells, pointing to the importance of IL-6 signalling in mediating the effects of TLR2 activation.
Conclusions: These data suggest that infections that are able to stimulate TLR2 *in vivo* may modulate the Treg/Th17 balance in MS patients, facilitating the elimination of infectious agents at the possible cost of increased risk of autoimmune reactions. A degree of flexibility in recognition of pathogen- or danger-associated molecular patterns by TLR2 suggests that not only bacterial, but also viral and self structures may act as agonists *in vivo*.

P0680
Interferon-alpha plays complex roles in human regulatory T cell deprogramming into Th1-like cells

S. Piconese,* Y. Pacella,* E. Timperi,* G. Labbadia† & V. Barnaba*
**Dipartimento di Medicina Interna e Specialità Mediche, 'Sapienza' University of Rome Policlinico Umberto I, Rome, Italy, †Dipartimento di Clinica e Terapia Medica Applicata, 'Sapienza' University of Rome Policlinico Umberto I, Rome, Italy*

Purpose/Objective: Regulatory T cells (Treg) are classically viewed as immune suppressive cells tipping the balance between host defence from pathogens and prevention of chronic inflammation and autoimmunity. Recent data indicate that Treg can dynamically adapt to different contexts and even dampen their suppressive program while acquiring the competence for unexpected inflammatory functions. The cytokine context may dictate the Treg fate decision between stability and deprogramming. Very little is known about the effects of interferon (IFN)-alpha on Treg. Indeed this cytokine, beyond a well-known antiviral activity and a pathogenic role in some autoimmune diseases, may display specific immunomodulatory or immunostimulatory properties in different settings. The purpose of this study was to characterize the functional changes induced in Treg upon exposure to IFN-alpha.
Materials and methods: Treg obtained from healthy donors were cultured with recombinant IFN-alpha under neutral (IL-2) or Th1-prone (IL-2^+ IL-12) conditions and Treg functions were tested by flow cytometry in terms of expansion, suppression, Tbet and IFN-gamma expression. To evaluate the effects of Treg exposure to IFN-alpha *in vivo*, Treg were similarly analysed by flow cytometry in patients with chronic HCV infection undergoing peginterferon/ribavirin therapy, before and 2 days after the starting of therapy.
Results: *in vitro*, in neutral culture conditions, IFN-alpha slightly increased Tbet and IFN-gamma expression by Treg; in the Th1-prone condition, the addition of IFN-alpha further enhanced IL-12-driven IFN-gamma production while slightly reducing Tbet upregulation, suggesting a complex role for IFN-alpha in supporting Treg deprogramming into Th1-like cells. IFN-alpha also exerted an anti-proliferative effect against both conventional T cells (Tconv) and Treg, without affecting anyway the Treg-intrinsic suppressive function in Tconv-Treg cocultures under neutral conditions. In the majority of HCV patients treated with peginterferon/ribavirin, we could observe a decreased Treg frequency and an enhanced IFN-gamma production by both Tconv and Treg after treatment. IFN-gamma secretion by the two cell subsets showed a linear correlation, suggesting that Tconv-derived IFN-gamma may play a role in Treg diversion into Th1-like cells.
Conclusions: Our data indicate that, under Th1 conditions, IFN-alpha may amplify Th1-type inflammation by inhibiting Treg expansion and fostering Treg deprogramming into Th1-like cells.

Modulation of Treg-mediated supression by iNKT cells in T1D

L. Usero,* A. Martínez,* C. Xufré,* R. Planas,† M. Vives,‡ D. Jaraquemada,§ M. Martí§ & C. Roura-Mir§

**Cellular Immunology Lab, Institut de Biotecnologia i Biomedicina, Barcelona, Spain, †Department of Neuroimmunology and Multiple Sclerosis Research, University Hospital Zurich Neurology Clinic, Zurich, Switzerland, ‡Laboratory of Immunobiology for Research and Diagnosis Applications (LIRAD), Germans Trias i Pujol Research Institute, Badalona, Spain, §Cellular Immunology Lab, Institut de Biotecnologia i Biomedicina, Barcelona, Spain*

Purpose/Objective: Type 1 Diabetes (T1D) is an organ-specific autoimmune disease mediated by the destruction of insulin-producing beta cells by T cells. T regulatory cells (Tregs) and invariant natural killer T cells (iNKT) are important to control pathogenic autoreactivity. Results from our group showed that both cell types were present at the diabetic pancreas although Tregs were preferentially located inside the islets while iNKTs migrated to the islets at late stages of the disease. An active cross-talk between Tregs and iNKTs at the target organ could result on a better regulation of autoagressive T cells. Thus, our aim was to study their functional interaction in T1D patients.

Materials and methods: iNKT and Treg cells were selected from healthy donors and T1D patients PBMCs based on the expression of the TCR α-chain Vα24Jα18 or $CD4^+$ $CD25^{++}$ and expanded *in vitro* with $CD1d^+$ APCs pulsed with αGalactosylCeramide or αCD3, respectively. We analyzed the capacity of the expanded iNKTs cells to modify the suppressor effect of Tregs in a proliferation assay in the presence of increasing numbers of iNKTs. We determined if the interaction needed cell-cell contact or cytokine secretion using a transwell system.

Results: The results showed that Treg cells suppressed Teff cell proliferation by limiting their IL2 production in a cell-cell contact-dependent manner. On the other hand, iNKTs increased up to a 40% the Teff proliferation supression by Tregs. This effect so far appears to be independent of cell-cell contact between INKTs and Tregs. The analysis of cytokine secretion demonstrated that iNKTs contributed to the supression of Teff cells maintaining a low IL-2 secretion rate. At the same time, iNKTs enhanced the secretion of other effector cytokines by Teff. This was confirmed by abrogation of cytokine secretion by the use of irradiated iNKTs or Teff. The possible secretion of soluble inhibiting factors by iNKTs that could enhance the Treg suppression is currently under investigation.

Conclusions: iNKT cells have an adjuvant effect on Tregsfunction as they increase their capacity to inhibit Teff cell proliferation *in vitro*. The co-localization of these two cell populations in the diabetic pancreas suggests that this effect could be taking place *in vivo*. This adjuvant effect could represent a tool to overcome the proposed resistance to suppression by Tregs of diabetic Teff cells.

P0682

Ontogeny, phenotype and functional properties of human $CD39^+$ regulatory T cells

E. Tolosa, I. Baumann, J. Viautour, A. Cuapio & A. Schram

Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Purpose/Objective: CD39 and CD73 are ectoenzymes that act in concert to hydrolyze extracellular ATP to generate adenosine, a molecule with anti-inflammatory properties. While murine Treg express both CD39 and CD73, and CD39-deficient animals show impaired regulatory function, the picture in humans is more complicated. $CD39^+$ Tregs can uniquely constrain Th17 cell responses, and are impaired in patients with multiple sclerosis. However, it remains the question whether the expression of CD39 is intrinsic to a particular subset of Tregs or if CD39 is transiently upregulated in activated Tregs.

Materials and methods: We used multiparameter flow cytometry to analyze the phenotpye and functional properties of the $CD39^+$ and CD39- Treg subsets in the thymus, cord blood and peripheral blood from children and adult donors. Using cellular dyes, we labeled the $CD39^+$ and CD39- subsets of Tregs in order to track them after activation, and performed proliferation assays to determine their respective suppressive capacity.

Results: Phenotypically, $CD39^+$ Tregs express higher levels of FOXP3, display markers characteristic of memory cells, and express chemokine receptors that can guide them to sites of inflammation. However, the expression of the activation marker CD69 is similar in the two subsets, and $CD39^+$ Tregs express lower levels of CD26 and CD38 compared to CD39- Tregs. Upon polyclonal activation, CD39- Tregs upregulate CD39 modestly, never reaching the levels of the $CD39^+$ Tregs. Interestingly, only $CD39^+$ Tregs upregulate CD73, which makes them more efficient at producing adenosine. Both subsets are suppressive, although $CD39^+$ Tregs are more efficient than their CD39- counterparts. In patients with juvenile rheumatoid arthritis, $CD39^+$ Treg are highly elevated in the synovial fluid, probably reflecting an attempt to control chronic inflammation. Regarding their origin, $CD39^+$ Tregs are already found in the thymus, and CD39 is not only expressed in a subset of the single positive $CD4^+$ $CD25^+$ thymocytes, but also by some double positive precursors. Cord blood cells also contain $CD39^+$ Tregs, although at lower levels that later in life, and $CD39^+$ Tregs were found to increase with age. Of note, in peripheral blood from adults both the $CD39^+$ and the CD39- subsets contain $CD31^+$ cells, indicating recent egress from the thymus.

Conclusions: Altogether, our results support the notion that CD39 does not reflect an activated status of Treg cells, but rather a subset that also originates in the thymus, displays specific migratory properties and is more efficient at suppression.

P0684

p27kip1 inhibits systemic autoimmunity through the control of regulatory T cell activity and differentiation

M. Iglesias,* J. Postigo,† I. Santiuste,* J. González,† L. Buelta,‡ E. Tamayo,† J. Merino† & R. Merino*

**Biología Molecular, Universidad de Cantabria-IBBTEC, Santander, Spain, †Biología Molecular, Universidad de Cantabria-IFIMAV, Santander, Spain, ‡Ciencias Médicas y Quirúrgicas, Universidad de Cantabria, Santander, Spain*

Purpose/Objective: Despite the importance of regulatory T cells (Tregs) in the maintenance of immunological tolerance, little information is still available about the molecular mechanisms that regulate the number and activity of these cells *in vivo*. Using different experimental approaches, other authors showed that Bcl-xl affected the development and activity of Tregs; however, the precise molecular mechanism by which these anti-apoptotic factors influenced Tregs was not elucidated in such studies. Since the cell cycle inhibitor $p27^{kip1}$ (p27) was involved in T-cell anergy, we also explored here its role in both Treg processes.

Materials and methods: (DBA/1 × B6) F1 Tg mice overexpressing human Bcl-2 in T cells and (DBA/1 × B6) F1 $p27^{+/-}$ were immunized with 150 μg of collagen bovine type II emulsified with complet Freund's adjuvant for the induction of Collagen-Induced Arthritis.

Depletion of Tregs was performed using an anti-CD25 mAb

For supression cocultures, $CD4^+$ CD25- effector T cells and $CD4^+$ $CD25^+$ regulatory T cells were purified by cell sorting and stimulated with anti-CD3 and antigen presenting cells under different Treg/Teff ratios.

In the differentiation cultures, $CD4^+$ $CD25^-CD62L^+CD44^-$ naïve T cells furified by cell sorting were cultured with anti-CD3/CD28 under Treg inducing conditions (TGFβ and IL-2).

Results: First, we demonstrated here that Tg mice overexpressing human BCL2 in T cells (BCL2-TgT mice) were protected against collagen type II-induced arthritis (CIA) by a Treg-dependent mechanism. In association with this protection, the overexpression of BCL2 in T cells enhanced the differentiation and activity of Tregs. Both BCL2 effects were independent of its anti-apoptotic activity but dependent on its capacity to induce the expression of the cell cycle inhibitor p27 that enhanced the strength of TGFb-signalling in T cells. Accordingly, the modulation of p27 expression in BCL2-TgT mice promoted CIA. In addition, p27 deficiency in aged B6 mice reduced the number and activity of Tregs and induced the development of autoimmunity.
Conclusions: Our results pointed to p27 as a critical regulator of Treg differentiation and function through the positive modulation of TGFb-signalling strength in T cells.

P0686
Potential induction of regulatory T cells by 5-Azacytidine and EGCG from non-regulatory T cells

R. Tatura, J. Steinmann, J. Buer & J. Kehrmann
Institute of Medical Microbiology, University Hospital Essen, Essen, Germany

Purpose/Objective: Regulatory T cells (Treg cells) play a pivotal role in establishing a peripheral immune tolerance. A deficit of Treg cells is supposed to play an essential role in Graft versus Host disease after bone marrow transplantation. Adoptive transfer of Treg cells is hoped to inhibit development or improve the course of disease. One approach is the *in vitro* induction of Treg cells by demethylating agents, as human Treg cells differ from non-regulatory T cells by protein expression as well as epigenetic differences in DNA methylation. The two DNA methyltransferase (DNMT) inhibitors, 5-Azacytidine (5-AZA), which is used for the treatment of myelodysplastic syndrome and epigallocatechin-3-gallate (EGCG), which is a main component of green tea, were analyzed for their potential in inducing a Treg cell phenotype on DNA-, RNA- and protein-level.
Materials and methods: Jurkat T cells and FACS-sorted human $CD4^+$ $CD25^-$ cells were analyzed after cultivation with 5-AZA or EGCG. DNA-methylation, FOXP3 protein expression by flow cytometry and FOXP3- and GARP-RNA-expression by real-time PCR after 4 and 7 days of cultivation were analyzed.
Results: 5-AZA induces a strong global DNA-demethylation and a FOXP3- and GARP-expression on protein as well as RNA-level in Jurkat and $CD4^+$ $CD25^-$ T cells. The potential of EGCG in global DNA-demethylation is similar to 5-AZA, but EGCG has only a very low potency of inducing FOXP3- expression in Jurkat and sorted $CD4^+$ $CD25^-$ T cells, while it was not able to induce GARP-expression in Jurkat and sorted $CD4^+$ $CD25^-$ T cells.
Conclusions: 5-AZA seems to be more suitable for induction of Treg cells than EGCG. We are currently analysing further phenotypic and also functional properties of the induced cells.

P0687
Quantification of regulatory T cells in septic patients by real-time PCR–based methylation assay and flow cytometry

J. Kehrmann,* R. Tatura,* M. Zeschnigk,† M. Adamzik,‡ M. Probst-Kepper§ & J. Buer*
**Institute of Medical Microbiology, University Hospital Essen, Essen, Germany, †Institute of Human Genetics, University Hospital Essen, Essen, Germany, ‡Department for Anaesthesiology and Intensive Care Medicine, University Hospital Essen, Essen, Germany, §Institute for Clinical Transfusion Medicine, University Hospital Essen, Braunschweig, Germany*

Purpose/Objective: During sepsis, a relative increase of regulatory T cells (Treg cells) has been reported. Its persistence is associated with a poor prognosis, lymphocyte anergy and immunoparalysis. As an exact quantification of human Treg cells by protein expression is currently unfeasible due to a lack of specific Treg cell molecules, a more precise and reliable method of quantifying Treg cells in septic patients is needed.
Materials and methods: We established a single-tube real-time PCR-based methylation assay for quantification of human Treg cells. This assay takes advantage of a Treg cell specific pattern within *FOXP3-TSDR*. We analyzed DNA-methylation of $CD4^+$ -isolated cells in blood samples from 30 septic patients and 30 healthy subjects in comparison to flow cytometric quantitation of $CD4^+$ $CD25^{hi}CD127^{low}$ T cells indicative of Treg cells.
Results: Both real-time PCR and flow cytometry demonstrated that the ratio of Treg cells to all $CD4^+$ cells was significantly higher in septic patients than in healthy subjects. The results yielded by the two methods were clearly positively correlated in healthy individuals, while they were only weakly positively correlated in septic patients.
Conclusions: The described methylation-sensitive real-time PCR assay of *FOXP3-TSDR* precisely quantifies natural Treg cells in septic patients by using the most specific feature of these cells known thus far. It allows for more reliable immune monitoring of Treg cells in septic patients. Due to the known altering protein expression phenotype of $CD4^+$ T cells after activation, results obtained by flow cytometry especially in the collective of septic patients should be considered with caution.

P0688
Rarity of human t helper 17 cells is due to retinoic acid orphan receptor-dependent mechanisms that limit their expansion

V. santarlasci,* L. Maggi,* M. Capone,* V. Querci,* F. Liotta,* R. De Palma,† E. Maggi,* L. Cosmi,* S. Romagnani* & F. Annunziato*
**Internal Medicine, University of Florence, Florence, Italy, †Department of General Pathology, Second University of Naples, Naples, Italy*

Purpose/Objective: We investigate the reason why $CD4(^+)$ T helper 17 (Th17) cells, despite their well-known pathogenic role in chronic inflammatory disorders, are very rare in the inflammatory sites.
Materials and methods: The ability of Th17 and Th1 human T cell clones to respond upon anti-CD3-CD28 or PMA plus ionomycin stimulation and their signaling activation pathway was investigated.
Results: We demonstrate that human Th17 cells exhibit low ability to proliferate and to produce the T cell growth factor interleukin-2 (IL-2), in response to combined CD3 and CD28 stimulation. This was due to the upregulated expression of IL-4-induced gene 1 (IL4I1) mRNA, a secreted L-phenylalanine oxidase, which associated with a decrease in CD3ζ chain expression and consequent abnormalities in the molecular pathway that allows IL-2 production and cell proliferation. High IL4I1 mRNA expression was detectable in Th17 cell precursors and was strictly dependent on Th17 cell master gene, the retinoid acid related orphan receptor (RORC). Th17 cells also exhibited RORC-dependent CD28 hyperexpression and the ability to produce IL-17A after CD28 stimulation without CD3 triggering.
Conclusions: Our findings suggest that the rarity of human Th17 cells in inflamed tissues results from RORC-dependent mechanisms limiting their expansion.

P0690
Regulatory T cells induced by mucosal B cells alleviate allergic airway hypersensitivity

K. Chu & B. Chiang
Graduate Institute of Immunology, National Taiwan University, Taipei city, Taiwan

Purpose/Objective: Asthma is one of the most common chronic airway inflammatory diseases. Induction of immunologic tolerance via

mucosa has been used for treating allergic diseases. B cells, the major cell population in Peyer's patches, have been shown to induce the development of Treg cells. This study aimed to investigate the role of B cells in Peyer's patches to tolerance induction and on Treg cell functions.

Materials and methods: *In vitro* suppressive assay and ELISA were used to evaluate the function of T cells stimulated by Peyer's patches B cells (Treg-of-B cells), the therapeutic potential of which was evaluated by an animal model of airway inflammation.

Results: Treg-of-B cells were found to exert suppressive function on T cell proliferation. Antigen-loaded B cells isolated from Peyer's patches were more tolerogenic and had the potential to generate more suppressive Treg-of-B cells via IL-10 production and cell-cell contract. Treg-of-B cells expressed CTLA4, ICOS, OX40, PD-1, and TNFRII and produced lower IL-2 and higher IL-10. In the murine model of asthma, an adoptive transfer of Treg-of-B cells pre- or post- immunization could sufficiently suppress Th2 cytokine production and eosinophil infiltration, and alleviate asthmatic symptoms.

Conclusions: B cells isolated from gut-associated lymphoid tissues, GALT, can generate regulatory T cells that may be important in oral tolerance and be applicable for alleviating allergic symptoms.

P0691

Role of the innate immune system in CD8$^+$ T regulatory T cell differentiation

A. L. Lemarquis,* U. Bjarnadóttir,† J. Freysdóttir*,†,‡ & B. R. Ludvíksson*,†

**Faculty of Medicine, University of Iceland, Reykjavík, Iceland, †Department of Immunology, Institute of Laboratory Medical Science, Landspítali University Hospital, Reykjavík, Iceland, ‡Centre for Rheumatology Research, The National University Hospital, Reykjavík, Iceland*

Purpose/Objective: Regulation of the immune system plays an important role in maintaining homeostasis in the human body. It«s role is of particular importance in autoimmune disorders, organ transplanting and the body's defences against pathogens and cancer. Recently growing interest is upon the role of CD8$^+$ T regulatory cells (T_{regs}) in this context. The aim of this study was to evaluate the role of the innate immune system in CD8$^+$ T_{Regs} differentiation and its regulatory capacity.

Materials and methods: naïve human CD8$^+$ T-cells, defined as CD25$^-$ CD45RA, were isolated and differentiated for five days in anti-CD3 coated plates with CD28 (1 μg/ml), IL-2 (200 IU) and TGF-β1 (10 μg/ml) with or without IL-1β (2.5 μg/ml) or TNF-α (10 μg/ml). To evaluate their suppressive function, cells were co-cultured with CFSE stained PBMC«s and Epstein-Barr infected B-cells charged with superantigens (EBB). The CD8$^+$ T_{Regs} differentiation of naïve CD8$^+$ T-cells was also tested in culture with allogeneic mature monocyte derived dendritic cells (mDC) with or without IL-2 and TGF-β1. Cells were analysed by flow cytometry to access their phenotype. CD8$^+$ T_{Regs} phenotype was defined as CD8$^+$ CD127$^-$ CD25^{high} FoxP3$^+$ (CD8$^+$ $_iT_{Regs}$).

Results: Exogenously added IL-1β and TNF-α did not suppress the differentiation of CD8$^+$ $_iT_{Regs}$ (%differentiated without IL-1β or TNF-α = 19.4% v.s. with IL-1β = 18.0% v.s. with TNF-α = 17.15%; P = n.s.). However the co-addition of IL-1β prevented $_iT_{Regs}$ suppressive function (%proliferating, $_iT_{Regs}$ 15.2% v.s. $_iT_{Regs}$ with IL-1β 22.3%; $P < 0.05$). Activation of naïve CD8$^+$ T-cells with allogeneic mDC resulted in a significant differentiation of CD8$^+$ $_iT_{Regs}$ (9.5%, $P < 0.03$). In addition such differentiation was enhanced by the exogenous administration of IL-2 and TGF-β1 (% differentiated without IL-2/TGF-β19.5% v.s. with 15.9%). Finally mDC expression of CD80 and CD86 was significantly downregulated following CD8$^+$ $_iT_{regs}$ expansion.

Conclusions: The study indicates that IL-1β and TNF-α do not affect CD8$^+$ $_iT_{Regs}$ differentiation. However it suggests that IL-1β may infer with its functionality. In addition, following stimulation with mDC significant proportion of nonresponding CD8$^+$ T-cells differentiate into $_iT_{Regs.}$ This may enhance our understanding of the interplay of innate immunity in autoimmunity.

P0692

Sequential expression of CD39 regulates late developmental Th17 plasticity imparting a regulatory cell phenotype

M. S. Longhi, A. Bai, Y. Wu, T. B. Strom, S. C. Robson

Medicine, Beth Israel Deaconess Medical Center, Boston, MA, USA

Purpose/Objective: CD39 is an immune cell phenotype marker that exhibits ectonucleotidase activity, converting extracellular nucleotides to nucleosides. Although CD39 has been associated with Treg, the ectoenzyme is also expressed by a subpopulation of memory T-cells (CD4^{mem}) with effector functions. We postulate that CD39 imparts plasticity to effector T helper type 17 (Th17) as well as co-ordinating Treg cellular programs of differentiation.

Materials and methods: Experiments were performed using peripheral blood mononuclear cells obtained from healthy blood donors. Sorted CD4$^+$ CD45RO$^+$ memory cells (CD4^{mem}) were exposed to 1) IL6$^+$ IL1β^+rTGFβ or 2) IL6$^+$ IL1β^+IL23 or 3) IL6$^+$ IL1β^+rTGF-β^+IL23 to induce Th17 polarization. Cells at Th17 stage were then treated with high dose IL2$^+$ anti-CD3/anti-CD28 to favour Treg differentiation and then re-exposed to Th17 differentiating conditions to induce putative reverse or suppressive Th17 (rev/regTh17) cells. Impacts of purinergic mediators on cell effector phenotype and functions were assessed.

Results: CD4^{mem} could be differentiated sequentially to Th17, Treg and rev/regTh17. In contrast to the inflammatory properties associated with prototypic Th17 cells, rev/regTh17 exhibited a suppressive phenotype (i.e. CD39^{high}, CD73^{high}, FOXP3$^+$) and were able to control CD4$^+$ CD25$^-$ cell proliferation and pro-inflammatory cytokine (IFNγ, IL17) production. At variance with Treg that following exposure to adenosine up-regulated CD39, CD73 and FOXP3 and became more suppressive, rev/regTh17 remained resistant to adenosine.

Conclusions: Differential levels of expression of CD39 designate early Th17 cells from later Treg/revTh17 cell plasticity. The potential for Treg to revert to the inflammatory Th17 phenotype is mitigated by expression of CD39, as indicated by enhancements of suppressive function *in vitro*.

P0693

Shifting gears: Immune system parameters of middle-aged marathon runners versus sedentary controls

I. Thomas,* N. Charokopos,† I. Panagoulias,* M. Leotsinidis‡ & A. Mouzaki*

**Department of Internal Medicine Division of Hematology, University of Patras Medical School, Patras, Greece, †Department of Pulmonology, General Hospital of Pirgos, Pirgos, Greece, ‡Laboratory of Public Health, University of Patras Medical School, Patras, Greece*

Purpose/Objective: To investigate the effect of strenuous exercise on the immune system and whether habitual long term exercise can actually preserve an immunological capacity compared to sedentary lifestyle, we examined lymphocyte subsets, cytokine levels and biochemical data of middle age marathon runners versus sedentary controls.

Materials and methods: Blood samples were collected from controls only once, whereas from marathon runners at three time points: within 1 h after the race, and seven days before and after the race. Routine complete blood counts were determined using an automatic blood counter. Major cytokines and cortisol levels were measured by enzyme-linked immunosorbent assays and peripheral blood lymphocyte subsets

were determined by two-color flow cytometry. Cytokine mRNA levels were measured by polymerase chain reaction (PCR).
Results: The race induced peripheral leukocytosis, attributed to neutrophilia. Plasma CPK and cortisol concentrations also increased significantly after the race. $CD4^+$ memory cells, total $CD8^+$ cells, $CD8^+$ naïve cells, $CD8^+$ memory cells, activated $CD8^+$ cells, NK cells, B cells and B1α cells were decreased after the race, whereas T regulatory cells ($CD4^+$ $CD25^+$ $FoxP3^+$) count was elevated significantly. Serum IL-1b, IL-6, IL-4, IL-10 and TGF-β1 levels were raised significantly post race, similar to mRNA levels measurements. One week later cytokine concentrations had dropped to original levels before the race, except for IL-2R, IL-4 and TGF-β1 which remained high. Compared to sedentary controls, B1α cells, activated $CD8^+$ cells and IL-2R concentration were at higher levels, while $CD4^+$ memory cells, activated $CD4^+$ cells and TGF-β1 levels were significantly lower.
Conclusions: Strenuous exercise results in a pro-inflammatory phenotype, as seen by the recruited cells and the secreted cytokines. This leads to suppression of host's defense and could predispose to autoimmunity. However, due to chronic regular exercise, athletes have developed regulatory mechanisms which balance effectively every polarization of the immune response and no cumulative effect of oxidative stress on cytokine balance seems to occur.

P0694

Study on the molecular mechanisms involved in the generation of regulatory T cells induced by B lymphocytes

S. Y. Chen* **& B. L. Chiang**[†]
**Graduate Institute of Clinical Medicine, National Taiwan University, Taipei, Taiwan, [†]Graduate Institute of Clinical Medicine and Graduate Institute of Immunology, National Taiwan University, Taipei, Taiwan*

Purpose/Objective: B lymphocytes have multiple functions in the immune system. In addition to the role in the humoral immunity, some recent studies have reported that B cells preferentially expand $Foxp3^+$ $CD4^+$ regulatory T cells (Tregs). It is well-known that the transcription factor Foxp3 confers the regulatory function of naturally occurring Tregs. Based on previous researches, it is speculated that B cells might play an important role to induce functional Tregs. However, efficient generation of Tregs is still an ongoing work.
Materials and methods: naïve splenic B and $CD4^+$ CD25-T cells cells from female Balb/c mice co-cultured together with anti-CD3/ anti-CD28 antibodies. After 3 days, the T cells were collected and measured for the suppressive ability by [3H] thymidine incorporation. Analysis of cell surface marker was carried out using a FACScan instrument and the cytokine profiles were measured by ELISA.
Results: The preliminary results showed while co-culture of naïve splenic B cells with $CD4^+$ CD25-T cells, the T cells converted into $CD4^+$ $CD25^+$ T cells (Treg-of-B) which could suppress proliferative response of $CD4^+$ CD25- responder T cells. The phenotypic analysis demonstrated that Treg-of-B cells expressed high level of ICOS and GITR but not Foxp3. The supernatant of T-B co-culture showed the production of IL-10, IL-4 and IL-2. The cytokine profile evolved over time, following second rounds of restimulaion with naïve fresh B cells, and resulted in the increased IL-10 production.
Conclusions: These results suggested the splenic naïve B cells can efficiently induce functional IL-10-producing Tregs *in vitro*. Some surface makers are similar to natural Tregs although the expression of Foxp3 is not a prerequisite for Treg-of-B activity. Thus, Treg-of-B cells can be exploited for the control of peripheral immunity or might be involved in the prevention of autoimmunity.

P0695

Targeted delivery of neural autoantigen to liver sinusoidal endothelial cells protects from experimental autoimmune encephalomyelitis

A. Carambia,* **B. Freund,**[†] **O. T. Bruns,**[‡] **D. Schwinge,*** **S. Lüth,*** **P. Nielsen,**[†] **H. Weller,**[§] **S. Salmen,**[§] **C. Schramm,*** **A. W. Lohse,*** **J. Heeren**[†] **& J. Herkel**[†]
**Department of Medicine I, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [†]Department of Biochemistry and Molecular Cell Biology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [‡]Heinrich-Pette-Institute, Leibniz Institute for Experimental Virology, Hamburg, Germany, [§]Institute of Physical Chemistry, University of Hamburg, Hamburg, Germany*

Purpose/Objective: Previously, we demonstrated that delivery of neural autoantigen to the liver by gene transfer induced TGF-β dependent conversion of $CD4^+$ $CD25^+$ $Foxp3^+$ regulatory T cells (Treg) from conventional $CD4^+$ CD25- T cells and protected mice from experimental autoimmune encephalomyelitis (EAE) (LŸth S et al., J Clin Invest 2008;118: 3403−10). However, the relevant liver cell types involved in hepatic Treg generation remained undefined.

Therefore, we aimed 1) to identify the liver cell type that can induce Treg conversion, and 2) to explore whether targeted delivery of autoantigen peptides to these Treg-inducing liver cells may serve the treatment of autoimmune disease.
Materials and methods: To assess the capacity of liver sinusoidal endothelial cells (LSEC) to induce Treg from $CD4^+$ CD25-Foxp3-non-Treg cells, we stimulated myelin basic protein (MBP)-specific non-Treg from tg4 × foxp3-gfp mice on primary LSEC or, as control, on splenic dendritic cells (DC, 5×10^4) in the presence of MBP-peptide (5 ng/ml). The suppressive activity of LSEC-induced Treg was assessed by transfer of 10^5 LSEC-stimulatedT cells to MBP-immunised mice one day after EAE induction. Alternatively, MBP peptides were delivered to LSEC of B10.PL mice *in vivo*, one day after EAE induction, by using a novel nanoparticle carrier, which selectively targets LSEC.
Results: Stimulation of non-Treg by LSEC, but not by DC efficiently induced antigen-specific $CD4^+$ $CD25^+$ $Foxp3^+$ Treg in the presence of exogenous TGF-β (30.4% versus 5.9%; $P = 0.0022$). Moreover, transfer of LSEC-stimulated $CD4^+$ T cells to MBP-immunised mice conferred almost complete protection from EAE for more than 20 days (EAE score 0.6 versus 3.1; $P = 0.0006$), after which recipient mice developed only mild disease symptoms. Importantly, the targeted delivery of MBP-peptides to LSEC *in vivo,* using nanoparticles that specifically target LSEC, efficiently induced complete and lasting protection from EAE (0.6 versus 4.0; $P = 0.0008$); in contrast, application of unloaded nanoparticles or free MBP-peptide did not alter EAE severity(EAE score 4.2).
Conclusions: We identified LSEC as a liver cell type capable of inducing TGF-β dependent antigen-specific Treg conversion. Therefore, nanoparticle-based delivery of autoantigen to LSEC may be a treatment option for autoimmune diseases.

P0696

The dependence on NFAT levels discriminates conventional T cells from Foxp3$^+$ regulatory T cells

F. Berberich-Siebelt,* M. Vaeth,* U. Schließer,† S. Reißig,‡ K. Satoh,§ H. Jonuleit,§ G. Müller,¶ A. Waisman,‡ E. Serfling,* B. Sawitzki,† A. Tüttenberg§ & M. R. Müller**
*Molecular Pathology, Institute of Pathology University of Würzburg, Würzburg, Germany, †Institute of Medical Immunology, CCM, Berlin, Germany, ‡Institute for Molecular Medicine, University Medical Center, Mainz, Germany, §Department of Dermatology, University Medical Center, Mainz, Germany, ¶Department of Tumor Genetics and Immunogenetics, MDC, Berlin, Germany, **Program in Cellular and Molecular Medicine, Harvard, Boston, MA, USA*

Purpose/Objective: Several lines of evidence suggest NFAT to control regulatory T cells: thymus-derived nTregs depend on calcium signals, the *Foxp3* gene harbors several NFAT binding sites and the Foxp3 protein interacts with NFAT. Therefore, we investigated the impact of NFAT on Foxp3 expression.
Materials and methods: *In vitro* and *in vivo* generated iTregs as well as nTregs from different NFAT deficient mice were analysed by FACS, immunofluorescence, immunoblot, PCR, ELISA, ChIP assays, and microarrays as well as adoptive transfer colitis and a skin transplant model.
Results: The generation of iTregs by TGFβ was highly dependent on NFAT expression as the ability of CD4$^+$ T cells to differentiate into iTregs diminished markedly with the number of NFAT family members missing. It can be concluded that the expression of Foxp3 in TGFβ-induced iTregs depends on the threshold value of NFAT rather than on an individual member present. This is specific for iTreg development, since frequency of nTregs remained unaltered in mice lacking NFAT1, NFAT2 or NFAT4 alone or in combination. Different from expectation however, the function of both nTregs and iTregs was independent on robust NFAT levels, reflected by less nuclear NFAT in nTregs and iTregs. Accordingly, absence of one or two NFAT members did not alter suppressor activity *in vitro* or during colitis and transplantation *in vivo*.
Conclusions: This scenario emphasizes an inhibition of high NFAT activity as treatment for autoimmune diseases and in transplantation, selectively targeting the proinflammatory conventional T cells, while keeping Tregs functional.

P0697

The differentiation and suppressive function of CD8$^+$ T regulatory cells

U. Bjarnadottir,* S. Halldorsdottir,*,† & B. R. Ludviksson*,†
Department of Immunology, Landspítali University Hospital, Reykjavík, Iceland, †Faculty of Medicine, University of Iceland, Reykjavík, Iceland

Purpose/Objective: CD8$^+$ T regulatory cells (CD8$^+$ T_{Regs}) display an immune-regulatory activity and play essential role as effector T-cells in several immune-pathologic manifestations such as autoimmune diseases (RA, SLE, MS), transplantation and protection of the host against infectious diseases and cancer. Therefore, they have a great potential as therapeutic targets and further research on surface markers, mRNA expression and cytokine secretion is needed to understand the cellular and molecular mechanisms underlying their mediated immune-suppressant. Our main objectives are to investigate the existence of induced CD8$^+$ T_{Regs} (CD8$^+$ iT_{Regs}) by inducing naïve CD8$^+$ CD25$^-$ T-cells *ex vivo* and confirm their suppressive activity.
Materials and methods: CD8$^+$ CD25$^-$CD45RA$^+$ were isolated from PBMCs and cultured in anti-CD3 coated plates with or without IL-2, TGF-β1 or CD28. Their phenotypic properties were analysed after 5 days using flow-cytometry. Furthermore, their suppressive activity was investigated by co-culturing developed CD8$^+$ iT_{Regs} with CFSE (carboxyfluorescein succinimidyl ester) labelled PBMCs and Epstein-Barr infected B-cells charged with superantigens (EBB).
Results: The *ex vivo* differentiation of human naïve CD8$^+$ T-cells into CD127-/CD8$^+$ /CD25^{high}/FoxP3^{high} iT_{Regs} was evaluated. It was demonstrated that it was dependent upon the presence of both TGF-β1 and IL-2 (%differentiation; CD3/CD28/IL-2: 4.2%, CD3/CD28/IL-2/TGF-β1: 14.4%; $P < 0.02$). Furthermore, it was found that the differentiation was dose dependent regarding exogenously added IL-2 ($P < 0.05$). Interestingly co-stimulation through CD28 did not have any additive effect upon CD8$^+$ iT_{Regs} differentiation. Additionally, the suppressive function of CD8$^+$ iT_{Regs} was confirmed to inhibit the proliferation of CD8$^+$ and CD4$^+$ T-cells.
Conclusions: The study presents the existence of CD8$^+$ T_{Regs} in human. Whereas their differentiation can be mediated *ex vivo* it increases our hope that it can be exploited as therapeutic treatment in T-cell mediated auto-immune diseases.

P0698

The effects of proinflammatory cytokines on the differentiation and function of human CD$_4^+$ induced regulatory T cells

S. Halldórsdóttir, L. Geirsdóttir, B. Gunnlaugsdóttir & B. R. Lúdvíksson
Department of Immunology, Institute of Laboratory Medical Science, Reykjavík, Iceland

Purpose/Objective: Regulatory CD4$^+$ T cells (T_{Regs}) are one of the key elements of peripheral tolerance. T_{Regs} are divided into two major classes; central natural T_{Regs} (nT_{Regs}) and peripherally induced T_{Regs} (iT_{Regs}) which are phenotypically indistinguishable but may differ particularly regarding their differentiation and function. It has been revealed that the innate immune system plays a significant role in the immunopathology of autoimmunity. However, its part in differentiation and function of human CD4$^+$ iT_{Regs} is still unclear. The aim of this study was to evaluate the effects of proinflammatory cytokines on the development and function of CD4$^+$ iT_{Regs}.
Materials and methods: Naive human T cells (CD4$^+$ CD25$^-$) were isolated from PBMC's and stimulated with 1 mg/L anti-CD3 and cultured in the presence of IL-2 (100 IU) and TGF-β1 (10 ng/ml) with and with/without IL-1β and TNFα for 5 days. The phenotype of iT_{Regs} was defined (CD4$^+$ /CD127$^-$/CD25^{hi}/Foxp3$^+$) and analysed by flow cytometry. The iT_{Regs} were then cocultured with CFSE labelled PBMC's and Epstein-Barr infected B cells pulsed with superantigens. The proliferation was assessed by flow cytometry. Statistical analysis was performed after analysis with Modfit.
Results: The highest fraction of *ex vivo* differentiated CD4$^+$ iT_{Regs} from naïve human CD4$^+$ T cells was found to be dependent upon the presence of both IL-2 and TGF-β1 ($P < 0.05$). IL-1β and TNFα significantly inhibited the differentiation of iT_{Regs} (% inhibition; TNFα = 68,3% versus IL-1β = 73,5%; $P < 0.05$). The suppressive function of *ex vivo* induced CD4$^+$ iT_{Regs} correlated positively with their increasing numbers (% suppression; 1:1 = 49.75 versus 1:32 = 18.12; $P < 0.05$). IL-1β and TNFα were both found to significantly inhibit the effector function of CD4$^+$ iT_{Regs} ($P < 0.05$). Finally, CD4$^+$ iT_{Regs} significantly suppressed the proliferation of both CD4$^+$ and CD8$^+$ human T cells in our system.
Conclusions: Our study demonstrates that *ex vivo* differentiation of human iT_{Regs} results in a highly functional CD4$^+$ iT_{Regs}. It is also clear that the proinflammatory cytokines of the innate immune system have a significant negative effect upon their differentiation and function. These findings may reflect possible immunopathogenic mechanisms behind autoimmune diseases driven through overactive innate immune responses.

P0699

The role of regulatory T cells during mCMV infections

N. Jost,* A. Roers,† T. Sparwasser,‡ W. Müller,§ J. Buer* & W. Hansen*

*Institute of Medical Microbiology, University Hospital Essen, Essen, Germany, †Institute for Immunology, Technical University of Dresden, Dresden, Germany, ‡TWINCORE, Institute of Infection Immunology, Hannover, Germany, §Faculty of Life Sciences, University of Manchester, Hannover, UK

Purpose/Objective: *Cytomegaloviruses* (*CMV*) set up latent infections in their hosts. In immunocompetent humans infection with *CMV* leads to a mild illness, but in immunocompromised patients primary infection as well as reactivated persistent virus cause life threatening diseases.

There is a growing body of evidence that regulatory T cells (Tregs) contribute to the establishment of persistent infection of different pathogens. Therefore we are interested in the impact of Tregs in the establishment of latency during *CMV* infections. Moreover, it has previously been shown that the immunosuppressive cytokine IL-10 has an impact on the outcome of murine *CMV* (*mCMV*) infections.

Materials and methods: In this study we used the well established mouse model for *CMV* infections. BALB/c mice were infected with *mCMV* Smith or *mCMV-Δm157-luc* strain. The frequency of Foxp3$^+$ Tregs and the mRNA profile of CD4$^+$ T cells in the course of infection were analyzed.

To shed light on the role of T cell derived IL-10 we infected *IL-10*$^{fL/fL}$ × CD4-Cre$^+$ mice, lacking IL-10 in T cells. FACS analyses on the activation status and cytokine production of T cells during *mCMV* infection were performed. For Foxp3$^+$ Treg depletion experiments we made use of the DEREG mouse model.

Results: We found that the frequency of Tregs does not alter during *mCMV* infection but isolated CD4$^+$ T cells showed increased levels of IL-10 mRNA.

In first experiments we could show that the T cell activation status was increased in *mCMV* infected *IL-10*$^{fL/fL}$ × CD4-Cre$^+$ mice in contrast to wild-type mice, determined by the downregulation of CD62L in addition to an increase in IFNγ and GzmB production. Similar results were obtained from Foxp3$^+$ Treg-depleted *mCMV* infected DEREG mice.

Conclusions: Our preliminary data suggest that Foxp3$^+$ regulatory T cells together with T cell derived IL-10 have an impact on the outcome of *mCMV* infections.

P0700

the role of the casein kinase 2 in regulatory t cell mediated suppression

A. Ulges & T. Bopp

Molecular Immunology, Institute for Immunology, Mainz, Germany

Purpose/Objective: During the last 20 years CD4$^+$ CD25$^+$ FoxP3$^+$ regulatory T cells (Tregs) have been established, as a subpopulation of T cells with regulatory features. Several animal models and patient studies have demonstrated their suppressive functions in many autoimmune diseases. Additionally they are able to inhibit efficient antitumor-immunity. Hence, Tregs display a promising target for therapeutic intervention in several diseases. Nonetheless, the knowledge about the molecular mechanisms underlying their suppressive properties has to be greatly increased, in order to develop novel and innovative Treg-based therapeutic strategies.

Materials and methods: Albeit multiple analyses of the transcriptome of Tregs, little attention has been payed on distinctive signalling pathways cardinally employed by Tregs. Therefore, we ran comparative kinome arrays with Tregs and conventional CD4$^+$ T cells. Our analyses showed that the Casein Kinase 2 (CK2) is one of the most abundantly active kinases in Tregs upon T cell receptor-mediated activation. To further characterize the function of the CK2 in Tregs *in vitro* we used the pharmacological Inhibitor DMAT in classical H3-Thymidin, as well CFSE-Proliferation assays. Additionally we created conditional knockout mice, deficient in the gene of the regulatory CK2-beta subunit, and further analysed the suppressive functions of CK2-beta deficient Tregs in a GvHD model.

Results: Results of our kinome array showed that the Casein Kinase 2 (CK2) is one of the most abundantly active kinases in Tregs upon T cell receptor-mediated activation. Pharmacological inhibition of the CK2, by CK2 inhibitor DMAT, demonstrated a crucial contribution of this enzyme to the suppressive properties of Tregs (unpublished data). In line with this result, conditional genetic ablation of the regulatory CK2-beta subunit underlined the importance of this kinase in Treg-mediated suppression *in vitro* as well as under homeostatic conditions *in vivo*. This finding was further confirmed by a greatly reduced suppressive capacity of CK2-beta deficient Tregs in a GvHD model.

Conclusions: Taken together, our data identify the CK2 as an important kinase essentially involved in the molecular mechanisms underlying Treg-mediated suppression.

P0701

The tumor suppressor gene CYLD controls the function of regulatory T cells

S. Reißig,* N. Hoevelmeyer,* B. Kalt,* A. Nikolaev,* B. Weigmann,† M. F. Neurath† & A. Waisman*

*Institut for Moleculare Medicine, University Medical Center, Mainz, Germany, †Department of Internal Medicine I, University Hospital Erlangen, Erlangen, Germany

Purpose/Objective: CYLD is a tumor suppressor gene mutated in familial cylindromatosis, an autosomal-dominant condition that predisposes to multiple skin tumors. In previous reports, CYLD was illustrated to be a negative regulator of the NF-κB pathway by acting as a deubiquitinating enzyme. To analyse the function of CYLD *in vivo* we used the CYLD$^{ex7/8}$ mice, which are characterized by loss of the full-length transcript and overexpression of a short splice variant of *cyld* (sCYLD).

Materials and methods: T cell development and T cell subpopulations in CYLD$^{ex7/8}$ mice were analysed by flow cytometry. The activation of T cells was examined by measurement of proinflammatory cytokines. To adress the suppressive function of CYLD$^{ex7/8}$ Tregs in a physiological context *in vivo*, an adoptive transfer model of colitis was used. The severity of colitis was determined by mini-endoscopy, body weight and histological analysis of the colon. Further, Western blot and RT-PCR were performed to investigate NF-κB signaling in CYLD$^{ex7/8}$ thymocytes and T cells.

Results: The overexpression of sCYLD resulted in splenomegaly and lymphadenopathy. Further, the numbers of mature B cells in spleen and lymph nodes were increased at the expense of T cells. Investigating T cell development in CYLD$^{ex7/8}$ mice we detected a profound impairment in the positive selection of thymocytes, thereby reducing T cells in thymus and periphery. Moreover, CYLD$^{ex7/8}$ T cells were hyperresponsive as a consequence of increased NF-kB activity. Expression of sCYLD markedly increased the numbers of regulatory T cells in thymus and peripheral organs, however the function of these cells was largely diminished accompanied by decreased expression levels of CD25 and CTLA-4.

Conclusions: Our study reveals a crucial role for CYLD in the regulation of T cell development and differentiation as indicated by a significant reduction of T cells in thymus as well as periphery. Interestingly, most of the T cells displayed an effector/memory phenotype. Further, overexpression of sCYLD impaired the *in vivo* immunosuppressive function of Tregs, probably by regulating the expression of CTLA-4 and CD25, which are both involved in the

suppressive function of Tregs. Hence, our data provide evidence for the involvement of sCYLD in controlling Treg cell development and function.

P0703

Transient depletion of regulatory T cells in transgenic mice enhances local immune responses to *Helicobacter pylori*

M. Blomquist, A. Ekman, C. F. Flach, J. Holmgren & S. Raghavan
Microbiology and Immunology, University of Gothenburg, Gothenburg, Sweden

Purpose/Objective: Immune suppressive $CD4^+$ $CD25^+$ $Foxp3^+$ regulatory T cells (Treg) have been shown to accumulate in the stomach during *H. pylori* infection, dampening immunity and contributing to chronicity of infection. The aim of the current study was to address whether *H. pylori* infection in the stomach can be eradicated by boosting immune responses, combining vaccination with transient depletion of Treg.
Materials and methods: Transgenic mice were used in which $Foxp3^+$ Treg co-express the diphtheria toxin receptor (DTR) allowing specific depletion of Treg by injection of diphtheria toxin. Groups of Foxp3-DTR mice were either immunized via the mucosal route with *H. pylori* antigens and cholera toxin adjuvant or left unimmunized. Treg were then transiently depleted at the time of challenge by injection of diphtheria toxin and bacterial colonization, immune responses and inflammation were evaluated 4 weeks post challenge. All comparisons were made between unimmunized and sublingually immunized mice that were either transiently depleted or not depleted of Treg.
Results: In unimmunized *H. pylori* infected mice, depletion of Treg resulted in a significant ($P < 0.05$) decrease in the bacterial load compared to undepleted infection controls. However, regulatory T cell depletion in sublingually immunized mice did not eradicate the *H. pylori* infection; with colonization in the stomach similar to immunized mice not depleted of Treg. Transient depletion of Treg in both sublingually immunized and unimmunized *H. pylori* infected mice was accompanied by significantly enhanced inflammation and CD4 infiltration, and an increase in IFNγ but a reduction in the IL-17 response in the stomach. Finally, depletion of Treg in Foxp3Tg mice without prior *H. pylori* infection resulted in an enhanced CD4 infiltration to the stomach but these cells did not secrete IFNγ or IL-17.
Conclusions: In summary, our results indicate that on of the mechanisms whereby Treg can dampen immunity and thereby promote chronicity of the *H. pylori* infection is by affecting the recruitment of CD4 T cells to the stomach.

P0704

Tribbles-1 is expressed by regulatory T cells and interacts with FOXP3

E. Dugast,* L. Docherty,† E. Kiss-Toth,† R. Danger,* J. P. Soulillou,* S. Brouard* & J. Ashton-Chess‡
**Immunointervention, INSERM U1064, Nantes, France, †Department of Cardiovascular Sciences, University of Sheffield, Sheffield, UK, ‡TcLand Expression, Immune-mediated Diseases and Transplantation, Nantes, France*

Purpose/Objective: We previously identified Tribbles-1 (TRIB1) as a blood and graft biomarker of chronic antibody-mediated rejection in kidney transplant recipients. Although TRIB1 is known to regulate MAPK signaling by interacting with certain MAPKKs, the functional role of TRIB1 in the immune system is still largely unknown. We previously screened different immune compartments and found TRIB1 to be principally expressed by peripheral blood cells including, among others, regulatory T cells (Tregs). We aimed to explore the potential role of TRIB1 in Tregs and to analyze any relationship it may have with Foxp3.
Materials and methods: We isolated $CD4^{pos}CD25^{high}CD127^{low}$ Tregs and $CD4^+$ CD25- T cells by CD4 positive enrichment followed by FACS cells sorting and measured TRIB1 and Foxp3 mRNA by qPCR. Next, physical interaction between TRIB1 and Foxp3 proteins was analyzed in live cells by the Protein Complementation Assay (PCA) in which HEK293 and HeLa cells were co-transfected with plasmids containing the Foxp3 and TRIB1 genes, each comprising a complementary fragment of GFP. Direct physical interactions between the two molecules leading to GFP fluorescence were analyzed by flow cytometry and microscopy. We subsequently analyzed Foxp3 and TRIB1 interaction in the nucleus of freshly-isolated human Tregs. To do this, we isolated nuclear proteins from human Tregs, immunoprecipitated the Foxp3 protein and then performed Western Blotting for the TRIB1 protein.
Results: Both TRIB1 and Foxp3 were expressed at significantly higher levels in Tregs versus their $CD4^+$ CD25- counterparts ($P < 0.001$). Moreover, within Tregs, TRIB1 and Foxp3 mRNA levels correlated tightly (Spearman $r = 1.0$; $P < 0.001$, $n = 7$). The PCA revealed a direct physical interaction between TRIB1 and Foxp3. This interaction took place in the nucleus and had a tendency to decrease upon deletion of the TRIB1 N-terminal (important for nuclear localization) but not the C-terminal. This direct interaction in the nucleus was confirmed in primary human Tregs by the Co-immunoprecipitation analysis.
Conclusions: Overall our results show a relationship between TRIB1 and Foxp3 in terms of their expression and physical interaction, suggesting a role for TRIB1 in Tregs.

A unique role of transforming growth factor beta in T cell mediated autoimmunity – modulation of the TCR threshold

F. Cyprian,* A. Henino,† L. Pace,‡ P. Rougerie,§ J. Delon,§ S. Amigorena‡ & J. C. Marie†
*Basic Medical Sciences and Research, University of Sharjah College of Medicine, Sharjah, United Arab Emirates, †Inserm U590 28 rue Laennec, Centre Léon Bérard, Lyon, France, ‡Institute Curie, Inserm U932, Paris, France, §Institute Cochin, CNRS UMR8104, Paris, France

Purpose/Objective: Balancing of the adaptive immunity is an essential prerequisite for maintaining immune homeostasis in vertebrates. During T cell development in the thymus, central tolerance eliminates most self-reactive T cells, which bear TCRs that bind to MHC-self-peptide complexes with high affinity. T cells bearing TCRs with low affinity to MHC-self-peptide complexes regularly escape this process and form the naïve T cell repertoire of the host.However, some of these weakly self-reactive T cells can become activated in the periphery and cause widespread inflammation and destruction of self-tissue culminating in autoimmunity. Thus, peripheral tolerance mechanisms are crucial to maintaining the organism integrity and are not completely understood. Transforming Growth Factor beta (TGFb), is an essential cytokine for regulatory T cells commitment, a subset of CD4 T cells required to maintain peripheral tolerance of T cells. Previous work from our lab suggested that TGFb could also act directly on T cells to maintain tolerance to self. Here, we confirm an essential role for and begin to elucidate the mechanism of TGFb signaling directly on CD8 T cells to maintain tolerance to self.
Materials and methods: Using mice with T cells bearing a defined TCR (F5), either responsive (TGFBRWT), unresponsive (TGFBRKO), or constitutively active TGFb signaling (TGFBRCA) and altered peptide ligands, we clearly established *in vivo* that TGFb signaling controls T cell self reactivity by modulating the TCR activation threshold to MHC-peptides.
Results: In the absence of TGFb signaling, T cells are more reactive to weak affinity peptides, while constitutive TGFb signaling impairs their response to high affinity cognate peptides. In addition, T cells lacking the TGFbR have prolonged contacts with peptide-loaded dendritic cells. Moreover, we observed that TGFb signaling directly controls both the level of phosphorylation down-stream of TCR and the recruitment of Lck to the immunological synapse. Finally, reconstitution of transgenic mice expressing a peptide for the F5 TCR under the MHC-I promoter with bone marrow from F5 TCR Tg TGFBRKO mice leads to massive T cell infiltration.
Conclusions: TGF-b signaling in T cells controls their activation by peptide MHC.

P0706

Cathepsin S dominates autoantigen processing in human thymic dendritic cells

C. Stoeckle,* P. Quecke,* T. Rückrich,† T. Burster,‡ M. Reich,† E. Weber,§ H. Kalbacher,‡ C. Driessen,† A. Melms* & E. Tolosa*
*Hertie Institute for Clinical Brain Research, University of Tuebingen, Tuebingen, Germany, †Department of Medicine II, University of Tuebingen, Tuebingen, Germany, ‡Medical and Natural Sciences Research Center, University of Tuebingen, Tuebingen, Germany, §Institute of Physiological Chemistry, Martin Luther University Halle-Wittenberg, Halle, Germany

Purpose/Objective: The interaction of developing thymocytes with peptide-MHC complexes on thymic antigen-presenting cells (APC) is crucial for T cell development, both for positive selection of 'useful' thymocytes as well as negative selection of autoreactive thymocytes to prevent autoimmunity. The peptides presented on MHC II molecules are generated by lysosomal proteases. At the same time, these proteases will also destroy other potential T cell epitopes from self-antigens. This will lead to a lack of presentation on negatively selecting thymic antigen presenting cells and consequently, escape of autoreactive T cells recognizing these epitopes. In order to understand the processes that govern generation or destruction of self-epitopes in thymic APC, we studied the antigen processing machinery and epitope processing in the human thymus.
Materials and methods: The antigen processing machinery of thymic APC was analysed using immunohistochemistry, RT-PCR and active site labeling. *In vitro* digests were performed using lysosomal contents from isolated conventional (mDC) and plasmacytoid dendritic cells (pDC) with myelin basic protein (MBP) and proinsulin as model autoantigens.
Results: We find that each type of thymic APC expresses a different signature of lysosomal proteases, with cortical thymic epithelial cells (cTEC) having a particularly unusual protease pattern. We also find that mDC are more efficient in processing autoantigen than pDC. In addition, we observed that cathepsin S plays a central role in processing of the autoantigens MBP and proinsulin in thymic DC. Cathepsin S destroyed a number of known T cell epitopes, which would be expected to result in lack of presentation and consequently, escape of autoreactive T cells.
Conclusions: The observation that in humans autoantigen processing is dominated by CatS in negatively selecting thymic DC and that CatS destroys known autoantigenic epitopes provides a mechanistic explanation of how autoreactive T cells recognizing these epitopes might escape deletion in the thymus. Cathepsin S therefore appears to be an important factor that influences selection of autoreactive T cells. Furthermore, the unusual and unique MHC II antigen processing machinery that we find in cTEC supports the notion that negative and positive selection occur on different sets of peptides in analogy to what has been described for $CD8^+$ T cells.

P0707

CD28 signaling is also involved in the $CD4^+$ T cell tolerance reaction to harmless exogenous antigen

A. Hegemann, E. Mettke, N. Reeg, Y. Yang, H. W. Mages, S. Gurka & R. A. Kroczek
Molecular Immunology, Robert Koch Institute, Berlin, Germany

Purpose/Objective: The correct decision between an inflammatory immune response versus immune tolerance to a defined antigen is of paramount importance for the survival of the host. CD28 has been described as pivotal for T cell immunity, but its role in a non-inflammatory T cell reaction to 'harmless' antigen, which we recently characterized[1], is unclear. The purpose of this study was to investigate an involvement of CD28 in this tolerance reaction.
Materials and methods: Adoptively transferred OT-II.WT $CD4^+$ T cells were activated by highly purified ovalbumin injected i.v. The role of CD28 was investigated using OT-II.CD28 KO T cells.
Results: Under non-inflammatory conditions, $CD4^+$ T cells de novo upregulate certain surface molecules (e.g. 4-1BB, CD160, RANKL), which are not expressed by T cells under inflammatory conditions. In addition, these 'non-inflammatory response T cells' (T_{nir}) produce IL-2 and other non-inflammatory cytokines, and proliferate. This early reaction to pure antigen leads to a threefold initial expansion of the T_{nir} population on day 2.5. Gene expression analyses and studies at the protein level revealed that CD28 has a dual role in the T_{nir} setting. On the one hand, absence of CD28 prevented upregulation of IL-2 and abrogated the expansion of T_{nir} cells, indicating that CD28 signaling has an essential role in the normal T_{nir} reaction to harmless environmental antigens, which finally leads to tolerance[1]. On the

other hand, absence of CD28 resulted in further upregulation of T_{nir}-specific cell activation molecules like 4-1BB and CD160, indicating a role of CD28 in the suppression of some T_{nir} reaction elements under non-inflammatory conditions.

Conclusions: Taken together, these data reveal a complex role of CD28 *in vivo*. CD28 thus not only acts as a potent T cell costimulator under inflammatory conditions, but also functions when harmless environmental antigens are presented to T cells. This conclusion extends the current paradigm, in which CD28 is exclusively regarded as a central mediator of the inflammatory T cell response.

P0708

Description of the HLA class I peptide repetoire in the human thymus

G. Espinosa,* J. Collado,* E. Scholz,* M. Carrascal,† F. Canals,‡ R. Pujol-Borrell,§ D. Jaraquemada* & I. Alvarez*

**Department of Cell Biology Physiology and Immunology, Institute of Biotechnology and Biomedicine, Universitat Autònoma de Barcelona, Bellaterra, Spain, †CSIC/UAB Proteomics Laboratory, IIBB-CSIC/IDIBAPS, Bellaterra, Spain, ‡Proteomics Laboratory Medical Oncology Research Program, Vall d'Hebron University Hospital Research Institute, Barcelona, Spain, §Laboratory of Immunobiology for Research and Diagnosis (LIRAD) Blood and Tissue Bank (BST), Department of Cell Biology Physiology and Immunology, Universitat Autònoma de Barcelona, Barcelona, Spain*

Purpose/Objective: The thymus is the organ where T lymphocytes mature and differenciate. For that, thymocytes must contact with antigen presenting cells through the interaction between the TCR and self peptides complexed with self HLA molecules. The peptide repertoire associated to HLA molecules in the thymus must mirror the repertoire that T cells will see in periphery, including the presence of peptides derived from tissue restricted antigens. So far the composition of the human peptidoma associated to HLA class I molecules remains unknown. The objective of the present work was to describe the HLA class I peptide repertoire from human thymus.

Materials and methods: Human thymus samples from children who underwent corrective heart surgery were lysed, peptide-HLA-I complexes were purified by immunoaffinity chromatography and the peptide pool was purified by ultrafiltration. Peptide sequences were obtained by LC-MS.

Results: A total of 230 HLA class I natural ligands were identified. The peptide pool was composed by high affinity HLA class I ligands. These peptides derived from proteins principally located in the cytosol and nucleus. Nineteen peptides were found in different thymus samples and some proteins generated more than one peptide. Finally, a peptide of the protein SPATIAL, with restricted tissue expression was identified.

Conclusions: An extensive analysis of the peptidoma bound to HLA class I molecules is presented here. This peptide pool has similar features to the peptide repertoires of other tissues: high affinity ligands derived from cytosolic and nuclear proteins. The presence of some peptides in several samples suggests an immunodominance during the processes of central tolerance. Finally, a peptide with restricted expression was identified, what can be relevant in the generation of central tolerance against the protein SPATIAL.

P0709

Effect of HCV-core expression in $CD4^+$ primary Lymphocytes

C. Fernández Ponce, M. Dominguez Villar, M. C. Durán, E. Aguado & F. Garcia Cozar

Biomedicin Biotechnology and Public Health, University of Cadiz, Cadiz, Spain

Purpose/Objective: Hepatitis C virus (HCV) infection is a worldwide health problem that affects more than 170 million patients and evolves into chronicity in over 85% of cases.

It has been shown that failure of an effective cellular response is pivotal to explaining viral persistence and accumulating evidence suggests that HCV (Hepatitis C virus) proteins suppress host immune responses by interfering in the function of immune cells, with HCV core being one of the most active.

It has previously been shown by us and others that HCV-core induces suppression when expressed in the $CD4^+$ tumor T cell line Jurkat the NK cell line YTS, or when added to $CD4^+$ T cell cultures.

As there is evidence indicating that HCV can be present in cells either than the hepatocyte, including $CD4^+$ lymphocytes, we intend to analyze the effect of HCV-core expression in $CD4^+$ primary lymphocytes.

Materials and methods: $CD4^+$ primary lymphocytes immunomagnetically purified from peripheral blood mononuclear cells (PBMC) were transduced with lentiviral supernatants containing an HCV-core-GFP expression cassette.

Results: HCV-core transduced $CD4^+$ T cells acquire a regulatory phenotype upregulating Foxp3 and CTLA4 and suppressing the response of bystander T cells.

Conclusions: Our results add a new element in this cell population, and give an example of the generation of $CD4^+$ T cells with regulatory activity by the expression of a single viral protein.

P0710

Exploring the basis of T cell selection: natural MHC class I and II peptides presented by dendritic cells in the human thymus

C. Stoeckle,* E. Adamopoulou,* S. Tenzer,† N. Hillen,‡ P. Quecke,* S. Tietz,* S. Stevanovic,‡ H. J. Schild,§ H. G. Rammensee,‡ E. Tolosa¶ & A. Melms*

**Hertie Institute for Clinical Brain Research, University of Tuebingen, Tuebingen, Germany, †Institute for Immunology, University of Mainz, Mainz, Germany, ‡Department of Immunology, University of Tuebingen, Tuebingen, Germany, §Institute of Immunology, University of Mainz, Mainz, Germany, ¶Department of Immunology, University of Hamburg, Hamburg, Germany*

Purpose/Objective: Central tolerance to self is imposed on T cells during their development in the thymus by interaction of the T cell receptor with peptide-MHC complexes displayed by thymic dendritic cells (DC) or medullary thymic epithelial cells (mTEC). T cells recognizing these ligands with high affinity will be deleted before they can escape into the periphery and cause autoimmune disease, a process called negative selection. However, the nature of the self-peptides on which negative selection occurs in the human thymus is entirely unknown.

Materials and methods: MHC class I and II molecule-peptide complexes were isolated by affinity chromatography from whole thymus, isolated DC and DC-depleted samples, bound peptides eluted with acid and subsequently analysed by mass spectrometry.

Results: We identified several hundred peptides in our samples, including a large number of ligands presented by negatively selecting dendritic cells. Analysis of eluted peptides revealed a significant degree of cross talk between MHC I and II pathways and the presence of both autoimmune and cancer-related epitopes.

Conclusions: We here provide the first data on the MHC-peptide matrix on which T cell selection occurs in the human thymus.

P0711

Flow cytometry-based method for detection of caspase dependent degradation of linker for activation of T cells

A. Miazek, M. Klossowicz, B. Scirka, K. Marek-Bukowiec & P. Kisielow
Tumor Immunology, Institute of Immunology and Experimental Therapy, Wroclaw, Poland

Purpose/Objective: Caspase/Granzyme B mediated protein degradation is involved in elimination of activated T cell receptor (TCR) signaling molecules during processes of thymocyte selection and maintenance of peripheral homeostasis of T cells. Key components of TCR signaling cassette e.g. TCR ζ chain, phospholipase C-γ1, proto-oncogene product Vav1, hematopoietic progenitor kinase 1, adaptor protein GADS undergo biological inactivation in response to pro-apoptotic or anergy inducing environmental stimuli. Although available Western immunoblotting-based techniques are appropriate for detection of protein degradation in bulk populations of target cells, quantitative assessment of this process at single cell level requires a different approach.
Materials and methods: We report on a novel, flow cytometry-based method for assessment of LAT integrity.This method exploits a loss of an anti-LAT antibody epitope recognition following caspase dependent proteolytic degradation of C-terminal domain of the LAT adaptor.
Results: We showed that upon physiological inputs including TCR engagement, Fas ligation, glucocorticoid hormone receptors stimulation or treatment with chemical apoptosis inducers, such as etoposide, staurosporine or ionomycin, COOH-terminal domain of LAT undergoes rapid degradation leading to a loss of an anti-LAT antibody epitope. The kinetics of this degradation process correlates with reported rates of caspase activation and in its initial phase precedes the phosphatidylserine translocation to the outer leaflet of the plasma membrane. As a result of the degradation, a NH2-terminal membrane spanning fragments of LAT are detectable. A most prominent of them the 17kDa fragment matches a peptide generated by *in silico* cleavage of a caspase target sequence present at position 160–164 (DLGD) of the mouse LAT. The screening of protease inhibitors indicated that caspase 8 is in part responsible for the degradation of LAT but other proteases, in particular serine protease(s) whose activity is blocked by PMSF may also be involved.
Conclusions: In contrast to available Western immunoblotting based approaches requiring millions of purified cells to meet sensitivity criteria, our method allows for single cell level assessment of LAT degradation in discrete populations of cells defined by multi-parameter flow cytometry. By assessing the integrity of LAT our approach offers insight into physiological processes attenuating TCR signaling by selective decomposition of the LAT signalosome.

P0712

In vitro-differentiated pDCs suppress costimulation blockade mediated DTH response in absence of CCR7-signalling

P. Mishra, U. Hadis & R. Förster
Hannover Medical School, Institute of Immunology, Hannover, Germany

Purpose/Objective: CCR7 is an important molecule for homing of naïve T cells to lymph node (LN). CCR7 is also necessary for homing of Treg cells into peripheral LNs and that this homing is a prerequisite for their *in vivo* function. Plasmacytoid dendritic cells (pDCs) are suggested to behave as antigen presenting cells in settings of tolerance induction such as oral tolerance and allograft survival. CCR7$^{-/-}$ mice harbour significantly reduced numbers of pDC within LNs, but not bone marrow or spleen. According to our recent findings, CCR7$^{-/-}$ recipients fail to prolong survival of cardiac allografts in a model of allotolerance induction by donor splenocyte transfusion (DST) in combination with anti-CD40L-mAb mediated costimulation blockade (CSB). Strikingly, adoptive transfer of syngeneic wild type pDCs was indeed sufficient to rescue graft survival in DST^{+}CSB-treated CCR7$^{-/-}$ recipients.
Materials and methods: Recently, we were able to standardize *in vitro* pDC differentiation protocol, by using Flt-3L directly sequestered into cell culture supernatant by B16FL melanoma cells. Preliminary results indicate that these *in vitro* pDCs are highly functional in inducing Tregs *in vitro*. In order to investigate the tolerogenic potential of these *in vitro* differentiated pDCs we standardised a delayed type hypersensitivity (DTH) model in CCR7$^{-/-}$ recipients.
Results: It is already known that LNs of CCR7$^{-/-}$ mice are devoid of T cells and DTH response to a T cell dependent antigen is delayed in these mice. However, we could observe DTH response when CCR7$^{-/-}$ mice were immunized with our earlier described allotolerance induction protocol of DST^{+}CSB. The recipients were subsequently challenged with allogenic splenocytes lysate emulsified together with complete freund's adjuvant (CFA). We further sorted pDC fraction from the conventional dendritic cell (cDC) fraction and adoptively transferred together with DST^{+}CSB to analyse the DTH response. We could observe that syngenic *in vitro* differentiated immature pDC but not cDC could suppress the allogen mediated DTH in CCR7$^{-/-}$ mice. On the other hand, TLR7/8 agonist, R848-stimulated pDCs fail to suppress the DTH response in CCR7$^{-/-}$ mice.
Conclusions: These observations further validates that pDC could act as immunogenic cell sentinels and also as tolerogenic cells which mediate Treg development and/or suppression of self- and allo-reactive cells.

P0713

Increased antibody levels against gut commensals are associated with regulatory T cell defect in patients with APECED

I. Hetemäki,* H. Jarva,* H. Tervo,* E. Bratland,† K. Kisand,‡ P. Peterson‡ & T. P. Arstila*
Haartman Institute, University of Helsinki, Helsinki, Finland, †Department of Medicine, Haukeland University Hospital, Bergen, Norway, ‡Institute of General and Molecular Pathology, University of Tartu, Tartu, Estonia

Purpose/Objective: APECED is a rare monogenic autoimmune disease, which is caused by a loss-of-function mutation in the Autoimmune Regulator (AIRE) gene. APECED is characterized by chronic mucocutaneous candidiasis and autoimmunity to multiple endocrine organs. Taken into consideration the gastrointestinal symptoms of the disease and the emerging role of commensals in controlling the immune system we set out to study the handling of commensal microbes and their effects on the immune system in patients with APECED.
Materials and methods: Plasma antibody levels against several commensal microbes were measured in 12 APECED patients and 26 healthy controls using an ELISA assay. The antibody levels were compared to T-cell data acquired using flow cytometry.
Results: The patients showed significantly elevated IgG responses against *Saccharomyces cerevisiae*, *E. coli* and *Pseudomonas fluorescens* displaying a Crohn's disease-like loss of tolerance to commensals. Remarkably, the antibody levels against *S. cerevisiae* showed considerable negative correlation to naïve recent-thymic emigrant regulatory-T-cell population and FOXP3 expression of Tregs creating a link between the commensal responses and impaired regulatory T cell function seen in APECED.
Conclusions: Our data on the elevated antibody levels against commensals are the first to depict loss of tolerance against non-self antigens in APECED. Moreover, the correlation of anti-commensal antibody levels to diminished Treg function creates a completely new approach to APECED disease pathogenesis and to the crosstalk of commensals and immune system.

Induction of allograft tolerance by monoclonal CD3 antibodies: a matter of timing

S. YOU,* J. Zuber,† C. Kuhn,* M. Baas,* F. Valette,* V. Sauvaget,* S. Sarnacki,‡ B. Sawitzki,§ J. F. Bach,* H. D. Volk¶ & L. Chatenoud*
*INSERM U1013, University Paris Descartes, Paris, France, †Transplantation, Necker Hospital, Paris, France, ‡Pediatric Surgery, Necker Hospital, Paris, France, §Institute of Medical Immunology, Charite University, Berlin, Germany, ¶Berlin-Brandenburg Center for Regenerative Therapies, Charite University, Berlin, France

Purpose/Objective: Despite remarkable progress in organ transplantation through the development of a wealth of immunosuppressive drugs highly effective at controlling acute ejection, two major problems still remain, the loss of grafts due to chronic rejection and the growing number of sensitized recipients due to previous transplants, transfusions or pregnancies. Induction of immune tolerance appears to be the only way to curb this complex situation. We have previously shown in autoimmunity that CD3 antibody therapy promotes tolerance only when applied in the context of a primed immune system. We sought to extend this observation to the transplant setting.

Materials and methods: Pancreatic islets from BALB/c mice were grafted under the kidney capsule of streptozotocin-treated diabetic C57BL/6 recipients. Five injections of Fc non-binding CD3 antibody $F(ab')_2$ fragments (50 μg/injection/day) were administered at the time (day-1) or after transplantation (day$^+$7 or 11). Graft survival was monitored by blood glucose measurements.

Results: We demonstrate that a short-term, low-dose course with CD3 antibodies starting on day$^+$7 or$^+$11 after transplantation induces long-term survival (>100 days) of fully mismatched islet allografts. Importantly, permanent acceptance of second islet grafts from the original but not third party donors proved that antigen-specific tolerance had indeed been induced in these recipients. Mechanistic studies revealed that antigen-specific regulatory and effector T cells are differentially affected by the treatment. CD3 antibody treatment preferentially induces apoptosis of activated alloreactive T cells which is mandatory for tolerance induction. As a consequence, anti-donor CD8 responses are dramatically reduced in tolerant hosts. In contrast, regulatory T cells are relatively spared from CD3 antibody-induced depletion and can transfer antigen-specific tolerance thus arguing for their prominent role in sustaining long-term graft survival.

Conclusions: Our data show that judicious use of CD3 antibodies can induce transplant tolerance to fully mismatched allografts in recipients primed to the alloantigens. From the translational point of view and due to the availability of humanized CD3 antibodies presently developed in autoimmmune diabetes, our finding provides further consideration of using CD3 antibody-based therapy in transplantation

P0715

Induction of anergic T cells by CD83highCCR7highHLA-DRhigh as well as CD83lowCCR7negativeHLA-DRlow IL-10-modulated human dendritic cell subpopulations

F. Kryczanowsky, E. Graulich, K. Rost & K. Steinbrink
Dermatology, University Medical Center Mainz, Mainz, Germany

Purpose/Objective: Our studies previously demonstrated that IL-10-modulated tolerogenic human dendritic cells (IL-10DC) induce anergic CD4$^+$ T cells. Here, we investigated both, CD83^{high}CCR7^{high}HLA-DR^{high} and CD83^{low}CCR7^{negative}HLA-DR^{low} IL-10DC subpopulations, with regard to their phenotype and tolerogenic capacity to generate anergic CD4$^+$ T cells in detail.

Materials and methods: Therefore, we compared the expression of costimulatory and inhibitory molecules of the B7- and ILT-family, respectively, between human mature DC (mDC) and both IL-10DC subpopulations. FACS sorting of both IL-10DC subpopulations was performed with regard to the high or absent expression of CCR7 (representing CD83^{high} or CD83^{low} DC). Subsequently, coculture experiments with naïve CD4$^+$ CD45RA$^+$CD25^{low} T cells were conducted.

Results: As compared to mDC, the CD83^{low} IL-10DC subset exhibited a significantly reduced expression of costimulatory molecules (CD80, CD86, B7-H2, CD40) accompanied by a slight upregulation of inhibitory molecules (B7-H1, ILT3, ILT4). In contrast, we observed minor changes in expression of costimulatory molecules but significantly enhanced levels of inhibitory molecules on CD83^{high} IL-10DC, demonstrating significant differences in expression of costimulatory and inhibitory molecules (B7-H1, B7-DC, ILT3) between the two IL-10DC subsets.

Notably, primary stimulation and restimulation experiments revealed that both subpopulations, in contrast to mDC and regardless of their maturation state, induced anergic CD4$^+$ T cells as evidenced by a significantly reduced T cell proliferation and diminished Th1 and Th2 responses (T-bet, IFN-γ; GATA-3, IL-5, IL-13).

Conclusions: In conclusion, both phenotypic mature CD83^{high} CCR7^{high}HLA-DR^{high} and immature CD83^{low}CCR7^{negative}HLA-DR^{low} IL-10DC subpopulation display properties of tolerogenic human DC which may be used for the development of novel therapeutic approaches for allergies, autoimmune disease or transplant rejections.

P0716

Involvement of human suppressor and non-suppressor FOXP3+ T cells in HIV-1 infection

L. Arruvito,[1] J. Sabatté,[2] J. Pandolfi,[1] P. Baz,[1] A. Billordo,[1] M. Lasala,[3] H. Salomón,[2] J. Geffner[2] & L. Fainboim[1]
[1]*Immunogenetics Laboratory, INIGEM-CONICET, Ciudad Autónoma de Buenos Aires, Argentina,* [2]*INBIRS, UBA, Ciudad Autónoma de Buenos Aires, Argentina,* [3]*Infectious Diseases, Clinical Hospital, Ciudad Autónoma de Buenos Aires, Argentina*

Purpose/Objective: FOXP3 is a key transcription factor for the development and function of regulatory T cells (Tregs); however, it can also be expressed by non-suppressor T cells. In the present study, we examined the different behaviors of FOXP3+ Tregs and FOXP3+ non-Tregs in HIV-1 infected patients.

Materials and Methods: PBMCs isolated from HIV-1 infected (n = 55) and healthy donors (HD, n = 27) were analyzed by flow cytometry to characterize five subsets of CD4+ T cells: CD45RA+ FOXP3^{low} (rTregs), CD45RA- FOXP3^{high} (aTregs), CD45RA- FOXP3^{low} (FOXP3+ non-Tregs), CD45RA+ FOXP3- (naïve) and CD45RA- FOXP3- (memory). Frequency and absolute number of each subset were compared and correlated with CD4 count, viral load (VL) and activation markers (HLA-DR and CD38). Moreover, *in vitro* susceptibility of different HD purified subset cells to HIV-1 BaL was assessed by flow cytometry and ELISA. Cytokine levels were evaluated using a multiplex approach.

Results: In addition to the absolute decrease of conventional T cells, patients present a significant decrease in all FOXP3+ T cells. aTregs from HIV-1 patients did not correlate with the CD4 count and none FOXP3+ T cells correlated with VL. Furthermore, an increase immune activation that inversely correlated with FOXP3+ non-Tregs was observed in those patients with lower CD4. We confirmed the HIV-1 infection of all CD4+ cells, presenting higher levels in aTregs, FOXP3+ non-Tregs and memory T cells. FOXP3+ non-Tregs have secreted a wide spectrum of Th1, Th2 and Th17-like cytokines in HD. Moreover, we found a dramatic decrease of Th1 and Th17-like cytokine secretion post infection of FOXP3+ non-Treg, polarizing towards a Th2 cytokine secretion.

Conclusions: In chronically infected HIV-1 patients, we found a decreased absolute number of suppressor aTregs and FOXP3+ non-Tregs. It still remains to be elucidated if the decreased number of suppressor Tregs plays a role as suppressor of the anti-viral immune

response or impacts on the immunological activation phase favouring virus replication. On the other side, our results establish a new basis for the reliable characterization of the role of FOXP3+ T cells in HIV-1 individuals.

P0717

Phagocytosis of infected apoptotic cells promote PGE2 production by dendritc Cells

F. Fortino Verdan,* A. Saraiva,† N. Dejani* & A. I. Medeiros†
**Biochemistry and Immunology, Faculdade de Medicina de Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, †Biological Science, Faculdade de Ciências Farmacêuticas — Unesp, Araraquara, Brazil*

Purpose/Objective: Phagocytosis of apoptotic cells promotes the synthesis of anti-inflammatory mediators such as PGE_2, TGF-β and IL-10 that may result in the suppression of host immune defense. However, a study using infected apoptotic cells showed that phagocytosis of these by dendritic cells (DC) promotes the production of anti-inflammatory cytokines such as TGF-b but also pro-inflammatory cytokines as IL-6 and IL-23, resulting in an immunostimulatory effect, the differentiation of Th17 cells. The role of PGE_2 in adaptive immunity has been investigated regarding lymphocyte differentiation and activation. Our aim was to evaluate the PGE_2 production from DC when co-cultured with different ratios of infected apoptotic cells.
Materials and methods: Infected apoptotic neutrophils were prepared as follows: C57BL/6J mice were injected i.p. with 3 ml thioglicollate with 3×10^6 live *Escherichia coli*, after 13 h, the cells were collected from peritoneal cavity lavage. Apoptosis of neutrophils were confirmed by flw cytometry using Annexin-V/PI staining. Bone marrow derived dendritic cells were co-cultured at different ratios (1:1, 1:3, 1:5) with infected apoptotic neutrophils during 18 h. Supernatant from co-culture was collected and PGE_2 production was determined by ELISA. We also evaluated the maturation level of DC after co-culture.
Results: Our results show that phagocytosis of infected apoptotic cells induces the production of high levels of PGE_2 at 1:3 (1500 pg/ml) and 1:5 (3400 pg/ml) ratio. Interestingly, the DC co-cultured with infected apoptotic cells deviated for immature state, with low levels of CD11c, MHC-II and CD86, contrasting with the activating stimulus LPS. Furthermore, the proportion of phenotypically immature cells increased in higher infected apoptotic cells rates.
Conclusions: DC does not acquire a predominant activated state when co-cultured with infected apoptotic cells and further characterization are needed to understanding this phenotypical state and its role in Th17 development. Also, the higher levels of PGE_2 suggest a role for this lipid mediator in Th17 differentiation in this context. However, the involvement of PGE_2 and the mechanism by which PGE_2 can work synergistically with TGF-b, IL-6 and IL-23 in the process of Th17 cell differentiation needs further characterization.

P0718

Phenotypic and functional characteristics of splenocytes in tetanus toxoid-hyperimmunized Balb/c mice is influenced by the context of tetanus toxoid application

M. Stojanovic, I. Zivkovic, A. Inic-Kanada, V. Petrusic, E. Marinkovic, I. Stojicevic & L. Dimitrijevic
Department of Research and Development, Institute of Virology Vaccine and Sera — Torlak, Belgrade, Serbia

Purpose/Objective: The hyperimmunization with tetanus toxoid (TTd) induces protective TTd-specific as well as autoreactive β2-glycoprotein I (β2GPI)-specific immune responses in BALB/c mice. The overall immune response characteristics, especially its pathogenic potential, depended on adjuvants applied prior and in combination with TTd. Beside structural homology between TTd and β2GPI, tolerance toward β2GPI could be impaired by adjuvants acting as polyclonal stimulators. In order to clarify the impact of adjuvants, phenotypic and functional analyses of immune system cells within spleen were done upon immunization completion.
Materials and methods: Non- or CFA-pretreated BALB/c mice were immunized with TTd (3×100 μg/dose; 2-week intervals) mixed with alum or 2.5M glycerol. *Ex vivo* analyses of CD3, CD4, CD8, CD19, CD 25, CD27 and mIgM expression on age-matched control and immunized mice's splenocytes were done by flow cytometry. Changes in TLR2, TLR4 and TLR9 expression were assessed indirectly, by measuring cytokine production, following *in vitro* stimulation of splenocytes with appropriate agonist.
Results: TTd-immunization diminished CD27 expression on T cells implying on their differentiation into potent effector cells. T cell activation (increase in CD25 expression and the raise of percentage of $CD4^+$ $CD8^+$ $CD3^+$) and B cell activation (rise in percentage of $CD19^+$ $CD25^+$ cells and the increase of mIgM density) occurred in all immunized mice, being more intensive in CFA-pretreated groups. Irrespective to the applied immunization protocol, statistically significant rise in abundance of CD4- CD8- cells (often cited as cells having suppressive potential) within T cell pool was registered too. Differences in cytokines production (IL4, IL10, IFNγ) registered upon *in vitro* stimulation with peptidoglycan, LPS and CpG ODN implied on context-dependant modulation of TLR2, TLR4 and TLR9 expression on splenocytes.
Conclusions: TTd-hyperimmunization promoted concomitant rise in abundance of activated cells and the cells that have suppressive potential. This could be regarded as an attempt of the system to retain control. Imbalance in percentages and activities between activated cells and those having suppressive potential, highly influenced by the context of TTd application, is most likely the cause for the observed pathology appearance after TTd hyperimmunization.

P0719

Processing of particle bound antigens by peripheral phagocytes induces immunological tolerance

F. Heymann,* J. Venturini,* G. Walenda,* F. Ginhoux,† J. Ochando,‡ G. Randolph,§ C. Trautwein* & F. Tacke*
**Deprtment of Medicine III, University Hospital Aachen, Aachen, Germany, †A*STAR, SigN, Singapore, Singapore, ‡Department of Nephrology, Mount Sinai Medical Center, New York, NY, USA, §Department of Pathology and Immunology, Washington University St. Louis, St. Louis, MO, USA*

Purpose/Objective: Phagocytes are key players in the upkeep of body homeostasis, e.g. by removing apoptotic material as well as forming a primary line of defense against invading microbiota. In this study we investigated the effect of systemically distributed particle bound antigens under sterile conditions to address the immunoregulatory capacities of phagocytes throughout the body in homeostasis.
Materials and methods: 0.5 μm fluorescent latex particles were covalently linked to ovalbumin (OVA) and injected i.v. into recipient mice. Latex particle distribution was followed up to 14 days in wildtype, CX3CR1.eGFP and CCR2.eGFP mice using flow cytometry and multiphoton microscopy to investigate uptake by distinct phagocyte subsets. Bone marrow transplants using CFP^+ donors were performed to assess latex particle distribution between resident macrophages and monocyte-derived phagocytes. Tolerance induction was measured by activation of regulatory T cells (Treg) and inhibition of OVA-specific CTL mediated target cell lysis. Interactions between latex-positive phagocytes and T cells were followed using intravital time lapse multiphoton microscopy in liver tissue as well as secondary lymphatic organs.

Results: Injection of OVA-latex particles (OVA-Lx) lead to a significant reduction in OVA-specific CTL lysis. Furthermore, OVA-Lx treatment induced expansion and enhanced activation of regulatory T cells. Latex particles were most efficiently taken up by liver resident phagocytes (resembling Kupffer cells) but not monocyte derived macrophages and were almost undetectable in secondary lymphatic tissues and bone marrow. Latex beads could be detected for up to 14 days after injection and did not redistribute significantly during that time period.
Conclusions: Peripheral phagocytes such as liver Kupffer cells provide not only a mechanism for clearing small sized particles from the circulation but can also act as efficient inducers of regulatory T cell activation, therefore providing a potential key mechanism in the upkeep of self-tolerance under homeostatic conditions.

P0720
Regulation of thymocyte negative selection by IL-15Ra and IL-15

M. Hou & N. Liao
Institute of Molecular Biology, Academia Sinica, Taipei city, Taiwan

Purpose/Objective: Central tolerance mechanisms operated during T cell development in the thymus handle the self-reactive T cell repertoire generated by TCR gene rearrangement. Thymocytes with TCR exceeding certain level of affinity for self-antigens either die by negative selection or differentiate into regulatory T (Treg) cells through interacting with self-antigens presented by medullary thymic epithelial cells and dendritic cells. Interleukin-15 and its receptors were reported to regulate the development of thymic NKT cells. However, the role of IL-15 system in the development of the majority of thymocytes remained unclear.
Materials and methods: By using TCR transgenic mice, we developed several experimental models to investigate the function of thymus negative selection in WT or IL-15 system deficient mice.
Results: Here we show that the deficiency of IL-15Ra and IL-15 in these antigen-presenting cells (APC) impaired thymocyte negative selection by self-antigen in the relatively low negative selection affinity range. While the development and function of naturally occurring Treg cells are normal in *Il15ra*$^{-/-}$ and *Il15*$^{-/-}$ mice. The mutant mice also developed autoimmune symptoms.
Conclusions: These results indicate that the IL-15 system of thymic APCs is required for optimal negative selection of thymocytes and thus regulation of T cell-mediated autoimmunity.

P0721
Role of the chemokine CCL2 in T cell tolerance

O. Cédile, M. Løbner, H. Toft-Hansen & T. Owens
Department of Neurobiology, Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark

Purpose/Objective: CCL2 is an inflammation-associated chemokine inducing the recruitment of immune cells to tissues. CCL2 and its receptor CCR2 are implicated in experimental autoimmune encephalomyelitis (EAE), a mouse model of multiple sclerosis. Mice lacking CCL2 or CCR2 are resistant to EAE.

We observed that transgenic mice expressing CCL2 in central nervous system (MBP/CCL2) were resistant to EAE. MBP/CCL2 crossed with 2D2 mice, whose T cells express the transgenic Vα3.2β11 T cell receptor (TCR) specific for the self-antigen myelin oligodendrocyte glycoprotein (MOG), were also resistant to EAE. Both MBP/CCL2 and 2D2 × CCL2 mice also showed ectopic expression of CCL2 in thymus. Our goal was to investigate whether thymic expression of CCL2 tolerized encephalitogenic T cells.
Materials and methods: Thymus and lymph node (LN) from C57BL/6 and transgenic mice were analyzed by flow cytometry LN from MOGp35-55 immunized mice were cultured with 10 μg/ml MOG peptide. After 4 days, cell proliferation was measured by CFSE dilution Stromal cells and thymocytes were separated using a Percoll gradient (densities 1.065 and 1.115) from thymi treated with TrypLE and DNase Transcripts were measured by quantitative PCR.
Results: We observed that in mice expressing CCL2 in thymus, LN cells proliferated poorly in response to MOG peptide *in vitro*. In 2D2 × CCL2 mice, transgenic Vα3.2$^+$ CD4$^+$ T cell development was severely impaired. Vα3.2$^+$ CD4$^+$ T cells were lost in both thymus and LN. We also showed that CCL2 transcripts were expressed in thymic stromal cells, which are important for T cell development and auto-reactive T cell deletion. We thus hypothesized that CCL2 was involved in regulation of auto-reactive T cell development. When we crossed MBP/CCL2 with OT2 mice, whose T cells express the transgenic Vα2β5 TCR specific for the non-self-antigen ovalbumin, CCL2 transcripts were not expressed in thymus and Vα2$^+$ CD4$^+$ T cells were relatively unaffected.
Conclusions: We conclude that in CCL2 transgenic mice, interaction between auto-reactive thymocytes and thymic stromal cells induces ectopic expression of CCL2, and that CCL2 expression in thymus is involved in impairment of auto-reactive T cell development which leads to protection against EAE. This identifies a novel role for CCL2.

Our goal now is to investigate thymic stromal cells in order to determine how auto-reactive T cells are impaired.

P0722
Stroma cells in the modulation of immunity and tolerance in the intestinal immune system

H. Chopra, B. Wahl & O. Pabst
Hannover Medical School, Institute of immunology, Hannover, Germany

Purpose/Objective: Mucosal tolerance is best studied in the intestinal immune system. Importantly, the effects of oral tolerance are not limited to intestine but act body-wide, actively inhibiting cellular and humoral immune responses, indicating that oral tolerance might be exploited therapeutically e.g. to treat autoimmune diseases. Low doses of antigen have been suggested to act primarily by inducing regulatory T cells, whereas high doses of antigen have been suggested to cause cell depletion by apoptosis and/or anergy of antigen-specific T cells.

Fibroblastic reticular cells (FRCs) are one of the main populations of nonhematopoietic stromal cells in lymph nodes. FRCs are also known to maintain the homeostasis of naïve T cells. Therefore, any effect of FRCs on activated T cells is highly significant.

Thus, the objective of this study is to investigate the role of stromal cells in T cell homeostasis.
Materials and methods: Either MLN or PLN fragments are grafted into the gut mesenteries after excision of endogenous MLN. Eight weeks after transplantation OT II Ly5.1 cells are adoptively transferred followed by oral Ova administration and intracellular staining to study expression of transcription factors for various CD4$^+$ T cell subsets is done on D5 after transfer.
Results: We observed higher secretion of FoxP3 in TxMLN as compared to TxPLN. Also our preliminary results suggested higher expression of T-bet in TxMLN in comparison to TxPLN while opposite effect was observed for Gata-3.
Conclusions: Stromal cells determine tolerogenic properties of transplanted LN.

P0724

Survival and immunosuppressive functions of myeloid-derived suppressor cells are not regulated by the CD95/CD95L system

R. D. S. Blossey, J. J. Meßmann, K. M. Debatin & G. Strauß
Department of Peadiatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany

Purpose/Objective: Myeloid-derived suppressor cells (MDSCs) represent a heterogeneous population of immature CD11b-expressing precursor cells, which accumulate in pathologic conditions. Depending on the expression of Ly-6C or Ly-6G, they are divided into two subpopulations: monocytic MDSCs (Ly-6C^{high}Ly-6G^{neg}) and granulocytic MDSCs (Ly-6G^{high}Ly-6C^{low}). Both subpopulations suppress T cell activation and proliferation. During this process they are in direct contact with CD95L-expressing T cells, able to induce apoptosis in CD95 expressing cells. Therefore, we analyzed apoptosis sensitivity of MDSCs after T cell contact in order to clarify whether apoptosis resistance might be a possible mechanism by which MDSCs survive T cell attacks and induce immune suppression.
Materials and methods: MDSCs were generated by culturing bone marrow cells for 4 days in the presence of GM-CSF. Both subpopulations were isolated by magnetic beads and expression of death receptor CD95 was defined by flow cytometry. CD95-sensitivity and apoptosis induction of MDSCs was analyzed by treating cells with recombinant CD95L, by co-culturing MDSCs with isolated T cells or by adding MDSCs in mixed lymphocyte reactions (MLR). Further, we analyzed whether usage of MDSCs derived from CD95 deficient lpr mice can increase the suppressive capacity of MDSCs.
Results: Granulocytic and monocytic MDSC subpopulations exhibited a comparable expression of CD95 and both underwent apoptosis in the presence of recombinant CD95L. Apoptosis induction was associated with activation of caspase-8 and -3 and was blocked by the caspase inhibitor zVAD-fmk. However, after co-incubation of MDSCs with CD95L-expressing naïve T cells no apoptosis induction of MDSCs was detected. Also, when MDSCs were added to allogeneic MLRs, they efficiently inhibited proliferation of T cells in a dose-dependent manner and did not undergo apoptosis. Usage of MDSCs from CD95 deficient lpr mice in allogeneic MLRs did not increase the inhibition of allogeneic T cell proliferation compared to CD95-expressing MDSCs. CD3/CD28- activated T cells could induce cell death in MDSC, however, in a CD95L-independent way.
Conclusions: Although MDSCs express CD95, they are insensitive to CD95L-mediated T cell-induced apoptosis showing that homeostasis and suppressive capacity of MDSC is not regulated by the CD95/CD95L system.

T cell apoptosis and induction of Foxp3$^+$ regulatory T cells underlie the therapeutic efficacy of CD4-blockade in experimental autoimmune encephalomyelitis

J. Duarte,* N. Carrie,† V. G. Oliveira,* C. Almeida,* L. Rodrigues,* P. Simas,* L. T. Mars† & L. Graca*
**Instituto de Medicina Molecular, Unversity of Lisbon, Lisbon, Portugal,* *†Centre de Physiopathologie Toulouse-Purpan, INSERM U1043 – CNRS UMR 5282, Toulouse, France*

Purpose/Objective: The pathogenesis of multiple sclerosis (MS) requires the participation of effector neuroantigen-specific T cells. Thus, T cell targeting has been proposed as a promising therapeutic strategy. However, the mechanism underlying effective disease prevention following T cell targeting remains incompletely known.
Materials and methods: We used different TCR transgenic mouse strains, namely MBP-specific and MOG-specific, to evaluate the mechanism underlying the effect of non-depleting anti-CD4 monoclonal antibodies (MAb) in protecting the mice from spontaneous and induced experimental autoimmune encephalopathy (EAE).
Results: We found, using several TCR-transgenic strains, that CD4-blockade is effective in preventing EAE and in treating mice after the disease onset. The mechanism does not rely on direct T cell depletion, but the anti-CD4 MAb prevents the proliferation of naïve neuroantigen-specific T cells, and acquisition of effector Th1 and Th17 phenotype. Simultaneously, the MAb favors peripheral conversion of Foxp3$^+$ Treg cells. Pre-existing effector cells, or neuroantigen-specific cells that undergo cell division in spite of the presence of anti-CD4, are committed to apoptosis.
Conclusions: Therefore, protection from EAE relies on a combination of dominant mechanisms grounded on Treg cell induction, and recessive mechanisms based on apoptosis of neuropathogenic cells. We anticipate that the same mechanisms may be implicated in other T cell-mediated autoimmune diseases that can be treated or prevented with antibodies targeting T cell molecules, such as CD4 or CD3.

The pre-B cell receptor; censoring the development of autoreactive B cells

O. Grimsholm, A. I. Bernardi, N. Almqvist & I. L. Martensson
Rheumatology and Inflammation Research, University of Gothenburg Institute of Medicine, Gothenburg, Sweden

Purpose/Objective: The surrogate light chain (SLC) is assembled from the VpreB and l5 polypeptides, encoded by genes that are expressed specifically in pro- and pre-B cells. During B cell development, functional recombination of the Ig heavy chain (HC) locus, in pro-B cells, leads to the assembly of mHCs with the invariant SLC, which results in the formation of a pre-B cell receptor (pre-BCR), transition to the pre-B cell stage and expansion by proliferation. We have previously found that cells that can potentially develop into autoreactive B cells are negatively selected at this transition: in mice that lack SLC (SLC$^{-/-}$), autoreactive B cells develop as well as plasma cells secreting autoantibodies typical of autoimmune diseases, e.g. systemic lupus erythematosus (SLE). Here, we have investigated the SLC$^{-/-}$ mice in greater detail with focus on the autoreactive B cells and the autoantibodies.
Materials and methods: SLC$^{-/-}$ and control mice were analysed to determine e.g. serum autoantibody levels, antigen specificity, antibody sequences, and cellular composition of lymphoid tissues by flow cytometry and immunohistochemistry, etc.
Results: Unexpectedly, we find that the B cell population with autoreactive characteristics present with a phenotype reminiscent of germinal centre B cells. In support of this germinal centres, typical of T cell-dependent immune responses, are detected by immunohistochemistry in 4–5 month old SLC$^{-/-}$ but not control mice. Around this time we detect plasma blasts/cells by flow cytometry SLC$^{-/-}$ and find that the levels of IgG autoantibodies are significantly elevated whereas those of IgM are increased already at 2–3 month. These observations are being further investigated.
Conclusions: Collectively, our findings demonstrate that lack of negative selection at the pre-BCR checkpoint allow for spontaneous germinal centre reactions and the production of IgG autoantibodies. These data argue that tolerance checkpoints later in B cell development are not sufficient or, alternatively, cannot fully replace that of the pre-BCR. They also imply that a B cell-intrinsic defect at the pro- to pre-B cell transition may have a detrimental effect on control of peripheral autoimmune reactions.

P0727

The regulation of immediate early response gene IEX-1 expression

A. Kasza, J. Kochan & M. Wawro
Cell Biochemistry, Jagiellonian University Faculty of Biochemistry Biophysics and Biotechnology, Krakow, Poland

Purpose/Objective: Identifcation of mechanisms of regulation of *IEX-1* expression by EGF and identification of proteins engaged in IEX-1 transcript turnover. *IEX-1* is an immediate early gene which expression is induced rapidly and transiently upon stimulation with growth factors, inflammatory cytokines, LPS or PMA. The protein product of the gene is involved in the regulation of apoptosis and can positively as well as negatively affect the cell survival. IEX-1 is also engaged in oncogenesis.
Materials and methods: human hepatoma HepG2 cell line, reporter vectors containing *IEX-1* promoter variants or IEX-1 3′UTR, luciferase essays, Northen blots, Western blots.
Results: Expression of *IEX-1* is regulated by both EGF and PMA in ERK1/2-dependent manner. EGF stimulation accompanied by ERK1/2-dependent phosphorylation of transcription factor Elk-1 suggests that Elk-1 may activate *IEX-1* transcription. Using reporter system with luciferase gene under the control of the *IEX-1* promoter we have shown that Elk-1 activates *IEX-1* promoter and that this regulation is SRF-independent. By series of genetic constructs containing variants of *IEX-1* promoter we have found that the region between -140 and -95 bp is essential for *IEX-1* promoter activity.

Moreover, using the reporter gene construct containing luciferase gene with attached *IEX-1* 3'UTR we have identified proteins possibly engaged in the regulation of IEX-1 mRNA half-life. These proteins include newly identified RNase MCPIP-1 which shorten the IEX-1 mRNA half-life and HuR involved in stabilization of this transcripts.
Conclusions: EGF regulates *IEX-1* expression through the activation of transcription factor Elk-1. The half-life of IEX-1 mRNA is regulated by MCPIP-1, TTP and HuR.

P0728

The role of calpain-calpastatin system in reduced apoptosis of childhood acute lymphoblastic leukemia cells

A. Mikosik,* K. Ruckemann-Dziurdzinska,* A. Ploszynska,† A. Balcerska† & J. M. Witkowski*
**Department of Pathophysiology, Medical University of Gdansk, Gdansk, Poland, †Department of Paediatrics Oncology Hematology and Endocrinology, Medical University of Gdansk, Gdansk, Poland*

Purpose/Objective: Acute lymphoblastic leukemia (ALL) is one of the most common malignancies among children. The disease is associated with excessive proliferation of lymphoid cells, as well as reduced susceptibility to programmed cell death. The blasts exhibit defective apoptosis leading to their accumulation but the mechanism of this low susceptibility to apoptosis is not fully understood. Calpains (m- and m-) are ubiquitous cysteine proteases activated by elevated cytoplasmic calcium. The role of calpains includes regulation of both proliferation and apoptosis, where they can act as either pro- and anti-apoptotic. Excessive activity of calpains is controlled by an endogenous inhibitor – calpastatin; in healthy cells calpains and calpastatin remain in a strictly regulated balance, forming the calpain-calpastatin system (CCS).

The aim of this study was to assess the potential role of CCS activity in the inhibition of apoptosis of ALL blasts and the effect of its pharmacological modulation.
Materials and methods: $CD19^+$ cells derived from bone marrow from ALL and non-oncological pediatric patients were studied. The CCS protein amounts were measured by FACS and the actual intracellular calpain activity was assessed by western blot detection of calpastatin degradation products. Apoptosis (spontaneous and Calpain Inhibitor IV – modulated) was assessed by flow cytometry, using JC-1 for detection of mitochondrial membrane depolarization and Annexin V plus 7-AAD staining for quantification of later stages of apoptosis.
Results: We have observed highly elevated amount and activity of m -calpain, whereas the level of m-calpain was low in the blasts compared to healthy B cells. The endogenous activity of calpain, measured by calpastatin degradation, was higher in the blasts, especially in the older (10^+ years) patients. Spontaneousapoptosis of the blasts was inhibited and correlated with the level and activity of m-calpain. The Calpain Inhibitor IV treatment strongly increased apoptosis.
Conclusions: The results show highly disturbed equilibrium of the enzyme and inhibitor in the CCS, which can lead to block the blast apoptosis in ALL. Calpastatin undergoes proteolytic degradation in blasts, losing ability to inhibit overactive calpain, which prevents cell death of blasts. This makes CCS a potential therapeutic target in childhood ALL.

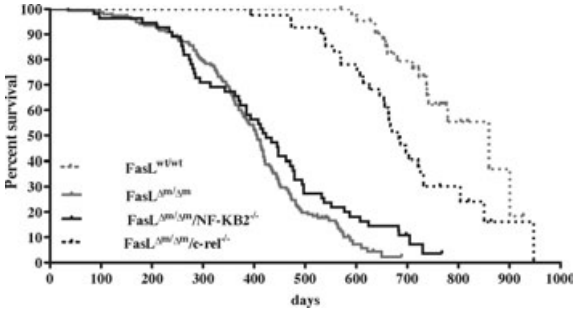
P0729

The roles of Fas death receptor signalling and NF-kB transcription factors in autoimmune disease

L. A. O'Reilly,* A. Lin,* D. Gray,* S. Gerondakis† & A. Strasser*
**Molecular Genetics of Cancer, The Walter and Eliza Hall Institute of medical Research, Melbourne, Vic., Australia, †NF-kB Lab, The Australian Centre for Blood Diseases, Melbourne, Vic., Australia*

Purpose/Objective: The death receptor Fas and its ligand, FasL, are guardians against autoimmune disease and lymphadenopathy. FasL is initially produced in membrane-bound form (mFasL), which can be processed into secreted FasL (sFasL). Mice expressing only sFasL (ΔmFasL) develop glomerulonephritis and SLE-like autoimmunity or histiocytic sarcoma because membrane-bound FasL is essential for Fas-induced apoptosis. With increasing age, the ΔmFasL mutant mice accumulate abnormally increased cytokine levels (IL-6, TNF-a) and activated (nuclear) NF-κB expressing cells within inflammatory infiltrates. This is manifest before overt disease, indicating that abnormally increased NF-κB activation and increased pro-inflammatory cytokines may be critical for disease development in mice in which Fas-induced apoptosis is impaired.

Aims: Determining whether NF-kB component(s) is/are critical for the development of SLE-like autoimmune disease and tumorigenesis has the potential to identify novel therapeutic strategies. We assessed the role of different NF-κB subunits in the development of autoimmunity in the $FasL^{\Delta m/\Delta m}$ mice by crossing these animals with gene-targeted mice lacking individual NF-κB components (*nfkb2*$^{-/-}$ *and c-rel*$^{-/-}$).
Materials and methods: Development of lymphadenopathy, splenomegaly, serum Ig levels, anti-nuclear antibodies, serum cytokine levels, T regs confocal analysis of organ specific autoantibodies and pathological features associated with glomerulonephritis, vasculitis, organ inflammatory infiltrates and tumourigenesis were assessed.
Results: We report that loss of *nfkb2* did not prolong survival of $FasL^{\Delta m/\Delta m}$ mutant mice; in fact, surprisingly, the $FasL^{\Delta m/\Delta m}$;*nfkb2*$^{-/-}$ double-mutant mice developed accelerated lympho-proliferative



disease. In contrast significant reduction of autoimmune pathology and greatly prolonged survival were seen in $FasL^{\Delta m/\Delta m}$ mice ($P < 0.0001$) that lacked the classical NF-kB pathway component c-Rel.

Conclusions: NF-kB2 dependent processes must normally restrain proliferation and/or survival of excess lymphocytes that accumulate as a consequence of defects in FasL-Fas mediated killing. However therapies targeting c-Rel expression, activation or function may be promising therapeutic strategies for a range of autoimmune diseases and possibly cancers, particularly those driven (at least in part) by defects in death receptor signalling.

The soluble cytoplasmic tail of CD45 (ct-CD45) induces a non-canonical form of anergy in human T cells

A. Puck, M. Seyerl, S. Hopf, O. Majdic, G. J. Zlabinger, J. Leitner, P. Steinberger & J. Stöckl

Center for Pathophysiology Infectiology and Immunology, Institute of Immunology, Vienna, Austria

Purpose/Objective: The cytoplasmic tail of CD45 (ct-CD45) is proteolytically cleaved and released upon activation of human phagocytes. The soluble ct-CD45 was found to act on T cells as an inhibitory, cytokine-like factor that reduces T cell proliferation. In this study, we aimed to elucidate the molecular mechanisms acting within T cells, upon ct-CD45 binding.

Materials and methods: Human primary T cells were stimulated *in vitro* via plate-bound antibodies in the presence of immobilized ct-CD45. The cells were analyzed for their cytokine release and proliferative capacity. Gene expression profiling was performed via microarrays and qPCR.

Results: Here, we demonstrate that ct-CD45 induces a novel form of anergy in human peripheral blood T cells. Ct-CD45 inhibited the proliferation of purified $CD4^+$ as well as of $CD8^+$ T cells, the cytokine production (IL-4, IFN-γ, IL-10, IL-17, IL-13) and the induction of typical T cell activation markers (CD25, CD69). Co-stimulation via CD28 or CD63 failed to prevent this inhibitory signal. Moreover, we found that T cells activated via CD3/CD28 or CD3/CD63 in the presence of ct-CD45 failed to proliferate in response to restimulation which was reversible by the addition of exogenous IL-2 or IL-7. Recent studies have clearly demonstrated that such a hypo-proliferative or anergic state in T cells is not a simple loss of signaling molecules, but an active process where 'anergy factors' are being induced and synthesized to establish and maintain the unresponsive state. Classical anergy-associated genes encode, among other proteins, transcription factors (early growth response protein 2 and 3, EGR2, EGR3), E3 ubiquitin ligases (e.g. Casitas B cell lymphoma b, CBL-b), and diacylglycerol kinases (e.g. DGK-α). However, when we analyzed the gene expression profile of ct-CD45-induced anergic T cells we did not observe induction of any of these anergy factors. Characterizing the expression patterns of cell cycle regulatory factors, we found inhibition in the induction of cyclin D1 while other cyclins were unaltered.

Conclusions: Ct-CD45 triggers an anergy program in T cells which is reversible by exogenous IL-2, acting independently of classical anergy factors. From our data, the inhibition of cyclin D1 suggests a cell cycle arrest in the early G1 phase, thus making it distinct from canonical T cell anergy.

Tonic type I interferons and CD40 Signals drive breakdown of $CD8^+$ T-cell tolerance following depletion of suppressive $CD4^+$ T cells

S. Muth,* K. Schütze,* S. Lienenklaus,† U. Kalinke,‡ H. Schild* & H. C. Probst*

**Institute for Immunology, University Medical Center, Mainz, Germany, †Molekulare Immunologie, Helmholtz-Zentrum für Infektionsforschung, Braunschweig, Germany, ‡Institute for Experimental Infection, TWINCORE Zentrum für Experimentelle und Klinische Infektionsforschung, Hannover, Germany*

Purpose/Objective: Autoreactive T cells that have escaped negative selection in thymus must be controlled in the periphery to prevent autoimmunity. Under steady state conditions resting dendritic cells (DC) continously present self-antigens resulting in the deletion or inactivation of autoreactive T cells and therefore play a key role in peripheral tolerance induction. We have recently shown that cognate interactions between $CD4^+$ FoxP3 regulatory T cells (Treg) and DC are essential to maintain the tolerizing capacity of the DC *in vivo*. DC that could not interact directly with Tregs were completely unable to induce peripheral $CD8^+$ T-cell tolerance. Instead those DCs showed an activated phenotype and primed a functional cytotoxic T-cell response. The objective of this study was to identify the signals that drive the functional activation of DC in the steady state following depletion of regulatory $CD4^+$ T cells.

Materials and methods: We use DIETER transgenic mice that allow the inducible presentation of virus derived cytotoxic T cell epitopes selectively on DC. Induction of antigen presentation on steady state DC in DIETER mice results in T cell tolerance if the DC can interact with suppressive $CD4^+$ T cells but T cell priming if such suppressive interactions are not possible. We use DIETER mice in combination with mice deficient for various DC activating molecules to identify the signals that drive the functional activation of DC in the steady state following depletion of regulatory $CD4^+$ T cells.

Results: We show that the functional activation of steady-state DC and the concomitant breakdown of T cell tolerance in the absence of Treg is driven by tonic levels of Typ I Interferon and CD40 Ligation delivered by adaptive immune cells but is independent of direct recognition of pathogen associated molecules through MyD88 dependent receptors.

Conclusions: Peripheral tolerance induction by steady state DC requires regulatory T cells which counterbalance DC activation through tonic levels of Type I Interferons and CD40 signals.

P0732

Toso deficiency results in defective survival of activated effector lymphocytes

J. Yu & K. Lee

Division of Molecular Immunology, Leibniz Research Center for Medicine and Biosciences (FZB), Borstel, Germany

Purpose/Objective: The regulation of lymphocyte apoptosis is critical to immune cell homeostasis and normal functioning of the adaptive immune system. Even a small imbalance in the regulation of lymphocyte survival and apoptosis can have severe pathological consequences. Recently we demonstrated that the immune-specific protein Toso represents the unique case of a cell surface molecule that protects from death receptor-induced apoptosis solely by cellular expression *(Nguyen et al., 2011)*. Here we investigated the role of Toso in survival and apoptosis of lymphocytes during cellular activation.

Materials and methods: Utilizing a genetic system of Toso-deficient mice our study followed a multidisciplinary approach, which involved biochemical, cell biological and immunological methods to analyze the impact of Toso on T and B cell function.

Results: Our studies showed that Toso is expressed exclusively in lymphoid organs, and is particularly highly expressed in T and B cells. Toso expression levels in T and B cells are regulated by cellular activation and pro-survival cytokines, such as IL-2, IL-4 and IL-15. To investigate the physiological function of Toso, we have successfully generated constitutive, as well as T and B cell specific conditional Toso knock-out mice. $Toso^{-/-}$ mice exhibited normal T and B cell development in the thymus and bone marrow, respectively, and had normal numbers of T and B cells in peripheral lymphoid organs. Functional studies showed that Toso deficiency results in increased sensitivity to TNFa-induced apoptosis and impaired survival and expansion of effector T and B cells. Furthermore, upon antigen receptor triggering $Toso^{-/-}$ B cells exhibited dramatically reduced proliferation, which was associated with a significantly higher degree of cell death. Consistent with an anti-apoptotic function of TOSO, increased apoptosis was also observed in activated $Toso^{-/-}$ T cells.

Conclusions: Given the anti-apoptotic/pro-survival function of Toso in death receptor signaling together with the remarkable upregulation of Toso expression in effector T and B cells, it is likely that Toso contributes to the generation and survival of effector T and B cells during an immune response. Thus, our studies provide important clues about the overall role of Toso in T and B cell immunity by regulating cellular apoptosis and survival of lymphocytes.

Poster session: Trafficking and Homeostasis

P0733
B cells determine T cell number and phenotype

A. C. Lino, E. Mohr & J. Demengeot
Institute Gulbenkian of Science, Lymphocyte Physiology, Oeiras, Portugal

Purpose/Objective: While it is well established that T cells promote B cells expansion by providing 'help' during immune challenges, B cells have also been proposed to enhance or dampen T cell activation. In an attempt to clarify this controversial issue, we tested the contribution of B cells in the regulation of T cell number and phenotype at steady state and in lymphopenic conditions.
Materials and methods: Steady state analyses were performed on mice either WT or genetically deficient for B cells ($JHT^{-/-}$), secreted IgM ($\mu S^{-/-}$), switched Ig and hypermutated IgM ($AID^{-/-}$) or total Ig ($AID^{-/-}\mu S^{-/-}$) by FACS. Lymphopenia induced proliferation was monitored upon adoptive transfer of $Foxp3^-$ CD4 T cells into $TCR\beta^{-/-}$, $Rag^{-/-}$ or $TCR\beta^{-/-}$ $AID^{-/-}\mu S^{-/-}$ recipient mice.
Results: Analysis of WT animals raised in strict SPF condition revealed a positive correlation between splenic B and T cells numbers. Strikingly, while presenting up to threefold more B than age-matched WT animals $\mu S^{-/-}$, $AID^{-/-}$ and $AID^{-/-}\mu S^{-/-}$ mice maintained a similar correlation between B and T cells numbers in the spleen. Supporting further the idea that B cells control T cell numbers, mice devoid of B cells ($JHT^{-/-}$) presented a 2-fold reduction in the number of peripheral but not thymic T cells, when compared to age matched WT animals. Moreover, adoptive transfer of WT B cells corrected the T cell phenotype in $JHT^{-/-}$ mice. The reduction in T cell numbers in $JHT^{-/-}$ mice affected all subsets of T cells but was most marked for activated and Foxp3+ regulatory CD4 T cells. Adoptive transfer of $Foxp3^-$ CD4 T cells into lymphopenic mice B cell deficient ($Rag^{-/-}$) or not ($TCR\beta^{-/-}$) revealed that B cells also promote T cell recovery as well as Foxp3 induction in lymphopenic settings. This result was reproduced when using T cell less, Ig less recipient mice ($TCR\beta^{-/-}AID^{-/-}\mu S^{-/-}$), suggesting that B cell enhancing effect on T cells it is independent of the control B cells exert on the microbiota.
Conclusions: Our results indicate that B cells promote peripheral T cell expansion and/or maintenance as well as conversion to a Foxp3+ phenotype. This work should help reconsidering the contribution of B cell to disrupted homeostasis in conditions of autoimmunity, immunodeficiency and lymphopenia, the latter often induced upon chemotherapy.

P0735
Characterization of lymphocyte egress from salmonella-infected Peyer's patches

O. Schulz, M. Friedrichsen & O. Pabst
Hannover Medical School, Institute of Immunology, Hannover, Germany

Purpose/Objective: Lymphoid organ hypertrophy is a well acknowledged phenomenon which arises during inflammation. Here we characterize hypertrophy of intestinal Peyer's patches (PP) during local *Salmonella* infection.
Materials and methods: Using PP cell-specific labelling combined with intestinal lymph isolation, we established a method to selectively monitor lymphocyte egress from PP. We mark all PP cells *in-vivo* by FITC injection and monitor the kinetics of their replacement by incoming non-labelled lymphocytes and the dissemination of FITC-labelled cells into lymph.
Results: In *Salmonella*-infected PP, FITC-labelled lymphocytes were retained substantially longer than in non-infected PP. Moreover, the number of PP-derived cells in intestinal lymph was reduced during infection. Lymphocyte proliferation or increased recruitment did not substantially contribute to PP hypertrophy. These results reveal that infected PP establish an exit blockade, characterized by retention of incoming lymphocytes and reduced egress of PP-derived lymphocytes into intestinal lymph.

Signals initiating lymphocyte sequestration in lymphoid organs include type I interferons (IFNalpha/beta) and tumor necrosis factor (TNF)-alpha, both suggested to interfere with sphingosine-1-phosphate (S1P)-guided entry into lymph. In our model, neither type I interferon receptor (IFNAR) nor p55/TNF receptor (TNFR1) were required for lymphocyte entrapping in *Salmonella* infected PP, even though inhibition of S1P function largely blocked lymphocyte exit from PP into lymph. Moreover, lymphocyte sequestration in infected PP was independent of CD69.
Conclusions: We conclude that PP hypertrophy during infection primarily results from reduced lymphocyte egress. Moreover, our results indicate that the mechanisms which establish lymphocyte retention in infected lymphoid organs are different from those mediating transient lymphocyte retention.

P0737
Different actors, different acts, same play — plasticity of dendritic cell migration

F. Eppler,* T. Quast,* Y. Homsi,† S. Levy,‡ T. Lang† & W. Kolanus*
**Life&Medical Sciences Institute (LIMES), Laboratory of Molecular Immunology University of Bonn, Bonn, Germany, †Life&Medical Sciences Institute (LIMES), Laboratory of Membrane Biochemistry University of Bonn, Bonn, Germany, ‡Department of Medicine, Division of Oncology, Medical Center, Stanford University, San Francisco, CA, USA*

Purpose/Objective: Chemotaxis of peripheral dendritic cells (DCs) to secondary lymphoid tissue is an essential requirement for adaptive immunity. Recent observations suggest that migration of DCs is characterized by a high degree of plasticity depending on their own proteome and the composition of their environments. In contrast to cell migration on two-dimensional substrates, which highly depends on integrin-mediated cell attachment and the subsequent generation of intracellular force and traction, interstitial migration differs substantially. In this 3D-environment DC migration functions adhesion-independent and is predominantly based on a highly dynamic actin cytoskeleton. We are interested in defining the specific role of different molecules which regulate these distinct migration modes of DC.
Materials and methods: We employ a wide variety of methods in the field of cell biology, immunology, biochemistry and molecular biology. These state-of the art techniques include molecular genetics for manipulation of both human and murine cells, standard analytical/preparative biochemistry, highly resolved static and dynamic light microscopy and flow cytometry. Furthermore, we employ different *in vitro* cell adhesion and migration assays.
Results: Our group has shown that the tetraspanin CD81 plays a crucial role in Rac activation and the formation of actin based membrane protrusions during integrin-dependent migration on 2D-surfaces. Interestingly, we found that CD81 is dispensable for adhesion-independent DC migration in complex 3D-environments. In contrast, activity of Dynamin 2, a large GTPase which is upregulated following maturation of BMDCs, is needed for functional DC migration on 2D- and in 3D-environments, since treatment with chemical Dynamin inhibitors strongly attenuates migration of DCs in these settings.
Conclusions: DCs are able to adapt to different mechanical migration modes. Migration-modulators can either be part of the overall migration machinery, such as Dynamin 2, or they are specific regulators of distinct migration modes, like CD81 in the adhesion-dependent migration on 2D-substrates. Both the elucidation of new modulators and the subsequent characterization of the precise molecular function in DC migration could improve DC-mediated vaccination.

P0738

Lymphotoxin beta regulates lymphatic vessel expansion in mucosal ectopic lymphoneogenesis

S. Nayar,* M. M. Chung,* P. Rankin,* T. Cloake,* C. Pitzalis,† P. Lane,‡ C. Buckley* & F. Barone*

*Rheumatology, University of Birmingham, Birmingham, UK, †Queen Mary University, Rheumatology, London, UK, ‡Infection and immunity, University of Birmingham, Birmingham, UK

Purpose/Objective: Defective drainage of immune cells from inflammatory sites contributes to persistence of inflammation. Lymph nodes show synchronized expansion of the vascular and lymphatic system in response to immunization. We used a novel model of ectopic lymphoneogenesis in WT and KO mice, to evaluate whether similar events take place in the periphery and assess the modifications occurring to the vascular systems in different phases of the inflammatory process.
Materials and methods: Histological analysis in WT and LTβRKO salivary glands, cannulated with 10^{-8} p.f.u. of adenovirus, was performed at different time points post cannulation (pc). Flow cytometry was used to identify in digested tissues the CD45-EPCAM-CD31+GP38$^-$ blood endothelial cells (BEC) and CD45-EPCAM-CD31+GP38+ lymphatic endothelia cells (LEC). Immunofluorescence (IF) for CD31 and Lyve was used to validate the FACS data.
Results: By flow cytometry we observed a significant deflection in the BEC percentage of in the early phases of the inflammatory process, followed by a progressive return to resting conditions during resolution. Conversely a significant increase in the number of LEC was observed in the early phase, followed by a significant decrease ($P > 0.01$) at the peak of the inflammatory process and a drastic increase during resolution $P = 0.01$. Interestingly, while LEC expansion was due to increase in the number of small lymphatics, the second peak corresponded to the histological finding of a small number of lymphatic with an enlarged lumen. This change in number and shape of the lymphatic bed coincided with the infiltration of B-lymphocytes and peak of lymphotoxin signal in the gland. Accordingly, cannulation of LTβRKO, demonstrated absence of the second peak of LEC proliferation and lack of lymphatic expansion by IF, suggesting a role for this molecule in lymphatic modification during inflammation. LTβRKO mice did not show significant differences in the percentage of BEC as compared to the WT.
Conclusions: Ectopic lymphoid follicles associated vasculogenesis fails to recapitulate the regulation observed in secondary lymphoid organs. The changes observed in the lymphatic bed seems to be regulated by the presence of ectopically expressed lymphotoxin, suggesting a novel therapeutic role for this molecule in inflammation.

P0739

Postnatal dynamics in small intestinal immune cell populations

N. Torow,* O. Pabst† & M. W. Hornef*

*Hannover Medical School, Microbiology, Hannover, Germany, †Hannover Medical School, Immunology, Hannover, Germany

Purpose/Objective: More than half of the body's professional immune cells are involved in the maintenance of intestinal homeostasis. Already in the fetus gut associated lymphoid tissues begin to form and the highly dynamic process of intestinal immune homeostasis is initiated. During delivery of the neonate a transition of the intestine from a sterile to an increasingly colonized environment occurs. The commensal flora is a very important modulator of the innate and adaptive immune mechanisms that contribute to the homeostasis. Therefore, we hypothesised that the postnatal adaptation and colonization of the small intestine directly influences the intestinal immune cell composition. The present study aims to investigate the postnatal dynamics in small intestinal immune cell populations.
Materials and methods: Small intestine immune cells were isolated and subjected to FACS analysis. The following markers of CD45+ cells were assayed to define subpopulations: CD4, CD8$\alpha\alpha$, CD8$\alpha\beta$, TCR$\alpha\beta$, TCR$\gamma\delta$, MHCII, MHCII CD11c, MHCII CD11b F480.The immune cell subsets in the small intestine of B6 mice were analysed at d6, d12, d28 and d56 after birth.
Results: During the 2nd week after birth mainly the B cell population (MHCII$^+$ CD11c-CD11b-F480-) expands and reaches a peak around day 12. TCR$\gamma\delta$ and CD8$\alpha\alpha$ subsets start to expand between d12 and day 28 after birth whereas the TCR$\alpha\beta$ and CD8$\alpha\beta$ positive population increases only after day 28. The relative abundance of the CD4 positive cells decreases from day 12 onwards. The myeloid fraction of the small intestinal immune cells (MHCII+ CD11c+ and MHCII+ CD11b+ F480+) remains quite stable over time.
Conclusions: The lymphocyte composition in the small intestine is highly dynamic whereas the relative abundance of the myeloid compartment remains stable during the postnatal period.

P0740

TCR triggering controls IL7 responsiveness and homeostatic expansion of CD4+ T cells during IL7 therapy

D. Leboeuf,* O. Hennion-Tscheltzoff,* S. D. Gauthier,* C. L. Mackall† & M. Guimond*

*Maisonneuve Rosemont Hospital Research Center, Immunology and Microbiology, Montreal, QC, Canada, †NCI, Pediatric Oncology Branch, Bethesda, USA

Purpose/Objective: Lymphocyte regeneration following high dose chemotherapy occurs via homeostatic peripheral expansion (HPE). While HPE efficiently regenerates CD8$^+$T cells, it is inefficient for CD4$^+$ and induces a skewing of the lymphocyte repertoire towards cells with high affinity for self-peptide MHC complexes (p-MHC). Interleukin-7 (IL7) is essential for thymopoiesis and HPE of naïve T cells. Previous studies in humans have demonstrated that supraphysiological doses of IL7 could increase T cell counts and TCR diversity. However, the exact mechanism is not completely understood. Given the critical role of thymopoiesis in CD4$^+$ recovery, we hypothesized that the proliferative effect of IL-7 therapy must rely largely on recent thymic emigrants (RTE) expansion.
Materials and methods: Adoptive transfer of single positive CD4 and CD8 thymocytes and LN T cells into wt or lymphopenic hosts was used for all experiments. IL7 treatment consists of six daily doses of 10 μg.
Results: Following adoptive transfer of RTEs isolated from Rag-GFP mice, we did not find evidence that IL7 therapy induced stronger proliferation of RTEs. However, single positive CD4$^+$ thymocytes (CD4$^+_{SPT}$) were more responsive to IL7 therapy according to stat5 phosphorylation and BCL-2 induction and that lower doses of IL7 were sufficient to induce proliferation *in vivo*. We also found that CD4$^+_{SPT}$ were more sensitive to TCR signalling than RTEs and peripheral CD4$^+$ T cells (CD4$^+_{PERI}$) according to miR181a micro-RNA quantification. Despite the requirement of TCR stimulation for IL7 to induce proliferation of CD4$^+_{PERI}$ and CD4$^+_{SPT}$, residual proliferation of CD4$^+_{SPT}$ was observed upon transfer into IL7 treated MHC II$^{-/-}$ hosts. This proliferation was abrogated when IL7 therapy was delayed; suggesting that TCR triggering received inside the thymus was responsible for this effect. Increasing the number of dendritic cells by treating mice with FLT3 ligand augmented proliferation of CD4+ T cells by IL7. Finally, we found that cells undergoing proliferation during IL7 therapy were low affinity CD4$^+$ cells to p-MHC.
Conclusions: Together our data support a model wherein IL7 therapy affects CD4$^+$ T cells as they egress from the thymus and once in the periphery, these cells rapidly diminish their responsiveness to IL7. Therefore a residual thymic function is likely to augment the success of IL7 therapy in lymphopenic patients.

DELTA4BAFF alternative splicing is regulated by interferon-gamma AND SC35 protein

J. O. Pers,* G. J. Tobon,* L. Corcos,† G. Dujardin,† P. Youinou* & L. Le Pottier*
*EA 2216 'Immunology & Pathology', Brest University and European University of Brittany, Brest, France, †INSERM UMR1078, Brest University and European University of Brittany, Brest, France

Purpose/Objective: The B-cell activating factor (BAFF) is a potent survival factor involved in the pathogenesis of autoimmune diseases. Recently, we reported the discovery of a new transcript for BAFF, Δ4BAFF – lacking exon 4 -, which is mainly detected in autoimmune diseases and acts as a transcription factor for its own gene. However, the mechanisms implicated in Δ4BAFF induction and up-regulation are unknown. In this study we analyzed the induction and regulation of Δ4BAFF.
Materials and methods: First, to study the alternative splicing of *BAFF* exon 4, we transfected a minigene construct, centered on exon 4, into RAMOS B cells.To determine the proteins implicated in exon 4 inclusion/exclusion, we co-transfected the minigene together with each of the plasmids coding for the main splicing proteins (SC35, SRp40, SRp55, SRp20 and hnRNPA1), and the ratios between exon4 inclusion/exclusion were evaluated by RT-PCR. Second, we examined the effects of different cytokines on *Δ*4BAFF induction.
Results: RAMOS cells presented exon 4 skipping (ratio inclusion/exclusion: 6.8) after minigene transfection. Following co-transfection of the minigene with coding plasmids for splicing proteins, only the overexpression of SC35 showed effect in the splicing of exon 4, promoting exon 4 inclusion (ratio: >30).Incubation of different cell lines with several cytokines showed that IFN-$\gamma$was able to induce Δ4BAFF-transcript. Thus, after IFN-γ stimulation in the minigene model, the ratio inclusion/exclusion markedly decreased (1.5). IFN-γmodifies the balance between SC35 and another member of hnRNPs family (hnRNP C1/C2) favouring the alternative splicing of exon 4.
Conclusions: These results demonstrated that IFN-γ induces Δ4BAFF, modifying the function of SC35 protein and increasing the expression of hnRNPC1/C2. Our study provides an expanded conceptual view of BAFF gene regulation, and contributes to a better understanding of the mechanisms involved in BAFF up-regulation in autoimmunity.

Discovery of a new alternative splice variant of human Interleukin-4 and study of its functionality as a nonsense-mediated decay

C. Hauvespre,* V. Courtois,* K. De Luca,* C. Legras-Lachuer† & R. Sodoyer*
*Sanofi Pasteur, Research, Marcy l'Etoile, France, †ProfileXpert-LCMT, Faculté de Médecine et de Pharmacie, Lyon, France

Purpose/Objective: Interleukin-4 (IL-4) is a pleiotropic cytokine regulator of immunity in health and disease states. IL-4 is a cytokine responsible of the Th2 response during infections with parasites, allergy or asthma. An alternatively spliced variant of human IL-4, known as IL-4δ2, is deleted of the second exon. IL-4δ2 can be considered as an inhibitor of IL-4 in immune response. Doing experiments on human T cells, a new alternative splice variant of IL-4 has been cloned and sequenced. In the present study, we explain the discovery of a new alternative spliced variant of IL-4 and investigate the expression of this new transcript.
Materials and methods: A bioinformatics study is conducted to investigate the presence of the alternative splice site consensus sequences. Using a transfection and a non-sens mediated decay (NMD) inhibition approach by cycloheximide (CHX), we show that this new transcript is targeted by NMD degradation.
Results: 101 base-paired (bp) of the second intron are retained between the second and the third exon. Alternative splicing consensus sequences are presents in the flanking sequences of the retention. The base-pairs retained downstream the second exon generate a frame-shiftinducing a premature stop codon (PTC) in the third exon. This PTC is located 53 bp upstream the junction between the exons 3 and 4, the last junction exon-exon. This is characteristic of a nonsense-mediated decay (NMD) construct.
Conclusions: The function of this new variant is likely to be involved in the regulation of the IL-4 expression. Thereby, we can imagine a role in regulating the Th2 response by this new mRNA.

P0743

DNA double stranded breaks enhance the transcription of AIRE target genes

M. Guha, U. Halasorg, K. Kisand & P. Peterson
Biomedicum, Institute of General and Molecular Pathology, Tartu, Estonia

Purpose/Objective: The autoimmune regulator (AIRE*)* gene shows a predominant expression in thymus and is the major regulator of negative selection of autoreactive T-cells. Mutations in AIRE protein result in onset of autoimmune polyendocrinopathy-candidiasis-ectodermaldystrophy (APECED). One reported AIRE interacting parter is topoisomerase 2 and this interaction has been found to promote topoisomerase 2a initiated double stranded breaks. We aimed to study the possible involvement of double stranded DNA breaks in AIRE transcriptional activation of target genes in AIRE-expressing HEK293 cells after the treatment with etoposide or merbarone, the well known inhibitors of topoisomerase 2a.
Materials and methods: HEK cell line culture – AIRE inducible stable cell line was cultured in DMEM media supplemented with 10% tetracyclin negative fetal calf serum, 100 U/ml penicillin/streptomycin and 0.15 mg/ml G418. AIRE expression was induced with Doxycyline (Dox) at 2.0 μg/ml next day after plating. The protein expression was verified with western blotting.

RNA isolation and real time PCR- Total RNA was isolated from cells at different time intervals using Trizol reagent following manufacturer's protocol. Yield and purity of RNA was determined by nanodrop. Gene expression level of AIRE target gene was detected by quantitative PCR using qPCR SYBR Green Core Kit on ABI Prism 7900HT.
Results: We observed an upregulation of the AIRE target genes after the treatment with etoposide that stabilizes topoisomerase 2 to DNA and prevents religation of DNA breaks. In contrast, another topoisomerase 2 inhibitor, merbarone, which blocks topoisomerase mediated DNA cleavage did not result in up-regulation of AIRE target genes. This effect was not a consequence of variability in Aire expression levels but rather indicates the specific differencies of these two topoisomerase 2 inhibitors and a possible role of double stranded breaks in up-regulation of Aire target genes. We next examined the extent of DNA double stranded breaks under our experimental settings using BrdU TUNEL assay and FACS analysis. The analysis showed that indeed there was a significant increase in DNA double stranded breaks under the etoposide treatment compared to nontreated cells or cells that were treated with merbarone. Further, in co-immunoprecipitation experiment, we found AIRE interaction with topoisomerase 2 and this interaction increased in presence of etoposide.
Conclusions: With these results we conclude that etoposide enhances the up-regulation of AIRE target genes through the involvement of DNA double stranded breaks.

P0744

Epigenetic regulation of CTLA4 in different subpopulations of T cells

J. Kaurson, K. Kisand, K. Kisand & R. Uibo
Immunology Group Institute of General and Molecular Pathology, University of Tartu, Tartu, Estonia

Purpose/Objective: Cytotoxic T lymphocyte antigen 4 (CTLA4) transmits inhibitory signals to T cells and is critical for maintaining tolerance to self antigens. It is differentially expressed in T cell subpopulations. Regulatory T cells (Tregs) express CTLA4 constitutively, but in effector T cells CTLA4 expression is up-regulated in response to T cell activation. The mechanisms governing regulation of CTLA4 expression in T cell subpopulations are not entirely clear. Chromatin structure and histone modifications are important regulatory factors that affect the transcriptional status of genes. This study aims to determine if differential expression of CTLA4 is regulated through epigenetic mechanisms by comparing histone modification profiles of T cell subpopulations.
Materials and methods: Using immunomagnetic separation, naïve $CD4^+$ and $CD8^+$ T cells and $CD4^+$ $CD25^+$ Tregs were isolated from peripheral blood mononuclear cells. Purity of cells was determined by flow cytometry. Chromatin immunoprecipitation (ChIP) was performed with antibodies to various histone modifications, including histone H3 trimethylation at lysine 4 (H3K4me3) and at lysine 27 (H3K27me3). ChIP samples were analyzed by qPCR with primers covering different regions of *Ctla4*, including non-coding regulatory regions.
Results: H3K4me3 is a marker of active promoters and enhancers. We found that the promoter, gene body and distal regulatory regions were enriched for H3K4me3 in Tregs. In naïve $CD4^+$ and $CD8^+$ T cells, level of H3K4me3 was also high at the promoter and promoter proximal regions, although lower compared to Tregs. There was no marked difference in the level of the transcriptionally silenced euchromatin marker, H3K27me3 between Tregs and $CD4^+$ T cells. In $CD8^+$ T cells, however, all the studied regions were enriched for H3K27me3.
Conclusions: This bivalent chromatin pattern consisting of a repressive and an activating epigenetic marker could represent a 'transcription-ready' state for CTLA4 in naïve $CD8^+$ T cells. However, since Tregs and naïve $CD4^+$ T cells are very similar in their epigenetic profiles, it is possible that differential expression of CTLA4 in T cell subpopulations is regulated by other mechanisms as well. RNA Pol II presence together with epigenetic changes at the promoter and potential distal regulatory regions upon activation of T cells need further studies.

Evaluation of hematopoietic differentiation by expression level of key molecules

K. Polgarova, E. Fronkova, E. Mejstrikova, T. Kalina & O. Hrusak
2nd Faculty of Medicine and University Hospital Motol, Childhood Leukaemia Investigation Prague (CLIP), Charles University, Prague, Czech Republic

Purpose/Objective: For a long time, hematopoiesis has been seen as a continuous restriction of cell fate potentials till the development of mature blood cells of all lineages. However, in last years several works documented unexpected plasticity of hematopoietic cells. So called lineage infidelity and/or aberrant expression of different molecules, including the key cell fate regulators, is usually observed in acute leukemia (AL). How exactly these changes affect the cell behavior in background of differentiation and whether they rise from naturally present plasticity of normal cells remains often unclear. Therefore we aimed to evaluate the simplified transcription profile of hematopoietic progenitors of different lineages in relation to the profile of their malignant counterparts as defined by flow cytometry.
Materials and methods: Using qRT-PCR we investigated mRNA expression of 90 different molecules and five control genes in sorted hematopoietic progenitors. The genes included key differentiation and proliferation regulators (e.g. EBF1, MNDA) and also molecules without known function in hematopoiesis (e.g. NFIL3, PAWR). The tested subpopulations included $CD34^+$ Lin- cells, B-lymphoid and myeloid subpopulations from bone marrow, T-lymphoid subpopulations from thymi and blasts from different AL cases (lymphoblastic, myeloblastic, AL of ambiguous lineage).
Results: The basic differences between lineages were observed in expression of well known lineage markers and regulators, e.g. CD19, PAX5, GATA3, thus forming expected clusters in clustering analysis; however, even some of these basic molecules (e.g. CD79a) presented with low aberrant expression not attributable to the contamination, observed mainly in early developmental stages. Specific transcription patterns were observed in AL of different lineages disclosing possible importance of currently poorly described genes (e.g. CCDC26). Complete changes in transcription profile towards different lineage was observed in particular stages of ambiguous lineage AL suggesting role of specific regulators (e.g. CSF3 signaling).
Conclusions: The fidelity of transcription profile of different lineages was lower than expected and in early stages comparable to AL. Our results show a need to redefine so called aberrant expression present also in normal hematopoietic progenitors.

Patterns of DNA methylation in the T-cells and monocytes from the elderly and the young

L. Tserel,* M. Saare,* K. Kisand,* L. Milani,† A. Metspalu† & P. Peterson*
**Molecular Pathology and Centre for Translational Genomics, University of Tartu, Tartu, Estonia,* †*Estonian Genome Centre and Centre for Translational Genomics, University of Tartu, Tartu, Estonia*

Purpose/Objective: During the process of aging, several changes contribute to the suppressed immune responses in the immune system of elderly individuals. Both adaptive and innate immune systems are affected. In T-cell compartment, the changes include aberrant T cell phenotypes and reduced activity. This is mainly the result of thymic involution that leads to the reduction of naïve and increase of memory and activated T cell numbers. In turn, monocytes are key regulators of the innate immune system because of their antigen presentation and phagocytic function. Although the numbers of monocytes are stable during the aging, their functional capacity to activate TLR or to express cytokines is often decreased.

DNA methylation is an epigenetic modification that plays an important role in several processes, including aging. DNA methylation occurs throughout the genome including repeats, genes and intergenic regions. CpG islands are 0.5–2 kb regions of DNA with high GC content that are often associated with promoter regions. The CpG methylation is linked with transcriptional silencing, as it can block the binding of transcription factors and recruit DNA binding repressors. In this study, we have identified genome-wide DNA methylation differences in CD4 and CD8 T cells and in monocytes of young and elderly individuals.
Materials and methods: $CD4^+$ and $CD8^+$ T cells, and $CD14^+$ monocytes were purified from the peripheral blood of four healthy young and four aged volunteers of Estonian Genome Centre using Ficoll gradient method combined with magnetic activating cell sorting (MACS) method. To assess the whole genome methylation and

expression patterns, Infinium HD Methylation Assay and HumanHT-12 v4 Expression BeadChips were used.
Results: We identified methylated CpG sites in human peripheral blood CD4 and CD8 T-cells and in monocyte cell populations. Many CpG sites were specifically methylated in T-cell or monocyte subpopulations. Importantly, we found several CpG positions that were differentially methylated in young and elderly individuals suggesting age-related methylation changes in studied cell populations. We have also analyzed the correlation of CpG methylation with nearby gene expression in corresponding cell populations.
Conclusions: Human peripheral blood $CD4^+$ and $CD8^+$ T-cell and monocyte populations have differential methylation patterns in young and elderly individuals. The differential methylation may contribute to the phenotypic and functional changes, and to suppressed activities of the immune responses during aging.

P0747

T helper 9 cell development under epigenetic control during T cell maturation

A. Ramming, D. Druzd, J. Leipe, H. Schulze-Koops & A. Skapenko
Division of Rheumatology and Clinical Immunology, Medizinische Klinik und Poliklinik IVUniversity of Munich, München, Germany

Purpose/Objective: Histone modification patterns are key players in T helper (Th) cell regulation. However, their impact on differences in cytokine response patterns during maturation of the adaptive immune system is less understood. Here, we analyzed histone modifications in promoter regions of T-bet, GATA-3, PU.1, IRF4 and RORC in T cells of different maturation-status.
Materials and methods: Recent thymic emigrants (RTEs), matured naïve and memory CD4 T cells were isolated from cord blood of neonates or peripheral blood of adults for studying histone modification patterns and related gene and cytokine expression.
Results: The repressive histone H3 lysine 27 trimethylation (H3K27me3) dominated the PU.1 promoter in RTEs, whereas in matured naïve and further in memory T cells H3K27me3 overrepresentation was increasingly counterbalanced by permissive methylation at H3K4 and histone H3 acetylation. Notably, naïve T cells required more intense stimulation to switch the chromatin pattern in the PU.1 promoter from a repressive to a permissive state and thus to produce interleukin (IL)-9 than memory T cells. Inhibition of repressive histone methylation by the specific inhibitor, 3-deazaneplanocin A, induced Th9-specific PU.1 expression even with stimulation conditions that would normally lead only to the production of Th0 cytokines. On the other hand, prevention of histone acetylation by the histone acetyltransferase inhibitor, curcumin, diminished PU.1 expression after stimulation that would normally induce production of IL-9. Whereas RTEs differentiated into Th9 cells producing exclusively IL-9, matured naïve or memory CD4 T cells developed into effectors consisting of IL-9-producing cells as well as of cells capable of IL-4, IFN-γ, IL-5, or IL-17 co-production together with IL-9.
Conclusions: The data indicate that Th9 cell development is under stringent control during T cell life suggesting a growing contributive role of IL-9 in immune responses initiated by matured T cells.

P0748

The influence of NF-κB signaling in the conserved regulatory region of the AIRE gene

K. Kõnd, V. Kont, M. Saare & P. Peterson
Department of General and Molecular Pathology, University of Tartu, Tartu, Estonia

Purpose/Objective: The *AIRE* (Autoimmune Regulator) gene is essential for the establishment of central tolerance in the thymus. In humans, mutations in the *AIRE* gene cause the autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED). *AIRE* regulates the promiscuous gene expression of tissue-restricted antigens (TRAs). NF-κB is essential in the transcriptional regulation of *AIRE* gene and the lack of NF-κB decreases Aire dependent TRA gene expression. Human *AIRE* and mouse *Aire* share a similar conserved sequence containing NF-κB binding sites 3 kb upstream of the transcription start site. The aim of the research was to study whether the NF-κB pathway affects AIRE expression through the upstream NF-κB binding site containing conserved sequence.
Materials and methods: We cloned the NF-κB conserved sequence upstream of different *AIRE* promoter fragments in a luciferase reporter plasmid. HEK293 cells were transfected with the reporter constructs and the NF-κB pathway was activated by TNFα or PMA/ionomycine stimulation. The effect of the NF-κB conserved sequence was assessed by the luciferase activity. In addition, we overexpressed various Rel family members and stimulated the cells with TNFα or PMA/ionomycine and the activity of the promoter constructs was measured via luminescence.
Results: Our preliminary results show that the NF-κB signaling does not activate the reporter gene expression through the conserved sequence upstream of *AIRE* promoter region. However, analysis of the *AIRE* promoter region without the NF-κB conserved region showed that gene expression was activated through the *AIRE* promoter during TNFα or PMA/ionomycine stimulation.Overexpression of Rel family members showed no significant effect on the activation of the promoter constructs with or without NF-κB conserved region.
Conclusions: In conclusion, our findings based on luciferase assays suggest that the conserved NF-κB sequence upstream of *AIRE* promoter region does not mediate activating signals, although, further analyses are required to reveal the asssociation between NF-κB signaling and the conserved NF-κB binding sites upstream of *AIRE* gene.

P0749

Transcriptional regulation of GARP expression

S. Haupt, Q. Zhou, S. Herrmann, H. Schulze-Koops & A. Skapenko
Division of Rheumatology and Clinical Immunology, Medizinischen Klinik und Poliklinik IV University of Munich, München, Germany

Purpose/Objective: The membrane-associated molecule, glycoprotein A repetitions predominant (GARP) is highly expressed on activated regulatory $CD25^+$ CD4 T cells (Tregs), but not on resting Tregs or resting or activated $CD25^-$ CD4 T cells. The aim of this work was to delineate the transcriptional regulation of GARP gene expression.
Materials and methods: Human GARP promoter sequences were cloned into the basic pGL4.10 vector. Several CNS regions were inserted upstream of the minimal promoter of the pGL4.24 vector. Foxp3 was integrated in the mammalian expression vector pDEST12.2. The mouse T cell line, EL-4, was transfected with the promoter-reporter-constructs and stimulated with anti-CD3/anti-CD28 antibodies. In addition, cells were transfected with the Foxp3 expression vector and/or treated with retinoic acid (RA). The enhancer/attenuater function of CNS on the promoter activity was analyzed after transfection of CNS-reporter-constructs and stimulation with PMA and ionomycin. Chromatin immunoprecipitation of freshly isolated and activated human $CD4^+$ $CD25^+$ and $CD25^-$ T cells was performed to evaluate the trimethylation state of histone 3 at lysine 4 and at lysine 27, as well as the acetylation state of histone 3 of promoter and CNS regions.
Results: Foxp3 and RA synergistically induced luciferase expression in a concentration dependent manner. Histone modifications at the promoter region changed in $CD25^+$ Tregs towards a more accessible chromatin configuration upon T cell activation. In contrast, in $CD25^-$ T cells it was rather repressively modified. A CNS region located upstream of the GARP gene exhibited an open chromatin configuration in $CD25^+$ T cells upon TCR stimulation. When inserted upstream of a minimal promoter, this CNS region enhanced luciferase activity in response to T cell stimulation.
Conclusions: Thus, GARP transcription appears to be initiated by coordinate action of Foxp3 and RA and is additionally modulated via CNS. The transcriptionally active status of the GARP gene is supported by histone modifications in the promoter and conserved regions.

Poster Session: Asthma/Allergy

A fusion protein of flagellin and ovalbumin as novel vaccine candidate for allergies: suppressing TH2 responses and preventing murine intestinal allergy

S. Schülke,* M. Burggraf,† Z. Waibler,‡ A. Wangorsch,* S. Wolfheimer,* S. Vieths,* M. Toda† & S. Scheurer§
*Allergology, Paul-Ehlich-Institut, Langen, Germany, †Junior Research Group 'Allergy models', Paul-Ehlich-Institut, Langen, Germany, ‡Junior Research Group 'Novel vaccination strategies and early immune responses', Paul-Ehlich-Institut, Langen, Germany, §Paul-Ehrlich-Institut, Allergology, Langen, Germany

Purpose/Objective: The TLR5 agonist flagellin has been associated with immune modulatory functions making it an interesting adjuvant for allergy treatment. In this study we investigated the potency of fusion proteins containing *Listeria monocytogenesis*-derived flagellin flaA to induce DC activation and modulate ovalbumin-specific T cell responses. Moreover, we checked the fusion proteins potency for the treatment of allergies *in vivo*.
Materials and methods: Bone marrow-derived myeloid dendritic cells (mDC) from BALB/c, C57BL/6, IL-$10^{-/-}$, and TLR-signalling deficient ($MyD88^{-/-}$) mice were stimulated with rOva, rflaA, rflaA plus rOva, or a recombinant fusion protein consisting of rflaA and rOva (rflaA:Ova). Immune modulating properties of rflaA plus rOva and rflaA:Ova were investigated by DC:T cell co-culture using $CD4^+$ T cells from Ova-TCR transgenic or Ova/alum-immunized mice. A murine model of Ova-induced intestinal allergy was applied to assess the capacity of flaA:Ova as potential allergy vaccine.
Results: rflaA:Ova induced up-regulation of TLR5 on mDC and, dose-dependently, even higher IL-6 and IL-10 secretion than equimolar amounts of rflaA. Moreover, rflaA:Ova induced IL-10 mediated suppression of TH1 and TH2 cytokine secretion from Ova-TCR transgenic $CD4^+$ T cells and $CD4^+$ T cells derived from T_H2-biased mice upon Ova/alum immunization. The strong activation of mDC by rflaA:Ova could be suppressed in a dose-dependent manner by application of both inflammasome (Z-VAD-FMK, glybenclamid) and proteasome (lactacysteine) inhibitors. Prophylactic vaccination with rflaA:Ova was shown to protect against intestinal allergy, reduce T cell activation and T_H2 cytokine secretion. Additionally, rflaA:Ova suppressed Ova-specific IgE and induced Ova-specific IgG2a antibodies, whereas rflaA or rOva provided alone or as a mixture did not have comparable protective effects.
Conclusions: The rflaA:Ova fusion protein showed enhanced TLR-mediated immune modulating capacities, probably attributed to the proximity of the adjuvant and allergen. rflaA:Ova was able to suppress TH2 responses both *in vitro* and *in vivo*. Therefore, rflaA: allergen fusion proteins are promising vaccine candidates for intervention in IgE-mediated allergy.

P0751

A hypoallergenic variant of the major birch pollen allergen Bet v 1 shows distinct characteristics in antigen processing and T cell activation

C. Kitzmueller*, M. Wallner,† S. Deifl,* S. Mutschlechner,* G. Zlabinger,‡ F. Ferreira† & B. Bohle*
*Institute for Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria, †Department of Molecular Biology, University of Salzburg, Salzburg, Austria, ‡Institute of Immunology, Medical University of Vienna, Vienna, Austria

Purpose/Objective: BM4 is a novel genetically engineered variant of Bet v 1, the major birch pollen allergen. BM4 differs from Bet v 1 in only five amino acids but lacks the typical Bet v 1-like fold. As a consequence, BM4 displays negligible IgE-binding while it contains all relevant T cell epitopes of Bet v 1 except one. The aim of this study was to compare BM4 and Bet v 1 with regard to internalization, antigen-processing and presentation by antigen-presenting cells as well as T cell activation.
Materials and methods: Proliferative responses to BM4 and Bet v 1 of peripheral blood mononuclear cells and Bet v 1-specific T cell clones were analysed. Fluorescently labelled BM4 and Bet v 1 were used to study surface binding, endocytosis and intracellular degradation by monocyte-derived DC (mdDC). Both proteins were digested by endolysosomal extracts of mdDC. BM4- and Bet v 1-pulsed mdDC were employed to assess the kinetics of activation of Bet v 1-specific T cell clones and the polarization of naïve T cells.
Results: BM4 displayed a significantly stronger T cell-activating capacity than Bet v 1. Furthermore, BM4 bound more efficiently to the surface of mdDC. Internalisation and trafficking into acidic compartments as well as lysosomal degradation were faster for BM4 than for Bet v 1. BM4-pulsed mdDC induced enhanced proliferative responses at earlier time-points in Bet v 1-specific T cell clones. T cells primed with BM4-pulsed mdDC synthesized less IL-5 than those primed with Bet v 1-pulsed mdDC.
Conclusions: The loss of the Bet v 1-fold changes the protein's interaction with the human immune system at the level of antigen-presenting cells resulting in altered T cell responses. By combining low IgE-binding with a strong T cell-activating capacity that modulates the allergen-specific T cell response, BM4 represents a highly interesting candidate for specific immunotherapy of birch pollen allergy.

P0753

A peptide mimicking an important carbohydrate epitope cross-reactive between birch proteins and celery allergen Api g 5

A. Lukschal, J. Wallmann, M. Bublin,† H. Breiteneder,† B. Hantusch,‡ I. Pali-Schöll§ & E. Jensen-Jarolim[4,5]
*Division of Comparative Immunology and Oncology, Center for Pathophysiology Infectiology and Immunology, Institute of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria, †Department for Medical Biotechnology, Research Center for Pathophysiology Infectiology and Immunology, Institute of Pathophysiology and Allergy, Medical University of Vienna, Vienna, Austria, ‡Institute of Pathology, Medical University of Vienna, Vienna, Austria, §Center for Pathophysiology Infectiology and Immunology Institute of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria, ¶Messerli Research Institute of Universtity of Veterinary Medicine, Vienna, Austria

Purpose/Objective: Allergic reactions to celery are often caused by cross-reactivity to major birch pollen allergens like Bet v 1 and Bet v 2. Nevertheless, about 40% of the cross-reacting IgEs are directed towards yet unidentified allergens of 32–63 kDa in birch, and towards Api g 5 in celery. It has been demonstrated that IgE-binding to Api g 5 is strongly dependent on its carbohydrate moieties. Monoclonal antibody BIP 3 was originally raised against birch pollen extract and cross-reacts with Api g 5. For epitope definition, we aimed to generate peptides mimicking the BIP 3 epitope, so called mimotopes.
Materials and methods: Phages from a random-peptide phage-display library were selected for specific binding to monoclonal antibody BIP 3 and for their ability to inhibit IgE-binding of allergic patients to birch pollen extract. Three phage clones were chosen for intraperitoneal immunization of BALB/c mice and induced antibodies were tested on blotted birch pollen extract. To test if the mimicked epitope was comprised of carbohydrate moieties, we compared serum reactivity of immunized mice to Api g 5 and the structurally unrelated plant glycoprotein horse radish peroxidase (HRP). As a negative

control nonglycosylated grass pollen allergen Phl p 5 was used in ELISA.
Results: After 3 rounds of biopanning 7 different sequences were derived from 14 positive phage clones. The most frequent sequence also elicited the strongest immune reaction in mice. All 3 clones selected for immunization induced antibodies crossreactive for the major 63 kDa band recognized by BIP 3 in birch pollen extract and Api g 5. The antibodies induced by the mimotope immunizations were also reactive towards natural purified Api g 5 and the glycoprotein HRP, but not to the control allergen Phl p 5.
Conclusions: The peptide mimotopes characterized in this study mimic a carbohydrate epitope cross-reactive between Api g 5 and high molecular weight birch pollen proteins. As a peptide mimotope can be considered a superior immunogen in comparison to carbohydrate moieties, it may be suitable for epitope-specific immunotherapy and diagnosis.

P0754

A pollen hybrid molecule as novel therapeutic for the treatment of Fagales multi-sensitization

U. Pichler,* M. Hauser,* E. Hoflehner,† P. Briza,‡ S. Mutschlechner,§ B. Bohle,§ U. Wiedermann-Schmidt,† F. Ferreira* & M. Wallner*
**Department of Molecular Biology, Laboratory for Allergy Diagnosis and Therapy, University of Salzburg/Christian Doppler, Salzburg, Austria, †Department of Specific Prophylaxis and Tropical Medicine, Medical University of Vienna, Vienna, Austria, ‡Department of Molecular Biology, University of Salzburg, Salzburg, Austria, §Department of Pathophysiology, Laboratory for Immunomodulation, Medical University of Vienna/Christian Doppler, Vienna, Austria*

Purpose/Objective: Allergies against birch pollen and pollen of related trees belonging to the botanical order of *Fagales* are the most common cause for spring pollinosis in the temperate climate zone of the Northern hemisphere. However, specific immunotherapy is mainly performed with birch pollen extracts, limiting the success of this therapeutic intervention in areas where birch is not endemic.
Materials and methods: Thus, in the present study we generated a pollen hybrid molecule (PH) by PCR-based recombination of T cell epitopes of the low IgE-binding isoforms of the major allergens from birch, hazel, alder, oak, and hornbeam. *In silico* analyses of PH revealed that the molecule carries an epitope previously identified as critical for the Bet v 1-fold and closely connected to IgE binding, immunogenicity, and T cell polarization of Bet v 1. Therefore, the structure of PH was modified accordingly by replacing seven consecutive amino acids within the Bet v 1-part of the molecule by the homologous sequence of Mal d 1, resulting in a fold-variant of the molecule (PH4).
Results: Both hybrid molecules showed reduced binding of Bet v 1-specific IgE antibodies and an elevated activation of PBMCs from birch pollen allergic donors. Compared to the parental allergens, the pollen hybrid molecules could induce antigen-specific T_H1 cells in a mouse immunization model. In dendritic cells the modified structures of both hybrids directly affected antigen-uptake and processing. The prophylactic potential of both proteins was tested in a mouse model of oral tolerance, indicating that the pollen hybrids could protect mice from *Fagales* pollen induced lung inflammation.
Conclusions: Compared to wild-type allergens the pollen hybrid molecules interacted differently with dendritic cells, leading to a deviated T cell response *in vivo*. In combination with the low IgE binding properties our immunological data emphasizes the potential of PH and PH4, respectively, as novel tools for the treatment of *Fagales* multi-sensitization.

P0756

Absence of Foxp3+ regulatory T cells during allergen provocation does not exacerbate murine allergic airway inflammation

A. M. Baru, V. Ganesh, C. Hesse, C. Untucht & T. Sparwasser
Twincore, Institute of Infection Immunology, Hannover, Germany

Purpose/Objective: Tregs have been implicated in modulating allergic immune responses. However, their influence on distinct phases of development of allergies remains unclear. In this study we aimed to comprehend the specific involvement of $Foxp3^+$ Tregs in airway inflammation during allergen provocation. This reflects a clinically relevant situation, assuming prior allergen sensitization to have already occurred, and thus addresses a potential Treg mediated therapeutic role.
Materials and methods: Standard OVA-Alum model was used for induction of allergic airway inflammation in Foxp3-eGFP-DTR transgenic (DEREG) mice. A group of sensitized mice received diphtheria toxin treatment to deplete Tregs prior to allergen challenge. Serum immunoglobulin levels were determined by ELISA to confirm comparable sensitization across groups. Inflammation was scored by differential cellular infiltration in broncheo-alveolar lavage (BAL) and cytokines secretion by *in-vitro* re-stimulated mediastinal lymph node cells. Lung pathology was assessed by histology and qPCR.
Results: Comparable antigen-specific serum immunoglobulin levels implicate equivalent sensitization across all groups of mice. No significant alteration was observed in numbers or types of cells infiltrating BAL of Treg depleted mice. Th2 cytokines secreted by re-stimulated mediastinal lymph node cells were comparable. Double blinded histological analysis of lung sections revealed no enhanced pathology in lungs of Treg depleted mice. To rule out strain specific differences we followed similar regimen in DEREG mice on a comparatively allergy resistant genetic background (C57BL/6). Consequently, Treg depletion during allergen challenge did not enhance lung inflammation even in C57BL/6 mice.
Conclusions: Absence of $Foxp3^+$ Tregs during allergen challenge does not exacerbate allergic airway inflammation in mice. Differential disposition to allergies due to genetic backgrounds does not alter the inflammatory response observed in this regimen. We propose less pronounced role of $Foxp3^+$ Tregs under physiological conditions in inhibiting allergic responses during the allergen provocation phase as compared to their influence during the sensitization phase. These results signify the temporal regulation exerted by $Foxp3^+$ Tregs and may influence their application as potential therapeutics.

Acrolein blocks antibody-formation upon nasal sensitization with KLH in BALB/c mice

F. Roth-Walter,* A. Willensdorfer,* C. Stremnitzer,† C. Schultz,† S. Diesner,† R. Zadnikar,* J. Fazekas,† E. Untersmayr,† I. Pali-Schöll* & E. Jensen-Jarolim*
**Messerli Research Institute Comparative Medicine, University of Veterinary Medicine Vienna Medical University Vienna and University Vienna, Vienna, Austria, †Division 1-Comparative Immunology and Oncology, Department of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria*

Purpose/Objective: Smokers have an increased risk for respiratory diseases. Hence, we sought to investigate the contribution of acrolein during nasal sensitization, since acrolein is generated in large amounts in cigarettes.
Materials and methods: BALB/c mice were nasally sensitized 6 times in biweekly intervals with KLH alone or with KLH in conjunction with acrolein. Immune response was analyzed on the level of specific antibodies in ELISA and by cytokine determination from splenocytes after antigen-specific -stimulation.

Results: In the absence of adjuvant, nasal application of KLH alone was sufficient to induce KLH-specific antibody-titers of IgG1, IgG2a, IgG2b, IgA and IgE, whereas nasal sensitization with KLH in the presence of acrolein completely abrogated antibody-formation. In contrast, KLH-stimulated splenocytes of mice sensitized with KLH in conjunction with acrolein secreted higher levels of IFN-g than mice sensitized with KLH alone.
Conclusions: Nasal application of acrolein impairs the induction of a proper humoral immune response by preventing antigen-specific antibody formation, but it supports innate release of IFN-γ. Hence, acrolein in smoke significantly modulates the innate and adaptive immune responses in smokers, thereby likely affecting susceptibility to infections in smokers.

P0759

Allergen-specific immunotherapy induces regulatory sialylated IgGs

M. Ehlers,* C. M. Oefner,† A. Winkler,† C. Hess,† D. Petzold* & M. Berger‡
**Institute for Systemic Inflammation Research, University of Luebeck, Luebeck, Germany, †Laboratory of Tolerance and Autoimmunity, German Rheumatism Research Center, Berlin, Germany, ‡Charité, Central Institute for Laboratory Medicine and Pathobiochemistry, Berlin, Germany*

Purpose/Objective: Allergen-specific immunotherapy (SIT; hyposensitization) is associated with the development of regulatory T cells and allergen-specific IgG serum antibodies. However, the function of SIT-induced IgG is still unclear. Recently, it has been shown that the Fc glycosylation pattern determines the pro- or anti-inflammatory effector function of IgG antibodies, whereby sialylated IgGs are anti-inflammatory. However, the IgG Fc glycosylation pattern induced by SIT is unknown. We sought to examine the Fc glycosylation and anti-inflammatory quality of IgG molecules formed upon allergen-specific tolerance induction.
Materials and methods: We administered chicken ovalbumin (OVA) under inflammatory or tolerance conditions to mice and analyzed OVA-reactive IgG Fc glycosylation. The anti-inflammatory function of differentially glycosylated anti-OVA IgGs was further investigated by studies with dendritic cell (DC) cultures and in an *in vivo* model of allergic airway disease. Additionally, we analyzed the Fc glycosylation pattern of birch pollen-reactive serum IgGs following successful SIT in patients.
Results: Stimulation with protein antigens/allergens under inflammatory conditions induced de-sialylated IgGs. In contrast, tolerance induced immunosuppressive sialylated IgGs that were sufficient to block antigen-specific T and B cell responses, DC maturation and allergic airway inflammation. Importantly, successful SIT in allergic patients also induced sialylated allergen-specific IgGs.
Conclusions: Our data show a novel antigen-specific immunoregulatory mechanism mediated by anti-inflammatory sialylated IgGs that are formed upon tolerance induction. These findings may help to understand und to develop novel allergen-specific therapies for the treatment of allergy.

P0760

Allergen-specific mucosal IgA induced following sublingual immunotherapy protect against allergic inflammation in a murine model of allergic inflammation

C. Rask, J. Brimnes, S. Urioste, K. Lund & V. Renard-Wagtmann
ALK-Abelló, Pharmacology, Hoersholm, Denmark

Purpose/Objective: Sublingual immunotherapy (SLIT) with allergen extract has been shown to be efficacious in treating allergy. A hallmark of allergen-specific immunotherapy is the induction of non-IgE allergen-specific antibodies primarily of the IgG1 and IgG4 isotypes which may, in addition to being robust markers of immunotherapy, be at least partly responsible for the clinical effect of the treatment through their capacity to compete with effector-cell bound IgE antibodies for allergen binding. It has also been hypothesized that allergen-specific IgA antibodies induced after successful SLIT could act in a similar manner and prevent allergen absorbance, and thereby subsequent allergic reactions. The objective of this study was to use a knock-out mouse strain lacking active transport mechanisms of IgA to mucosal surfaces for exploring the role of SLIT-induced mucosal IgA in protection against allergic inflammation.
Materials and methods: Wild type (WT) and poly immunoglobulin receptor knock-out (pIgRKO) mice were sensitized to *Phleum pratense* (Phl p) by intraperitoneal injections of alum-adsorbed allergen extract. Sensitized mice were administered Phl p extract or buffer sublingually. Thereafter, mice were challenged intra-nasally with Phl p pollen in order to mimic a grass pollen season. Numbers of sneezes, allergen-specific antibody levels and total numbers of eosinophils in nasal lavage (NAL) and bronco-alveolar lavage (BAL) were used as read-outs for the efficacy of SLIT. Moreover, the induction of allergen-specific IgA on mucosal surfaces and in serum was determined following 9 weeks of sublingual administration.
Results: SLIT with Phl p extract in WT mice significantly suppresses allergen-induced inflammation measured as attraction of eosinophils to BAL and induction of allergen-specific IgE antibody response in BAL and serum. This protection following Phl p SLIT towards allergen-induced inflammation could not be observed in the pIgRKO mice lacking active transport of IgA to mucosal surfaces. In addition, we could find higher allergen-specific IgA response in saliva, serum and BAL from WT mice as compared to pIgRKO mice.
Conclusions: Allergen-specific mucosal IgA antibodies are induced after SLIT in WT mice and seem to play a protective role against allergic inflammation in a murine model of grass pollen induced allergic rhinitis.

P0761

Allergen–specific T and B cell proliferation in pollen allergic patients measured by a CFSE dilution based assay

J. Eckl-Dorna,* R. Campana,† R. Valenta† & V. Niederberger*
**Otorhinolaryngology, Medical University of Vienna, Vienna, Austria, †Division of Immunopathology, Center of Physiology and Pathophysiology, Medical University of Vienna, Vienna, Austria*

Purpose/Objective: In past years alternative methods to radioactive measurements for cellular proliferation, such as assessment of dilution of the dye 5, 6-carboxy-fluorescein diacetate succinimidyl ester (CFSE) in the flow cytometer, have been established. The latter method has one major advantage: It allows not only for measurement of proliferation in total peripheral blood mononuclear cells (PBMCs) but also in subpopulations e.g. T cells or B cells by multicolour flow cytometry. In the present study we sought to establish a CFSE dilution based assay to determine which cell types contribute to a proliferative response to allergen *in vitro*.
Materials and methods: To that aim we isolated PBMCs from birch and grass pollen allergic patients and labelled them with CFSE. Cells were cultured in the presence or absence of highly purified recombinant allergens (rBet v 1, rPhl p 5) for 1 week whereupon proliferation was measured by flow cytometry.
Results: T cell proliferation upon allergen stimulation was observed in PBMC cultures of all patients over a wide range of allergen concentrations using co-staining for CFSE and the pan T cell marker CD3. More importantly co-staining for the B cell marker CD20 revealed, that also a subfraction of B cells proliferated in response to allergen stimulation.

Conclusions: Thus we demonstrated that in PBMC cultures of allergic patients both B and T cells proliferate specifically in response to allergen stimulation *in vitro*. Since each of the tested patients mounted allergen-specific antibody responses it is possible that the proliferating B cell sub-fractions contained allergen-specific B cells. The fact that in PBMC cultures of allergic patients not only T cells proliferate in response to allergen should be borne in mind when interpreting classical proliferation assays such as ^{3}H thymidine incorporation.

Purpose/Objective: Wheat is an important source for IgE-mediated food allergy. Avoidance of wheat products is currently the only therapy for wheat food allergic patients whereas allergen-specific approaches such as immunotherapy would require a detailed knowledge and availability of the disease-causing allergens. Aim of this study was the isolation, identification and characterization of new allergens recognized by wheat food allergic patients for diagnosis and treatment of wheat food allergy.
Materials and methods: We screened a wheat cDNA library with serum IgE antibodies from patients suffering from wheat food allergy. The cDNA coding for novel wheat food allergen, alpha-purothionin, could be isolated and identified by sequence analysis. Recombinant alpha-purothionin was expressed, purified and characterized regarding molecular properties. The IgE-reactivity was tested in wheat food allergics, grass pollen allergic patients and non-atopic individuals. Allergen-specific rabbit antibodies were used to screen different cereal and bread extracts. To investigate the allergenic activity, we performed basophil degranulation experiments.
Results: In this study we report the isolation of an IgE-reactive cDNA clone coding for a novel wheat food allergen alpha purothionin which belongs to a family of plant defence proteins. Homologue proteins to alpha purothionin could be detected by allergen specific rabbit antibodies in many other cereal and bread extracts. Serum IgE antibodies from wheat food allergic patients reacted specifically with alpha purothionin and allergenic activity was demonstrated in basophil degranulation and skin prick test experiments.
Conclusions: Recombinant alpha purothionin may be useful for the diagnosis and possibly immunotherapy of IgE-mediated wheat food allergy.

P0764

Analysis of the lung inflammation induced by Alternaria alternata spores or extracts in C57BL/6, TLR-4 and MyD88 knockout mice

O. Denis,* M. Vincent,* G. Treutens,* S. De Prins* & K. Huygen†
**Allergology Program, Scientific Institute of Public Health (WIV-ISP), Brussels, Belgium, †Service Immunology, Scientific Institute of Public Health (WIV-ISP), Brussels, Belgium*

Purpose/Objective: The mould *Alternaria alternata* is an important cause of allergic rhinitis and asthma and exposure to airborne spores of *Alternaria* can trigger severe asthma. Our objective was to analyse the lung immune response induced in mice instilled with spores or extracts of *Alternaria* and to analyze the requirement of TLR4 and MyD88 signalling for its development.
Materials and methods: WT C57BL6, TLR4 KO or MyD88 KO mice were instilled with *Alternaria* spores or extracts. Cellular recruitment in the lungs was analysed early (3 days) or later (5 weeks) during the response. Cytokine/chemokine lung expression profiles were investigated at the same time points by RT-qPCR.
Results: After 3 days, C57BL/6 mice showed an accumulation of neutrophils in the airways, this recruitment was the strongest with the spores. This stronger inflammatory property was confirmed by a stronger activation of IL-17, CXCL-2, CCL-3 and IL-1a expression in the lungs of mice stimulated with the spores. After 5 weeks a mixed lung inflammatory response was induced by the spores. In contrast, only eosinophils were recruited after extract instillation. This correlated with an increased lung expression of IL-4, IL-13, CCL11 and CCL24. Of note, the expression of IL-33 was similar for spores and extracts at week 5 but only the extract induced an early expression of this cytokine at day 3. Very similar cell recruitments were observed in wild type C57BL/6 mice and in TLR-4 KO mice stimulated with the extracts. However mice genetically inactivated in the MyD88 adaptor had an almost complete inhibition of lung neutrophil recruitment at day 3 and eosinophils at week 5. This correlated with a decreased expression of inflammatory gene expression, an inhibition of IL-33 expression at day 3 and a decreased IL-4, IL-13, CCL11 and CCL24 expression at week 5.
Conclusions: *Alternaria* spores and extracts have inflammatory and allergic properties, be it that spores have a tendency to induce inflammatory responses while extracts induce stronger allergic responses. TLR-4 signalling is dispensable but MyD88 is compulsory for these responses. Moreover, there is a correlation between an early IL-33 expression, a low inflammatory response and the accumulation of eosinophils during the chronic phase induced by the extract.

P0766

Apoptotic effect of Tamoxifen on neutrophils bronchial cells in horses with Recurrent Airway Obstruction: a new therapeutic approach

G. Moran,* B. Perez,* N. Morales,* L. Vidal,* J. S. Galecio,† J. S. Galecio,† N. Vasquez,‡ H. Folch§ & C. Henriquez§
**Pharmacology, Universidad Austral de Chile, Valdivia, Chile, †Veterinary Clinical Science, Universidad Austral de Chile, Valdivia, Chile, ‡Pathology, Valdivia Hospital, Valdivia, Chile, §Immunology, Universidad Austral de Chile, Valdivia, Chile*

Purpose/Objective: Recurrent airway obstruction (RAO, 'heaves') is an asthma-like condition that develops in mature horses following stabling and exposure to dusty hay and straw. The hallmark of this disease is that hay/straw exposure induces clinical airway obstruction, airway neutrophilia and increased airway mucous production in RAO susceptible horses. The aim of this work was to evaluate the rate of apoptosis in bronchial neutrophils in RAO-affected horses during acute crisis and remission; to observe the effect of the treatment on the

apoptosis rate of affected horses with tamoxifen; and to evaluate the concordance of these findings with clinical signs, levels of specific immunoglobulin and type of cells found in bronchoalveolar lavage fluid (BALF).

Materials and methods: For this purpose, nine RAO susceptible horses sensitized to *Aspergillus fumigatus* (RAO herd) were selected for use in this study. The animals will be exposed to dusty/moldy hay, and once the signs of the disease appear were carefully evaluated recording clinical signs, result of endoscopic examination; and BALF evaluation (immunoglobulin and cellular content). Later, will be treated with 100 mg PO of tamoxifen every other day in a remission environment. During treatment and after the drug administration ended, periodical evolution of RAO signology. The sampling will include physical and endoscopic examination and collection of BALF and blood for analysis. Flow cytometry using commercial AnnexinV-FITC and propidium iodide was used to quantify early and late apoptotic leukocytes, respectively.

Results: The results showed a significant increase in early apoptosis in peripheral blood and bronchial granulocytic cells in RAO-affected horse's treatred with tamoxifen. In addition, we showed that RAO-affected horses treated with this drug displayed a significant decrease in neutrophils in BALF and a concomitant improvement in their clinical status; with a decrease in total levels of immunoglobulins against *A. fumigatus*.

Conclusions: Our study showed that tamoxifen, a drug used for breast cancer, has the ability to induce apoptosis in granulocytic cells from peripheral blood and BALF with a concomitant improvement in their clinical status. Finally, further *in vitro* and *in vivo* studies are needed to better understand tamoxifen treatment because as an anti-carcinogen, tamoxifen could be used to treat chronic, inflammatory pathologies including those associated with granulocytes and allergic diseases, such as asthma or equine RAO

P0767

Association of HLA-DR1 with the allergic response to the major mugwort pollen allergen: molecular background

B. Knapp,* G. Fischer,† D. Van Hemelen,‡ I. Fae,† B. Maillere,§ C. Ebner,¶ W. Schreiner,* B. Bohle‡ & B. Jahn-Schmid‡

**Department for Biomedical Computersimulation and Bioinformatics, Medical University Vienna, Vienna, Austria, †Department of Blood Group Serology, Medical University Vienna, Vienna, Austria, ‡Department of Pathophysiology and Allergy Research, Medical University Vienna, Vienna, Austria, §CEA iBiTecS, Service d'Ingénierie Moléculaire des Protéines, Gif-sur-Yvette, France, ¶Allergieambulatorium, Reumannplatz, Vienna, Austria*

Purpose/Objective: Mugwort pollen allergens represent the main cause of pollinosis in late summer. The major allergen, Art v 1, contains only one single immunodominant, solely HLA-DR-restricted T cell epitope (Art v 1_{25-36}). The frequency of HLA-DRB1-01 is highly increased in mugwort-allergic individuals and HLA-DR1 serves as restriction element for Art v 1_{25-36}. However, Art v 1_{25-36} also binds to HLA-DR4 with high affinity and DR1-restricted Art v 1_{25-36} -specific T cell receptors can be activated by HLA-DR4 molecules.

Materials and methods: To understand the predominance of HLA-DR1 in mugwort allergy in spite of the degeneracy in HLA/peptide-binding and TCR-recognition, we investigated the molecular background of Art v 1_{25-36}/MHC/TCR interactions in the context of HLA-DR1 compared to -DR4.

Results: The majority of Art v 1_{25-36} -specific T cell lines and clones from HLA-DR1 carrying, mugwort pollen-allergic donors reacted to synthetic and naturally processed Art v 1 – peptides when presented by HLA-DR1 or HLA-DR4 expressing antigen presenting cells. However, at limiting peptide concentrations DR1 was more effective in T cell stimulation. In addition, the minimal epitope for 50% of Art v 1_{25-36} – specific T cells was shorter for DR1 than for DR4. *In vitro* binding assays of Art v 1_{25-36} mutant peptides to isolated DR1- and DR4-molecules indicated similar binding capacities and use of the same register. In silico simulation of Art v 1_{25-36} binding to HLA-DR1 and -DR4 suggested similar binding of the central part of the peptide to either molecule, but a higher flexibility of the N- and C-terminal amino acids and detachment at the C-terminus in HLA-DR1.

Conclusions: The predominance of HLA-DR1 in the response to Art v 1_{25-36} may be explained by the tendency of superior peptide presentation by DR1 compared to DR4 found *in vitro*. Computer simulation supported our experimental data by demonstrating differences in peptide mobility within the HLA-DR complex which may influence TCR-binding. We suggest that the minor differences observed *in vitro* may be more relevant in the microenvironment *in vivo*, so that only presentation by HLA-DR1, but not -DR4 permits successful T cell activation.

P0768

Bone marrow-derived dendritic cells inappropriately reflect allergen sensitization with house dust mite aeroallergens in the context of complement activation

Y. Laumonnier, C. Engelke, I. Schmudde, H. Ströver & J. Köhl

Insitute for systemic inflammation research, University of Luebeck, Luebeck, Germany

Purpose/Objective: Pulmonary dendritic cells play critical roles in allergen uptake and Th cell differentiation towards Th2 and Th17 effector cells. Previous studies have demon-strated a protective role for C5a and a proallergic role for C3a during allergen sensi-tization suggesting that C3a and C5a either promote or suppress DC functions during initial allergen encounter. Using bone-marrow-derived (BM) DCs as a surrogate for pulmonary APCs, we aimed at better defining the roles of C3a and C5a in DC-mediated development of maladaptive Th2 and Th17 immunity in allergic asthma.

Materials and methods: GM-CSF-differentiated bone marrow BMDC from wildtype (wt), $C3aR^{-/-}$, $C5aR^{-/-}$ and $C3aR^{-/-}$/$C5aR^{-/-}$ mice were obtained after 9 days and were pulsed *in vitro* for 24 h with crude extract from house dust mite (HDM). 1×10^6unpulsed or pulsed cells were then transferred intra-tracheally into wt recipient mice. The following parameters were used to define the allergic phenotype: airway hyperresponsiveness (AHR), inflammatory cell infiltration, *ex vivo* cytokine production from pulmonary lung cells, histologic examination of mucus production.

Results: We found that BMDCs from wt and $C3aR^{-/-}$ mice induced a strong asthmatic response, characterized by a marked increase in AHR, strong Th2 but minor Th17 and Th1 cytokine production and a mixed eosinophilic and neutrophilic infiltration of the lung. In contrast, AHR, Th2 cytokine production and eosinophilic inflammation were substantially decreased following adoptive transfer of $C5aR^{-/-}$ or $C3aR^{-/-}$ $C5aR^{-/-}$ BMDCs. However, mice treated with $C3aR^{-/-}$ $C5aR^{-/-}$ BMDCs showed strong neutrophilic infiltration and an increased IFN-g production.

Conclusions: We found that adoptive transfer of allergen-pulsed $C5aR^{-/-}$ or $C3aR^{-/-}$ BMDCs does not recapitulate the findings of an increased allergic phenotype in $C5aR^{-/-}$ mice and a decreased allergic phenotype in $C3aR^{-/-}$ mice after intratracheal HDM administration. In the BMDC adoptive transfer setting, C5aR plays a critical role in the development of asthma whereas the role of C3aR is at best minor. Our data suggest that adoptive transfer of allergen-pulsed BMDC does not appropriately reflect the sensitization process towards aeroallergens such as HDM by lung resident DCs, at least in the context of complement activation.

P0769

Caffeic acid decreases eosinophilic airway inflammation on blomia tropicalis murine model of allergy

T. Cana Brasil Carneiro,* R. Santos Costa,* N. V. Queiroz Carneiro,* S. Assis Lima,* A. T. Cerqueira Lima,* M. Santos Serafim Machado,* K. M. Campos Dourado,* L. C. Pontes de Carvalho,† N. M. Alcântara Neves* & C. Alexandrina Viana Figueirêdo*
**Imunofarmacologia, Universidade Federal da Bahia, Salvador Bahia, Brazil, †Imunologia, Fundação Osvaldo Cruz, Salvador Bahia, Brazil*

Purpose/Objective: To evaluate the anti-allergic effect of Caffeic Acid (CA) in a murine model of allergy to *Blomia tropicalis* mite.
Materials and methods: Groups of 6 AJ mice were sensitized by subcutaneous injections with 100 μg of *B. tropicalis* antigen in 4 mg/ml aluminum hydroxide on days 0 and 7. Twenty-four hours (24 h) after the last sensitization the animals received four (4) intranasal challenges (10 μg per animal) at intervals of 1 day. Allergic animals were treated orally with 10, 100 or 200 mg/kg of CA or with 3 mg/kg of Dexametazone (Dex). On day 15 the animals were euthanized and some parameters were evaluated such as number of leukocytes/eosinophils in bronchoalveolar lavage (BAL), determination of eosinophil peroxidase activity (EPO) in BAL and levels of IgE anti-Bt in the serum.
Results: Treatment of animals with CA demonstrates the ability of CA in reducing allergic parameters such as the total number of cells andnumber the eosinophils in BAL ($P < 0.01$) in relation to the untreated BT-sensibilized and challenged mice. The oral treatment with CA also displayed a significant reduction in the levels of EPO in BAL ($P < 0.001$). As expected, the administration of 3 mg/kg of Dex significantly suppressed the number of eosinophils and total inflammatory cells ($P < 0.001$) and decreased EPO activity in BAL ($P < 0.001$). Bt-immunized mice produced higher levels of specific IgE antibodies than the normal control group ($P < 0.001$). However, treatment with CA was not able to reduce IgE antibody levels, in contrast to animals treated with Dex ($P < 0.05$).
Conclusions: CA effectively reduced some immunological parameters related to cell migration responsible for airway inflammation in a murine model of allergy induced by *B. tropicalis* but did not interfere in IgE antibody production.

P0770

Can innate inflammatory factors break immunotherapy-induced T cell tolerance in patients with allergic asthma?

U. C. Kucuksezer,* I. Tahrali,* S. Adin-Cinar,* B. Gemicioglu,† A. C. Akdis,‡ M. Akdis‡ & G. Deniz§
**Immunology, Institute of Experimental Medicine, Istanbul University, Istanbul, Turkey, †Pulmonology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey, ‡Immunology, Swiss Institute of Allergy and Asthma Research, Davos, Switzerland, §Immunology, Institute of Experimental Medicine, Istanbul University, Istanbul, Turkey*

Purpose/Objective: Asthma is a disease of the respiratory system, with 3 main subgroups; the allergic group forming the biggest proportion. Allergen-specific immunotherapy cures allergic diseases, with great success. The immunologic mechanisms and contributing factors of immunotherapy is still a question to be answered. Innate inflammatory cytokines and ligands for certain Toll like receptors (TLRs) are shown to release T-cell unresponsiveness to allergens in PBMCs of healthy individuals, which may resemble convertion of healthy status to allergic.
Materials and methods: This study aims to investigate roles of these inflammatory factors in immunotherapy model which provides allergen-specific and induced unresponsiveness in allergic asthmatic patients. PBMCs isolated from 3 allergic asthma patients who received immunotherapy to known allergens were stained with CFSE in order to investigate allergen-specific $CD4^+$ T cell proliferation, cultured with the existence and absence of immunotherapy allergen as well as control allergen, and stimulated with IL-1beta, IL-6 and ligands for TLR4 and TLR8.
Results: First results of this ongoing study support the tolerance-breaking effects of IL-1beta and IL-6.
Conclusions: More number of patients should be investigated in order to reveal the possible roles of these inflammatory conditions in breaking of peripheral tolerance

P0771

CD4+ CD25+ FOXP3+ T cells are Decreased in Patients with Allergic Conjunctivitis

J. G. C. Jorge,* S. A. M. E. Sánchez-Alonso,† P. O. J. L. Palomares-Ordoñez,† H. E. Hong,* P. T. M. Pérez-Tapia‡ & J. M. M. C. Jiménez-Martínez†
**Departamento de Farmacobiología, Centro de investigación y de Estudios Avanzados del I.P.N., Mexico City, Mexico, †Unidad de Investigación Instituto de Oftalmología Fundación Conde de Valenciana, Departamento de Inmunología, Mexico City, Mexico, ‡Escuela Nacional de Ciencias Biológicas del I.P.N., Unidad de Desarrollo e Investigación en Bioprocesos, Mexico City, Mexico*

Purpose/Objective: Allergic conjunctivitis (AC) is one of the most common eye disorders in clinical practice. It has been shown that AC is a disorder mediated by Th2 lymphocytes producing IL-4 and IL-5, where the eye damage is caused by a type I hypersensitivity. On the other hand, It has been suggested in asthma and rhinitis that T regulatory cells (Tregs) $CD4^+$ $CD25^+$ $FOXP3^+$ have been involved in control allergic status, favoring an optimal microenvironment with immunosuppressive cytokines (IL-10, TGF-β). Meanwhile the immune status of the ocular microenvironment has evolutionally adapted itself to prevent the induction of excess inflammation, thereby protecting its delicate structures from the damages of inflammation. However, it is not been established whether Treg cells can modulate allergic response. Based on the above background, the present study focused to observe the role of Treg cells in human allergic conjunctivitis.
Materials and methods: Peripheral blood mononuclear cells (PBMC) were isolated from blood samples of healthy donors (HD) and AC-patients, and then PBMC were labeled with mAbs against CD4, CD25 and FOXP3. Also PBMC were co-cultured with their autologous monocytes. After 24 h, the culture medium was removed and optimal dose of antigen stimulation *Dermatophagoides pteronyssinus* (*Der p*) was added. After 7 days, all cells were labeled with mAbs against CD4, CD25 and FOXP3. The cells labeled were analyzed by flow cytometry. The supernatant culture was recovered to analyze by ELISA the cytokines IL-10 and TGF-β.
Results: AC-patients showed 55-times more $CD4^+$ $CD25^+$ cells than HD. Most of $CD4^+$ $CD25^+$ cells were $FOXP3^-$, when we compared mean fluorescence intensity (MFI) of FOXP3 in $CD4^+$ $CD25^+$ cells, we observed a decreased expression in AC-patients than HD. We note significant increase in $CD25^+$, $CD4^+$ $CD25^+$ after antigen stimulation. However, no changes were detected in frequency of $CD4^+$ $CD25^+$ $FOXP3^+$ and $FOXP3^-$ cells after stimulation with *Der p*. interestingly, we observed a decreased MFI for FOXP3 in AC-patients after culture than HC in PBMC. In supernatant of PBMC cultures from AC patients, no differences were observed in TGF-β levels after *Der p* stimulation. In contrast, we found increased IL-10 concentration after antigenic stimulation.
Conclusions: Despite we observed higher frequency of $CD4^+$ $CD25^+$ in AC-patients, these cells were $FOXP3^-$, more interesting, the few cells $FOXP3^+$ showed a diminished MFI. The increase in IL-10 but not TGF-β, may be associated with Th2 dominant environment. These

data suggest that allergic conjunctivitis status could be related with a regulatory dysfunction, as has been suggested in asthma and rhinitis.

P0773

Chimeras of Bet v 1 and its homologue Api g 1 show highly varying degrees of lysosomal stability

B. Gepp,* N. Lengger,* P. Briza,† M. Hauser,‡ U. Smole,* F. Ferreira,‡ C. Radauer* & H. Breiteneder*
**Department of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria, †Department of Molecular Biology, University of Salzburg, Vienna, Austria, ‡Christian Doppler Laboratory for Allergy Diagnosis and Therapy, University of Salzburg, Vienna, Austria*

Purpose/Objective: We have previously shown that the major birch pollen allergen Bet v 1.0101 and its homologue in celery Api g 1.0101 differed in their ability to polarise the allergen-specific immune response. In order to identify surface regions responsible for this behaviour, we produced four chimeric proteins of Bet v 1.0101 and Api g 1.0101. In each of them, roughly one fourth of the surface area of Api g 1.0101 were replaced by the corresponding residues of Bet v 1.0101. Resistance to lysosomal degradation enhances immunogenicity. Therefore, our aim was to test the lysosomal stability of these chimeric proteins.
Materials and methods: Chimeric proteins of Bet v 1.0101 and Api g 1.0101 were constructed. The surface residues forming the P-loop (Api-Bet-1), the region opposite of the P-loop (Api-Bet-2), the area surrounding the C-terminus (Api-Bet-3), or the C-terminal alpha helix (Api-Bet-4) of Bet v 1.0101 were grafted onto Api g 1.0101. The resulting proteins were expressed in *Escherichia coli* and purified by standard chromatographic methods. Secondary structures were checked by circular dichroism spectroscopy. For the lysosomal degradome assay, Bet v 1.0101, Api g 1.0101 and the chimeras were digested with mircosomal/endo-/lysosomal enzymes. Reactions were stopped by heat denaturation followed by SDS-PAGE analysis and mass spectrometry.
Results: All chimeric proteins adopted secondary structures equivalent to Api g 1.0101. Results for the degradome assay showed that one of the four chimeric proteins (Api-Bet-2) had a remarkably higher lysosomal stability compared to Bet v 1.0101 and Api g 1.0101. A 50% degradation of Bet v 1.0101 and Api g 1.0101 was observed after 12 h while 80% of Api-Bet-2 remained stable even after 96 h. In contrast, almost total degradation was observed for Api-Bet-1, -3 and -4 after 12 h.
Conclusions: Altering the protein structure when constructing allergen chimeras can result in unexpected increase or decrease of the overall protein stability. In our study, which was supported by grants P22559-B11 (CR) and SFB-F4608 (HB) from the Austrian Science Fund, we produced a chimeric protein whose stability was remarkably greater than the starting molecules Bet v 1.0101 and Api g 1.0101. This change may result in a shift of the immune response polarisation as compared to the wildtype allergens.

P0775

CMRF-35-like molecule 1 (CLM-1) regulates IL-4-dependent responses and is required for allergic eosinophilic airway inflammation

I. Moshkovitz,* D. Karo-Atar,* M. Itan,* A. Hershko† & A. Munitz*
**Clinical Microbiology and Immunology, Tel-Aviv University, Tel-Aviv, Israel, †Department of Medicine, Meir Medical Center, Laboratory of Allergy and Clinical Immunology, The Herbert Center of Mast Cell Disorders, Kfar Saba, Israel*

Purpose/Objective: Asthma is a chronic disease of the airways, which is currently on the rise. IL-4 is a hallmark and central cytokine orchestrating multiple Th2 immune responses/diseases including asthma. Thus, defining pathways regulating IL-4-induced responses may have significant therapeutic potential. CMRF-like-molecule-1 (CLM-1) is an immunoreceptor tyrosine-based inhibitory motif-containing receptor, which is predominantly expressed by myeloid cells. Notably, the *in vivo* role of CLM-1 is unknown and whether it regulates IL-4-induced responses is unclear.
Materials and methods: Wild type (WT) and *Clm1*$^{-/-}$ mice were challenged with *Aspergillus fumigatus* (Asp) extract or IL-4. CLM-1 expression was assessed in the lungs (flow cytometry). Broncho alveolar lavage fluid (BALF) and lung draining lymph nodes were assessed for total and differential cell counts. Th2 cytokine/chemokine content and IgE levels were assessed in BALF and serum, respectively. WT and *Clm1*$^{-/-}$ bone marrow (BM) derived macrophages (MΦ) and eosinophils (Eos) were stimulated with IL-4 and assessed for CCL17 and Relm-α secretion.
Results: CLM-1 was differentially expressed by various lung myeloid cells. Following Asp-challenge, CLM-1 was specifically upregulated by eosinophils and alveolar macrophages. Asp-challenged *Clm1*$^{-/-}$ mice displayed decreased BAL cellular infiltration as well as decreased chemokine and IgE production. Surprisingly, Asp-challenged *Clm1*$^{-/-}$ mice displayed elevated levels of IL-4 suggestive of inappropriate IL-4 consumption by IL-4-responsive cells. Consistently, IL-4-challenged *Clm1*$^{-/-}$ mice displayed decreased BAL cellular infiltration as well as decreased chemokine levels. Indeed, IL-4-stimulated *Clm1*$^{-/-}$ BM-MΦ and BM-Eos displayed significantly decreased Relm-a and CCL17 production in comparison with IL-4-activated WT cells. IL-4R levels were indifferent between WT and *Clm1*$^{-/-}$- cells. Finally, human CLM-1 was upregulated in peripheral blood eosinophils and monocytes obtained from allergic rhinitis patients.
Conclusions: These results demonstrate a key role for CLM-1 in the regulation of allergic airway inflammation likely by regulating IL-4 mediated effects. To the best of our knowledge, this is the first line of evidence suggesting a role for CLM-1 as an activation molecule *in vivo*.

P0776

Contribution of sensitization phase to intensity of contact hypersensitivity reaction in rats

A. Popov,* I. Mirkov,* D. Miljkovic,† S. Belij,* J. Dokic,* L. Zolotarevski,‡ D. Kataranovski* & M. Kataranovski*
**Department of Ecology, Institute for Biological Research 'Sinisa Stankovic', Beograd, Serbia, †Department of Immunology, Institute for Biological Research 'Sinisa Stankovic', Beograd, Serbia, ‡Military Medical Academy, Institute for Pathology, Beograd, Serbia*

Purpose/Objective: Allergic contact dermatitis is a common skin inflammatory disease in humans, which pathophysiology is studied mostly on animal model referred to as contact hypersensitivity (CHS). For development of this reaction priming of hapten-specific T cells is necessary (sensitization phase), with subsequent activation of hapten-specific effector T cells, mediators of skin inflammation during elicitation phase. Relationship between sensitizing dose and the intensity of CHS expression was shown in humans, however mechanisms underlying such dose-response are virtually unexplored. In this study, the impact of sensitization phase on the intensity of CHS expression was investigated in a rat model of CHS to dinitrochlorobenzene (DNCB) using low (0.4%) and high (4%) sensitization doses at a constant challenge dose (0.13% or 1.3% DNCB) for each of the sensitizing doses.
Materials and methods: Ear thickness, cell infiltration and IFN-γ content in the medium conditioned by organ-cultured ear skin explants were analyzed during elicitation phase. Basic indices of draining lymph node (DLN) activity (cellularity, proliferation), CD4+/CD8+ composition, the production of interferon-γ (IFN-γ) and

interleukin-17 (IL-17), main effector cytokines in CHS, were analyzed during sensitization and elicitation phases.
Results: Sensitization with high DNCB dose resulted in significantly more intensive inflammatory ear skin response (each of the parameters measured) to challenge with either 0.13% or 1.3% DNCB dose, compared to the response of animals sensitized with low DNCB dose and challenge with respective dose. Higher DLN cellularity, proliferation, CD4+ and CD8+ cell number, and *in vitro* hapten stimulation of IFN-γ and IL-17 production following sensitization with 4% versus 0.4% might have contributed to more pronounced CHS expression in these animals. DLN (auricular) of animals sensitized with 4% and elicited with 0.13% or 1.3% expressed higher proliferation as well as inflammatory cytokine production compared to 0.4%/0.13% or 0.4%/1.3% sensitization/elicitation regime, respectively.
Conclusions: Presented data demonstrated contribution of the strength of sensitization to the intensity of CHS response suggesting that it depends greatly on generation of effector (IFN-γ and IL-17) producing cells.

P0777
Cross-reactivity profiling allows classification of allergenic pectate lyases into two distinct families

M. Wolf,* M. Hauser,* M. Wallner,* M. Himly,* C. Ebner,† P. Briza,‡ A. Mari,§ H. Behrendt¶ & F. Ferreira*
**Department of Molecular Biology Christian Doppler Laboratory for Allergy Diagnosis and Therapy, University of Salzburg, Salzburg, Austria, †Allergieambulatorium am Reumannplatz, Vienna, Austria, ‡Molecular Biology, University of Salzburg, Salzburg, Austria, §IDI-IRCCS, Center for Molecular Allergology, Rome, Italy, ¶Technische Universität and Helmholtz Center, ZAUM Center for Allergy and Environment, Munich, Germany*

Purpose/Objective: The botanically unrelated families of Asteraceae and Cupressaceae are widely distributed over the Northern hemisphere. Especially in the USA, Europe, and East Asia their pollen represents one of the clinically most relevant allergenic sources. However, the major disease eliciting allergens all belong to the same protein family of pectate lyases. To date, recombinant allergenic pectate lyases showing native folds are not available, thus most studies elucidating pectate lyase allergies were performed with allergen extracts.
Materials and methods: In the present study, the five most important natural allergenic pectate lyases from Asteraceae as well as Cupressaceae pollen were characterized. Therefore, the allergens were purified to homogeneity from crude pollen extracts by standard chromatography techniques. Direct and inhibition ELISA were performed to determine patients' serum IgE binding to the different allergens including sera from four distinct geographical areas (Northern America, the Mediterranean Area, Central Europe, and Asia, respectively). Furthermore, cross-reactivity of purified allergens was assessed in a mouse model.
Results: Purified proteins were characterized physicochemically in terms of identity, structural integrity, and proteolytic stability. The optimized methods allowed purification of structurally intact pectate lyases without detectable auto-proteolysis, degradation, or truncation products. In ELISA experiments, the different cohorts included in the study reacted strongly with the sensitizing pectate lyase, endemic in the particular geographic area. For both, human as well as murine sera, a high degree of cross-reactivity was observed within the pectate lyase families of Asteraceae and Cupressaceae, respectively, whereas between the two families the level of cross-reactivity was limited.
Conclusions: These results allow the classification of allergenic pectate lyases according to their botanical origin in two distinct families, which will provide the basis for the selection of suitable candidate molecules for molecule based allergy diagnosis and therapy.

P0778
Curation of the IUIS allergen database based on sequence similarity and protein family classification

C. Radauer,* A. Pomés,† A. Nandy,‡ F. Ferreira,§ P. Rozynek,¶ M. Raulf-Heimsoth,¶ R. E. Goodman & H. Breiteneder***
**Department of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria, †Indoor Biotechnologies Inc., Research and Development, Charlottesville, VA, USA, ‡Allergopharma Joachim Ganzer KG, Research and Development, Reinbeck, Germany, §Christian Doppler Laboratory for Allergy Diagnosis and Therapy, University of Salzburg, Salzburg, Austria, ¶Ruhr-University Bochum, Institute of Prevention and Occupational Medicine of the German Social Accident Insurance, Bochum, Germany, **Lincoln, Food Allergy Research & Resource Program, University of Nebraska, Lincoln, NE, USA*

Purpose/Objective: The IUIS Allergen Database (www.allergen.org) is the official site of the unambiguous and systematic nomenclature of allergens. Allergen names consist of an abbreviation of the scientific name of their source, an allergen and an isoallergen number. We aimed to correct existing database entries based on new sequence information.
Materials and methods: The database was manually searched for entries with missing sequence data, biochemical names similar to those of other allergens from the same source, or inconsistent allergen numbers. Allergen sequences were analysed by pairwise and multiple sequence alignments and phylogenetic trees derived from these alignments.
Results: Four types of incorrect allergen designations were identified. (1) Highly similar allergens from the same source with different numbers. This applies to Amb a 1 and Amb a 2 from ragweed (60−70% sequence identity between Amb a 1 and Amb a 2 isoallergens), to Ara h 3 and Ara h 4 from peanut (91% sequence identity) and to the nine *Chironomus thummi thummi* allergens ($\chi^2 = 1-9$) from the globin family, some with sequences identities >50%. (2) Different numbers for homologous allergens from different species from the same taxonomical family. Sec c 1 from rye and Tri a 28 from wheat are dimeric α-amylase inhibitors. Hor v 21 (γ-hordein) from barley has 76% sequence identity to γ-secalin from *Secale strictum*, a homologue of Sec c 20 from rye. (3) Duplicate entries. Hor v 1 and Hor v 15 from barley refer to the same monomeric α-amylase inhibitor BMAI-1. Equ c 4 and Equ c 5, horse dander latherins, were originally identified based on peptide sequences belonging to the same complete sequence. (4) Single entries referring to a group of different proteins. Caseins from cow's milk are collectively termed Bos d 8. However, caseins comprise four different proteins (αS1, αS2, β, and κ) with sequence identities between α and β-caseins below 20% and no homology to κ-caseins.
Conclusions: Based on these Results: , the IUIS Allergen Nomenclature Sub-Committee renamed Amb a 2.01 to Amb a 1.05, Ara h 4.01 to Ara h 3.02, $\chi^2 = 4-8$ to isoallergens of $\chi^2 = 3$, Sec c 1 to Sec c 28, and Hor v 21 to Hor v 20. The entries Hor v 1 and Equ c 5 were deleted. Bos d 8 was split into four entries: Bos d 8.0101 (αS1-casein), Bos d 9.0101 (αS2-casein), Bos d 10.0101 (β-casein), and Bos d 11.0101 (κ-casein).

This study was supported by grant P-22559-B11 from the Austrian Science Fund.

Decreased NK regulatory cells in children with atopic dermatitis

E. Aktas Cetin,* N. Akdeniz,* S. Baris,† M. Kosker,‡ F. Cosan,§ I. Barlan,† Y. Camcioglu¶ & G. Deniz*

Department of Immunology, the Institute of Experimental Medicine (DETAE), Istanbul University, Istanbul, Turkey, †Division of Pediatric Allergy and Immunology, Marmara University, Istanbul, Turkey, ‡Department of Pediatric Infections Disease, Faculty of Medicine, Istanbul University Cerrahpasa, Istanbul, Turkey, §Division of Rheumatology Department of Internal Medicine, Faculty of Medicine, Kocaeli University, Kocaeli, Turkey, ¶Department of Pediatric Infections Disease, Faculty of Medicine, Istanbul University Cerrahpasa, Istanbul, Turkey

Purpose/Objective: Atopic dermatitis (AD) is a chronic relapsing inflammatory skin disease characterized by distributed eczematous skin lesions. Numerous studies demonstrated increased frequency of allergen-specific Th2 cells producing increased interleukin (IL)-4, IL-5 and IL-13 in the peripheral blood of AD patients. However little is known about the role of natural killer (NK) cells. NK cells are one component of the innate immune system and have the ability to both lyse target cells and it has been showed that human NK cells are able to polarized functionally different subsets. Recent studies showed that NK cells also display potent regulatory function. In this study, NK1 and NK regulatory cytokine profiles, the expression of activatory receptors as well as the cytotoxic activity of NK cells in AD were investigated.
Materials and methods: The study group consists of children with AD ($n = 8$, mean age = 9.2 ± 3) and healthy subjects ($n = 6$, mean age = 8.6 ± 4). The patients were multisensitized to at least three aeroallergens and had high serum total IgE levels. Peripheral blood mononuclear cells (PBMC) were used as effector cells and K562 cell line was used as target cell with an effector: target (10:1) ratio. Cytotoxic activity (by using CFSE-labeled K562 as target cells), expression of $CD16^{bright}CD56^{dim}$ and $CD16^{dim}CD56^{bright}$ NK cell subsets, NK cell activatory receptors and intracellular IL-10 & IFN-γ levels were also determined by flow cytometry. Statistical analyses were performed by Mann−Whitney *U*-test.
Results: In AD patients $CD16^{bright}CD56^{dim}$, $CD16^{dim}CD56^{bright}$ NK cell subsets, percentages of $CD3^{-}$ $CD16^{+}$ $CD56^{+}$ cells and NK cell cytotoxic capacity were significantly decreasedcompared tohealthy subjects ($P = 0.002$, $P = 0.037$ and $P = 0.007$, respectively). In addition, C type lectin activatory receptor NKG2D/CD94 was found diminished in AD patients in comparison to healthy subjects ($P = 0.05$ and $P = 0.012$, respectively). IL-10 secreting regulatory NK cell ratio dramatically decreased in AD patients, whereas IFN-γsecreting of NK1 cells was found to be similar in both groups.
Conclusions: Our results suggested that decreased expression of $CD16^{bright}CD56^{dim}$, $CD16^{dim}CD56^{bright}$ subsets, activatory receptor NKG2D/CD94, cytotoxic activity and IL-10 secretion of NK cells might play a role in the pathogenesis of atopic dermatitis.

Design of a hypoallergenic Alt a 1 trimer for specific immunotherapy

S. Gutfreund,* T. Twaroch,* S. Spitzauer† & R. Valenta*

Department of Pathophysiology and Allergy Research, Christian Doppler Laboratory for Allergy Research, Center for Pathophysiology Infektiologie and Immunology, Vienna, Austria, †Department of Laboratory Medicine, Institute of Medical and Chemical Laboratory Diagnostics, Vienna, Austria

Purpose/Objective: *Alternaria alternata* is one of the major elicitors of fungal allergy and plays a major role in the development of severe respiratory forms of allergy. Alt a 1, a protein of approximately 13 kDa has been identified as the major allergen in *Alternaria*. Alt a 1 binds the majority of *Alternaria*-specific IgE and exhibits high allergenic activity in sensitized patients. The objective of this study was the design, construction and characterization of a hypoallergenic Alt a 1 for specific immunotherapy.
Materials and methods: In order to reduce IgE reactivity and allergenic activity of Alt a 1 the cystein residues stabilizing the proteins fold were mutated to serines. To increase the molecules immunogenicity and ability to induce allergen-specific protective IgG antibodies upon immunization, a recombinant trimeric form of the mutant was expressed in *Escherichia coli*.
Results: The monomeric Alt a 1 serine mutant had completely lost IgE reactivity and a recombinant Alt a 1 trimeric form was expressed in *E. coli* and purified..
Conclusions: The recombinant hypoallergens may be used for specific immunotherapy of allergy to *Alternaria*.

P0781

Design of hypoallergenic derivatives of the major cat allergen Fel d 1 by rational reassembly as a mosaic protein

M. Curin,* I. Swoboda,* M. Focke,* K. Blatt,† P. Valent,† H. Grönlund,‡ S. Spitzauer§ & R. Valenta*

Department of Pathophysiology and Allergy, Christian Doppler Laboratory for Allergy Research, Research Medical University of Vienna, Vienna, Austria, †Division of Hematology and Hemostaseology, Department of Internal Medicine I, Medical University of Vienna, Vienna, Austria, ‡Department of Medicine, Clinical Immunology and Allergy Unit, Karolinska Institute and University Hospital, Stockholm, Sweden, §Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria

Purpose/Objective: Due to the perennial exposure to cats and due to the high association with severe asthma manifestations the major cat allergen Fel d 1 is regarded as one of the most important respiratory allergens. The objective of this study was the rational design of recombinant Fel d 1 derivatives with reduced IgE reactivity and preserved T cell epitopes that are suitable for vaccination and tolerance induction.
Materials and methods: Seven recombinant mosaic proteins were generated by reassembly of non-IgE-reactive peptides of Fel d 1 which contained the sequence elements for induction of allergen specific blocking IgG antibodies and those containing important T cell epitopes. Recombinant mosaic proteins were expressed in *E. coli* using codon-optimized synthetic genes. They were compared with recombinant Fel d 1 regarding their structural fold by circular dichroism, IgE-binding capacity, ability to activate allergic patients' basophils and ability to induce allergen-specific blocking IgG antibodies upon immunization.
Results: Although each of the mosaic proteins had lost the alpha helical fold typical for Fel d 1, a strong reduction in IgE reactivity as well as allergenic activity in basophil activation assays was only obtained for three constructs, two reassembled fragments (Fel d 1 MB, Fel d 1 MC) and a fusion of the latter two in which the cysteines of Fel d 1 MC were replaced by serines. Immunisation of rabbits with the hypoallergens induced high levels of IgG antibodies that inhibited IgE reactivity of cat allergic patients to Fel d 1 in a comparable manner as IgG antibodies induced with the wildtype allergen.
Conclusions: In conclusion, we report the development of hypoallergenic reassembled Fel d 1 proteins suitable for vaccination and tolerance induction in cat allergic patients.

P0782

Development and characterization of recombinant olive pollen allergens, rOle e 5, 6 and 8 for diagnosis and therapy of olive pollen allergy

T. Garmatiuk,* T. Twaroch,* S. Quirce,† M. Curin,* H. Hochwallner,* S. Spitzauer‡ & R. Valenta*
*Department for Pathophysiology and Allergy research, Christian Doppler Laboratory for Allergy research, Center for Pathophysiology Infektiologie and Immunology, Vienna, Austria, †Department for Allergy, Hospital La Paz Health Research Institute, Madrid, Spain, ‡Department of Laboratory Medicine, Clinical Institute for Laboratory Medicine, Medical University of Vienna, Vienna, Austria

Purpose/Objective: Olive pollen is one of the most important causes of allergy in Mediterranean countries and certain parts of America. Ole e 1 an approximately 20 kDa protein is the major allergen in olive pollen which is recognized by more than 90% of olive pollen allergic patients. The aim of our work was to investigate the prevalence of IgE recognition of three olive pollen, Ole e 5 a superoxide dismutase, Ole e 6, a 10 kDa protein with yet unknown biological function and Ole e 8, a calcium-binding protein.
Materials and methods: Thirty sera from clinically well characterized patients with olive pollen allergy from Spain were tested for IgE reactivity to olive pollen extract and purified Ole e 1 by immunoCAP measurements. Recombinant olive pollen allergens, rOle e 5, rOle e 6 and rOle e 8 were expressed as C-terminally hexahistidine-tagged proteins in *Escherichia coli* and purified using Ni-NTA agarose. The structure of rOle e 5, rOle e 6 and rOle e 8 were studied by UV-circular dichroism. IgE reactivity with sera from olive pollen allergic patients was tested by ELISA.
Results: Circular dichroism showed that the recombinant allergens were folded proteins with a predominant beta sheet structure in the case of rOle e 5 and rOle e 8 and alpha helical structure in the case of Ole e 6. Despite symptoms of olive pollen allergy, only twenty six of the patients were positive when tested for IgE reactivity with total olive pollen extract. Twenty three showed IgE reactivity to the major olive pollen allergen Olee 1 (78%), 57% of exhibited IgE reactivity with rOle e 5.20% and 27% of patients reacted with Ole e 6 and Ole e 8 respectively. Interestingly, all four patients negative for olive pollen extract could be detected with a combination ofrOle e 5, rOle e 6 and rOle e 8.
Conclusions: We have produced three recombinant olive pollen allergens rOle e 5, rOle e 6 and rOle e 8 which are useful for component-based testing of olive pollen allergy and eventually for allergen-specific immunotherapy of olive pollen allergy.

P0783

Development of A Rhinovirus-Induced House Dust Mite Asthma Exacerbation Mouse Model

L. Tao,* F. Goh,* D. NG,* X. Zhang,* V. Chow,† N. Bartlett,‡ S. Johnston‡ & F. Wong*
*Pharmacology, National University of Singapore, Singapore, Singapore, †Microbiology, National University of Singapore, Singapore, Singapore, ‡Respiratory Medicine & Allergy, Imperial College London, London, UK

Purpose/Objective: Rhinovirus (RV) causes the majority of virus-induced asthma exacerbations. The purpose of the present study was to establish an asthma exacerbation mouse model by combing a mouse model of allergic asthma using a clinically relevant allergen house dust mite (HDM) with intra-tracheal inoculation of RV.
Materials and methods: Mice were sensitized and challenged with HDM or saline, and infected with RV-1B, a minor group RV which binds to mouse airway epithelial cells or UV-inactivated RV. Bronchoalveolar lavage fluid and lung homogenates were examined for inflammatory cells infiltration, and Th2 cytokine protein and mRNA expressions. Airway hyperresponsiveness was measured using direct airway resistance analysis.
Results: Compared to HDM/UV-inactivated RV-treated mice, HDM/RV-treated mice developed significant increases in airway infiltration of neutrophils, eosinophils and lymphocytes. The HDM/RV-treated group also produced higher protein levels of IL-4, IL-5, IL-13. Besides, the HDM/RV-treated group generated higher mRNA levels of eotaxin-1 and MUC5AC. However, although we found significant difference in airway hyperresponsiveness to methacholine challenge between saline/RV-treated group and saline/UV-inactivated RV-treated group, the difference between HDM/UV-inactivated RV-treated group and HDM/RV-treated group did not reach significant level.
Conclusions: Taken together, we have developed a model of RV-1B-induced exacerbation of the Th2 responses in HDM-mediated allergic asthma. Additional works are required to illustrate enhanced airway hyperresponsivness in HDM/RV-treated mice. This new asthma exacerbation model will be useful to study asthma immunology and for novel drug discovery and development.

Different TLR agonists exert diverse effects on immune cells from allergic individuals

S. Deifl,* C. Kitzmüller,* P. Zlabinger,† P. Steinberger† & B. Bohle*
*Department of Pathophysiology and Allergy Research, Christian Doppler Laboratory for Immunomodulation, Center for Pathophysiology Infectiology and Immunology, Vienna, Austria, †Center for Pathophysiology Infectiology and Immunology, Institute of Immunology, Vienna, Austria

Purpose/Objective: Toll-like receptor (TLR) ligands have been considered as promising adjuvants in vaccines for allergen-specific immunotherapy. We compared different TLR-ligands, namely Pam3CSK4 and FSL-1, targeting TLR2, lipopolysaccharide (LPS) and monophosphoryl lipid (MPL) A, targeting TLR 4 and flagellin, targeting TLR5, regarding their immunostimulatory effects on cells from allergic donors.
Materials and methods: Peripheral blood mononuclear cells (PBMC) were stimulated with TLR-ligands in the presence or absence of autologous plasma and the levels of pro- and anti-inflammatory cytokines were assessed in supernatants. Monocyte-derived dendritic cells (mdDC) were tested for upregulation of CD40, CD80, CD83, CD86, CD58, CCR7 and PD-L1 in response to TLR ligands. Their functional activity was tested in mixed leukocyte reactions (MLR). Moreover, their expression of different members of the IL-12 family was assessed by real-time PCR. $CD4^+$ $CD45RA^+$ T cells were incubated with autologous TLR-activated mdDC to study their polarizing potential to induce Th1- or Th2-like responses. Finally, the influence of TLR ligands on allergen-uptake by monocytes was analysed using fluorescently-labelled Bet v 1, the major birch pollen allergen.
Results: All TLR ligands induced TNF-α and IL-10 synthesis in PBMC from allergic patients whereas only TLR4 ligands induced IFN-γ production. The presence of autologous plasma elevated all cytokine levels. All TLR ligands induced the functional maturation of mdDC. However, different expression patterns of surface molecules on mdDC in response to different TLR ligands were found. LPS-matured mdDC primed Th1-like cells. In contrast, MPL-A, Pam3CSK4 and FSL-1 promoted Th0-like responses, whereas flagellin-matured mdDC induced the differentiation of Th2-like cells. All TLR ligands except flagellin enhanced the uptake of allergen by APC.
Conclusions: Activation of TLR4, TLR5 and the heterodimers TLR1/2 and TLR2/6 has different effects on functional maturation and allergen-uptake of antigen-presenting cells from allergic patients, thereby resulting in different T cell-polarizing capacities. Our data indicate that not all TLR-ligands are equally well suited as adjuvants in allergy vaccines.

P0785

Directed *in vitro* evolution as a tool for the identification of conformational IgE epitopes of the major birch pollen allergen Bet v 1

E. Guhsl,* G. Hofstetter,* C. Ebner,† W. Hemmer,‡ H. Breiteneder* & C. Radauer*

*Department of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria, †Ambulatorium für Allergie und Immunologie Reumannplatz, Vienna, Austria, ‡Floridsdorfer Allergiezentrum, Vienna, Austria

Purpose/Objective: Only little is known about the IgE-binding epitopes of the major birch pollen allergen Bet v 1, which have been shown to depend on the native structure of the allergen. In order to identify conformational epitopes, we performed directed *in vitro* evolution of non-IgE-binding structural homologues to proteins carrying single Bet v 1 epitopes. To this end, we chose (S)-norcoclaurine synthase (NCS) from *Thalictrum flavum* (meadow rue), a structural homologue of Bet v 1 with only 25% sequence identity as a template subjected to a combination of random mutagenesis and phage display.
Materials and methods: NCS was expressed in *Escherichia coli* and purified by chromatographic methods. Secondary structure was verified by circular dichroism spectroscopy. IgE binding to birch pollen allergic patients' sera was tested by IgE ELISA. Random mutagenesis of NCS was performed by PCR using mutagenic nucleotide analogues. Phage display libraries in the filamentous phage M13 were created by inserting PCR products into the phagemid pTP127. Bet v 1-specific antibodies were purified from a pool of Bet v 1-sensitised patients' sera by affinity chromatography using immobilised Bet v 1. Several panning rounds were performed to select phages with binding activity to Bet v 1-specific IgE. IgE binding activities of enriched phages and of bacterial colonies representing single clones were analysed by transfer to nitrocellulose and immunostaining.
Results: Purified recombinant NCS revealed a secondary structure with high similarity to that of Bet v 1, but no IgE binding in an ELISA using individual sera from 35 Bet v 1-sensitised birch pollen allergic patients. Phage libraries with diversities of 10^5-10^6 different clones were created. Sequencing of 27 randomly picked clones from the unselected libraries showed average mutation rates of 16/161 amino acids (range 8–24). IgE immunoblotting of phages enriched by two rounds of biopanning showed an increase of the amount of bound IgE, whereas the unselected library lacked IgE binding ability. Screening of single clones after the first panning round yielded 4 of 20 clones which expressed IgE binding mutant proteins.
Conclusions: *In vitro* evolution of NCS by random modifications of surface residues is a suitable tool for defining IgE binding residues on Bet v 1.

This study was supported by grant P-22559-B11 from the Austrian Science Fund.

P0786

Dry-roasting enhances peanut immunogenicity and promotes Th2-biased responses in a murine model of peanut allergy

W. R. Hillson, A. E. Moghaddam & Q. J. Sattentau

Sir William Dunn School of Pathology, University of Oxford, Oxford, UK

Purpose/Objective: Peanut allergy is a significant public health concern in many Western developed countries, but its aetiology remains unclear. Thermal processing (including roasting) has been implicated epidemiologically and serologically in peanut allergenicity, but no direct *in vivo* evidence for this putative link has so far been identified. Oxidation has been linked to altered immunogenicity, and our group has previously demonstrated Th2 immunomodulatory activity of oxidation-derived DAMPs such as reactive carbonyl species (RCS). Here we have studied the biochemical properties of DR peanut allergens and have determined their immunogenic and allergenic profiles in a murine model of food allergy.
Materials and methods: Total peanut protein extracts and purified major allergens Ara h 1 and 2/6 were prepared from commercial or in-house dry-roasted (DR) peanuts. To compare the allergenicity of DR with raw peanut allergens, BALB/c mice were s.c. primed with non-crosslinked fractions and subsequently challenged via the intra-gastric route with total peanut extract. Balb/c mice were also directly sensitized and challenged intra-gastrically with total peanut extract.
Results: In line with previous data, DR peanut proteins showed significant increases in RCS content, a hallmark of oxidative stress, and a high level of protein aggregation. Mice immunized s.c. with DR antigens demonstrated a stronger adaptive immune response than those immunized with raw, as revealed by allergen specific Th2-biased T and B cell responses, including a greater induction of functional IgE production. Only mice systemically sensitized by DR-derived allergens responded robustly with Th2 cytokines such as IL-4 and IL-5 in their mesenteric lymph nodes upon gastric challenge. The enhanced allergenic profile of DR peanuts was also confirmed in a direct GI sensitization and challenge model, resulting in enhanced Th2 and IgE responses.
Conclusions: Together these data provide the first direct link between roasting and enhanced peanut allergenicity in a murine model, lending support to epidemiological and serological findings in humans. The enhanced overall immunogenicity of DR peanut cannot be explained by crosslinking alone since this effect was observed even when such species were depleted. Given our preliminary data, the modulated immunogenic profile may be explained in part by the presence oxidation products (including RCS) in DR peanut.

P0787

Ectopic activation of the JAK/STAT pathway leads to loss of barrier function in Drosophila melanogaster airways

K. Kallsen,* K. Uliczka,* H. Heine† & T. Roeder*

*Department of Zoophysiology, Institute of Zoology, Kiel, Germany, †Division of Innate Immunity, Research Center Borstel, Borstel, Germany

Purpose/Objective: *Asthma bronchiale* is a chronic inflammatory disease of the lungs that is becoming a major health issue in industrialized countries. Asthma pathogenesis is thought to depend on the interaction of genetic and environmental factors but the underlying molecular mechanisms are not well understood. Asthma susceptibility genes like STAT6 are most likely involved in the pathogenesis. For this gene, many functions have been described in asthma related adaptive immune responses. However, the major STAT6 expressing cell type is the bronchial epithelial cell. So far, asthma research has mainly focused on the adaptive immune response. Recently, the epithelium has gained more and more attention. In asthmatics, not only is the epithelium abnormal and has a disturbed barrier function, but also STAT6 expression is enhanced. Therefore it is necessary to analyze the effects of the activation of JAK/STAT signaling on the airway epithelium.
Materials and methods: To address this question we used *Drosophila melanogaster* as a model organism. *Drosophila* has unique advantages for this purpose like the absence of an adaptive immune response and the structure of its airways which consist of epithelial cells only. Furthermore, *Drosophila* has a simplified JAK/STAT signaling system, which is composed of only one representative protein at each position of the cascade.
Results: Here we show that the JAK/STAT pathway can be activated in the airways by hypoxia, a condition important in asthma pathogenesis. Larvae with constitutive JAK/STAT activation do not survive their developmental L2 stadium. A conditional activation after the L2 stadium induces phenotypical changes in the tracheae: liquid filled

branches und melanization, an immune reaction of *Drosophila*. Microarray analyses of these tracheae suggest an involvement of WNT and TGF-β pathways in the induction of this phenotype.
Conclusions: Our data indicate a crucial role of JAK/STAT signaling in the barrier function of the Drosophila airway epithelium. This function is likely to be conserved. Therefore, it is possible that the asthma susceptibility gene STAT6 is important to maintain the barrier function of the human airway epithelium (supported by DFG, SFB/TR22, project A07).

P0788
Effect of boiling and autoclaving on allergenicity of Anisakis simplex

N. Carballeda-Sangiao,* F. Olivares,† A. I. Rodriguez-Mahillo,* I. Moneo,* M. Tejada,† A. Mendizabal‡ & M. Gonzalez-Muñoz*
**Immunology, Hospital Carlos III, Madrid, Spain, †Centro Superior de Investigaciones Cientificas, Instituto de Ciencia y Tecnologia de los Alimentos y Nutricion, Madrid, Spain, ‡Mercamadrid, Instituto de Salud Publica, Madrid, Spain*

Purpose/Objective: *Anisakis simplex* is a fish parasite with a worldwide distribution. Humans are accidental hosts. The ingestion of parasitized fish with live larvae L3 can result in the development of anisakiasis and sometimes can induce IgE-mediated reactions. Some authors claim that infection is the only mechanism for allergic disease. However, others consider that allergic episodes can be elicited by infection or exposure to allergen remaining in food with dead larvae. It is believed that is due to heat stable and pepsin resistant allergens for example Ani s 4. The aim of this work was to detect the presence of biologically active heat resistant *A. simplex* allergens after high temperature and pressure treatment (autoclaving) of parasitized fish muscle.
Materials and methods: Fish fillets from hake (*Merluccius merluccius*) and tuna (*Thunnus thynnus*) were artificially parasitized with *A. simplex* and subjected to boiling (10 min) followed by autoclaving during 40 min at 121°C. Fish muscle extracts (FME) were obtained by grinding followed by sonication and centrifugation. *A. simplex* larvae were treated in the same conditions to obtain an L3 extract (ASE). *A. simplex* heat resistant antigens and allergens were detected and quantified in FME and ASE by immunoblot using specific rabbit antisera and/or sensitised patients' sera pool. Autoclaving buffer of the larvae (AB) was also analysed. The FME was tested in a flow cytometry basophil activation test on *A. simplex* sensitized patients. A non parasitized fish muscle extract was used as a negative control.
Results: We could detect several antigens between 6 and 16 kDa and above 36 kDa in the AB but not in the ASE. When revealing with patients' sera pool we detected several allergens between 6 and 16 kDa.

In the FME we mainly detected an allergen around 20 kDa and an antigen around 16 kDa. This extract activated the basophils of sensitized patients in a dose-dependent way.
Conclusions: The presence of heat resistant antigens and allergens from *A. simplex* in artificially parasitized autoclaved fish muscle and autoclaving buffer was demonstrated.

P0790
Efficacious peptide-based immunotherapy in a model of allergic airways inflammation occurs independently of IL-10

K. J. Mackenzie, P. M. Fitch, D. Nowakowska, M. D. Leech, A. J. McFarlane, A. Ilchmann, S. E. M. Howie, J. Schwarze & S. M. Anderton
MRC Centre for Inflammation Research, University of Edinburgh, Edinburgh, UK

Purpose/Objective: Immunotherapy using short allergen-derived peptides holds promise for the treatment of allergic asthma, and also offers potential as a preventative approach. However, greater understanding of the immunological mechanisms involved in peptide-based immunotherapy (PIT) is required to maximise translational opportunities.
Materials and methods: We have developed a murine model of allergic airway inflammation driven by adoptively transferred Th2 polarised (hence antigen-experienced) ovalbumin (OVA)-reactive $CD4^+$ T cells (OT-II cells). Robust features of allergic airway inflammation are induced in this model following OVA airway challenge, and the Th2 cells are congenically marked, enabling tracking. PIT was applied to this model using the immunodominant OVA T cell epitope pOVA 323–339 given intravenously prior to allergen challenge, and the effects of PIT on disease parameters and immunological readouts were then assessed.
Results: PIT significantly reduced the severity of AAI in this model. Four days after PIT, immediately prior to OVA challenge, PIT treated mice had substantially increased numbers of OT-II cells in lymphoid organs, compared to controls. This is in marked contrast to the early deletional effects of PIT we have previously seen using antigen-naïve OT-II cells. Th2 OT-II cells from PIT treated mice were also unable to induce disease upon direct transfer into the lungs and subsequent OVA airway challenge. Importantly, although Th2 OT-II cells from PIT treated, but not control, mice produced substantial quantities of IL-10 in response to OVA challenge *in vitro*, PIT remained efficacious even in conditions of IL-10R blockade. Furthermore, the therapeutic effects of PIT were evident even in the context of increased severity of allergic airways inflammation induced by IL-10R blockade.
Conclusions: PIT is effective at combating the pathogenic effects of antigen-experienced Th2 cells in a model of allergic airway inflammation. Although PIT induces substantial IL-10 production from Th2 OT-II cells in this model, the therapeutic effects of PIT were not dependent on IL-10.

P0793
Epicutaneous sensitization induces a Der p 2-specific, TH2-biased antibody response independent of TLR4 expression

C. Stremnitzer,* K. Szalai,† A. Willensdorfer,† P. Starkl,* S. Schrom,* U. Reichart,‡ S. Knapp§ & E. Jensen-Jarolim¶
**Department of Pathophysiology and Allergy Research, Comparative Immunology and Oncology, Medical University of Vienna Vienna, Austria, †Comparative Medicine Messerli Research Institute, University of Veterinary Medicine, Vienna, Austria, ‡Institute of Animal Breeding and Genetics, University of Veterinary Medicine, Vienna, Austria, §Division of Infectious Diseases and Tropical Medicine, Department of Medicine I, Center for Molecular Medicine of the Austrian, Academy of Sciences, University of Veterinary Medicine Vienna, Medical University Vienna, University Vienna, Vienna, Austria, ¶Comparative Medicine Messerli Research Institute, University of Veterinary Medicine Vienna, Medical University Vienna, University Vienna, Vienna, Austria*

Purpose/Objective: The major house dust mite allergen Der p 2 is a structural and functional homologue of MD2 (TLR4-CD14-MD2 complex). An asthma model in TLR4-deficient mice has suggested that the allergic immune response against Der p 2 is dependent on TLR4 signaling. We investigated whether similar mechanisms are important for mediating Der p 2-induced allergy of the skin.
Materials and methods: C57BL/6 WT and TLR4-deficient mice were epicutaneously sensitized 4 times in 3 week intervals with recombinant Der p 2 in combination with or without LPS. Immune response was monitored for specific antibodies by ELISA. Skin sections were analyzed for histological changes and immune cell infiltration.
Results: Co-application of low and high LPS doses with Der p 2 induced similar levels of allergen-specific IgG1 and IgE antibodies in C57BL/6 WT and TLR4-deficient mice. In skin sections, increased

infiltration of mast cells could be determined in both mouse strains, already 6 h after the final challenge. Moreover, we observed high allergenic potential of Der p 2 alone, based on high antibody titers and immune cell infiltration.
Conclusions: Our results suggest that epicutaneous sensitization to Der p 2 does not depend only on activation of TLR-4 signalling but also on other, yet undefined mechanisms.

P0794
Epigenetic effects in mice following ozone exposure

A. Jang, D. Bae & C. Park
Internal Medicine, Soonchunhyang University, Bucheon, Korea

Purpose/Objective: Ozone exposure can be inducing and inciting factor for asthma. Epigenetics is the study of inherited changes in phenotype or gene expression caused by mechanisms other than changes in the underlying DNA sequence. The epigenetic effect to ozone exposure needs to be determined. The aim of this study was to investigate the effects of ozone exposure on epigenetic change, airway hyperresponsiveness, and airway inflammation in a murine model.
Materials and methods: BALB/c mice were exposed to 2 ppm ozone for 3 h, 3 days, 7 days, 14 days, and 21 days. Enhanced pause (Penh) to methacholine was measured. Cell differentials in bronchoalveolar lavage (BAL) fluid were done. Epigenetic enzyme such as DNMT1, DNMT3A, MECP2, HDAC3, and MBD1−4 were quantified in the lung tissue homogenate using real time PCR.
Results: The ozone exposure group for for 3 h, 3 days, 7 days, 14 days, and 21 days. demonstrated increased Penh at methacholine concentration of 12.5, 25, 50 mg/ml, with shift in the dose-response curve to the left, compared with that of filtered air group. Neutrophilsand lymphocytes in BAL fluid were increased in ozone exposed group compared with those in filtered air group. After ozone 2ppm exposure DNMT1, MECP2 increased in 21 days and DNMT3a and HDAC3 increased in3 h, 3 days, and 21 days, and MBD1−4 variably increased by ozone exposure time.
Conclusions: These findings demonstrate that ozone exposure can change enzymes related to epigenetics.

P0795
Evidence for T cell-independent boost of allergen-specific secondary IgE responses by B cell epitopes

M. Narayanan,* M. Focke-Tejkl,† R. Valenta‡ & B. Linhart§
**Department of pathophysiology and Allergy Research, Center for Pathophysiology Infectiology and Immunology, Medical University of Vienna, Vienna, Austria, †Christian Doppler Laboratory for Allergy Research, Medical University of Vienna, Vienna, Austria, ‡Department of pathophysiology and Allergy Research, Doppler Laboratory for Allergy Research, Center for Pathophysiology Infectiology and Immunology Christian, Medical University of Vienna, Vienna, Austria, §Department of pathophysiology and Allergy Research, Center for Pathophysiology Infectiology and Immunology, Vienna, Austria*

Purpose/Objective: IgE-mediated allergy, a hypersensitivity disease affecting more than 25% of population, is characterized by the induction of an allergen-specific Th2 response and the production of allergen-specific IgE antibodies. Clinical studies showed that systemic allergen-specific production in allergic patients is strongly boosted by respiratory allergen contact and that patients become more sensitive to allergen contact. Despite the key role of IgE antibodies for the pathology of allergic disease, the mechanisms underlying allergen-specific secondary antibody responses are still not completely understood. The aim of this study was to investigate what allergen epitopes (B cell, T cell epitopes) are needed for the boosting of allergen-specific secondary IgE responses.
Materials and methods: Based on the hapten-carrier model developed by Benacerraf, a 31 amino acid peptide derived from the major grass pollen allergen Phl p 1, which was devoid of T cell epitopes recognized by BALB/c mice, was coupled to unrelated carrier molecules. Immunization of BALB/c mice with the peptide/carrier allowed the induction of peptides-specific IgE antibody responses. Sensitized mice were then boosted with peptide constructs devoid of carrier-specific T cell epitopes and for control purposes with the original immunogens, the original carrier molecules without peptide or PBS. Peptide-specific IgE responses were determined by ELISA and by using rat basophil degranulation assays.
Results: Interestingly, we found that peptide-constructs devoid of the original carrier molecules and thus devoid of T cell epitopes could induce increases of secondary peptide-specific IgE responses. Application of the T cell epitope-containing carriers alone had no influence on ongoing IgE responses.
Conclusions: Our results suggest that B cell targeting approaches may be needed for the treatment of established allergy.

P0797
Extracellular heat shock protein 70 inhibits impairment of airway neutrophils responses in induced allergic airway inflammation

E. Servuli, N. Troyanova, E. Bolkhovitina & A. Sapozhnikov
Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Immunology, Moscow, Russia

Purpose/Objective: Immune responses of airway neutrophils are thought to be impaired in asthma. Stress-associated chaperon heat shock protein 70 (Hsp70) is known to be potent to alter neutrophil activation in response to bacterial infection. Here we analyze the effect of extracellular Hsp70 application on neutrophil infiltration and activity upon induced allergic airway inflammation (IAAI).
Materials and methods: IAAI in BALB/c mice was induced by intraperitoneal ovalbumin (OVA)/Alum injection and subsequent OVA aerosol challenges. A group of mice received intra-pharyngeal injection of murine Hsp70 at 24 h after the last allergen challenge. Total and differential number of bronchoalveolar lavage (BAL) cells and percentage of neutrophils in bone marrow was analyzed at 48 h after the last allergen challenge. Potential of bone marrow neutrophils from Hsp70 treated mice to generate reactive oxygen species (ROS) in response to phorbol-meristil acetate was investigated.
Results: Hsp70 application decreased total BAL cell number and eosinophil percentage, however maintained neutrophil infiltration at 48 h after the last allergen challenge. The percentage of neutrophils in bone marrow of mice that received Hsp70 was comparable to that exhibited allergic inflammation. Simultaneously treatment with Hsp70 restored the ability of bone marrow neutrophils to generate ROS, which was detected to be suppressed in mice with IAAI.
Conclusions: Thus protective mechanism of extracellular Hsp70 in IAAI could be related to inhibition of airway neutrophil responses impairment.

Functional characterization of allergen-specific T cell responses in a humanised mouse model using a human mugwort-specific T-cell receptor and HLA-DR1

A. Neunkirchner,* L. F. Mager,† V. M. Reichl,* K. G. Schmetterer,* D. Wojta-Stremayr,* E. Rosloniec,‡ R. Naumann,§ B. Jahn-Schmid,¶ B. Bohle** & W. Pickl*

*Christian Doppler Laboratory for Immunomodulation, Institute of Immunology, Medical University of Vienna, Vienna, Austria, †Institute of Immunology, Medical University of Vienna, Vienna, Austria, ‡Medicine-Rheumatology and Pathology, Veterans Affairs Medical Center, Memphis, TN, USA, §Transgenic Core Facility, Max Planck Institute for Molecular Cell Biology and Genetics, Dresden, Germany, ¶Department of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria, **Department of Pathophysiology and Allergy Research, Christian Doppler Laboratory for Immunomodulation, Medical University of Vienna, Vienna, Austria

Purpose/Objective: Chicken Ovalbumin (Ova) is a frequently used model allergen in allergy and asthma research and most *in vivo* experiments are performed in T cell receptor (TCR) transgenic (tg) mice expressing a murine TCR specific for Ova in the context of a murine restriction element ($I\text{-}A^d$). We here aimed to generate double tg mice expressing a human TCR specific for the immuno-dominant epitope of the major mugwort (*Artemisia vulgaris)* pollen allergen Art v 1 in the context of the human restriction element HLA-DR1.

Materials and methods: To obtain high expression levels the allergen-specific human TCR variable sequences were chimerized with murine TCR constant sequences. Resulting transgenes were cloned into the pT_{cass} vector system and thus put under the transcriptional control of the natural TCR alpha and beta promotor/enhancer elements. Allergen-specific TCR tg founder mice were cross-bread with HLA-$DR1^+$ B10.M-$DR1^{dlAb1\text{-}Ea}$ mice.

Results: Immunophenotyping of double tg TCR/HLA-DR1 mice revealed clear-cut expression of the Art v 1-specific TRBV18 chain on peripheral blood $CD3^+$ T cells and HLA-DR1 expression on $CD14^+$ monocytes and $B220^+$ B cells. *In vitro,* splenocytes from TCR/HLA-DR1 double tg mice but not of HLA-DR1 single tg mice or wt mice specifically proliferated upon incubation with the human-relevant immuno-dominant Art v 1_{25-36} peptide or whole Art v 1 protein. No proliferation was observed upon incubation with control peptides or proteins. Allergen-specific cellular proliferation is accompanied by the production of a balanced cytokine milieu including IFN-gamma, IL-2, IL-4, IL-6, IL-13 and IL-17. The effect on T-cell phenotype, specific antibody production and lung function after *in vivo* challenge with specific allergen via the airways will be described and discussed.

Conclusions: A humanised allergy model, in which all components of the allergen-specific synapse are well-defined enables to analyze the relevant T-cell dependent pathways by which allergic diseases can be influenced *in vivo* and will provide important insights into the pathophysiology of allergic diseases and their possible cure in the future.

The research was funded by the Christian Doppler Society, the Austrian Science Fund (FWF): SFB 4609-B19 and SFB F1816-B13 and the Austrian Research Promotion Agency Bridge grant: 812079 & Biomay AG.

Granulocyte/macrophage colony-stimulating factor-dependent CD11b lung dendritic cells are required for induction of T helper 2 immunity to inhaled dust mite allergen

Q. Zhou,* A. W. Ho,† Y. Tang,‡ F. Ginhoux,§ B. Y. Chua,‡ H. S. Wong‡ & D. M. Kemeny‡

*Microbiology, National university of Singapore, Singapore, Singapore, †Immunos, Singapore Immunology network, Singapore, Singapore, ‡Microbiology, National University of Singapore, Singapore, Singapore, §Immunos, Singapore Immunology Network, Singapore, Singapore

Purpose/Objective: Although it is well established that dendritic cells (DCs) are essential for allergic immune responses in several mouse models of asthma but the specific role of different lung DC subsets in initiating Th2 immunity remains poorly understood. The purpose of this study was to investigate the contribution of tissue resident dendritic cells in inducing Th2 immune response to the tropical allergen *Blomia tropicalis*.

Materials and methods: C57BL/6 mice were intra-nasally sensitized with Blomia tropicalis extract (Blo t) and subsequently challenged via the same route. Bronchoalveolar lavage (BAL) eosinophils and neutrophils were determined by expression of Singlec-F and Ly6-G respectively. Mucus secretion was detected with periodic acid Schiff stain (PAS). T cell cytokines were determined by culture of draining lymph node cells with 20 mg/ml Blo t extract for 5 days and assay of culture supernatants by ELISA (R&D systems).

Results: Intra-nasal administration of Blo t without adjuvant induced a robust allergic response characterized by high eosinophil (60%) and low neutrophil (10%) infiltration. Hematoxylin and eosin staining identified substantial mononuclear cell infiltration of the lungs and PAS staining demonstrated mucus hyper-secretion and goblet cell hyperplasia. Draining lymph node cells cultured with Blo t extract secreted large amounts of IL-4 (200 pg/ml), IL-5 (2000 pg/ml), IL-13 (4000 pg/ml) and very little IFN-g (<100 pg/ml). Blo t extract was able to enhance the uptake (10−20% by day 3) and presentation of ovalbumin (OVA) by CD11b lung DCs, leading to OVA-specific T cell proliferation and Th2 differentiation in lung draining lymph nodes. When CD11b lung DCs were depleted by crossing CD11c-Cre and IRF4-flox mice, the Th2 immune response to inhaled Blo t allergens was attenuated and allergic airway inflammation decreased. Administration of anti-granulocyte/macrophage colony-stimulating factor (GM-CSF)-neutralizing Abs during the sensitization stage markedly reduced Blo t-elicited allergic responses and was associated with reduced antigen presentation capacity of CD11b lung DCs.

Conclusions: Taken together these data suggest that GM-CSF-dependent CD11b DCs play a critical role in the initiation of Th2 responses to Blo t allergens.

P0800

Heroin and histamine

U. Maurer,* R. Jarisch,† A. Pollesböck,‡ W. Hemmer,† F. Wantke† & B. Spitzer‡

*Biomedical Analytics, University of Applied Sciences, Wiener Neustadt, Austria, †Floridsdorfer Allergy Center, FAZ, Vienna, Austria, ‡Landesklinikum Mostviertel, Mauer, Amstetten, Austria

Purpose/Objective: In 2011 more than 200 narcotic drug-related deaths have been verified in Austria. To support the hypothesis that anaphylaxis is involved in long-term drug addiction as a possible cause of death we investigated useful markers measured in baseline bloods of long-term heroin addicts.

Materials and methods: Quantitative laboratory tests were performed to determine the concentrations of Histamine, Diamine oxidase (DAO), Tryptase and Lipoprotein-associated phospholipase A_2 ($LpPLA_2$) in drug addicts ($n = 72$) and healthy controls ($n = 103$).

Blood samples of drug addicts were taken before and 3h after substitution (Substitol®retard).

To verify the hypothesis, we documented self-reported anaphylactic reactions shown during drug addiction plus the expression of anaphylactic symptoms after substitution within 180 min.

Results: We found significantly elevated Histamine (0.51 ± 0.33 ng/ml versus 0.18 ± 0.15 ng/ml; $P < 0.001$), Tryptase (5.53 ± 3.93 versus 3.96 ± 1.99 μg/l; $P < 0.001$) and $LpPLA_2$ (399.71 ± 118.04 ng/ml versus 333.28 ± 85.95 ng/ml; $P < 0.001$) levels in heroin addicts compared with healthy controls, while DAO (14.00 ± 7.73 versus 11.02 ± 4.91 U/ml; $P < 0.001$) was significantly decreased.

Anaphylactic reactions during long-term drug addiction were reported in 69 of 72 cases. Skin involvement (urticaria, flushing, and pruritus) is reported in 60%, respiratory tract involvement (dyspnoea and angioedema) in up to 50%.

Prescription of substitution has caused side effects merely in 13 of 72 cases. Unspecific symptoms like tiredness, feeling of warm, headache and pruritus have been documented.

Conclusions: These results show 3-fold increased Histamine concentrations ($P < 0.001$), elevated Tryptase ($P < 0.001$), and $LpPLA_2$ ($P < 0.001$), concentrations in baseline bloods of heroin addicts compared with healthy controls, DAO ($P < 0.001$) was reduced. It indicates that long-term heroin consumption influences the release of mast-cell mediators. Hence, anaphylactic reactions were described in long-term drug addicts, containing the skin and the respiratory tract as the main organs.

These observations suggest that raised histamine may induce arrhythmias and ischaemic changes which finally may be a cause of heroin-induced fatalities. This study however emphasizes, that heroin might be an important trigger of anaphylaxis.

P0801
Heterogeneity of allergen-specific Th2 cells in Type I allergy

N. Zulehner,* B. Nagl,* V. Leb-Reichl,† C. Walterskirchen,* G. Zlabinger,† W. Pickl† & B. Bohle*

**Department of Pathophysiology and Allergy Research, Center for Pathophysiology Infectiology and Immunology, Vienna, Austria, †Center for Pathophysiology Infectiology and Immunology, Institute of Immunology, Vienna, Austria*

Purpose/Objective: The important roles of allergen-specific Th1, Th2 and Treg cells in IgE-mediated allergy have been well defined in the past. However, the involvement of Th17 cells in Type I allergy is not clear yet. Therefore, we investigated the existence of allergen-specific Th17 cells.

Materials and methods: Supernatants of 40 allergen-reactive $CD4^+$ clones expanded from peripheral blood of allergic patients were assessed for cytokine production after specific stimulation using the Luminex System. The expression of lineage-specific transcription factors of the clones was analyzed by qPCR and compared to *in vitro* differentiated Th1, Th2 or Th17 cells. Intracellular cytokine staining of allergen-stimulated peripheral blood mononuclear cells and clones was done by flow cytometry.

Results: Twenty two of 40 allergen-specific clones (55%) produced IL-4 and negligible amounts of IFN-g and were thus considered as Th2 cells. In addition to IL-4, these clones produced TNF-α, IL-10 and/or IFN-γ showing high heterogeneity within the Th2 lineage. Nine of 40 clones (23%) produced IL-17 upon stimulation with allergen. Interestingly, all IL-17-producing clones concomitantly synthesized substantial amounts of IL-4. Analysis of lineage-specific transcription factors showed that both, $IL\text{-}4^+IL\text{-}17^-$ and $IL\text{-}4^+IL\text{-}17^+$, clones display expression profiles characteristic for Th2 cells. *Ex vivo*, the existence of allergen-specific $IL\text{-}4^+IL\text{-}17^+$ T cells in peripheral blood from allergic individuals was confirmed by intracellular cytokine staining of allergen-stimulated proliferating T cells.

Conclusions: We found no evidence for allergen-specific Th17 cells causing IgE-mediated allergy. However, we identified a subset of allergen-specific $IL\text{-}4^+IL\text{-}17^+$ Th2 cells and observed high heterogeneity of allergen-specific Th2 clones.

P0802
Hypoallergenic Der p 1/Der p 2 combination vaccines for immunotherapy of house dust mite allergy

K. Chen,* K. Blatt,† W. R. Thomas,‡ I. Swoboda,§ P. Valent,† R. Valenta§ & S. Vrtala*

**Deparment of Pathophysiology and Allergy Research, Center for Pathophysiology Infectiology and Immunology Medical University of Vienna, Vienna, Austria, †Division of Hematology and Hemostaseology, Department of Internal Medicine I, Medical University of Vienna, Vienna, Austria, ‡Centre for Child Health Research, Telethon Institute for Child Health Research, Perth, WA, Australia, §Department of Pathophysiology and Allergey Research, CD Laboratory f Allergy Research, Center for Pathophysiology Infectiology and Immunology Medical University of Vienna, Vienna, Austria*

Purpose/Objective: More than 50% of allergic patients suffer from house-dust mite (HDM) allergy. Group 1 and 2 allergens are the major HDM allergens.

Production and preclinical characterization of a recombinant hypoallergenic combination vaccine for specific immunotherapy (SIT) of HDM allergy.

Materials and methods: Synthetic genes coding for two hybrid proteins consisting of reassembled Der p 1 and Der p 2 fragments with (rDer p 2/1C) and without (rDer p 2/1S) cysteines were expressed in *Escherichia coli* and purified to homogeneity by affinity chromatography. Protein fold was determined by circular dichroism analysis, allergenic activity by testing IgE reactivity as well as basophil activation assays and presence of T cell epitopes by lymphoproliferation in allergic patients. Mice and rabbits were immunized to study the molecules ability to induce an allergic response and if they induce allergen-specific IgG capable of inhibiting allergic patients' IgE binding to the allergens, respectively.

Results: rDer p 2/1C and rDer p 2/1S were expressed in large amounts in *E. coli* as soluble and folded proteins. Due to lack of disulfide bonds, rDer p 2/1S did not form aggregates and was obtained as monomeric protein, whereas rDer p 2/1C formed aggreates. Both hypoallergens lacked relevant IgE reactivity and had reduced ability to induce allergic inflammation and allergic responses, but induced similar T cell proliferation as the wildtype allergens. Immunization with the hypoallergens (rDer p 2/1S > rDer p 2/1C) induced IgG antibodies in rabbits that inhibited IgE reactivity of HDM-allergic patients to Der p 1 and Der p 2.

Conclusions: The preclinical characterization indicates that in particular rDer p 2/1S may be used as a safe hypoallergenic molecule for tolerance as well as vaccination approaches to treat HDM allergy.

P0803
Identification and characterization of pulmonary stem cells in the pathogenic mechanism and alleviation of allergic airway inflammation

C. J. Chiu & B. L. Chiang

Graduate Institute of Immunology, National Taiwan University, Taipei, Taiwan

Purpose/Objective: Asthma is a very complex and heterogeneous disease that is characterized by airway inflammation and airway hyperresponsiveness (AHR). Recent studies have been focused on characterization and identification of lung stem cells for regenerative therapy in asthma. Based on the theory of alveolar development in the newborn lung, pulmonary stem cells are enriched in the neonatal mice

and becoming the rare population in the well-development adult mice. Therefore, we isolated and explored the biological effect of the potential SSEA-1^+ pulmonary stem cells (PSCs) derived from neonatal mice.

Materials and methods: SSEA-1^+ PSCs derived from neonatal mice were enriched by magnetic beads. The characteristics of SSEA-1^+ PSCs were evaluated using immunofluorescence staining, real-time PCR, and FACS analysis. Further, *in vivo* biological function of SSEA-1^+ PSCs was studied and analyzed in OVA-induced asthmatic mice.

Results: Single-cell suspensions derived from neonatal mouse lung tissue were SSEA-1^+ or Sca-1^+ population. SSEA-1^+ PSCs were highly expressed in the neonatal mice, and then were downregulated in the adult mice. Enriched SSEA-1^+ PSCs have the ability to differentiate into AQP5^+ type I pneumocytes and surfactant protein C-expressed type II pneumocytes. FACS and real-time PCR showed that CCSP transcript and protein level were increased in SSEA-1^+ PSCs compared with SSEA-1^- Sca-1^- pulmonary cells. Adoptive transfer of SSEA-1^+ PSCs reduced AHR and prevented airway damage through decreasing eosinophil infiltration and inhibiting IL-5, eotaxin and TSLP production in OVA-induced asthma mice.

Conclusions: In conclusion, SSEA-1^+ PSCs might have the potential to repair lung damage or to inhibit inflammatory effects in the pathological process of asthma. Therefore, we conclude that the potent immunomodulatory effect of PSCs might be beneficial for treating asthma disease.

P0804

Identification of a major IgE-binding epitope of beta-parvalbumins using scFv antibodies

D. Ackerbauer, M. Kostadinova, M. Bublin & H. Breiteneder
Department of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria

Purpose/Objective: Fish allergy is associated with IgE-mediated hypersensitivity reactions to β-parvalbumins, which are small calcium-binding muscle proteins, and represent the major for 95% of fish allergic patients. A high degree of cross-reactivity of parvalbumins from various fish species has been described. We aimed to express and purify single chain variable fragment (scFv) antibodies specific for β-parvalbumins for their detection in fish protein extracts and for the identification of major IgE epitopes.

Materials and methods: The phage clone gco9 specific for β-parvalbumins was isolated from the ETH-2 phage display library by sequential panning against parvalbumins from Atlantic cod, carp and rainbow trout. The soluble scFv-gco9 was expressed in the *E. coli* non-suppressor strain HB2151 and extracted from the periplasm. The purified antibody was obtained by nickel-based affinity chromatography and its specificity was tested in Western blot using fish protein extracts. The binding capacity of scFv-gco9 for the natural parvalbumins Gad m 1, Cyp c 1 and Onc m 1 of Atlantic cod, carp and rainbow trout, respectively, was tested in ELISA. Inhibition ELISAs were performed to investigate the ability of this antibody to block sIgE-binding to β-parvalbumins in sera of fish allergic patients.

Results: The purified scFv-gco9 was able to detect β-parvalbumins of Atlantic cod, carp and rainbow trout as single 12 kDa bands in Western blot using fish protein extracts. The antibody also strongly recognized natural Gad m 1, Cyp c 1 and Onc m 1 in direct ELISA. The binding capacity of scFv-gco9 to nGad m 1 was independent of the presence or absence of Ca^{2+} ions. In contrast, a mouse monoclonal anti-parvalbumin antibody only reacted with the calcium-bound form. In competitive ELISA, the scFv antibody was able to inhibit binding of sIgE from fish allergic patients' sera to all three β-parvalbumins by 80%.

Conclusions: In this work, supported by grant SFB-F4608 from the Austrian Science Fund, we isolated and produced a scFv antibody specific for a calcium-independent major IgE epitope of Atlantic cod β-parvalbumin.

IgE knock-in mice reveal a key role for IgE in basophil-mediated active systemic anaphylaxis

P. Yu,* W. Lübben,* A. Okhrimenko,* C. Stöberl,† A. Turqueti-Neves,‡ S. Bauer,* G. Riethmüller§ & D. Voehringer¶
**Institute of Immunology, Philipps-Universität Marburg, Marburg, Germany, †Institute of Immunology, LMU München, München, Germany, ‡Department of Infection Biology, Institute of Medical Microbiology Immunology, Erlangen, Germany, §Institute of Immunology, LMU München, Mü, Germany, ¶Department of Infection Biology, Institute for Medical Microbioloby, Erlangen, Germany*

Purpose/Objective: IgE production is tightly regulated at the cellular and genetic level and is believed to be central to allergy development. At least two pathways exist that lead to systemic anaphylaxis reactions *in vivo*: IgE-sensitized mast cell and IgG1-sensitized basophil mediated anaphylaxis. Although passive anaphylaxis, by application of allergen and allergen-specific antibodies in mice allows for the determination of the contribution of different immunoglobulin isotypes, the analysis of a dynamic, immunization mediated antibody responses is not currently possible.

Materials and methods: We generated IgE knock-in mice (IgE^{ki}) which express the IgE heavy chain instead of IgG1 in order to analyze the contribution of IgG1 and IgE to active anaphylaxis *in vivo*.

Results: IgE^{ki} mice display increased IgE production both *in vitro* and *in vivo*. In addition a defect of membrane expression of chiemric IgE *in vivo* was observed, which suggests that mIgE expression id fundamentally differenet from mIgG1 expression *in vivo*

The sensitization of IgE^{ki} mice by immunization followed by antigen challenge leads to increased anaphylaxis. Homozygous IgE^{ki} mice, which lack IgG1 due to the knock-in strategy, are most susceptible to active systemic anaphylaxis. Depletion of basophils demonstrates their importance in IgE-mediated anaphylaxis.

Conclusions: Therefore we propose that an enhanced-, antigen-specific, polyclonal, IgE response, as is the case in allergic patients, is the most efficient way to sensitize basophils to cause systemic anaphylaxis *in vivo*.

IgE reactivity profiling of allergic individuals in the Philippines

C. R. Cabauatan,* C. Lupinek,* R. Weiss,† M. Focke-Tejkl,* P. L. Bhalla,‡ M. B. Singh,‡ P. A. Knight,‡ M. van Hage,§ J. D. A. Ramos¶ & R. Valenta**
**Department of Pathophysiology and Allergy Research, Center for Pathophysiology Infectiology and Immunology Medical University of Vienna, Vienna, Austria, †Department of Molecular Biology, Christian Doppler Laboratory for Allergy Diagnostic and Therapy, University of Salzburg, Salzburg, Austria, ‡Plant Molecular Biology & Biotechnology Laboratory, Melbourne School of Land and Environment, The University of Melbourne, Parkville, Vic., Australia, §Department of Medicine Clinical Immunology and Allergy Unit, Karolinska Institutet and University Hospital, Stockholm, Sweden, ¶The Graduate School, University of Santo Tomas, Manila, Philippines, **Department of Pathophysiology and Allergy, Research Center for Pathophysiology Infectiology, Christian Doppler Laboratory for Allergy Research, Immunology Medical University of Vienna, Vienna, Austria*

Purpose/Objective: There is only limited information about allergy and relevant allergens in the Philippines. This study aimed to investigate the allergen profile in the Philippines.

Materials and methods: A questionnaire for Allergy Screening from the International Study of Asthma and Allergy in Childhood was used to identify individuals with and without allergic symptoms. Allergen specific-IgE antibodies were determined by ELISA using pollen extracts from several local grasses such as *Cynodon dactylon, Chloris barbata, Imperata cylindrica, Saccharum spontaneum, Sporobulus indicus, Oryza sativa* and *Zea mays*. In addition, chips containing 103 micro-arrayed purified allergen molecules were used to determine the molecular IgE reactivity profiles in random subgroups of 79 symptomatic and 20 asymptomatic subjects. IgE binding studies were performed in purified rOry s 1 from rice and galactose-α1,3-galactose (α-Gal); and IgE inhibition assay with glycosylated nPhl p 4 was done. Nitrocellulose-blotted extracts from local grasses were analyzed for the presence of major grass pollen allergens with specific antibody probes.
Results: Interestingly, we found that not only symptomatic subjects but also asymptomatic individuals exhibited IgE reactivity to pollen extracts of local grasses. A detailed characterization of the IgE reactivity profiles with micro-arrayed allergens revealed an unusual preferential sensitization to mainly glycosylated grass pollen allergens such as nCyn d 1 and nPhl p 4 in both groups whereas the major protein allergens in grass pollen were not recognized. The specificity of the IgE reactivity to carbohydrate epitopes with poor allergenic activity was confirmed by IgE inhibition studies. No sensitization to the allergenic α-Gal was observed. Symptomatic allergic sensitizations were confined to non-glycosylated protein allergens from house dust mites and animals.
Conclusions: Our study reveals that subjects from the Philippines exhibit a high prevalence of asymptomatic IgE sensitization to non-allergenic carbohydrate epitopes in grass pollen whereas symptomatic allergic sensitization seems to be confined to protein allergens from mites and animals. These results have impact on the development of allergen-specific forms of immunotherapy.

P0807
Immature dendritic cells in patients with ill-controlled asthma

C. J. Chang,* Y. H. Yang,† H. Y. Hsu,† K. H. Chu,† C. J. Chiu† & B. L. Chiang†
**College of Medicine, Graduate Institute of Oncology, National Taiwan University, Taipei, Taiwan, †Department of Pediatrics, National Taiwan University Hospital, Taipei, Taiwan*

Purpose/Objective: Ill-controlled allergic asthma, a chronic inflammatory disease, has been increasingly observed in both developed and developing countries. Inhalant steroid has been applied to control disease that is transient used to reduce disease severity, however, which could not be used to cure disease completely. Therefore, to approach alternative pathogenic mechanisms involved asthma facilitates to develop new therapeutic targets. Previous studies revealed Th2 cells and other inflammatory cells play a major role in the initiation and pathological development of asthma, therefore, allergenic antigens specific adoptive immune responses play an important role in pathogenic mechanisms of disease. Dendritic cells (DCs) are professional antigen presenting cells that play a crucial role to establish adoptive immune responses to various inflammatory stimuli. The well accepted concept that human blood monocytes can be induced to develop immature DCs after treating GM-CSF and IL-4.
Materials and methods: In our study, MoDCs were used to evaluate whether function of DCs involved pathogenicity of asthma that MoDCs derived from 6 patients with ill-controlled asthma or derived from 10 health donors. All of patients were discontinued to treat systemic or inhalant steroid before blood collection.
Results: MoDCs derived from asthma patients presented lower levels of accessory molecules, including CD40, CD80, CD83, CD86 or MHC class II compared with those molecules derived from MoDCs of healthy donors. Consistently, MoDCs cultured from patients presented potent capability to uptake fluoresce-conjugated model antigen than MoDCs derived from health donors. In addition, results of mix lymphocytes reaction revealed that MoDCs generated from patients have a weak capacity to prime naïve CD4+ T cells proliferation compared with those derived from health donors. These data indicate that patients with ill-controlled asthma have less potency of MoDCs. Interestingly, both MoDCs derived from patients and health donors were activated and maturated after LPS stimulation, however, most of MoDCs cultured from asthma patients still have shown weak potency to prime naïve T cells than those generated from health donors.
Conclusions: These data indicate that less potent and immature DCs in patients with ill-controlled asthma might be play a role in pathogenic mechanism of disease.

P0808
Immune mechanisms mediating suppression of allergic airway inflammation upon *Salmonella* infection

V. Ganesh, A. M. Baru, C. Untucht & T. Sparwasser
Twincore, Institute of Infection Immunology, Hannover, Germany

Purpose/Objective: Prevalence of asthma, a Th2 biased inflammatory airway disease has dramatically increased over the past few decades. Mere reciprocal regulation of Th1 and Th2 phenotypes failed to justify the concomitant rise in allergic and autoimmune disorders characterized by dys-regulated Th1 or Th17 immune responses. Recent studies have highlighted the role of immune-regulatory mechanisms in modulating allergic reactions. A longitudinal study by Pelosi *et al.* (Allergy, 2005) demonstrated an inverse correlation between *Salmonella* infection and susceptibility to asthma, however, the mechanism remains obscure. In this study we attempted to identify the mechanism(s) mediating this suppression.
Materials and methods: Experimental allergic airway inflammation was induced by standard OVA-Alum model. A group of mice were infected with *Salmonella* during the regimen. Inflammatory responses were estimated by cellular infiltration in broncheo-alveolar lavage (BAL). Serum immunoglobulin levels and cytokines from *in vitro* re-stimulated mediastinal lymph node cells were measured by ELISA. Lung pathology was determined by histology and quantitative PCR. Alteration in cellular frequencies was determined by flow cytometry. *In vitro* differentiation and stability of Th2 cells were investigated.
Results: Mice infected with *Salmonella* showed markedly reduced total cellular infiltration and eosinophilia in the BAL. Infected mice showed increased titers of antigen-specific IgG2a in sera, but no significant alteration in IFN-g was detected. Reduced IL-4 secretion was observed which correlated to decreased MUC5AC expression in the lungs. No demonstrable change in the frequencies of $Foxp3^+$ Tregs was observed. Infected mice showed a significant increase in cells expressing $CD11b^+/Gr1^+/Ly6C^{int}$. Using *in vitro* co-cultures we demonstrate that $CD11b^+/Gr1^+/Ly6C^{int}$ cells do not inhibit Th2 differentiation but destabilize Th2 phenotype by down-modulating GATA-3 expression.
Conclusions: We observed amelioration of airway inflammation in *Salmonella* infected mice. This suppression was Treg independent. No substantial shunt towards a Th1 phenotype was detected. We demonstrate expansion of $CD11b^+/Gr1^+/Ly6C^{int}$ cells upon *Salmonella* infection, which exert their suppressive function by influencing the Th2 stability. This could be a potential mechanism of protection from asthma.

P0809

Immunological reactions to the carbohydrate antigen alpha-Gal

D. Kollmann,* C. Ebner,† W. Emminger,‡ A. Mangold,§ H. J. Ankersmit§ & B. Bohle*

**Department of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria, †Allergy Clinic Reumannplatz, Allergy Clinic Reumannplatz, Vienna, Austria, ‡Allergy Clinic Rennweg, Allergy Clinic Rennweg, Vienna, Austria, §Department of Surgery, Medical University of Vienna, Vienna, Austria*

Purpose/Objective: Galα1-3Galβ1-4GlcNAc-R (alpha-Gal) is a carbohydrate expressed by non-primate mammalians. It is the main reason of hyperacute graft rejection in xenotransplantation. Recently, alpha-Gal has been described as an important allergenic structure in red meat allergy. Since the role of carbohydrates in allergy is still controversial, we sought to investigate the relevance of alpha-Gal in meat allergy and to identify proteins carrying the allergenic sugar.

Materials and methods: Twenty patients who had experienced generalized urticaria after consuming meat were included. All patients showed IgE-reactivity to beef or pork in ImmunoCAP. IgG and IgE antibodies specific for alpha-Gal were analysed by ELISA. Protein extracts were produced from beef and pork and used in immunoblots to test IgE-reactivity to individual meat proteins. Additionally, sera from 15 patients receiving a biological heart valve and 8 patients receiving mechanical prostheses obtained preoperatively, 10 days and 3 months postoperatively were analysed.

Results: All meat-allergic patients displayed alpha-Gal-specific IgG and 19/20 patients showed alpha-Gal-specific IgE. In immunoblots, 13/19 alpha-Gal sensitized patients showed IgE specific for a protein of approximately 160 kDa, equivalent to bovine gamma globulin (BGG). The same protein was detected to be glycosylated. In inhibition-ELISA, IgE-reactivity to BGG was completely abolished after pre-incubation with alpha-Gal. The majority of biovalve recipients displayed high levels of alpha-Gal-specific IgG which increased in 12/15 individuals 10 days post surgery. Five of these patients showed increased alpha-Gal-specific IgE levels already 10 days post surgery. None of the patients with mechanical bioprostheses showed a rise in alpha-Gal-specific antibodies.

Conclusions: Our data indicate that IgE-reactivity to alpha-Gal on BGG plays an important role in meat allergy. We currently investigate why the presence of high levels of alpha-Gal-specific IgG antibodies is incapable of blocking IgE-binding to the carbohydrate. The occurrence of alpha-Gal-specific IgE in biovalve recipients post surgery indicates, that sensitization to alpha-Gal can develop although alpha-Gal-specific IgG is present.

P0810

Immunomodulatory and bronchodilatory potential of *Allium cepa* L. and its flavonoid quercetin *in vitro*

T. T. Oliveira,* K. M. C. Dourado,* T. C. B. Carneiro,* M. S. S. Machado,* R. S. Costa,* E. S. Velozo,† L. C. Pontes de Carvalho,‡ D. F. S. A. Vasconcelos,* N. M. Alcântara Neves* & C. A. Figueiredo*

**Institute of Health Sciences, Biorregulation, Salvador Bahia, Brazil, †Faculty of Pharmacy, Pharmacy, Salvador Bahia, Brazil, ‡Gonçalo Moniz Research Institute, FIOCRUZ, Fiocruz, Salvador Bahia, Brazil*

Purpose/Objective: This study was conducted investigating the *in vitro* anti-inflammatory activity and bronchodilator potential of the methanolic extract of the *Allium cepa* L. *(AcE)* and its flavonoid quercetin (Qt) on the production of IL-4, IL-5 and IL-13 by spleen cell; production of nitric oxide on peritoneal macrophages cultures, and their bronchodilator potential on isolated trachea from mice.

Materials and methods: To this end, the allergic process was induced in A/J mice by the administration of *Blomia tropicalis* antigen. The animals were sensitized with 100 μg per animal − s.c. in 4 mg/ml of [AL $(OH)^3$] on days 0 and 7; after the last sensitization the animals received four intranasal challenged (10 μg per animal − i.n) with *Blomia tropicalis* (*BtE*) mite at intervals of one day. Spleen cells isolated from allergic animals were incubated with different concentrations of *AcE* and Qt, stimulated or not with pokeweed mitogen (PWM, 2.5 μg/ml); cultures were then incubated for 2 days and supernatants were collected for cytokine measurement. Peritoneal macrophages were isolated from normal mice and incubated with different concentrations of *AcE* and Qt for 1 h in the presence or not of LPS (concentration) for 24 h. After this period, the supernatants were collected and analyzed for nitrite by Griess reaction. The amount of nitrite in the sample was determined using a sodium nitrite standard curve. Additionally, trachea from non sensitized mice were sectioned into rings, and placed in tanks for isolated organ with Krebs-bicarbonate solution and aerated with a carbogen mixture (95%O_2 and 5% CO2). The rings were contracted with carbachol to evaluate the presence of functional epithelium, and after reaching a plateau of contractile state, the rings were stimulated with bradykinin. Cumulatively increasing concentrations of *AcE* or Qt were added. Concentration response curve was constructed and the data were analyzed.

Results: The production of inflammatory cytokines (IL-4, IL-5 and IL-13) and nitric oxide was significantly reduced by the treatment with different concentrations of *AcE* and Qt when compared with positive control. Also was observed a dilator effect of *AcE* and Qt on carbachol-induced contraction in isolated trachea.

Conclusions: The results obtained in this study suggest that *Allium cepa* L. and Qt have potential as anti-asmatic drugs by both immunomodulatory and bronchodilatory properties. The molecular mechanisms whereby*Allium cepa* L. and Qtact are under exploration by our group.

P0812

Induction of mucosal tolerance with structurally different antigens: studies on underlying mechanisms

J. Akgün, I. Schabussova, K. Hufnagl, C. Wild & U. Wiedermann

Institute of Specific Prophylaxis and Tropical Medicine, Medical University Vienna, Vienna, Austria

Purpose/Objective: In a mouse model of poly-sensitization, we have shown that intranasal administration of a linear synthetic hybrid, composed of immunodominant T-cell epitopes of the major birch and grass pollen allergens Bet v 1, Phl p 1 and Phl p 5, induced tolerance in mice sensitized with the 3 allergens. Tolerance induction was associated with reduced allergic inflammation and increased production of the regulatory cytokine IL-10 in the lungs. On the other hand, tolerance induction with the whole recombinant (*r*) Bet v 1 led to reduction of airway inflammation within the lung without the induction of IL-10 in the lung. Thus, we want to understand the mechanistic pathways of tolerance induction by these two structurally different antigens by investigation of their uptake and presentation by antigen presenting cells.

Materials and methods: In order to follow up their internalization, hybrid and rBet v 1 were conjugated with the fluorescence dye 5 (6)-Carboxyfluorescein (FAM). For *in vivo* studies, constructs were administered intranasally. After various time points (0, 1, 6, 24 and 48 h) the antigen uptake in the nasal-associated lymphoid tissue (NALT), lung, bronchial lymph nodes, spleen and blood was investigated by flow cytometry. Furthermore, FAM-hybrid and FAM-rBet v 1 were co-cultured with isolated murine mononuclear lung cells *in vitro* in a time dependent manner (0, ½, 1, 6 and 24 h) and cells capturing these antigens were identified and characterized.

Results: *In vivo*, both antigens were taken up by two main populations: CD11c(+) CD11b(+) macrophages and CD11c(+) CD11b(−) dendritic cells in the lung and NALT. Interestingly, more FAM-hybrid than FAM-rBet v 1 molecules were detected within the lung cells. None

of the investigated antigens have been detected in the spleen or in the blood. *In vitro*, macrophages, dendritic cells and additionally B cells were internalising the antigens, and B cells displayed the population with the highest antigen uptake capacity. With respect of the time kinetic these B cells internalised the FAM-hybrid about 6 h earlier than the FAM-rBet v 1.

Conclusions: *In vivo* and *in vitro* kinetic studies demonstrate that there are differences between the antigen uptake of the linear multipeptide (hybrid) and the conformational allergen (rBet v 1). Further studies on internalisation pathways are currently ongoing.

P0813

Inflammatory marker sTREM-1 reflects the clinical stage and respiratory tract obstruction in allergic asthma bronchiale patients and correlates with number of neutrophils

M. Buc,* M. Bucova,* M. Suchankova,* M. Dzurilla,* D. Kantarova,† H. Novosadova,‡ E. Tedlova,‡ S. Urban,‡ E. Hornakova,‡ M. Seligova,‡ V. Durmanova,* J. Javor* & E. Paulovicova§

**Department of Immunology, School of Medicine, Comenius University, Bratislava, Slovakia, †Internal Department, Jesenius School of Medicine, Comenius University Martin, Slovakia, ‡Department of Pneumology and Phthisiology, School of Medicine, Comenius University, Bratislava, Slovakia, §Slovak Academy of Science, Institute of Chemistry Centre of Excellence Glycomed, Bratislava, Slovakia*

Purpose/Objective: TREM-1 (Triggering receptor expressed on myeloid cells), is constitutively expressed on the surface of myeloid cells-neutrophils, monocytes and macrophages. The membrane form of TREM-1 can be cleaved from the surface of activated myelocytes and its soluble form (sTREM-1) is released into microenvironment. The highest levels of sTREM-1 have been found in patients with sepsis and other inflammatory diseases caused mainly by extracellular microorganisms as well as inflammatory states of non-infectious origin. The knowledge that asthma bronchiale is an inflammatory disorder has prompted us to investigate the plasma levels of new inflammatory marker sTREM-1 that is released from the surfaces of activated neutrophils and monocytes.

Materials and methods: The plasma levels of sTREM-1 were analysed by a sandwich Elisa test in the cohort of 76 patients with allergic asthma bronchiale and 39 healthy controls. Either Anova or Mann−Whitney *U*-test were used to determine the difference and the statistical significance. The association of sTREM-1 plasma levels with clinical stage of AB was evaluated by Kruskal Wallis test. For correlation analysis of non-parametric continuals and nominal variables the Spearmans' two-tailed test was used.

Results: Our results revealed more than 3.5 times higher levels of sTREM-1 in AB patients (92.3 pg/ml ± 125.6) compared with healthy subjects (25.7 pg/ml ± 9.2; $P = 0.0001$). Higher levels of sTREM-1were found also in patients with exacerbated AB (170.5 pg/ml ± 78.2) compared with non-exacerbated AB patients (59.1 ± 78.2; $P < 0.0001$), patients with respiratory tract obstruction (176.4 pg/ml ± 177.8) than those without obstruction (51.99 pg/ml ± 64.0; $P < 0.0001$) and patients with anti-IgE therapy ($P < 0.0001$). Levels of sTREM-1 correlated with number of leucocytes ($P = 0.002$), and absolute number of neutrophils ($P = 0.001$).

Conclusions: The levels of sTREM-1 in AB patients have not been studied yet, so we cannot compare our Results: . Plasma levels of sTREM-1 are highly elevated in severe forms of asthma, reflect the clinical stage of AB, state of exacerbation, respiratory tract obstruction and correlate with the number of leukocytes, mainly neutrophils. Our results highlight the potential usefulness of the assessment of the soluble form of TREM-1 in plasma of AB patients.

P0814

Inhibition of histamine H1 receptor activity modulates proinflammatory cytokine production of dendritic cells through c-Rel dependent pathway

J. L. Suen & C. L. Lee

Graduate Institute of Medicine, Kaohsiung Medical Universtiy, Kaohsiung, Taiwan

Purpose/Objective: Histamine displays diverse effects on immune regulation through four types of histamine receptors (HRs). Among them, type 1 receptor (H1R) plays an important role in allergic inflammation. Dendritic cells (DCs), which express at least three types of HRs, are professional antigen-presenting cells controlling the development of allergic inflammation. However, the molecular mechanisms involved in H1R-mediated NF-kB signaling of DCs remain poorly defined.

Materials and methods: Bone marrow-derived dendritic cells (BM-DCs) were treated with H1R inverse agonist ketotifen to interrupt the basal H1R-mediated signaling. The crosstalk of H1R-mediated signaling and NF-κB pathway was examined by NF-κB subunits analysis using Western blotting and TNF-α promoter activity using chromatin immunoprecipitation assay.

Results: The data showed that blockage of H1R signaling by ketotifen inhibited the proinflammatory cytokine TNF-α and IL-6 production of BM-DCs. H1R specific agonist was able to enhance the TNF-α production, but this overexpression was significantly inhibited by NF-κB inhibitor, suggesting crosstalk between H1R and NF-κB signaling in DCs. After comprehensive analysis of NF-κB subunits, c-Rel protein level was found to be significantly down-regulated in ketotifen-treated BM-DCs, which led to inhibition of the promoter activity of TNF-α.

Conclusions: Our results suggest that c-Rel controls H1R-mediated proinflammatory cytokine production in DCs. This study provides a potential mechanism of H1R-mediated signaling and NF-κB pathway crosstalk in allergic inflammation.

P0815

Inhibition of the co-stimulatory molecule OX40 significantly inhibits inflammation in the chronic house dust mite model of allergic airway inflammation

K. Burrows,* C. Dumont,† K. Dixon,* M. Catley,* D. Marshall* & S. Shaw*

**Pharmacology, UCB Pharma, Slough, UK, †Cellular Sciences, UCB Pharma, Slough, UK*

Purpose/Objective: Allergic asthma is a chronic inflammatory disease of the lungs that is punctuated by exacerbations caused by infection or exposure to allergens. Using a mouse model that mimics certain aspects of allergic asthma this study investigated how blocking OX40 would effect the recruitment of inflammatory cells to the lung.

Materials and methods: Male balb/c mice were treated with a murine OX40 targeting antibody twice weekly, via subcutaneous injection, from day 0 for 5 weeks. From day 0, mice were sensitized to house dust mite (HDM) extract via intranasal administration 4 times a week for 5 weeks.

At the end of week 5, the study was terminated. Blood was taken from the animals and serum prepared. Animals were cannulated and brochoalveolar lavage (BAL) fluid was collected. Lungs were removed and tissue digest carried out in order to release immune cells within the lung tissue. Inflammatory cell types in the BAL and lung tissue digests were determined using flow cytometry.

Results: Blockade of OX40 resulted in a significant decrease in the number of eosinophils, neutrophils and CD4+ T cells in both the BAL and lung tissue digest compared to vehicle treated animals.

Blocking OX40 significantly reduced the number of IFN-γ (Th1), IL-17A (Th17) and IL-4 (Th2) producing CD4+ T cells in both BAL and lung tissue digests.
Conclusions: Blocking OX40 significantly reduces the infiltration of numerous inflammatory cell types into the lungs of mice. It is also interesting that blocking OX40 has effects on Th17 and Th1 cells. This indicates that blocking OX40 may be beneficial in the treatment of allergic asthma.

P0816
Inhibitory effects of hydrogen sulfide on lung oxidative stress in allergic mice

H. H. A. Ferreira,* L. R. Benetti,* D. Campos,* S. A. Gurgueira,† A. E. Vercesi,† S. A. Teixeira,‡ J. Florenzano,‡ C. E. V. Guedes* & S. K. P. Costa‡
**Laboratory of Inflammation Research, São Francisco University, Bragança Paulista SP, Brazil, †Laboratory of Bioenergetics, State University of Campinas, Campinas SP, Brazil, ‡Department. of Pharmacology, University of Sao Paulo, São Paulo SP, Brazil*

Purpose/Objective: Recent studies show that endogenous hydrogen sulfide (H_2S) plays an anti-inflammatory role in the pathogenesis of airway inflammation. This study investigated whether exogenous H_2S may counteract oxidative stress-mediated lung damage in allergic mice.
Materials and methods: Female BALB/c mice previously sensitized with ovalbumin (OVA) were treated with sodium hydrosulfide (NaHS) 30 min before OVA challenge. Forty-Eight hours after antigen-challenge, the mice were killed and leukocyte counting as well as nitrite plus nitrate concentrations were determined in the bronchoalveolar lavage fluid, and lung tissue was analysed for nitric oxide synthase (NOS) activity, iNOS expression, superoxide dismutase (SOD), catalase, glutathione reductase (GR) and glutathione peroxidase (GPx) activities, thiobarbituric acid reactive species (TBARS) and 3-nitrotyrosine containing proteins (3-NT).
Results: Pre-treatment of OVA-sensitized mice with NaHS resulted in significant reduction of both eosinophil and neutrophil migration to the lungs, and prevented the elevation of iNOS expression and activity observed in the lungs from the untreated allergic mice, although it did not affect 3-NT. NaHS treatment also abolished the increased lipid peroxidation present in the allergic mouse lungs and increased SOD, GPx and GR enzyme activities.
Conclusions: These results show, for the first time, that the beneficial *in vivo* effects of the H_2S-donor NaHS on allergic airway inflammation involve its inhibitory action on leukocyte recruitment and the prevention of lung damage by increasing endogenous antioxidant defenses, thus making of H_2S donors a potential new class of therapeutical agents useful for treatment of lung diseases characterized by the presence of inflammatory cells and oxidant/antioxidant imbalance.

P0817
Intratracheal administration of Fab fragments of an antigen-specific monoclonal antibody suppresses asthmatic responses in mice

S. Yoshino, N. Mizutani, Y. Ammmori & H. Torii
Pharmacology, Kobe Pharmaceutical University, Kobe, Japan

Purpose/Objective: Fab fragments (Fabs) of antibodies maintain the ability to bind specific antigens but lack the binding site for complement (C) as well as the site for binding to receptors on effector cells including mast cells, basophils, and macrophages that play an important role in immune and allergic diseases. In the present study, we investigated whether intratracheal administration of Fabs of a monoclonal antibody (mAb) specific for ovalbumin (OVA) was able to suppress asthmatic responses in mice.
Materials and methods: Asthmatic responses were induced in Balb/c mice either by passive sensitization with anti-OVA pAbs or by active sensitization with OVA followed by intratracheal challenge with the antigen. Fabs prepared by the digestion of an anti-OVA IgG1 (O1−10) mAb with papain were intratracheally administered 30 min before the antigenic challenge. Normal IgG Fabs were used as a control.
Results: Intratracheal administration of O1−10 Fabs markedly suppressed the early and late phases of asthmatic responses caused by passive sensitization with anti-OVA pAbs as well as by active sensitization with OVA when the *in vivo* responses were measured by specific airway resistance (sRaw). Control Fabs failed to affect the asthmatic responses. The significantly reduced number of neutrophils in bronchoalveolar lavage fluids (BALF) as well as in the lung tissue was seen in mice treated with O1−10 FabsO1−10. Fabs were also effective in suppressing asthmatic responses induced by passive sensitization wtih anti-OVA IgE mAb (OE-1). In cotrast, intratracheal injection of intact O1−10 failed to suppress the asthmatic responses. The suppression of asthmatic responses by O1−10 Fabs was associated with significantly higher and lower levels of MMCP-1 and C3a, respectively. *In vitro* studies revealed that the capture of OVA by O1−10 Fabs resulted in prevention of the following binding of intact anti-OVA pAbs or OE-1 to the captured OVA.
Conclusions: Asthmatic responses appear to be downregulated by intratracheal administration of Fabs of an antigen-specific mAb via the mechanism of the formation of antigen and Fab complexes in the airway, resulting in the prevention of antigen and intact antibody binding essential for induction of asthmatic responses.

P0818
Isolation and characterisation of CD8 T cells with receptor specificity for house dust mite allergen, Der p 1

K. H. S. Wong, G. M. Grotenbreg & D. M. Kemeny
Department of Microbiology Yong Loo Lin, Immunology Programme, School of Medicine, National University of Singapore, Singapore, Singapore

Purpose/Objective: CD8 T cells have multiple functions in asthma. Tc2 CD8 T cells exacerbate airway inflammation through the secretion of type 2 cytokines, while the Tc1 CD8 T cells may inhibit type 2 airway inflammation and airway hyperresponsiveness via a number of different mechanisms such as the production of type 1 cytokines and perforin-mediated cytotoxicity. Therefore, there exists the potential to target CD8 T cells to for treatment of asthma and other allergic diseases. Our aim was to isolate CD8 T cells specific for the house dust mite protein, Der p 1, and to characterise the T cell receptor (TCR) of these allergen specific T cells.
Materials and methods: DNA vaccination was employed to generate a CD8 T cell response in C57BL/6 mice. Plasmid vector encoding a MHC I epitope from Der p 1 was delivered intradermally by skin tattoo and CD8 T cell responses measured by IFN-g ELISPOT and flow cytometry with MHC I tetramers. T cells isolated from immunized mice were cultured *in vitro* with the antigenic peptide and screened for antigen specificity using MHC I tetramers. TCR genes were identified using 5' RACE amplification.
Results: Following DNA vaccination, 1−1.5% of splenic CD8 T cells were shown to be specific for the Der p 1 epitope. Screening following 4 cycles of re-stimulation showed that 95% the CD8 T cells in the culture were Der p 1-specific. These CD8 T cells killed peptide pulsed EL4 cells and secreted IFN-g and TNF-a. 5' RACE amplification followed by sequencing of TCR genes showed that the cells were clonal with alpha (TRAV7-5*01F) and beta (TRBV5*01F) TCR chains.
Conclusions: We have generated a CD8 T cell response by DNA vaccination and characterized the TCR usage of allergen specific T cells

that recognize an epitope derived from the house dust mite protein, Der p 1. This will facilitate investigation into CD8 T cell regulation of asthma by allergen specific CD8 T cells and the development of a CD8 based vaccine for asthma.

P0819

Isolation, expression and characterization of IgE reactive-portions of high molecular weight glutenin like wheat food allergens

A. Baar,* S. Pahr,* C. Constantin,* S. Giavi,† N. Papadopoulos,† A. Pelkonen,‡ M. Mäkelä,‡ C. Ebner,§ A. Mari,¶ S. Vrtala* & R. Valenta*

**Department of Pathophysiology and Allergy Research, Center for Pathophysiology Infectiology and Immunology, Vienna, Austria, †Allergy and Immunology Research Center, University of Athens, Athens, Greece, ‡Skin and Allergy Hospital, Helsinki University Central Hospital, Helsinki, Finland, §Ambulatory for Allergy and Clinical Immunology, Ambulatory for Allergy and Clinical Immunology, Vienna, Austria, ¶Center for Molecular Allergology, IDI-IRCCS, Rom, Italy*

Purpose/Objective: Wheat can be grown in a wide climatic and geographic range and is one of the most consumed cereals worldwide but it is also an important allergen source. In allergic patients wheat ingestion can lead to urticaria, atopic dermatitis, and gastrointestinal symptoms and to anaphylaxis.

Materials and methods: We isolated IgE-reactive clones from a wheat seed cDNA library with sera from wheat food allergic patients. Two of these clones showed sequence identities with a gene coding for the High molecular weight glutenin x-type subunit Bx7 precursor (HMW Bx7). The IgE reactive sequences were cloned into the *E. coli* expression vectors pMal-c4x or pET17b and expressed as soluble hexaistidine- and maltose-binding-protein-tagged fusion proteins (m43, m82) comprising aa 344−618 and aa 600-795 of the complete protein and as hexahistidne-tagged recombinant protein (43). Dot blot analyses were performed with sera from wheat food allergic patients. Moreover, antibodies were raised against 43 to detect homologous proteins in other allergenic plant food.

Results: The two tested wheat food allergic populations exhibited a similar allergen recognition frequency, 15% of the Greek ($n = 26$) and 10% of the Finnish ($n = 60$) patients showed IgE reactivity to the allergen portions m43 and m82. We detected homologous proteins with the rabbit anti-43 antibodies in extracts from spelt, rye, barley and sunflower seeds. Additional, we found HMW Bx7- related proteins in roll, brown bread, rye bread and in gluten free bread extracts.

Conclusions: In summary, we expressed two IgE reactive parts of the novel wheat food allergen HMW Bx7 as soluble proteins in *E. coli* and showed that they are useful for *in-vitro* diagnostic tests to detect wheat food allergic patients.

P0820

Low levels of serum B-cell activating factor among humans with high IgE reactivity to the nematode *Ascaris*

A. Bornacelly, N. Acevedo & L. Caraballo

Institute for Immunological Research, Immunology, Cartagena, Colombia

Purpose/Objective: The gene *TNFSF13B* encoding the B-Cell Activating Factor (BAFF) is a putative candidate for resistance to *Ascaris* in the 13q33 locus. The polymorphism rs10508198 (G>C) is associated with specific IgE/IgG levels to *Ascaris* and the resistance marker (rABA-1), suggesting that genetic variation in *TNFSF13B* may affect antibody response to *Ascaris*. Mechanisms are unknown but effects are more noticeable in asthmatics. We aim to analyze the serum BAFF levels (sBAFF) among high and low IgE/IgG producers and according to the BAFF-R expression, genotype and asthma status

Materials and Methods: We analyzed 842 subjects (375 asthmatics/467 controls) from Cartagena (Colombia) exposed to *Ascaris*. sBAFF levels were measured by ELISA (R&D Systems). Speci?c IgE/IgG against *Ascaris* and rABA-1 were measured by ELISA. Surface expression of BAFF (CD257) and BAFFR (CD268) was evaluated on monocytes and B cells ($n = 83$) by flow cytometry (Cyan ADP; Dako). Statistical analyses were done on IBM SPSS v20 and GraphPad Prism.

Results: There was an inverse relationship between sBAFF levels and sIgE to *Ascaris*; individuals with high IgE to *Ascaris* had less sBAFF levels (Mean SD: 842 ± 320 versus 788 ± 306 pg/ml in high-IgE, $P = 0.029$). In addition, sBAFF levels were inversely correlated to the surface expression of BAFF-R on $CD19^+$ B cells ($r^2 = -0.53$, $P = 4 \times 10^{-5}$). sBAFF levels did not differ among low and high anti-*Ascaris* IgG producers. Mutant CC homozygotes had more specific IgE to *Ascaris* ($P = 0.03$); increased probability of high IgE levels to *Ascaris* >75th percentile (OR 2.67, 95%CI 1.15−6.18, $P = 0.02$) and less IgG to *Ascaris* ($P = 0.002$). However this polymorphism was not associated with sBAFF levels (Mean SD GG: 831 ± 307 versus CC: 818 ± 282 pg/ml $P = 0.53$). Its effect remains to be evaluated at the transcriptional level since BAFF was not detected in the surface of $CD14^+$ monocytes or B cells. There was no difference in sBAFF levels between asthmatics and controls

Conclusions: sBAFF levels are related to the levels of specific IgE to *Ascaris*, supporting the role of *TNFSF13B*as underlying gene for *Ascaris* susceptibility on the 13q33 locus. We hypothesize that individuals with high IgE to *Ascaris* may harbor variants decreasing gene expression or leading to a hypoactive isoform. Causative polymorphisms and mechanisms remain to be elucidated

M-cell specific targeting by neuraminidase-functionalized microparticles as a novel oral immunotherapy for food allergy

C. Schultz,* S. C. Diesner,† F. Roth-Walter,[3,4] T. Eiwegger,¶ A. Pollak,¶ Z. Szepfalusi,¶ I. Pali-Schöll,‡ E. Jensen-Jarolim,‡ F. Gabor & E. Untersmayr***

**Department of Pathophysiology and Allergy Research, Center of Pathophysiology Infectiology and Immunology, Medical University of Vienna, Vienna, Austria, †Department of Pathophysiology and Allergy Research, Center of Pathophysiology Infectiology and Immunology Medical University of Vienna, Vienna, Austria, ‡Department of Pediatrics and Adolescent Medicine, Center of Pathophysiology Infectiology and Immunology Medical University of Vienna, Vienna, Austria, §Department of Pathophysiology and Allergy Research, Center of Pathophysiology Infectiology and Immunology, Institute of the University of Veterinary Medicine Vienna, Medical University of Vienna Messerli Research Vienna, Austria, ¶Department of Pediatrics and Adolescent Medicine, Medical University of Vienna, Vienna, Austria, **Department of Pharmaceutical Technology and Biopharmaceutics, University of Vienna, Vienna, Austria*

Purpose/Objective: There is still no accepted causative treatment available for food allergic disorders. Recently, we demonstrated in a murine study that mucosal M-cell targeting with *Aleuria aurantia* lectin (AAL)-coated Poly (D, L-lactide-co-glycolide) (PLGA) microparticles (MPs) represents a promising oral treatment approach in IgE mediated allergy. Due to its structural similarities with AAL we aimed to analyze neuraminidase (NA) from *Vibrio cholerae* as a novel M-cell-specific functionalization substance and compared NA-, AAL- and wheat germ agglutinin (WGA)-coated, allergen-loaded MPs as a treatment option in food allergy.

Materials and methods: Targeting substances and the functionalized MPs were characterized and tested for their suitability for oral application by Caco2-ELISA, digestion experiments and in a human M-cell like co-culture model. Next, we analyzed the therapeutic

properties of the coated MPs *in vitro* by stimulation of naïve splenocytes and *in vivo* in a BALB/c food allergy model.
Results: NA-coated MPs revealed high binding specificity to α-L-Fucose and Monosialoganglioside 1 (GM1) in cellular ELISA as well as significant enhanced transepithelial transport when M-cells were present in the co-culture model. For investigation of immunogenicity of NA and NA-functionalized MPs we stimulated splenocytes from naïve mice. Cytokine evaluations revealed a significant increase of IL-10 and IFN-γ. Intraperitoneal injection of the food allergen ovalbumin (OVA) followed by two oral challenges induced a strong IgE-mediated, OVA-specific response. After 6 oral treatments either with uncoated or WGA-, AAL- or NA-functionalized OVA-loaded PLGA-MPs, murine immune responses were re-evaluated. Treatment with NA-coated MPs induced increased OVA-specific IgG2a and IgA, whereas IgE and IgG1 levels decreased. In intestinal lavages, we observed a significant reduction of total and OVA-specific IgA levels compared to all other groups. Furthermore, significantly elevated IL-10 and IFN-γ were measured when splenocytes from animals treated with NA-coated MPs were stimulated with OVA.
Conclusions: Based on these results we propose NA to have a beneficial immunomodulatory capacity. NA represents a promising PLGA-MP functionalization substance for treatment of type I food allergy.

P0823
Molecular and immunological characterization of Der p 18, a chitinase-like house dust mite allergen

Y. Resch,* K. Blatt,† U. Malkus,‡ I. Swoboda,§ S. Seiberler,* I. Mittermann,* F. Horak,¶ N. Novak, V. Krzyzanek,†† P. Valent,† R. Valenta* & S. Vrtala‡‡**
**Department of Pathophysiology and Allergy Research, Center for Pathophysiology Infectiology and Immunology, Vienna, Austria, †Division of Hematology and Hemostaseology, Department of Internal Medicine I, Medical University of Vienna, Vienna, Austria, ‡Institute of Medical Physics and Biophysics, University of Münster, Münster, Germany, §Section of Molecular Biotechnology, University of Applied Science, Vienna, Austria, ¶Allergy Centre, Vienna West, Vienna, Austria, **Department of Dermatology and Allergy, University of Bonn, Bonn, Germany, ††Academy of Sciences of the Czech Republic, Institute of Scientific Instruments of the ASCR, Brno, Czech Republic, ‡‡Christian Doppler Laboratory for the Development of Allergen Chips, Medical University of Vienna, Vienna, Austria*

Purpose/Objective: The house dust mite allergen Der p 18 belongs to the glycoside hydrolase family 18 chitinases, which can be found in viruses, bacteria, fungi, plants, animals and humans. It is a major allergen in HDM-allergic dogs but its relevance for house dust mite allergic patients has not been studied in detail.

This study aimed to further characterize this allergen on a molecular, structural and immunological level.
Materials and methods: Der p 18 was expressed in *E. coli*, purified to homogeneity and its secondary structure was analyzed by circular dichroism. Der p 18-specific IgG antibodies were produced in rabbits to localize the allergen in mites using immunogold electron microscopy and to search for cross-reactive allergens in other allergen sources (i.e. mites, crustacea, mollusca, insects). IgE reactivity of rDer p 18 was tested with sera from 278 HDM-allergic patients and its allergenic activity was analyzed in basophil degranulation experiments.
Results: Recombinant Der p 18 was expressed as a folded protein which shows cross-reactivity with Der f 18 from *D. farinae* but not with proteins from the other tested allergen sources. The allergen is present in the gut wall of the mites but in contrast to most of the important HDM allergens only to a very small extent in the fecal pellets. Der p 18 reacted with IgE from 6.25% of mite allergic patients from Central Europe, however, the IgE reactivity was considerably higher in HDM-allergic patients suffering from atopic dermatitis (20%). rDer p 18 induced a dose-dependent upregulation of CD203c on basophils from Der p 18-positive patients.
Conclusions: Der p 18 is a genus-specific allergen, which seems to be important for patients with severe disease manifestations (e.g. atopic dermatitis).

P0824
Monitoring of regulatory T cells in children with allergy before and one year after sublingual specific immunotherapy (SLIT) by flow cytometry: preliminary study

A. Stelmaszczyk-Emmel,* A. Zawadzka-Krajewska† & U. Demkow*
**Department of Laboratory Diagnostics and Clinical Immunology of Developmental Age, Medical University of Warsaw, Warsaw, Poland, †Department Pediatrics Pneumonology and Allergology, Medical University of Warsaw, Warsaw, Poland*

Purpose/Objective: Allergen specific immunotherapy (ASIT) is being used for 100 years and is so far the only specific treatment of pollen/dust allergies. In spite of that, objective laboratory test to monitor the results of ASIT is not available yet. Recently different studies started to highlight the link between regulatory T cells (Tregs) and the outcome of immunotherapy. Some authors demonstrated that upregulation in Tregs may be considered as response-related biomarker for ASIT. The aim of the study was to test the frequency of $CD4^+$ $CD25^{high}$-$FoxP3^+$ $CD127^-$ regulatory T cells in patients with allergy before and one year after SLIT.
Materials and methods: The study involved 30 children with pollen allergy. All patients had characteristic symptoms of asthma, allergic rhinitis and allergic conjunctivitis. PBMCs were stained with monoclonal antibodies (anti-CD25 PE-Cy7, clone M-A251; anti-CD4 PE-Cy5; anti-CD127 PE and anti-FoxP3 Alexa Fluor 488, clone 259/D, Becton Dickinson). The samples were evaluated using flow cytometer Beckman Coulter FC500.
Results: Tregs in peripheral blood were identified as $CD4^+$ $CD25^{high}$-$FoxP3^+$ $CD127^-$ T cells. The number of Tregs is expressed as a percentage of all CD4+ T cells. The percentages of Tregs in both groups of patients (before $n = 25$ and after one year of SLIT $n = 17$) were similar (median 2.21; 2.81, respectively). Twelve patients were analyzed at both time points. Seven patients showed increase of Tregs after treatment and in case of 4 patients Tregs were lower. This results also did not differed significantly (before $n = 12$ median 2.67; one year after treatment $n = 12$ median 2.91).
Conclusions: This preliminary study did not demonstrate that natural Tregs can serve as potential biomarker of effectiveness of SLIT. But definitive conclusions should be drawn after enlargement of study population.

P0825
Naive and memory T cell response to Der p 1 allergen presented by dendritic cells in the presence of by *M. bovis* BCG bacilli in allergic asthma

M. Kowalewicz-Kulbat,* J. Staszek,* P. Szpakowski,* S. Kosinski,† M. L. Kowalski,† F. Biet‡ & J. Pestel§
**Department of Immunology and Infectious Biology, University of Lodz, Lodz, Poland, †Department of Clinical Immunology and Microbiology, Medical University of Lodz, Lodz, Poland, ‡INRA Centre de Tours, UR 918, Nouzilly, France, §Universite des Sciences et Technique de Lille, UMR 8576, Lille, France*

Purpose/Objective: Dendritic cells (DC) are crucial in the regulation of Th1/Th2 polarization. Allergy is caused by an excessive development of Th2 profile in immune response to environmental allergens. Many

asthmatic patients develop allergy to Der p 1-major allergen of *Dermatophagoides pteronyssinus* house dust mite. Mycobacteria as strong Th1 inducers are potent candidates to diminish the harmful Th2 profile in allergic disorders.

We asked a question whether in the presence of Der p 1, *Mycobacterium bovis* BCG vaccine and a recombinant BCG producing human IL-18 (rBCGhIL-18) were able to polarize Th2 towards Th1 lymphocyte response of naïve and memory T cells.

Materials and methods: Monocyte-derived dendritic cells (MoDC) were prepared from asthmatic patients who responded to Der p 1 in skin prick test and healthy BCG vaccinated donors. MoDC were stimulated for 24 h with Der p 1 in presence/absence of *M. bovis* BCG or rBCG-IL-18 bacilli. The response of naïve and memory T cells to pulsed MoDC was evaluated by determining the IFN-gamma and IL-5 production by ELISA test.

Results: In response to Der p 1-pulsed MoDC, autologous naïve and memory T cells from allergic patients produced IL-5 significantly more frequently and more intensively as compared with T cells from healthy donors. However, in the group of allergic patient's memory T cells, in response to Der p 1-MoDC released significantly more intensively IL-5 than naïve T cells. BCG and rBCG-hIL-18 bacilli in the presence of Der p 1 presented by MoDC decreased the IL-5 production neither by naïve nor memory T cells.

In contrast to healthy donors, naïve T cells from allergic patients, in response to Der p 1-stimulated MoDC produced significantly more intensively IFN-gamma than identically stimulated memory T cells. Interestingly, BCG and rBCGhIL-18 in the presence of Derp 1 significantly enhanced the intensity of IFN-gamma production by naïve and memory T cells in the group of allergic patients and healthy donors.

Conclusions: The BCG vaccine as well as rBCGhIL-18 was shown to display *in vitro* the ability to induce IFN-gamma production by naïve and memory T cells without the significant IL-5 supression. Thus the potential immunomodulatory role of BCG in allergic asthma seems to be more essential for Th1 enhancement than Th2 supression.

Participation of c-Jun N-terminal Kinase 2 (JNK2) in the induction of ovalbumin-induced bronchial asthma

J. Mizuguchi & M. Furuhata
Department of Immunology, Tokyo Medical University, Tokyo, Japan

Purpose/Objective: Bronchial asthma is a chronic inflammatory airway disease characterized by airway hypersensitivity (AHR), inflammatory cell infiltration into the airways including T-helper 2 (Th2) cells, eosinophils, and macrophages. Th2 responses are regulated by several factors including GATA3 and mitogen-activated protein kinases (MAPKs). cJun N-terminal kinase (JNK)2, a member of MAPKs, plays a crucial role in the induction of cell proliferation, apoptosis, and inflammation. In the present study, we examined whether JNK2 is involved in the induction of ovalbumin (OVA)-induced bronchial asthma using JNK2-deficient mice.

Materials and methods: C57BL/6J wild type (WT) and JNK2-deficient mice were sensitized with OVA in PBS intraperitoneally, followed by intranasal administration of OVA. T and B cells from WT or JNK2-deficient mice cells were transferred into Rag2-deficinet mice and immunized with OVA, followed by intranasal administration of OVA. Mice were assayed for AHR, histological section, cytokine levels in bronchoalveolar lavage (BAL) fluid, and antibody production 24 h after the last OVA administration.

Results: JNK2-deficient mice displayed reduced OVA-induced AHR, IgG1 and IgE antibody responses, and airway inflammatory lesion compared with WT mice. Cytokine levels including IL-4, IL-10, and IFN-γ in BAL fluid were also reduced in JNK2-deficient mice relative to WT mice. Transfer of JNK2-deficient T or B cells together with WT B or T cells into Rag2-deficinet mice resulted in diminished inflammatory responses compared with WT T cells plus WT B cells, suggesting that both T and B cells from JNK2-deficient mice are implicated in the pathogenesis of OVA-induced bronchial asthma.

Conclusions: JNK2 activation is involved in the induction of OVA-induced bronchial asthma, probably through participation of both T and B cells.

P0828

Persistence of allergen-specific IgE responses in patients suffering from AIDS

K. Marth,* E. Wollmann,* D. Gallerano,* R. Valenta* & E. Sibanda†
**Department of Pathophysiology, Center for Pathophysiology Infectiology and Immunology, Vienna, Austria, †Asthma Allergy & Immune Dysfunction Clinic, Asthma Allergy & Immune Dysfunction Clinic, Harare, Zimbabwe*

Purpose/Objective: The infection of CD4+ cells by HIV leads to the progressive destruction of CD4+ T lymphocytes and, after massive reduction of CD4+ cells, to AIDS. To study if HIV-infected patients suffering from AIDS with a severe reduction of CD4+ cells can suffer from symptoms of IgE-mediated allergy and produce allergen-specific IgE antibody.

Materials and methods: In total 69 HIV-infected allergic patients from Zimbabwe were studied. Among these patients, 27 had CD4 counts below 200. Allergy was diagnozed according to case history, physical examination and skin prick testing. Serological analysis of allergen-specific IgE antibodies was performed with an allergen chip, containing 163 purified allergen molecules or with the MAST-CLA® assay, containing a panel of 36 allergen extracts. IgE antibody levels specific for seasonal allergens (Art v 1, Art v 3, Bet v 1, Cup a 1, Cyn d1, Ole e1, Phl p 1) were quantified with ImmunoCAP measurements when follow-up sera obtained at different time points were available. HIV infection was confirmed serologically and the disease was staged clinically. Determination of CD4+ and CD8+T lymphocyte subset numbers were performed by flow cytometry.

Results: The predominant allergic symptoms of HIV-infected patients were IgE-mediated symptoms such as allergic rhinoconjunctivitis and urticaria whereas T cell mediated symptoms (e.g. atopic dermatitis) ceased in patients with very low CD4 counts. In accordance to the clinical symptoms IgE responses specific for house dust mite, grass pollen and moulds were most frequent. ImmunoCAP measurements of IgE levels specific for seasonal allergens indicated that even patients with CD4 counts <200 exhibited boosts of IgE production.

Conclusions: Our results indicate that allergen-specific IgE production and immediate IgE-mediated allergic inflammation do not require a fully functional CD4+ T lymphocyte repertoire.

P0829

Pneumococcal pneumonia suppresses allergy development but preserves respiratory tolerance in mice

C. Hartmann,* A. K. Behrendt,* S. Henken,† F. Wölbeling,* U. A. Maus† & G. Hansen*
**Pediatric Pneumology Allergology and Neonatology, Hannover Medical School, Hannover, Germany, †Experimental Pneumology, Hannover Medical School, Hannover, Germany*

Purpose/Objective: Neonatal colonization with *Streptococcus pneumoniae* (*S. pneumoniae*) is associated with an increased risk for recurrent wheeze and asthma, whereas killed *S. pneumoniae* showed some potential as an effective immunomodulatory therapy.

Materials and methods: We investigated the impact of lung infection with *S. pneumoniae* on the development and maintenance of allergic airway inflammation and respiratory tolerance in mice. BALB/c mice were infected intratracheally with *S. pneumoniae* either before or after tolerance or allergy inducing protocols using ovalbumin (OVA) as model allergen were initiated.
Results: Infection of mice with *S. pneumoniae* prior to sensitization suppressed the development of an allergic phenotype as judged by reduced eosinophils in bronchoalveolar lavage fluids and decreased IgE serum levels and Th2 cytokines, relative to non-infected allergic control mice. In contrast, infection of mice after manifestation of allergic airway inflammation combined with late mucosal re-challenge did not affect the allergic response. Moreover, induction and maintenance of respiratory tolerance to OVA challenge were not altered in *S. pneumoniae*-infected mice, demonstrating that mice remained tolerant to the model allergen and protected from the development of allergic airway inflammation regardless of the time point of infection.
Conclusions: Our results suggest that both, respiratory tolerance induction and maintenance resist an infection with *S. pneumoniae* in mice whereas early bacterial infection might decrease the manifestation of an allergic phenotype.

P0832

Prediction of the development of IgG enhancing allergen-specific IgE binding during birch pollen immunotherapy

R. Selb,* J. Eckl-Dorna,* S. Vrtala,† V. Niederberger* & R. Valenta†
**Otorhinolaryngology, Medical University Vienna, Vienna, Austria, †Pathophysiology Infectiology and Immunology, Medical University Vienna, Vienna, Austria*

Purpose/Objective: Allergen-specific immunotherapy (SIT), the administration of the disease-causing allergens, is a clinically effective treatment for IgE-mediated allergy. Besides reducing symptoms SIT also affects the course of the disease and has long-lasting effects. One major mechanism of SIT is the induction of allergen-specific IgG antibodies which block IgE recognition of allergens and thus IgE-mediated pathomechanisms. In the case of birch pollen allergy the occurrence of IgG antibodies which can enhance IgE recognition of the major birch pollen allergen, Bet v 1, presumably by a change of the conformation of the Bet v 1 allergen, has been reported.
Materials and methods: Here, we used Bet v 1-specific IgG antibodies induced by immunization of rabbits to study their effect on the binding of birch pollen allergic patients ($n = 18$) IgE to Bet v 1 before Bet v 1-specific SIT. Then we analyzed if the extent of blocking or enhancement of these IgG antibodies on patient's IgE binding to Bet v 1 is associated with alterations of cutaneous sensitivity to Bet v 1 after SIT.
Results: In 16 of the18 patients the inhibition of patients IgE binding to Bet v 1 by the Bet v 1-specific rabbit IgG antibodies was associated with a reduction of cutaneous reactivity to Bet v 1. Interestingly, in two patients who showed no reduction or even an enhancement of skin sensitivity, rabbit anti-Bet v 1 IgG had enhanced patients IgE binding to Bet v 1 in the ELISA test.
Conclusions: Our data thus provide evidence for the development of unfavourable allergen-specific IgE-enhancing IgG antibodies during SIT and indicate that it may be possible predict such responses by serological tests.

Reactive oxygen species generated by NAD(P)H oxidases in ragweed subpollen particles activate human dendritic cells

K. Pazmandi,* B. V. Kumar,* K. Szabo,* I. Boldogh,† A. Szoor,‡ G. Y. Vereb,‡ E. Rajnavolgyi* & A. Bacsi*
**Department of Immunology, Medical and Health Science Center, University of Debrecen, Debrecen, Hungary, †Department of Microbiology and Immunology, University of Texas Medical Branch, Galveston, TX, USA, ‡Department of Biophysics and Cell Biology, Medical and Health Science Center, University of Debrecen, Debrecen, Hungary*

Purpose/Objective: It has previously been reported that ragweed (*Ambrosia artemisiifolia*) pollen grains release subpollen particles (SPPs) of respirable size upon hydration. These SPPs contain allergenic proteins and functional NAD(P)H oxidases. In this study we have examined whether exposure to SPPs induces the activation of dendritic cells.
Materials and methods: To test this assumption, human monocyte-derived dendritic cells (moDCs) were treated with ragweed SPPs and the phenotypic and functional changes in the cells were analysed.
Results: We found that treatment with freshly isolated ragweed SPPs increased the intracellular levels of reactive oxygen species in moDCs. Phagocytosis of SPPs by moDCs, as demonstrated by confocal laser-scanning microscopy, led to an up-regulation of the cell surface expression of CD40, CD80, CD86, and HLA-DQ and an increase in the production of IL-6, TNF-alpha, IL-8, and IL-10. Furthermore, SPP-treated moDCs had an increased capacity to stimulate the proliferation of naïve T cells. Co-culture of SPP-treated moDCs with allogeneic $CD3^+$ pan-T cells resulted in increased secretion of IFN-gamma and IL-17 by T cells of both allergic and non-allergic subjects, but induced the production of IL-4 exclusively from the T cells of allergic individuals. Addition of exogenous NADPH further increased, while heat-inactivation or pre-treatment with diphenyleneiodinium, an inhibitor of NADPH oxidases, strongly diminished, the ability of SPPs to induce phenotypic and functional changes in moDCs, indicating that these processes were mediated, at least partly, by the intrinsic NAD(P)H oxidase activity of SPPs.
Conclusions: Collectively, our data suggest that inhaled ragweed SPPs are fully capable of activating dendritic cells in the airways and initiating both innate and adaptive immune responses.

P0837

Recognition of Phl p 5 B-cell epitope mimic H32 in patients from an Italian allergy clinic

A. Lukschal,* J. Wallmann,* A. Mari,† P. Palazzo,† M. Liso,† C. Harwanegg,‡ M. Mittlböck,§ K. Szalai,¶ I. Pali-Schöll¶ & E. Jensen-Jarolim¶
**Division of Comparative Immunology and Oncology, Institute for Pathophysiology and Allergy, Research Center for Pathophysiology Infectiology and Immunology, Vienna, Austria, †Center for Molecular Allergology, IDI-IRCCS, Rome, Italy, ‡Phadia Multiplexing Diagnostics, Vienna, Austria, §Section for Clinical Biometrics CeMSIIS, Medical University of Vienna, Vienna, Austria, ¶Institute of Pathophysiology and Allergy Research Center for Pathophysiology Infectiology and Immunology Medical University of Vienna, and Messerli Research Institute of Universtity of Veterinary Medicine Vienna Medi, Vienna, Austria*

Purpose/Objective: Sensitization to grass pollen is extremely common in patients suffering from respiratory allergy. Most of them show IgE reactivity to highly cross-reactive group 5 allergens like Phl p 5. We recently could show that a single epitope mimic of Phl p 5, named H32 had profound anti-inflammatory effects in an asthma therapy model in mice.

The aim of the present study was to investigate the prevalence of specific recognition of this mimotope (representing single IgE epitope)

in a representative population, in order to predict its potential impact for immunotherapy of grass pollen allergic patients.
Materials and methods: Mimotope H32 was spotted on an experimental version of the ISAC®-microarray2. Subjects (n = 992) visiting an allergy outpatient clinic in Rome were screened for IgE reactivity using this experimental ISAC. Of these patients 678 were also tested for specific IgG4 to Phl p 5 and/or H32 using the same microarray.
Results: In our study population 28% of patients harbored specific IgE to Phl p 5, whereas 11% reacted to the H32 mimotope. Of the 678 patients that were also screened for specific IgG4 against allergen and mimotope, 45.87% showed IgG4 reactivity to Phl p 5 and 28% towards H32 with low but significant correlation (P = 0.0007).
Conclusions: Although our cohort was biased by the selection criteria (visiting an outpatient allergy clinic), the Phl p 5-IgE-epitope mimicked by mimotope H32 obviously represents an important part of the IgG4 antigenicity of major grass pollen allergen Phl p 5. It may therefore be considered for further investigation into novel therapy strategies of asthma of Phl p 5-allergic patients.

Supported by grants SFB F01808-B13 and F4606-B19 of the Austrian Science Fund, Nano-Health 819721 of the Austrian Research Agency, and Italian Ministry of Health Current Research Program 2008–2010.

Redox-sensitive signaling pathway is upregulated in response to contact sensitizer in human derived monocyte cell

Y. K. Lee, Y. N. Yum, C. H. Lim, J. H. Kim, J. Y. Yang, S. Y. Han & K. H. Choi
Toxicological Evaluation and Research Department, National Institute of Food and Drug Safety Evaluation KFDA, Cheonwon-gun, Korea

Purpose/Objective: Allergic contact dermatitis (ACD) is a major cause of occupational skin disease that is caused by delayed-type hypersensitivity responses to antigens (skin sensitizer). A various cells in both skin and immune organs are related to induce ACD. Among them, dendritic cells (DCs) are palying a key role in ACD. But, it is not clear how skin sensitizers induce the activation of DCs. A several studies suggested that Keap1/Nrf2 pathway is involved in DCs activation. Thus, we assessed the activation of Keap1/Nrf2 pathway in U937 cells to skin sensitizers.
Materials and methods: U937 was purchased from ATCC, and was cultured in RPMI1640 supplemented with 10% heat-inactivated fetal bovine serum and 1% penicillin/streptomycine. Cells were seeded into a 24 well plate (1×10^6 cells/ml). After 24 h, cells were treated at different concentrations. After 24 h incubation with chemicals, cells were cheacked the expression of Nrf2.
Results: Keap1/Nrf2 pathway known to redox-sensitive is affected by redox potential through various mechanisms including direct protein modification, alteration of protein expression, phosphorylation status and transcriptional activity. And Keap1/Nrf2 pathway is a cellular signaling pathway for the detection of endogenous or exogenous electrophiles and is implicated in the regulated response of the cell to pro-oxidant and eletrophilic aggregations. It is suggested that Nrf2 pathway is activated by skin sensitizer in peripheral blood-derived DC, MCF-7 cell or human monocytic cells. Expression of Nrf2 was increased by skin sensitizers in U937 cells.
Conclusions: Our results supported that the Keap1/Nrf2 pathway is activated by skin sensitizer. In addition this study showed that activation of Keap1/Nrf2 pathway is involved in DCs activation.

Reduced B cell IL-10 in response to LPS in Allergic Asthma patients: an impaired Breg function?

L. E. P. M. van der Vlugt,* E. Mlejnek,* A. Ozir-Fazalalikhan,* T. R. Dijksman,* L. A. Labuda,* R. Schot,† P. S. Hiemstra,† G. M. Möller,† M. Yazdanbakhsh* & H. H. Smits*
**Parasitology, Leiden University Medical Center, Leiden, The Netherlands, †Pulmonology, Leiden University Medical Center, Leiden, The Netherlands*

Purpose/Objective: Allergic asthma is characterized by inflammatory responses against allergens. Murine studies have indicated that IL-10 producing B cells can potently reduce allergic and auto-immune inflammation. Several human regulatory B (Breg) cell subsets have been described with an impaired function in auto-immunity. Those include $CD1d^{hi}$, $CD24^{hi}CD38^{hi}$ and $CD24^{hi}CD27^{+}$ B cells. Here, we aim to study the frequency and function of IL-10 producing B cells in allergic asthma (AA) patients.
Materials and methods: We collected PBMCs from 13 AA patients and sex/age-matched healthy control (HC) subjects. Isolated peripheral B cells were analyzed for the expression of different regulatory B cells markers and, additionally, activated through the B cells receptor or by LPS, followed by a co-culture with endogenous $CD4^{+}$ T cells and Derp1.
Results: B cell phenotype analysis showed equal numbers of $CD1d^{hi}$ B cells, while $CD24^{hi}CD38^{hi}$ B cells were increased and $CD24^{hi}CD27^{+}$ B cells were decreased in AA patients. Subsequently, LPS, but not anti-IgG/anti-IgM stimulation, resulted in less intracellular IL-10 in B cells from AA patients. Subset analysis showed that the reduced intracellular IL-10 in AA patients was only present in $CD24^{hi}CD27^{+}$ B cells, but not in the other two Breg-related subsets. Next, co-cultures of LPS-primed B cells and memory $CD4^{+}$ T cells resulted in more $IL\text{-}10^{+}$ T cells in conditions of HC subjects compared to AA patients, which dependent on the presence of IL-10.
Conclusions: Altogether, this data indicate that $CD24^{hi}CD27^{+}$ B cells from AA patients are lower in number and produce less IL-10 in response LPS, resulting in less $IL\text{-}10^{+}$ T cells. These data suggest that a deficiency in IL-10 producing Breg cells may contribute to allergic asthma.

Role of B-lymphocytes in chemical-induced asthma

V. De Vooght,* V. Carlier,† S. Haenen,* F. Devos,* B. Nemery,* P. H. M. Hoet* & J. A. J. Vanoirbeek*
**Occupational Environmental and Insurance Medicine, Katholieke Universiteit Leuven, Leuven, Belgium, †Center for Molecular and Vascular Biology, Katholieke Universiteit Leuven, Leuven, Belgium*

Purpose/Objective: The role of B-lymphocytes in chemical-induced asthma is largely unknown. We used a mouse model of chemical-induced asthma and transferred B-lymphocytes from sensitized animals into naïve wild type mice, B-KO mice or SCID mice.
Materials and methods: On days 1 and 8, BALB/c mice were dermally sensitized with 0.3% toluene-2,4-diisocyanate (TDI) on both ears. On day 15, mice were sacrificed and the auricular lymph nodes isolated. B-cells (CD19+) were separated from the whole cell suspension and 175 000 cells were injected in the tail vein of naïve wild type, B-KO or SCID mice. Three days later, the mice received a single oropharyngeal challenge with 0.01% TDI or vehicle (acetone/olive oil) (controls). Airway reactivity to methacholine and total and differential cell counts in the BAL were measured 24 h after challenge. B-cells were characterized for the expression of surface markers and production of cytokines and were labeled with SNARF-1 for tracking.
Results: Wild type mice receiving B-cells from TDI-sensitized mice showed a 3-fold increase in methacholine reactivity and an 8-fold

increase in BAL neutrophils after challenge with TDI, compared to those challenged with vehicle. B-KO mice showed these responses only after transfer of B-cells from TDI-sensitized BALB/c mice. Similarly, transferring B-cells from TDI-sensitized mice in SCID mice also led to a significant increase in methacholine reactivity as well as airway inflammation upon TDI challenge. B-cells of TDI-sensitized mice expressed higher amounts of different surface markers and co-stimulatory molecules and were able to produce significant amounts of cytokines. The transferred B-cells could be visualized in cryosections of the lung.

Conclusions: We were able to passively sensitize naïve mice with B-lymphocytes from TDI-sensitized mice. These mice showed within 3 days an 'asthmatic' response upon challenge with TDI. The response in SCID mice leads to the hypothesis that B-lymphocytes can act without T-cells. The B-lymphocytes were able to generate a mixed B-effector (Be) 1-Be2 response.

Serum thymic stromal lymphopoietin is a candidate for biomarker of seasonal allergic rhinitis

T. Yamada, H. Yamamoto, S. Kubo, K. Ogi, M. Kanno, M. Sakashita & S. Fujieda

Division of Otorhinolaryngology Head and Neck Surgery, Faculty of Medical Science University of Fukui, Fukui, Japan

Purpose/Objective: Thymic stromal lymphopoietin (TSLP) is an IL-7-related cytokine enhanced under asthma-like conditions, conditioning antigen-presenting cells to orientate the differentiation of T cells towards a Th2 profile, and has been linked to allergic diseases. The present study investigated the relationship between serum TSLP levels and severity of seasonal allergic rhinitis.

Materials and methods: We conducted a randomized, double-blind, placebo-controlled study to determine whether orally administered olopatadine for prophylactic purposes might also be effective for the control of nasal allergy symptoms and serum cytokines in patients with seasonal allergic rhinitis. Amounts of serum TSLP in the patients were measured with a TSLP kit that was purchased from Peprotech. A total of 110 patients with seasonal allergic rhinitis caused by Japanese cedar pollen were randomized to the treatment. The subjects recorded their nasal allergic symptom scores was assessed by the Japanese version of the Rhinoconjunctivity Quality of Life Questionnaire.

Results: Treatment with oral olopatadine significantly suppressed sneezing, rhinorrhea, and nasal congestion. The serum TSLP levels during the peak Japanese cedar pollen season were lower in the olopatadine group than in the placebo group ($P < 0.0005$). The serum TSLP levels in the patients during the peak season were significantly correlated with disease severity (total nasal symptom scores) ($P < 0.005$).

Conclusions: These results suggest that TSLP plays a contributory role in the pathogenesis of seasonal allergic rhinitis and the serum level of TSLP is a candidate of biomarker in seasonal allergic rhinitis.

P0845

Structural basis for the enzymatic activity of the major pollen allergen Phl p 4

D. Zafred,* A. Nandy,† S. Wallner,‡ P. Macheroux‡ & W. Keller*

**Structural Biology, Institute of Molecular Biosciences, Graz, Austria, †Research and Development Division, Allergopharma Joachim Ganzer KG, Reinbek, Germany, ‡Institute of Bochemistry, Technical University of Graz, Graz, Austria*

Purpose/Objective: Phl p 4 is one of the major pollen allergens from the timothy grass (*Phleum pratense*) and thus cause of hay fever and other diseases related to pollen allergy. Structural and immunological characterization of the allergen has been conducted to the extent which enables prediction of the major epitopes and a rational design of hypoallergenic derivatives.

However, nothing is known about the enzymatic activity of the allergen and its connection to the allergenicity. Group 4 grass pollen allergens are the only known allergens with the oxidoreductase activity and possess a bicovalently attached FAD. Connection of enzymatic activity and allergenicity of some proteins was shown; most prominent among them are proteases.

Materials and methods: Recombinant allergens are being expressed in the *P. pastoris* expression system. Macromolecular crystallography followed by the X-ray diffraction has been used for the structure determination. Enzymatic assays based on colorgenic substrates and thermofluor experiments have been used for the enzymatic characterization and search for natural substrates. Further experiments with the stopped-flow methods will be used for revealing the redox potential of the FAD. In addition, point mutations are being introduced in order to reveal the role of the key side chains involved in the processes in the active site.

Results: We have revealed that the Phl p 4 catalyses oxidation of glucose, maltose and lactose in presence of an artificial electron acceptor (DCPIP). We have proven that the protein does not react with molecular oxygen, showing that it is a dehydrogenase. We have successfully solved its structure and based on the structural observations prepared active site mutants. Recently these have been successfully expressed in a small scale.

Conclusions: Large scale expression is on the way to produce enough protein for a search for natural substrates. Only after the thorough characterization of its catalytic properties the connection of allergenicity and catalytic properties can be proven or rejected. The active site mutations are planned to bring novel catalytic properties to the protein. If successful, we will prove a principle that far exceeds the interest of only the immunological scientific community.

Studies on allergic sensitization in the Lithuanian birth cohort

A. Zvirbliene,* I. Sezaite,* O. Rudzeviciene,† I. Butiene,† M. Petronyte,† D. Vaicekauskaite† & R. Dubakiene†

**Dept of Immunology and Cell Biology, Vilnius University Institute of Biotechnology, Vilnius, Lithuania, †Faculty of Medicine, Vilnius University, Vilnius, Lithuania*

Purpose/Objective: Cohort studies are of great importance in defining the mechanism responsible for the development of allergy-associated diseases, such as atopic dermatitis, allergic asthma and allergic rhinoconjunctivitis. Although these disorders share genetic and environmental risk factors, it is still under debate whether they are linked or develop sequentially along an atopic pathway. The current study was aimed to determine the pattern of allergic sensitization in the Lithuanian birth cohort ãAlergemol' ($n = 1558$) established as a part of the multi-center European birth cohort ãEuroPrevall'.

Materials and methods: The sensitization pattern in response to different food allergens in the group of infants with food allergy symptoms was studied using allergological methods *in vivo* and *in vitro*. The impact of maternal and environmental risk factors on the early development of food allergy at 6 and 12 months of age was evaluated.

Results: The analysis revealed 1.3% and 2.8% of symptomatic-sensitized subjects at 6 and 12 months of age, respectively. Our study showed that maternal diet, diseases, the use of antibiotics and tobacco smoke during pregnancy had no significant impact on the early sensitization to food allergens. However, infants of atopic mothers were significantly more often sensitized to egg as compared to the infants of non-atopic mothers.

Conclusions: The rate of food sensitization in early age in the Lithuanian birth cohort was different from that reported for other European cohorts.

P0848

The effect of ligand-binding on structure, stability and biological activity of Bet v 1

C. Asam,* A. L. Batista,† A. Moraes,† V. S. De-Paula,† F. C. L. Almeida,† P. Briza,‡ B. Bohle,§ F. Ferreira,* A. P. Valente† & M. Wallner*

**Christian Doppler Laboratory for Allergy Diagnosis and Therapy/ Molecular Biology, University of Salzburg, Salzburg, Austria, †Centro Nacional de Ressonância Magnética Nuclear de Macromoléculas/Instituto de Bioquímica Médica, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, ‡Department of Molecular Biology, University of Salzburg, Salzburg, Austria, §Department of Pathophysiology Christian Doppler Laboratory for Immunomodulation, Medical University of Vienna, Vienna, Austria*

Purpose/Objective: In industrialized countries 25% of the population are affected by asthmatic and allergic diseases – still the allergy eliciting mechanism has to be elucidated. Allergenic PR-10 family members strongly bind hydrophobic molecules, suggesting that these interactions could affect their allergenicity. Bet v 1.0101, the major birch allergen, and Na-deoxycholate, a well-known ligand for Bet v 1.0101 with structural similarities to plant steroids, were selected for allergenicity analysis. The influence of ligand binding on conformation, stability, IgE-binding, and thus biological activity of Bet v 1.0101 were investigated in detail.
Materials and methods: Recombinant and heavy isotope labeled Bet v 1.0101 was produced in *E. coli*, purified to homogeneity and characterized physico-chemically. Melting curves of Bet v 1.0101 with and without ligand were recorded by circular dichroic (CD) measurements. IgE epitopes of free and ligand bound Bet v 1.0101 were mapped by NMR spectroscopy using purified human IgE antibodies from serum of a birch pollen allergic patient. Moreover, mediator release assays were performed with either naked or ligand bound Bet v 1.0101 to assess the influence of ligand on biological activity.
Results: CD measurements revealed that ligand bound Bet v 1.0101 has an increased thermal stability. NMR spectroscopy verified that two Na-deoxycholate molecules can bind the Bet v 1.0101 molecule in its hydrophobic cavity. Despite the binding of Na-deoxycholate influenced the 3D structure of Bet v 1.0101, the overall topology of the protein was not altered. The mapped IgE epitopes in free and ligand bound Bet v 1.0101 were identical. Unbound and ligand bound Bet v 1.0101, both induce crosslinking of the Fce receptors on RBL cells but interestingly ligand bound Bet v 1.0101 triggered half-maximal mediator release at lower concentrations.
Conclusions: Ligand binding of Bet v 1.0101 stabilizes the molecule, still the structure and thus IgE epitopes are not affected. IgE antibodies showed higher affinity to ligand bound allergen, inducing a higher crosslinking of the Fce receptors on basophils. These findings lead to the speculation that IgE antibodies were originally produced against Bet v 1.0101 bound to a hydrophobic ligand. However, further studies are needed to gain a better understanding of these mechanisms.

Purpose/Objective: More than 20 allergens have been identified in house dust mites (HDM), but little is known about the clinical relevance of the high molecular weight mite allergens. The objective of this investigation was to study the importance of the high molecular weight allergen Der p 11 for HDM allergic patients.
Materials and methods: A synthetic gene coding for Der p 11 was expressed in *E. coli* and rDer p 11 was purified to homogeneity. The secondary structure of the protein was determined by circular dichroism analysis and its localization was determined in the mites by immunogold electron microscopy. The IgE reactivity of rDer p 11 was tested with sera from HDM allergic patients from Europe and Africa in dot-blot assays and the allergenic activity was evaluated by the up-regulation of CD203c expression in allergic patients' basophils.
Results: rDer p 11 is a stable, alpha-helical protein, which shows homology to paramyosins from invertebrates. The allergen is located in the muscle beneath the skin of mite bodies but not in the feces of mites. The IgE-binding frequency of rDer p 11 (Austria 12%, France 5%, Italy 7% and Sweden 11%) and its allergenic activity were low in European populations, though a considerably higher IgE binding frequency of rDer p 11 (36%) was found in Zimbabwe.
Conclusions: Der p 11 might be an important cross-reactive allergen in certain geographical areas.

P0850

The pattern of total/specific IgE levels distribution in Korean by National Health and Nutrition Examination Survey

E. J. Kim,* Y. M. Lim,* Y. A. Kim,† Y. M. Cho,† M. J. Chang,† S. J. Hong,‡ K. W. Oh,† S. S. Kim§ & J. S. Lee*

**Center for Immunology and Pathology, Korea National Institute of Health, Cheonwon-gun, Korea, †Division of National Health and Nutrition Examination, Korea Centers for Disease Control and Prevention, Cheonwon-gun, Korea, ‡Department of Pediatrics, Asan Medical School, Seoul, Korea, §Division of AIDS, Korea National Institute of Health, Cheonwon-gun, Korea*

Purpose/Objective: Allergies diseases increase in worldwide and become serious problems because they may lead lifetime chronic disease. Allergic sensitization is known to be one of the diagnostic tools for allergic diseases and determination of total/specific IgE is a simple

method for measuring allergic sensitization. Total IgE levels are known to be affected by various factors, such as age, gender, ethnicity, and geographic area, and total IgE values are not always dependent on specific IgE elevation. Thus, cutoff values of total IgE can vary among different environmental conditions. Therefore, we evaluated the distribution of total and specific IgE levels by the age and gender using population based studies like preschool children survey and National Health and Nutrition Examination Survey in Korea.

Materials and methods: Serum specific IgE tests for 3 allergens (*D. farinae*, Cockroach, Dog) and total IgE tests were performed on 2342 people above age 10 in general population as well as 510 of preschool children aged 3−6 by using UniCAP System. Atopy was defined as a positive specific IgE response (≥0.35 kU/l) to at least one of the allergens. Allergic diseases were defined as a history of asthma, allergic rhinitis or atopic dermatitis diagnosed at any point in the lifetime.

Results: Rapid increase of total IgE was observed in preschool age group and it decreased in the age group of 10−40. Then it increased again in the age group above 50. The most prevalent sensitized allergen was *D. farinae* throughout the entire age group.

Conclusions: Total and specific IgE levels showed various range with age and gender. It was supposed that income and education level may affect total IgE levels. Atopic prevalence and total IgE can be related with allergic diseases. Further investigation is needed with broad ranges of age to give clues for diagnosis and treatment of allergic disease.

P0853

The role of mast cells, IL-13 en TRP channels in a mouse model of chemical-induced airway hyperresponsiveness

F. Devos, V. De Vooght, B. Nemery, P. H. M. Hoet & J. A. J. Vanoirbeek

Occupational Environmental and Insurance Medicine, Katholieke Universiteit Leuven, Leuven, Belgium

Purpose/Objective: The mechanisms of occupational asthma caused by chemicals are still not completely understood. We used an established mouse model of chemical-induced asthma to examine the role of the neurogenic system, as well as the role of IL-13 and mast cells by using different knock-out mice.

Materials and methods: On days 1 and 8, wild type C57Bl/6 mice and mice deficient in IL-13, transient receptor potential (TRP) V1, TRPA1 or mast cells received dermal applications of 1% toluene-2.4-diisocyanate (TDI) or vehicle (acetone/olive oil) on both ears. On day 15, the mice received a single intranasal challenge with 0.1% TDI or vehicle. In a second experiment, TDI sensitized wild type C57Bl/6 mice received an intraperitoneal injection of the NK1R antagonist RP67580 (1 $\mu g/\mu l$) prior to the challenge. Airway reactivity to methacholine, lung inflammation, lymphocyte subpopulations in the draining auricular lymph nodes and total serum IgE were assessed 24 h after the challenge.

Results: IL-13, TRPV1, TRPA1 and mast cell deficient mice showed a significantly lower airway hyperreactivity compared to wild type mice, without any sign of lung inflammation, 24h after TDI challenge. Treatment with the NK1R antagonist also resulted in a significant decrease in airway hyperreactivity. In the auricular lymph nodes T-helper cells, T-cytotoxic cells and B-cells were significantly lower in mast cell deficient and IL-13 deficient mice, compared to wild type mice.

Conclusions: These results indicate the importance of IL-13, TRPA1 and TRPV1 channels and mast cells in the development of immune-mediated bronchial hyperreactivity.

P0854

Transfer of allergen-expressing bone marrow under costimulation blockade leads to robust long-term tolerance in IgE-mediated allergy

U. Baranyi,* L. Linhart,† M. Gattringer,* A. Farkas,* K. Hock,* J. Iacomini,‡ T. Rülicke,§ R. Valenta† & T. Wekerle*

**Department of Surgery, Medical University of Vienna, Vienna, Austria, †Department of Pathophysiologie, Medical University of Vienna, Vienna, Austria, ‡Transplantation Research Center, Harvard Medical School, Boston, MA, USA, §Institute of Laboratory Animal Science, University of Veterinary Medicine, Vienna, Austria*

Purpose/Objective: Molecular chimerism induces tolerance in diseases for which the culprit antigens have been well characterized as is the case in IgE-mediated allergy. While robust and durable tolerance was established towards the grass pollen allergen Phl p 5 with this strategy, it requires myelosuppressive conditioning of the recipient (i.e. irradiation). Here we investigated, if an acceptable recipient conditioning without irradiation can be developed.

Materials and methods: Towards this end we generated a novel transgenic mouse (on the Balb/c background) expressing the major grass pollen allergen Phl p 5 ubiquitously on the surface. This transgenic mouse served as cell donor. Balb/c recipients were conditioned with either 1 Gy total body irradiation or no irradiation in addition to a short term treatment of rapamycin (day-1, -0, -2) and costimulation blockade (anti-CD40L, d0 or CTLA4-Ig, d2 1 mg each). 15×10^6 BMC harvested from the Phl p 5-transgenic mouse (Balb/c background) were transferred iv into conditioned recipients. Subsequently, mice were challenged several times with splenocytes (+AlOH3) of transgenic mice and control allergen (Bet v 1, weeks 4, 7, 10 after BM transplantation [BMT]). Tolerance was analyzed by ELISA for allergen-specific isotypes and T-cell proliferation assays. Airway hyperresponsiveness was determined by whole body plethysmography.

Results: Minimally irradiated recipients (1 Gy) developed persistent and stable macrochimerism (chimerism levels e.g. 35w postBMT): 35% T cells 25% myeloid cells) ($n = 19$). In contrast non-irradiated recipients were not macrochimeric at any time point ($n = 20$). Strikingly, however, Phl p 5-specific IgE was not detectable both in chimeric mice (20/20) and in non-irradiated non-chimeric recipients (e.g. w20 post BMT 7/10). High levels of Bet v 1-specific IgE developed in both groups. Furthermore Phl p 5-specific T-cell proliferation was not detectable at the end of follow up (w35 post BMT). Additionally preliminary data reveal no airway hyperresponsiveness in chimeric recipients (6/6) compared to untreated sensitized controls ($n = 3$).

Conclusions: Transfer of allergen-bearing BMC with costimulation blockade and short course rapamycin leads to robust tolerance without myelosuppressive recipient conditioning. These data suggest that preventive cell-therapy is feasible with clinically acceptable toxicity.

P0855

Vaccination with carrier-bound peptides from the major birch pollen allergen Bet v 1 lacking allergen-specific T cell epitopes reduces Bet v 1-specific T cell responses

B. Linhart,* M. Focke-Tejkl† & R. Valenta*

**Department of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria, †Christian Doppler Laboratory for Allergy Research, Medical University of Vienna, Vienna, Austria*

Purpose/Objective: Recently a strategy for the development of safe allergy vaccines has been developed, which is based on the hapten-carrier principle. Allergen-derived peptides lacking IgE-reactivity and allergen-specific T cell epitopes were coupled to a carrier molecule,

which provided T cell help for the induction of a protective allergen-specific IgG antibody response. These vaccines should increase safety of immunotherapy by reducing IgE- as well as T cell-mediated side effects. In this study we investigated in a mouse model whether vaccination with carrier-bound peptides from the major birch pollen allergen Bet v 1 lacking allergen-specific T cell epitopes has influence on Bet v 1-specific T cell responses.

Materials and methods: Three Bet v 1-derived peptides, devoid of Bet v 1-specific T cell epitopes, were coupled to KLH and adsorbed to aluminium hydroxide to obtain a Bet v 1-specific allergy vaccine. Groups of BALB/c mice where immunized with the peptide vaccine before or after sensitization to Bet v 1. Bet v 1- and peptide-specific antibody responses were analyzed by ELISA. T cell responses to Bet v 1, KLH, and the peptides were studied in proliferation assays.

Results: Prophylactic and therapeutic vaccination with carrier-bound Bet v 1 peptides induced a Bet v 1-specific IgG_1 antibody response without priming/boosting of Bet v 1-specific T cells. Both, prophylactic and therapeutic vaccination of mice with the peptide vaccine suppressed Bet v 1-specific T cell responses. Thus, vaccination with carrier-bound allergen-derived peptides lacking allergen-specific T cell epitopes induced allergen-specific antibodies capable of suppressing allergen-specific T cell responses.

Conclusions: Carrier-bound allergen peptides inducing allergen-specific blocking IgG may be useful for the treatment and prevention of allergy.

P0856

Vitamin D drives alpha-1-antitrypsin expression in human lymphocytes and predicts levels in airway lavage

S. Dimeloe,* L. Rice,* P. Pfeffer,* A. Gupta,* D. F. Richards,* Z. Urry,* S. Farooque,* S. Saglani,† A. Bush,† J. Raynes‡ & C. M. Hawrylowicz*

**MRC and Asthma UK Centre for Allergic Mechanisms of Asthma, King's College London, London, UK, †MRC and Asthma UK Centre for Allergic Mechanisms of Asthma, Imperial College London Royal Brompton Hospital, London, UK, ‡Immunology and Infection Department, London School of Hygiene and Tropical Medicine, London, UK*

Purpose/Objective: Epidemiological data associate vitamin D sufficiency with pulmonary health. This study investigated novel properties of vitamin D relevant to airway immune homeostasis, beyond well-documented effects on antimicrobial pathways and regulatory T cells. Alpha-1-antitrypsin (α-1-AT) protects the airway from neutrophil elastase, and additionally exerts immunomodulatory properties; its regulation by vitamin D was therefore examined.

Materials and methods: α-1-AT mRNA and protein expression were analyzed by qPCR and ELISA in peripheral leukocytes from healthy blood donors, human airway-derived populations, and clinical samples (peripheral lymphocytes, bronchoalveolar lavage and matched serum) from adult and paediatric asthmatics and controls. Ethical approval and patient/parental consent were obtained.

Results: SERPINA1 (encoding α-1-AT) was among the genes most highly upregulated by vitamin D treatment (1α,25-dihydroxyvitamin D3, 10^{-7}M) in peripheral CD4 T cells *in vitro*. ELISA confirmed vitamin D-induced α-1-AT secretion by CD4 and CD8 T cells, but not myeloid populations, which secreted comparable α-1-AT when LPS-activated. Human airway-derived T cells also responded to vitamin D to markedly upregulate SERPINA1. In contrast matrix metalloprotease-9, which degrades α-1-AT, was significantly inhibited in total airway cells. In a small number of adult asthmatics, oral vitamin D treatment (1α,25-dihydroxyvitamin D3, 0.5 μg/day) promoted peripheral T cell SERPINA1 expression *in vivo*, and in a larger paediatric cohort, serum vitamin D (25-hydroxyvitamin D3) correlated highly with airway α-1-AT.

Conclusions: These studies identify α-1-AT as a vitamin D-regulated molecule in human peripheral and airway-resident lymphocytes. Vitamin D status appears also to predict α-1-AT levels in the human airway. This finding has clinical implications, since α-1-AT regulates elastolysis in the airway. The immunological implications, given the immunomodulatory properties of α-1-AT, are now under further active investigation.

P0857

Wasp venom activates DC in a TLR-4-dependent way, resulting in subsequent histamine release by circulating basophils

N. Cools,* C. H. Bridts,† C. Mertens,† L. S. De Clerck,† Z. N. Berneman* & D. G. Ebo†

**Laboratory of Experimental Hematology, Antwerp University Hospital, Antwerp, Belgium, †Department of Immunology Allergology and Rheumatology, University of Antwerp, Antwerp, Belgium*

Purpose/Objective: The activation of dendritic cells (DC) via Toll-like receptors (TLR) plays a decisive role in shaping the outcome of primary immune responses. Recently, others have suggested that allergens may interact with TLR signal transduction, thereby inducing allergic inflammation. Hymenoptera venoms are important allergens that can elicit both local and systemic allergic reactions, including life-threatening anaphylaxis. In this study, we anticipate elucidating possible mechanisms of innate sensing of wasp venom by DC, and investigate the role of TLR.

Materials and methods: Monocyte-derived dendritic cells were *in vitro* generated from healthy controls. Next, phenotype, cytokine profile, and basophil stimulatory potential of DC upon stimulation with wasp venom was investigated. In order to evaluate the mechanism by which wasp venom triggers a pro-inflammatory innate immune response, DC were treated with a Toll-interleukin 1 Receptor (TIR) domain-containing Adapter Protein (TIRAP) inhibitory peptide.

Results: Using HEK293-derived cells that stably express human TLR genes (TLR2, 3, 4, 5, 7, 8, and 9), we identified that wasp venom (Pharmalgen) was recognized by TLR4. Furthermore, *in vitro* generated DC displayed an activated phenotype upon wasp venom stimulation, as evidenced by induction of the secretion of an array of both Th1 and Th2 pro-inflammatory cytokines. A TIRAP inhibitory peptide diminished the ability of DC to secrete pro-inflammatory cytokines. Importantly, conditioned medium of wasp venom stimulated DC induced pronounced histamine release by circulating basophils as compared to conditioned medium of control DC.

Conclusions: Here we show possible involvement of TLR4 in sensing wasp venom. Indeed, wasp venom induced a pro-inflammatory response by DC, in part by direct activation of TLR4. Furthermore, we provide evidence that activation of DC by wasp venom results in subsequent histamine release by basophils. We hypothesize that loss of control of DC-basophil crosstalk contributes to inflammatory responses in patients with hymenoptera venom allergy. For this, we are currently investigating if the proposed mechanisms can be affected by hymenoptera venom immunotherapy.

P0858

Whole milk and butter; clinically significant anti-inflammatory effects

E. van der Gaag & E. Korf
Pediatrics, Ziekenhuis Groep Twente, Hengelo, The Netherlands

Purpose/Objective: Recurrent respiratory tract symptoms are a common phenomenon in children. They include wheezing, coughing, rasping and the common cold. Whole milk and natural butter contain fat soluble vitamins, among others vitamin A and E, but also vitamin C, all vitamins with anti-oxidative capacities. We hypothesize that with a dietary change to these dairy products, respiratory tract symptoms will decrease.

Materials and methods: Children aged between 1–6 years with recurrent respiratory tract symptoms were included. The intervention consisted of a dietary advice of daily whole milk/yoghurt and natural butter for 3 months. The control group could continue their usual semi skimmed milk and low fat margarine consumption as before. Respiratory symptoms were collected with 3-month diaries.

Results: Of the 43 patients were included in the intervention group, 25 in the control group. After 3 months of following the dietary advice, the children were significantly less rasping; from 16.3 (SEM = 1.5) to 6.0 (SEM = 1.0) days a month ($P < 0.000$). Also, days with fever (4.5–1.4 days a month, $P < 0.000$), coughing (17.6–10.1 days a month, $P < 0.000$) and common cold decreased significantly (17.2–11.7 days a month, $P = 0.007$) in the intervention group. Wheezing was not affected by the dietary advice (4.5–3.2 days a month, $P > 0.05$). The body mass index was not altered after the change in diet ($P = 0.660$).

Conclusions: Consumption of whole milk and butter for 3 months significantly decreases respiratory tract complaints in children. Wheezing, the only symptom reactive to medication (bronchodilatators), was not affected by the dietary advice.

We conclude that a simple dietary change can improve respiratory tract complaints without side effects significantly.

12/15-lipoxygenase-mediated lipid oxidation regulates maturation of dendritic cells

T. Rothe,* E. Zinser,† S. Rössner,† S. Uderhardt,* V. Bochkov,‡ O. Oskolkova,‡ G. Schett,* A. Steinkasserer† & G. Krönke*
*Department of Internal Medicine 3, Institute for Clinical Immunology, Erlangen, Germany, †Department of Internal Medicine I, University Hospital Erlangen, Erlangen, Germany, ‡Department of Vascular Biology and Thrombosis Research, Medical University of Vienna, Vienna, Austria

Purpose/Objective: The enzyme 12/15-lipoxygenase (12/15-LO) mediates lipid oxidation and its expression is restricted to different cells of the monocytic lineage. To further determine the physiological role of this enzyme, we studied a potential role of 12/15-LO during the regulation of DC maturation and the shaping of the consecutive T-cell response.
Materials and methods: We analysed bone marrow-derived DCs of 12/15-LO-deficient mice with regard to their maturation status and cytokine profile *in vitro*. Moreover we examined the consequences of 12/15-LO-deficiency on autoimmune diseases like EAE.
Results: Differentiated bone marrow-derived DCs highly expressed 12/15-LO. These cells were enriched in 12/15-LO-specific phosphatidylcholine-derived oxidation products (oxPAPC). Deletion of 12/15-LO resulted in an increased expression of co-stimulatory molecules. Likewise, 12/15-LO$^{-/-}$ DCs displayed an altered cytokine profile with an elevated expression of the Th17-promoting IL-23 subunit p19. Addition of the 12/15-LO product oxPAPC, in turn, interfered with the maturation of DCs and the expression of p19. After initiation of a specific immune response 12/15-LO-deficient mice displayed an altered cytokine expression profile within their lymph nodes and showed an increased differentiation of Th17 T-cells. In accordance with these findings, the Th17-driven disease model of experimental autoimmune encephalomyelitis (EAE) exacerbated in 12/15-LO$^{-/-}$ mice.
Conclusions: Together these data identify 12/15-LO as a major source of bioactive phospholipid oxidation products in DCs and indicate a central role for enzymatic lipid oxidation during the regulation of the maturation status of DCs and the initiation of an adaptive immune response.

Activation of invariant natural killer T-cells in periodontitis lesions

M. Nowak,* B. Krämer,† M. Haupt,‡ P. N. Papapanou,§ J. Kebschull,¶ P. Hoffmann,** S. Jepsen,‡ S. Perner,* I. G. H. Schmidt-Wolf†† & M. Kebschull‡
*Department of Prostate Cancer Research, Institute of Pathology, University of Bonn, Bonn, Germany, †Department of Internal Medicine I, University of Bonn, Bonn, Germany, ‡Department of Periodontology Operative and Preventive Dentistry, University of Bonn, Bonn, Germany, §Division of Periodontics Section of Oral and Diagnostic Sciences, Columbia University College of Dental Medicine, New York, NY, USA, ¶Cold Spring Harbor Laboratory, Watson School of Biological Sciences, Cold Spring Harbor, NY, USA, **Department of Human Genetics, University of Bonn, Bonn, Germany, ††Department of Internal Medicine III, University of Bonn, Bonn, Germany

Purpose/Objective: Periodontitis is one of the most prevalent human inflammatory diseases. The major clinical phenotypes of this polymicrobial, biofilm-mediated disease are chronic and aggressive periodontitis, the latter being characterized by a rapid course of destruction that is generally attributed to an altered immune-inflammatory response against periodontal pathogens. Whereas aggressive periodontitis has been causally linked to infection with *Aggregatibacter actinomycetemcomitans* (A.a.), the major pathogen in chronic periodontitis is *Porphyromonas gingivalis* (P.g.). Still, the biological basis for the pathophysiological distinction of the two disease categories has not been well documented yet. Type I natural killer T (NKT) cells are a lymphocyte subset with important roles in regulating immune responses to either tolerance or immunity, including responses against bacterial pathogens. Here, we delineate the mechanisms of NKT cell activation in periodontal infections.
Materials and methods: Dendritic cells (DC) were generated from murine bone marrow by 6-days-culture with GM-CSF. NKT cells were isolated from murine livers. DC were challenged with A.a. or P.g. for 24 h. before they were used as stimulator cells for NKT cells for 24–48 h. before cytokines were tested by ELISA. Inflammatory responses in DC upon challenge with A.a. and P.g. were analyzed by Illumina microarray analysis of *in-vitro* infected DC. *De novo* glycosphingolipid turnover in bacterial challenged DC was tested using a fluorescent alpha-galactosidase A substrate and flow cytometry.
Results: We show a selective infiltration of type I NKT cells in aggressive, but not chronic periodontitis lesions *in vivo*. Murine DCs infected with A.a. triggered a type I interferon response followed by type I NKT cell activation. This stimulation was dependent on the expression of CD1d molecules and signaling via Toll-like receptors in DCs. In contrast, infection with P.g. did not induce NKT cell activation. The stimulatory capacity of DCs on NKT cells required DC self-activation through binding of type I interferon receptors and beta-interferon secretion. Addition of exogenous beta-interferon to P.g.-infected DCs restored the ability to activate NKT cells.
Conclusions: Our study provides a conceivable biological distinction between the two periodontitis subforms and identifies factors required for the activation of the immune system in response to periodontal bacteria.

P0861

Activation of Th17 pathway in potentially prediabetic first degree relatives and type 1 diabetic patients after exposure of diabetes-associated autoantigens

J. Vcelakova,* L. Petruzelkova,* V. Stavikova,* S. Kolouskova,* Z. Vesely† & K. Stechova*
*2nd School of Medicine Charles University and University Hospital Motol, Paediatrics, Prague, Czech Republic, †2nd School of Medicine Charles University and University Hospital Motol, Bioinformatics Centre, Prague, Czech Republic

Purpose/Objective: Type 1 Diabetes (T1D) appears to be mainly a Th mediated autoimmune process however its complexity is still not fully understood. New discovery of molecule or pathways converge in beta-cell destruction is a potential target for future therapeutic avenues. In our study we analysed the effect of diabetes-associated autoantigens on peripheral blood mononuclear cells (PBMC) by gene expression microarray and quantitative RT-PCR with the aim to identify prediabetes-associated cell processes.
Materials and methods: PBMC were sampled from first degree relatives of T1D patients (FDR), T1D patients and healthy controls (HC). Isolated PBMC were cultivated with and without mixture of diabetogenic autoantigens (GAD65, IA2 and proinsulin derived peptides) for 72 h. Then co-culture total RNA was isolated and gene expression arrays were done on 43 probands by high density Phalanx array. We saw the significant changes in Th-17 pathway. In the next step we analysed 53 probands by qRT-PCR TaqMan Gene Expression assays (Life Technologies) focusing on known players of this pathway (RORC, STAT3, IL-17A and TGFβ).
Results: We observed higher expression of IL-17A at T1D patients compared to FDR autoantibody negative ($P = 0.035$). Interestingly we saw significantly higher gene expression of TGFβ ($P = 0.01$) and

STAT3 ($P = 0.007$) comparing T1D patients and FDR autoantibody positive to HC. Gene expression of RORC had similar trend as the TGFβ and STAT3 but the difference was not significant ($P > 0.05$).
Conclusions: TGFβ cytokine is responsible for Th17 and Treg lymphocytes balance. In our study higher expression of TGFβ is associated with Th17 pathway change which is in contrast to previous study. Better understanding of this step can contribute developing immune-based intervention therapy.

P0862

Aggravation of atherosclerosis by MHC class II antigen deficiency is associated loss of regulatory T cells and expansion of pro-inflammatory Ly-6hi monocytes

M. Wigren, S. Rattik, H. Björkbacka, G. Nordin Fredrikson & J. Nilsson
Lund University, Clinical Sciences, Malmö, Sweden

Purpose/Objective: Adaptive immunity in atherosclerosis includes both pro- and anti-inflammatory immune responses. It has been assumed that atherosclerosis involves a loss of tolerance against modified self-antigens generated in response to hypercholesterolemia and that presentation of such antigens on MHC class II molecules lead to activation of pro-inflammatory Th1 cells. Furthermore, anti-inflammatory Tregs have been shown to reduce atherosclerosis development indicating that it might be possible to modulate the balance of pro- and anti-inflammatory responses. We have previously shown that immunizations of hypercholesterolemic mice with an Apo B-100 peptide based vaccine have the ability to reduce atherosclerosis and at the same time increase Treg frequency. Moreover, in hypercholesterolemic mice immunizations with the adjuvant Alum alone also reduce atherosclerosis and increase Tregs which is associated with a capture of oxLDL antigens.
Materials and methods: To further study the role of adaptive immune responses in atherosclerosis we have used hypercholesterolemic mice lacking MHC class II ($ApoE^{-/-}$ $MHCII^{-/-}$).
Results: As expected $ApoE^{-/-}$ $MHCII^{-/-}$ mice had reducedlevels of CD4+ cells, including Tregs as well as low levels IgG and IgM and Th1 and Th2 cytokines in plasma. CD115+ monocytes were reduced in spleen as well as the plasma levels of TNF-a, IL-1b and IL-6 indicating reduced systemic inflammation. In spite of this, $ApoE^{-/-}$ $MHCII^{-/-}$ mice had significantly more atherosclerosis as assessed both by en face Oil Red O staining of the aorta ($4.7 \pm 2.9\%$ versus $1.9 \pm 1.3\%$; $P < 0.01$) and cross-sectional area of subvalvular lesions ($7.7 \pm 2.2 \times 10^5$ versus $4.6 \pm 2.8 \times 10^5$ mm^2; $P < 0.05$). Moreover, macrophage accumulation in lesions was significantly increased ($44.8 \pm 8.0\%$ versus $24.8 \pm 7.8\%$ MOMA-2 stained area; $P < 0.001$). Furthermore, pro-inflammatory Ly-$6c^{hi}$ monocytes were increased in the spleen.
Conclusions: The present observations unexpectedly show that the net effect of MHC class II-dependent antigen presentation in atherosclerosis is athero-protective. The combination of reduced frequency of protective Tregs together with the increase in disease promoting Ly-$6c^{hi}$ monocytes can be the cause of the increased atherosclerosis in this animal model.

P0863

Allergic diseases exhibit various TREC number in $CD4^+$ and $CD8^+$ T-cell subpopulations

E. A. Blinova,* V. S. Kozhevnikov* & V. A. Kozlov†
**Research Institute of Clinical Immunology RAMS, laboratory of clinical immunopathology, Novosibirsk, Russia, †Research Institute of Clinical Immunology RAMS, laboratory of immunopoiesis regulation, Novosibirsk, Russia*

Purpose/Objective: We used T-cell receptor excision circles (TREC) to investigate the mechanisms for replenishment of the peripheral T cell poll in allergic diseases. The study included 26 patients with atopic dermatitis (AD), mean age 26 ± 9.7 years and 50 patients with different form of bronchial asthma (BA), mean age 43 ± 13.8 years. Since the number of TREC decreased with age, for each group of patients was selected a group of 22 healthy people. The average age of donors was 27 ± 4.6 years for patients with AD, and 43 ± 12.3 years for patients with BA, respectively.
Materials and methods: TREC number was measured by quantitative Real-time PCR technique in pure populations of CD4+ and CD8+ lymphocytes using specific primers, probe and standard. CD4+ and CD8+ T cells were sorted by flow cytometer FACSAria (Beckton Dickinson) using fluorescent-conjugated anti-CD3 and anti-CD4 antibodies. Reanalysis of the isolated subsets showed that the purities were at least 95%.
Results: Patients with AD had reduced TREC levels in CD4+ and CD8+ cells, but absolute TREC content in this populations was the same as in normal controls. Also absolute number of CD4+ and CD8+ cells was increased in AD. In contrast, patients with BA had no dissimilarities in the TREC number within both CD4+ and CD8+ T-cell subpopulations from healthy volunteers, as there were no significant differences in TREC content depending on the form of asthma and IgE levels. But a large variation was observed in TREC level according to the duration of the disease. Adults suffering from asthma about 1 year had increased absolute and relative numbers of TREC regarding to healthy controls, whereas in patients with disease duration >1 year they were comparable with donor values. Both groups of patients with the different disease duration had enlarged absolute number of CD4+ T cells and slightly extended absolute number of CD8+ T cells.
Conclusions: Thus, men suffering from AD have a normal thymic function, and TREC 'dilution' caused by a high rate of the peripheral T cell proliferation under conditions of the chronical antigen stimulation. In the onset of BA peripheral expansion and thymopoiesis are imbalance, and thymic emigrants make a grater contribution to the replenishment of the T cell pool. Patients suffering from asthma more than 1 year received additional corticosteroids therapy, that may be related to the turning of TREC level to the normal range in these people.

P0864

Altered co-stimulatory phenotype of Nrf2 knockout dendritic cells is not a result of elevated ROS levels

L. Abbas Al-Huseini, S. Sethu, J. Hamdam, Y. Tingle, C. Goldring, K. Park & J. Sathish
Translatinal Medicine, Molecular and Clinical Pharmacology, Liverpool, UK

Purpose/Objective: Dendritic cells (DCs) are antigen-presenting cells which play a pivotal role in adaptive immune responses. Cellular redox state has an important impact in DC immune function. The redox homeostasis in DCs is mainly controlled through the activity of the transcription factor, Nrf2. Our previous findings revealed that loss of Nrf2 resulted in enhanced co-stimulatory molecule expression and altered immune functions in dendritic cells. In the current study, we

investigated whether the loss of Nrf2 alters basal ROS levels in DCs. Additionally; we tested whether the increase in the co-stimulatory molecule expression is directly due to any changes in ROS levels in Nrf2 knockout DCs.
Materials and methods: Bone marrow-derived immature DCs from Nrf2 knockout and Nrf2 wild type mice were assayed for ROS levels by flow cytometry. ROS levels were lowered by treatment with vitamins C and E (ROS scavengers) followed by evaluation of co-stimulatory molecule expression and ability of DC to stimulate T cell proliferation.
Results: Nrf2 knockout DCs have higher levels of basal ROS compared to Nrf2 wild DCs. Vitamin C & E treatment reduced the levels of ROS in Nrf2 knockout DCs to levels comparable to that of the wild type. However, elevated co-stimulatory molecule (MHCII and CD86) expression of Nrf2 knockout DCs could not be reversed by vitamins treatment.
Conclusions: Our results indicate that the increase in ROS levels in Nrf2 knockout DCs does not contribute to the increase in the co-stimulatory molecule expression.

P0865

Amelioration of experimental autoimmune encephalomyelitis by quinoline-3-carboxamide ABR-215757 is due to target of T cell activation

S. Helmersson,* A. Sundstedt,† P. Andersson,* T. Leanderson* & F. Ivars*
**Lund University, Immunology, Lund, Sweden, †Active Biotech AB, Active Biotech AB, Lund, Sweden*

Purpose/Objective: ABR-215757 (5757) is a quinoline-3-carboxamide (Q-compound) currently in clinical development for systemic lupus erythematosus (SLE). Q-compounds have shown efficacy in different autoimmune diseases where they ameliorate the disease. However, the mechanism of action is still unknown.
Materials and methods: Experimental autoimmune encephalomyelitis (EAE) is a T cell dependent mouse model of multiple sclerosis. We have used this model to try to understand the mechanism underlying the amelioration by 5757.
Results: Of the 5757 effectively reduces induction of EAE. This mechanism is an early effect since treatment with 5757 during the first 5 days of the disease also reduces EAE development. Influx of T cells and myeloid cells to the brain is significantly reduced by 5757. EAE is a T cell dependent disease and the activation of T cells occurs early in the peripheral lymphoid organs. T cells show a reduced proliferation in the presence of 5757. The effector function of the T cells is affected since T cells from treated animals show a reduced production of IFN-γ and IL-17. The *ex vivo* antigen specific recall response is also heavily reduced in cells from 5757 treated animals.
Conclusions: Taken together, this suggests that 5757 treatment affects T cell activation and maturation of effector cells, thereby reducing EAE development.

P0866

Analysis of *in vitro* T-cell responses of PBMCs from patients with pemphigus vulgaris and healthy controls using desmoglein 3 peptides and peptide conjugates as antigens

H. Szabados,* K. Uray,* P. Silló,† F. Hudecz,‡ S. Kárpáti† & S. Bösze*
**Eötvös Loránd University, Research Group of Peptide Chemistry Hungarian Academy of Sciences, Budapest, Hungary, †Department of Dermato-Venereology and Skin Oncology, Semmelweis University, Budapest, Hungary, ‡Department of Organic Chemistry, Eötvös Loránd University, Budapest, Hungary*

Purpose/Objective: Pemphigus vulgaris (PV) is a rare, life-threatening autoimmune bullous skin disorder. The presence of autoreactive serum antibodies (IgG1 and IgG4) against desmosomal adhesion proteins, desmoglein 1 (Dsg1) and desmoglein 3 (Dsg3), results in mucosal lesions, mucocutaneous blisters and erosions. Autoantigen-specific T-cells also play a crucial role in the initiation and perpetuation of Dsg3/Dsg1-specific T-cell responses. In PV the CD4+ autoreactive T-cells recognize specific immunodominant regions from proteins Dsg3 and/or Dsg1. Patients show autoimmunity only to protein Dsg3 in the early stage of disease, while at the later stage, non-crossreactive immunity appears to both proteins Dsg3 and Dsg1. Protein Dsg3 is the primary target antigen in PV.
Materials and methods: In our study T-cell epitope regions have been selected and represented by synthetic oligopeptides. Synthetic peptides with distinct *in vitro* T-cell response on the peripheral blood monomorphonuclear cells (PBMC) isolated from PV patients have been chosen for conjugation. Conjugating the T-cell peptides to carrier molecules can increase their *in vitro* stimulating activity on PBMC. The selected peptides were conjugated to oligotuftsin [$(TKPKG)_4$] carrier. These peptides and peptide conjugates were used for *in vitro* stimulation of the PBMC from PV patients and healthy controls. After 24 and 48 h of incubation the produced IFN-γ was determined from the supernatants by ELISA.
Results: The synthetic Dsg3 peptides and peptide-oligotuftsin conjugates induced different *in vitro* IFN-γ production rate on PBMC obtained from PV patients and healthy controls determined by ELISA. The *in vitro* stimulatory activity of oligopeptides and peptide-conjugates will be discussed.
Conclusions: Our approach identified promising oligopeptide conjugate candidates as synthetic antigens.

P0867

Analysis of peripheral blood CD56+ and CD57+ NK and NKT cells subsets in pregnant women

K. Halacheva,* S. Buzalov,† M. Angelova,† B. Popov* & E. Slavov*
**Trakia University Medical faculty, Molecular biology immunology and medical genetics, Stara Zagora, Bulgaria, †Trakia University Medical faculty, Obstetrics and Gynecology, Stara Zagora, Bulgaria*

Purpose/Objective: Increased peripheral blood natural killer (NK) cells have been associated with unexplained reproductive failures. Data about the functional role of different NK cells and natural killer T cells (NKT) subsets during pregnancy are contradictory. The aim of this study was to investigate the differences in the relative distribution and the phenotype characteristic of peripheral blood subpopulations of NK and NKT cells in pregnant women with unexplained pregnancy loss compared to healthy pregnant women.
Materials and methods: Fifteen women in the first trimester of pregnancy with a history ofpregnancy loss (Group I), 12 healthy women in the first trimester of pregnancy (Group II), and 27 non-pregnant fertile women with a history of successful pregnancies (Controls) were included in this study. Five-color flow cytometry was used to assess the percentage of peripheral blood $CD3^-$ CD56+ cells (CD56-NK), $CD3^-$ CD57+ cells ($CD57^-$NK), $CD3^+$ CD56 + ($CD56^-$NKT, $CD3^+$ CD57+ cells ($CD57^-$NKT).
Results: CD56-NK and CD57-NK as a mean percentage of total peripheral lymphocytes were significantly decreased in the healthy pregnant women (8.97 ± 3.09 and 3.42 ± 1.75, respectively) compared to controls (12.64 ± 4.4 and 5.73 ± 2.63) and to Group I (13.32 ± 4.92 and 6.22 ± 2.81). Pregnant women with a history of pregnancy loss had significantly higher percentage of CD56-NK and CD57-NK (13.32 ± 4.92 and 6.22 ± 2.81) than those of Group II (8.97 ± 3.09 and 3.42 ± 1.75), but no differences were found when compared to controls (12.64 ± 4.4 and 5.73 ± 2.63). CD56-NKT percentage was nearly equal in all study groups (Group I − 5.66 ± 3.08, Group II − 4.64 ± 2.97, Controls − 4.50 ± 2.71). CD-57-NKT was significantly decreased in healthy pregnant women (6.02 ± 4.35) compared to

Group I (10.30 ± 5.67) and decreased without reaching statistical significance compared to Controls (9.00 ± 5.33).
Conclusions: On the basis of these results we may suppose that CD57 positive NKT and NK subsets may be involved in the immunological phenomenon of pregnancy and in the immune response disturbances in risk pregnancy.

P0868

Antigen presenting cells are important to modulate CD4+ T cells in renal ischemia and reperfusion injury

M. T. Amano, M. Correa-Costa, T. T. Braga, V. Andrade-Oliveira, A. Castoldi, M. Y. Miyagi, M. I. Hiyane & N. O. S. Camara
Institute of Biomedical Sciences University of Sao Paulo, Immunology, São Paulo, Brazil

Purpose/Objective: Ischemia and reperfusion injury (IRI) is an acute inflammatory response considered to be the main cause of acute renal injury in kidneys. Antigen presenting cells (APC), as dendritic cells (DC) and macrophages, have an important role in IRI, although a few is known about their functionality and their possible role in T cell activation in this model. In this way, we investigated whether APC were involved in IRI and their participation in T cell modulation in this model.
Materials and methods: We used C57Bl/6 and C57Bl/6$^-$ CD11c-DTR mice to perform the ischemia and sham group as control. In order to deplete, we used a clodronate protocol to deplete phagocytes or the CD11c-DTR mice diphtheria toxin (4 ng/g of mice) to deplete CD11c+ cells.
Results: We observed that after 24 h of reperfusion, urea (>250 mg/dl) and creatinine (>1 mg/dl) levels were increased in ischemic group, indicating injury. No difference of DC numbers were observed in the kidney and draining lymph nodes, however, DC from ischemic group were more activated, presenting more pronounced expression of CD86. We then used two models of depletion of APC, as mentioned above. Both protocols resulted in increased levels of urea (>300 mg/dl) and creatinine (>2 mg/dl) in the serum of APC depleted mice. In order to investigate the influence of DC in CD4+ T cell modulation in IRI, we analyzed the phenotype of CD4+ T cells in DC depleted mice after ischemia and reperfusion induction and we observed that the population of CD4$^+$ CD69+ (activated) T cells was increased, while no differences were observed in CD4$^+$ CD25+FOXP3+ T cells (Tregs), indicating that DC might be important for the regulation of T cell response in IRI.
Conclusions: We concluded that APC are involved in IRI and they modulate CD4+ T cells in order to control the injury.
Support: FAPESP, CNPq.

P0870

Assessment of CD8 positive NK cells and T cells subsets in pregnant women

E. Slavov,* S. Buzalov,† M. Angelova,† B. Popov* & K. Halacheva*
**Trakia University Medical faculty, Molecular biology immunology and medical genetics, Stara Zagora, Bulgaria, †Trakia University Medical faculty, Obstetrics and Gynecology, Stara Zagora, Bulgaria*

Purpose/Objective: The purpose of the study was to estimate the phenotype alterations in the peripheral blood NK and T lymphocyte subsets of women with unexplained pregnancy loss compared to healthy pregnant women.
Materials and methods: Fifteen women in the first trimester of pregnancy with a history of previous pregnancy loss (Group I), 11 non-pregnant women with a history of previous pregnancy loss (Group II), 12 women in the first trimester of pregnancy with no history of previous pregnancy loss (Group III), and 27 healthy fertile women with a history of successful pregnancies (controls) were included in the study. Five-color flow cytometric analysis was used to assess the percentage of CD3$^-$ CD56+ cells (NK), CD3$^+$ CD56+ T cells (NKT), CD8$^+$ CD11b$^+$ cells (CD8/CD11b) and their subsets: CD3$^-$ CD56$^+$ CD8$^+$ CD11b$^+$ NK cells (CD8+NK), CD3$^-$ CD56$^+$ CD8bright CD11b$^+$ NK cells (CD8brNK), CD3$^-$ CD56$^+$ CD8$^-$ CD11b$^+$ NK cells (CD8-NK), CD3$^+$ CD56$^+$ CD8$^+$ CD11b$^+$ NKT cells (CD8+NKT), CD3$^+$ CD56$^+$ CD8bright CD11b$^+$ NKT cells (CD8brNKT), CD3$^+$ CD56$^+$ CD8$^-$ CD11b$^+$ NKT cells (CD8-NKT), and CD3$^+$ CD56$^-$ CD8$^+$ CD11b$^+$ T cells (CD8+T).
Results: We found that the percentage of NK (8.9 ± 3.0) and CD8/CD11b (9.4 ± 4.7) in Group III was significantly lower compared to controls (12.6 ± 4.4; 13.4 ± 4.8 respectively). The percentage of these populations in Group I and Group II did not differ compared to controls. The percentage of NK in Group I (13.3 ± 4.9) was significantly higher, compared to Group III. The percentage of NKT in all the groups was nearly equal. A significantly lower percentage of CD8$^+$T was detected in Group III compared to controls (3.2 ± 2.4 versus 5.0 ± 1.8) and to Group II (3.2 ± 2.4 versus 6.6 ± 4.8). The percentage of CD8-NK and CD8-NKT cells was lower in Group III compared to Group I and Group II. The percentage of CD8+NK and CD8+NKT in all the groups was nearly equal. A significantly lower percentage of CD8brNK and CD8brNKT cells was detected in Group III compared to Group II.
Conclusions: Our results can suggest that, in addition to NK cells, T cells with a phenotype CD3$^+$ CD56$^-$ CD8$^+$ CD11b+ could be involved in the immune response during normal pregnancy. Further studies are needed to clarify the role of CD8$^+$ CD11b+ T cells, CD8+NK and CD8+NKT cell populations in complications of pregnancy.

P0871

Astrocytic FasL induces apoptosis of autoimmune T cells and is crucial for recovery from EAE

X. Wang,* F. Haroon,* S. Karray,† M. Deckert‡ & D. Schlüter*
**Institute of Medical Microbiology, Otto-von-Guericke University Magdeburg, Magdeburg, Germany, †INSERM U753, Institut Gustave Roussy, Villejuif, France, ‡Institute of Neuropathology, University of Cologne, Cologne, Germany*

Purpose/Objective: Experimental autoimmune encephalomyelitis (EAE) is an autoimmune disease characterized by accumulation of T cells in the CNS and its recovery requires the termination of inflammation and apoptosis of infiltrating T cells in the CNS. However, the T cell apoptosis inducing cell population still remains to be identified. To address the role of astrocytic FasL in the regulation of T cell apoptosis in EAE, astrocyte-specific FasL deficient mice were generated and investigated for EAE.
Materials and methods: Astrocyte-specific FasL knockout mice were generated by utilizing the Cre/loxP system under control of the human glial fibrillary acid protein (GFAP) promoter. EAE was induced by immunizing mice with MOG_{35-55} peptide and assessed daily by clinical score. Demyelination was detected by histology. Infiltrating leukocytes were isolated from spinal cord and characterized by flow cytometry. Expression of cytokines in spinal cord was analyzed by qRT-PCR. *In vitro* co-cultures of FasL$^+$ and FasL$^-$ astrocytes, respectively, with T cells were used to study the induction of T cell apoptosis as determined by annexin V and caspase-3 staining.
Results: FasL was efficiently and specifically deleted in astrocytes of GFAP-cre FasL$^{fl/fl}$ (KO) mice, while its expression was not affected in FasL$^{fl/fl}$ (control) mice. Compared with FasL$^{fl/fl}$ littermates, GFAP-cre FasL$^{fl/fl}$ mice developed significantly more severe EAE accompanied with widespread demyelination and more T cell infiltration. At day 22 post immunization, mRNA levels of IL-17, IFN-g, TNF and GM-CSF were also significantly elevated in the spinal cord of GFAP-cre FasL$^{fl/f}$

mice. Consistently, astrocytes isolated from GFAP-cre FasL$^{fl/fl}$ mice failed to induce T cell apoptosis *in vitro*.
Conclusions: FasL expression of astrocytes is required for the induction of T cell apoptosis and the elimination of infiltrating T cells in the CNS, which contributes to the recovery of EAE.

P0872
Calcitriol modulates the CD46 pathway by controlling its expression and function on T cells

K. Kickler,* S. Ni Choileain,* A. Williams,† A. Richards* & A. L. Astier*
**MRC Centre for Inflammation Research, University of Edinburgh, Edinburgh, UK,* †*MRC Centre for Regenerative Medicine, University of Edinburgh, Edinburgh, UK*

Purpose/Objective: The complement regulator CD46 is a costimulatory molecule for human T cells that induces a regulatory Tr1-like phenotype, characterized by large amounts of IL-10 secretion and low levels of IFNg. Secretion of IL-10 upon CD46 costimulation is largely impaired in T cells from patients with multiple sclerosis (MS). Vitamin D can exert a direct effect on T cells, and may be beneficial in several pathologies, including MS. Herein, we examined whether active vitamin D ($1,25(OH)_2D_3$ or calcitriol) could modulate the CD46 pathway and restore IL-10 production by CD46-costimulated T cells from patients with MS.
Materials and methods: CD4+ T cells were purified from the blood of 15 healthy donors and 11 patients with relapsing-remitting MS (7 IFNbeta treated, 4 untreated). We compared T cell responses to CD3/CD46 costimulation in presence or absence of calcitriol. We assessed the levels of expression of CD46, CD25 and CTLA-4 on activated T cells, and we measured proliferation and quantified IL-10 and IFNg production.
Results: In healthy T cells, calcitriol increased expression of CD25 and CTLA-4 expression on CD46-costimulated T cells, while it concomitantly decreased CD46 expression. Similar changes were observed in MS T cells except for CD25: while CD25 was normally induced by CD46 costimulation in MS T cells, addition of calcitriol consistently inhibited its induction. Despite the aberrant effect on CD25 expression, calcitriol increased the IL-10:IFNg ratio, characteristic of the CD46-induced Tr1 phenotype, in both T cells from healthy donors and patients with MS. Moreover, bystander CD4$^+$ T cells activated in presence of supernatants from CD46-costimulated T cells with calcitriol exhibited a lower proliferation rate.
Conclusions: We show that calcitriol affects CD46 expression and functions, and that it promotes anti-inflammatory responses mediated by CD46. Moreover, it might be beneficial for T cell responses in MS, although further studies should be performed to fully understand the effects of calcitriol on the CD46 pathway in T cells.

CCL17-producing dendritic cells at the crossroads of intestinal inflammation

A. Heiseke,* I. Förster,† W. Reindl* & A. Krug*
**Klinikum rechts der Isar – TUM, 2. Medizinische Klinik, München, Germany,* †*Life & Medical Sciences (LIMES) Institute Universität Bonn, Immunology and Environment, Bonn, Germany*

Purpose/Objective: The incidence of intestinal inflammations such as Crohn's disease and ulcerative colitis is constantly rising in Western countries. As current treatment options are not effective in all patients the need to find new drug targets is urgent. CCL17, a chemokine predominantly produced by dendritic cells (DCs) has been implicated to have proinflammatory roles in several atopic diseases as well as atherosclerosis. As central player of the innate and adaptive immune system, DCs play a fundamental role in the development of intestinal inflammation. Recent publications provided insights in the diversity of DC subsets involved in this process. In the work presented here, we assessed the role of CCL17 and CCL17-expressing DCs in particular, in murine experimental colitis.
Materials and methods: By challenging CCL17-deficient mice with chemically and immunologically induced colitis, the role of CCL17 was investigated. To characterize the different subsets of DCs cells within the secondary lymphatic tissues during colitis development multicolour FACS analysis and functional *ex vivo* assays were performed.
Results: CCL17-deficient mice displayed markedly reduced signs of inflammation after disease induction in two models of experimental colitis. Reduced disease development was associated with diminished levels of T_H1/T_H17 cells, as well as higher levels of Foxp3$^+$ regulatory T cells. Characterization of cell infiltrates into the lamina propria revealed that inhibition of colitis induction in CCL17-deficient mice was accompanied by increased numbers of CD103$^+$ DCs, as well as reduced expression of CCR7, crucial for recruitment to the mesenteric lymph nodes, on DCs within the colon. Further, the majority of CCL17-expressing DCs in the inflamed colon are found in the MHCII^{high}CD11b$^+$ CD103$^{+/-}$ CD8α^- intestinal DC subset, which was shown to have proinflammatory activity.
Conclusions: The work presented here clearly demonstrates a central role for CCL17 and CCL17-producing DCs in the development of intestinal inflammation. The in-depth characterization of these DCs will provide further essential insights in the processes shaping the intestinal immune response.

P0874
CD8 T cell – Dendritic Cell crosstalk up-regulates CD40L expression and IL-12p70 production

Q. W. Tay, L. C. Ho, P. Y. Low & D. M. Kemeny
National university of Singapore, Microbiology, Singapore, Singapore

Purpose/Objective: CD8 T cells have been shown to skew the immune response by stimulating dendritic cells (DC) to produce IL-12p70. The purpose of our study was to investigate the effect on CD8 T cell expression of CD40L.
Materials and methods: Ovalbumin (OVA)-specific T cell receptor transgenic mouse CD8 T cells (OT-I) were isolated by positive selection using anti-CD8 coated MACS beads and co-cultured splenic DC isolated using Optiprep and by positive selection with anti-CD11c coated MACS beads, and cultured in complete medium (RPMI 1640, 10% Fetal calf serum (FCS), antibiotics and non-essential amino acids and 0.5% 2 mercaptoethanol). CD40L expression was measured by Flow cytometry, IL-12p70 was determined by ELISA (R&D systems). CD8 T cells were activated with PMA (10 ng/ml) and Ionomycin (400 ng/ml) to induce CD44^{high} effector memory cells. CD11c+ splenic DCs were pulsed with 1 μg/ml of peptide (typically SIINFEKL) for 1 h before co-culture with pre-activated CD8 T cells at a ratio of 1 DC to 3 T cells. Altered SIINFEKL peptides (SAINFEKL, EIINFEKL, SIIRFEKL, SIINYEKL) were purchased from AnaSpec Inc (USA).
Results: Co-culture of effector memory CD8 T cells with DC up regulated CD8 T cell expression of CD40L that reached a maximum after 6 h. IL-12p70 levels in the culture reached 80% of its maximum value after 8 h. Altered peptide ligands SAINFEKL and SIINYEKL induced intermediate levels of CD40L while EINFEKYL and SIIRFEKL failed to induce CD40L on CD8 T cells. There was a corresponding reduction in IL-12p70 in the medium. Using CD8 T cells stimulated with anti-CD3 and CD28 addition of IL-12p70 enhanced CD40L expression on CD8s and addition of IL-12p70 neutralising antibody reduced CD40L expression.
Conclusions: CD8 T cell receptor dependent signals stimulate DCs to secrete IL-12p70 that up-regulates CD40L expression on CD8 T cells.

Characterization of swine skin and lung dendritic cells and their response to influenza virus

N. Bertho,* P. Maisonnasse,* E. Bouguyon,* F. Marquet,* B. Da Costa,* G. Simon† & I. Schwartz-Cornil*
*INRA, Animal Health, JOUY-EN-JOSAS, France, †ANSES, Porcin Virology and Immunology Unit, Ploufragan, France

Purpose/Objective: Swine is a natural host of influenza virus. Swine influenza strains can contaminate humans. Once infected, swine present identical symptoms as human, such as anorexia, pyrexia, cough, fever and nasal discharge. It has been recently shown in the mouse that dendritic cells (DC), and among them inflammatory TNF/iNOS-producing DC (Tip DC), are partly responsible both for the virus clearance and for the inflammatory pathology (Aldridge, PNAS 2009). Moreover, lung DC can be infected by influenza virus, although, interestingly, only the cross-priming CD103^{pos} DC subpopulation actually releases viral particles (Moltedo, PlosPathogen 2011). To establish if these DC/influenza interactions are idiosyncratic in the mouse model or can be generalized to natural hosts of influenza virus, we wanted:

1 To characterize the swine DC subpopulations network, first in the skin and then in the lung.

2 To describe their susceptibility to influenza virus infection and their capacity to produce new virions.

Materials and methods: Primary skin and lung cells were extracted and Facs-phenotyped (CadM1, CD206, CD209, CD14). Putative DC subpopulations were cell-sorted and the expression of genes specific for DC subpopulations (Flt3, ZBTB46, MAFB, BatF3, CSF1-R, XCR1, CX3CR1, CCR2, CLEC10A) were tested by q-PCR. Lung DC were infected with swine influenza virus and effective infection and virus production were tested by NP and NS1 immunofluorescence staining and by titration of the virus release.

Results: In a previous study, we described the different DC subpopulations present in pig skin (Marquet, PlosONE 2011). The deepening of this last study allowed us to revisit the classification of human skin DC subpopulations according to phenotypic and transcriptomic similarities between swine, human and mouse subsets, by reclassifying CD14^{pos} dermal DC as monocyte-derived DC and by identifying unambiguously the CD172a^{neg}/CadM1^{pos}/XCR1^{pos} cDC as equivalent to the murine CD103^{pos} cross-priming dermal DC.

We then identified the lung counterparts of these skin DC subpopulations and described their capacities to replicate influenza virus.

Conclusions: All together these data establish the swine as a model of choice for the study of normal and pathologic immune responses against influenza infection.

Circulating dendritic cells of multiple sclerosis patients are dysregulated and their frequency is correlated with MS-associated genetic risk factors

N. Hellings,* K. Thewissen,* A. H. Nuyts,† N. Deckx,† V. F. I. Van Tendeloo,† P. Stinissen,* Z. N. Berneman† & N. Cools†
*Hasselt University, Biomedical Research Institute (BIOMED), Diepenbeek, Belgium, †Antwerp University, Experimental Hematology, Antwerp, Belgium

Purpose/Objective: Dendritic cells (DC) are widely known as professional antigen-presenting cells and provide an important link to the adaptive immune system where they regulate the balance between immunity and tolerance. Alternations in the DC compartment can ultimately lead to the induction or perpetuation of autoimmune diseases such as multiple sclerosis (MS). This study aims to identify alterations in DC phenotype and functionality in MS. Moreover, the contribution of genetic risk factors to DC alterations was determined.

Materials and methods: An *ex vivo* analysis of myeloid (mDC) and plasmacytoid DC (pDC) was carried out on peripheral blood of MS patients (n = 104) and age- and gender-matched healthy controls (HC, n = 112). Frequencies and expression of costimulatory (CD80 and CD86) and migratory molecules (CD62L, CCR5 and CCR7) were investigated. Interleukin (IL)-12p70 and interferon (IFN)-α secretion was measured following Toll-like receptor (TLR) challenge. Study subjects were genotyped for HLA-DRB1*1501 and IL-7R α.

Results: A significant decrease of circulating pDC was found in peripheral blood of patients with chronic progressive MS (CPMS) compared to relapsing-remitting (RR) MS and HC. No differences in blood frequencies of mDC were found between different study groups. Both mDC and pDC of MS patients show shifts in the expression of CD86, CCR5 and CCR7 indicating that activation and migratory patterns of DC change during MS. Moreover, RRMS patients showed a reduced upregulation of CD86 on pDC and enhanced IL-12 production by mDC after TLR ligation, indicative of altered DC responsiveness. Treatment of MS is associated with a decrease of CD62L-positive mDC and pDC. HLA-DRB1*1501 carriers have reduced frequencies of circulating mDC as compared to non-HLA-DRB1*1501 carriers. Moreover, patients not carrying the protective IL-7Rα haplotype 2 have lower frequencies of pDC in the peripheral blood, indicating that genetic risk factors may impact the DC compartment of MS patients.

Conclusions: Our data indicate that circulating DC subsets undergo changes in phenotype and functionality during MS disease. This study further provides evidence that MS-associated genetic risk factors such as HLA-DRB1-1501 and absence of IL-7Rα haplotype 2 have an impact on the DC compartment and thereby may contribute to the induction and/or maintenance of autoimmune responses.

P0878

Contrasting responses of DC and NK cells to IFN-I contribute to host resistance to viral infection

T. P. Vu Manh,* T. Baranek,* Y. Alexandre,* N. Zucchini,* S. H. Robbins,* K. Crozat,* U. Kalinke† & M. Dalod*
*CIML, Immunology, Marseille, France, †TWINCORE, MHH/HZI, Hannover, Germany

Purpose/Objective: Type I interferons (IFN-I) play a major role in immune defense against viral infections in mammals. Depending on the target cells, IFN-I either promote or inhibit cell proliferation and survival. How IFN-I mediate such opposite effects is not well understood. On dendritic cells (DC), IFN-I promote the up-regulation of major histocompatibility class I and co-stimulatory molecules, and the trans-presentation of IL-15. On natural killer (NK) cells, IFN-I promote entry into cell cycle, survival and cytotoxicity. However, the mechanism of action of IFN-I on NK cells, either directly by IFNAR triggering or indirectly through IL-15 presentation by DC, is still controversial.

Materials and methods: We combined the use of mutant mice, functional genomics, and flow cytometry analysis of transduction molecule phosphorylation to investigate how murine cytomegalovirus (MCMV) infection modulates the transcriptome and the antiviral activity of DC subsets and NK cells, in particular the role of IFN-I.

Results: We showed that splenic DC subsets undergo similar transcriptomic changes early after infection, with the induction of many IFN-I-stimulated genes, including genes involved in the recognition of viral infection, and inhibition of genes involved in proliferation. We showed that this occurs at least in part under cell-intrinsic instruction by IFN-I. NK cells induced genes involved in proliferation, which can be accounted for by stimulation through IL-15. We demonstrated that MCMV infection *in vivo* or IL-15 stimulation *in vitro* increase E2F expression and phosphorylation in NK cells, in a phosphatidylinositol 3-kinase dependent manner. Finally, we showed that the ability of DC, but not of NK

cells, to respond to IFN-I contributed to promote health over disease during MCMV infection.

Conclusions: In conclusion, we showed that DC and NK cells respond differently to IFN-I during a viral infection *in vivo*. DC are highly sensitive to IFN-I stimulation, due in part to their higher expression of STAT1/2. NK cells respond weakly to direct IFN-I stimulation but strongly to IFN-I-induced IL-15. This study demonstrates how contrasting responses of primary cell types to IFN-I can emerge as a result of combined quantitative differences in the signaling module downstream of IFNAR and qualitative differences in sensitivity to secondary cytokine mediators induced by IFN-I.

DCs expressing IDO controls the fungal loads, activation co-stimulatory molecules and T cells proliferation in PCM developed by B10.A and A/J mice

E. F. Araujo & V. L. G. Calich
Institute of Biomedical Sciences, Immunology, Sao Paulo, Brazil

Purpose/Objective: PURPOSE/OBJECTIVES: *Paracoccidioides brasiliensis* is a pathogenic fungus restricted to Latin America and its natural route of infection is the inhalation of fungal particles. In paracoccidioidomycosis (PCM), the regulatory mechanisms mediated by innate and cellular immunity are still unclear. Indoleamine, 23-dioxygenase (IDO) is an IFN-gamma induced enzyme which catalyzes the tryptophan metabolism along the kynurenine pathway. It is known that IDO can control host-pathogen interaction by inhibiting the proliferation of intracellular microorganisms due to tryptophan starvation and by its immunosuppressive effect on T cell immunity. The aim of our work was to investigate the influence of IDO on the behavior of dendritic cells (DCs) in the course of the infection of susceptible (B10.A) and resistant (A/J) mice clarifying some important aspects on the immunosuppression associated with the severe forms of PCM.

Materials and methods: We worked with B10.A and A/J mice using control and 1-methyl-DL-tryptophan (1MT, an IDO inhibitor)-treated mice. Control and 1MT-treated B10.A and A/J mice were infected i.t. with one million yeasts and analyzed at 96 h post infection. Dendritic cells of the lung were purified through magnetic beads and the parameters of influence of treatment with 1MT in IDO were analyzed such as mRNA expression; CFU counts; NO production; levels of kynurenine and cytokines; characterization of subpopulations of DCs present in the lungs; lymphocyte proliferation assay.

Results: In 96 h post infection of B10. A and A/J mice, 1MT was shown to decrease the frequency of DC cells expressing IDO and also the activation of co-stimulatory molecules CD40, MHC II and CD86. In both mouse strains IDO mRNA expression was augmented, driving tryptophan catabolism, kynurenine production and decreased fungal loads. On the other hand, 1MT restore proliferation of $TCD4^+$ and $TCD8^+$ cells in B10. A mice and $TCD8^+$ in A/J mice, showing a known effect on cells expressing IDO. In total lung cells (before magnetic beads) was observed the same effect of decreased co-stimulatory molecules, CD40, MHC II and CD86 in 1MT-treated mice.

Conclusions: CONCLUSION: DCs cells of resistant and susceptible mice use the enzyme IDO to control mechanisms of immunosuppression in infected mice, diminishing fungal burdens but also suppressing T cell proliferation.

DEF6, a Rho-GEF with a unique domain organisation involved in TCR mediated signal transduction aggregates via a coiled-coil domain to form cytoplasmic foci

E. Mollett,* F. Hey,† F. Sablitzky,‡ M. Searle* & P. Jones§
**Chemistry, University of Nottingham, Nottingham, UK, †Biochemistry, University of Leicester, Leicester, UK, ‡Genetics, University of Nottingham, Nottingham, UK, §Biomedical Sciences, University of Nottingham, Nottingham, UK*

Purpose/Objective: Itk, a Tec family tyrosine kinase, regulates signalling molecules at the immune synapse including DEF6 (also known as SLAT or IBP), a Rho-GEF with a poorly characterised role in TCR mediated signal transduction (Gupta *et al. J Biol Chem* 2003, 278, 23541). Itk- and DEF6- deficient T cells both fail to activate ERK (Chen *et al. Immunity* 2008, *29*, 899; Schaeffer *et al. Science* 1999, *284*, 638), have decreased susceptibility to CD3-induced apoptosis (Schaeffer *et al. Science* 1999, *284*, 638), and exhibit aberrant IL-17 expression (Gomez-Rodriguez *et al. Immunity* 2009, *31*, 587). DEF6-deficient mice develop a systemic autoimmune disease similar to SLE (Fanzo *et al. J Clin Invest* 2006, *116*, 703), and rheumatoid arthritis (Biswas *et al. Immunol Rev* 2010, *233*, 79). Mice primed to develop experimental autoimmune encephalomyelitis lacking DEF6 showed resistance to its development (Canonigo-Balancio *et al. J Immunol* 2009, *183*, 7259). Our study aims to investigate the link between Itk and DEF6, and to explore the molecular mechanisms of DEF6 function.

Materials and methods: Phosphorylation assay.
Transient transfection with GFP tagged constructs.
Structural prediction.

Results: We have found that Itk phosphorylates the PH domain of DEF6 (submitted). This lays N-terminal to the DH-like domain (DHL), a feature unique to DEF6 and its B cell homolog, SWAP70. Transient transfection of a DEF6 mutant mimicking Itk phosphorylation forms cytoplasmic foci in Cos7 cells that co-localize with DCP1, a marker of P-bodies; structures containing machinery to degrade RNA (Kedersha *et al. Methods Enzymol* 2007, *431*, 61). The DHL domain alone can form foci that do not co-localize with DCP1. Whilst the DHL domain exhibits GEF activity, structural prediction suggests it does not form the usual Rho-GEF DH domain structure. Additionally, the amino acid composition of the DHL domain is characteristic of a group of prion proteins (Fiumara *et al. Cell* 2010, *143*, 1121) and some P-body proteins. In DEF6 this region is likely to form coiled-coil rather than beta-sheet based aggregation to drive the formation of the foci.

Conclusions: Our data suggest that the atypical domain structure of DEF6 is responsible for maintaining a meta-stable conformation, easily changed by phosphorylation to promote GEF activity and/or cytoplasmic granule formation potentially involved in the regulation of translation.

P0881

Dendritic cell mediated immune reactions to mycobacterial antigens in young healthy BCG vaccinated individuals

P. Szpakowski, W. Rudnicka & M. Kowalewicz-Kulbat
Department of Immunology and Infectious Biology, University of Lodz, Lodz, Poland

Purpose/Objective: Dendritic cells (DC) are indispensible in initiation of adaptive responses to infective agents. The aim of study was to analyze the relationship between mycobacterial antigen induced responses of monocyte derived dendritic cells (DC) manifested on the level of surface receptors and cytokine production and capacity of mycobacterial antigen pulsed DC to stimulate autologous CD4, CD8 and CD56 cells. The study was performed in healthy subjects

(17–30 years old) who were given 2 or 3 doses of BCG vaccine at their childhood.
Materials and methods: Blood CD14+ monocytes separated with immunomagnetic method, cultured with IL-4 and GM-CSF gave DC. The receptors on DC stimulated with PPD or BCG bacilli and the phenotype and intracellular IFN-gamma in CD14-cell fractions responding to mycobacteria-pulsed DC were estimated by flow cytometry. ELISA was used for released cytokine detection.
Results: An individual variation was noticed in the responses of DC to PPD and whole BCG bacilli manifested on the level of co-receptors CD86, CD80, CD40, HLA-DR and DC-SIGN as well as IL-10 and IL-23 releasing. However, PPD and BCG caused a significant decrease in DC-SIGN on DC from almost all volunteers. As opposed to PPD, BCG enhanced a CD86 density on and IL-10 releasing by DC in the majority of donors. A high frequency of IL-10 production characterized DC from tuberculin-negative volunteers. An antigen presentation function of PPD or BCG pulsed DC towards autologous CD4+, CD8+ and CD56+ cells was estimated as an intracellular IFN-gamma. A great individual variation in the profile of responding T and NK cells was observed. There was a positive correlation between HLA-DR expression and IFN-gamma response of CD56+ cells stimulated with PPD-pulsed DC and a negative correlation between HLA-DR density and intracellular IFN-gamma in total lymphocytes.
Conclusions: The complexity of DC mediated immune reactions to mycobacteria requires regarding in a designation of better vaccines than BCG. Supported by the MS grant N N401 015236

P0882
Dendritic cells orchestrate innate immunity against bacterial kidney infection

A. Tittel, C. Heuser, N. Garbi & C. Kurts
Institutes of Molecular Medicine and Experimental Immunology, University of Bonn, Bonn, Germany

Purpose/Objective: Urinary tract infections, such as pyelonephritis (PN), affect a large proportion of the population worldwide and are mostly caused by the uropathogenic gram-negative bacteria *Escherichia coli* (UPEC). Dendritic cells (DCs) form an abundant network in the kidney tubulointerstitium. Their role in bacterial pyelonephritis is unknown. Here we studied that role in a murine pyelonephritis (PN) model induced by transurethral instillation of UPEC.
Materials and methods: Instillation of UPEC twice at a 3 h interval increased infection rates from 16% after a single instillation to 84%. To investigate the role of DCs in early PN we used CD11c transgenic deleter mice to deplete DCs with 8 ng/gbw diphtheria toxin. After kidney digestion renal phagocytes were intracellularly stained for CXCL2 and TNFa and were analyzed by flow cytometry.
Results: Already 3 h after the second instillation, resident kidney DCs produced most of the intrarenal CXCL2 and TNFa. These cells recruited and activated neutrophilic granulocytes, which are critical in the defense against PN. When we depleted DCs using CD11c. DTR mice during the first bacterial instillation, neutrophil recruitment as well as bacterial clearance was markedly delayed. However, DC depletion also caused infection-independent granulocyte release from the bone marrow commencing after 24 h. The resulting neutrophilia paradoxically improved bacterial clearance when DCs were depleted 1 day before infection. This side effect was also seen in CD11c. DOG mice, another transgenic line allowing conditional DC depletion. Here we introduce a new transgenic line, CD11c. LuciDTR mice, which is unaffected by such early neutrophilia. However, both CD11c. LuciDTR mice and CD11c. DTR mice, but not CD11c. DOG mice, showed neutrophilia after 72 h, which probably resulted from increased granulopoiesis.
Conclusions: All three lines feature time-windows, during which neutrophilia is negligible. Studies within these time windows allowed us to demonstrate that the tubulointerstitial DC network serves an innate immune sentinel function against bacterial pyelonephritis, by rapidly recruiting neutrophils into the infected kidney.

P0884
E2-2-mediated down-regulation of plasmacytoid dendritic cell function limits type I interferon, T cell responses and virus control in early life

E. Belnoue, P. Fontannaz, A. F. Rochat, C. Tougne, A. Bergthaler, P. H. Lambert, D. D. Pinschewer & C. A. Siegrist
Pathology-Immunology, University of Geneva, Geneva, Switzerland

Purpose/Objective: Cytopathic viruses causing acute infections in immunologically mature hosts often follow a prolonged course in early life, characterized by high viral titers maintained for several weeks. Accordingly, lymphocytic choriomeningitis virus (LCMV, WE strain) runs an acute course in adults but a protracted course in infant BALB/c mice, in which LCMV-specific T cells fail to expand and control infection. To identify whether these defects were due to a dysfunction of innate immunity in infant mice, we analyzed early events of viral infection.
Materials and methods: Type I IFN production was assessed early after LCMV infection of infant and adult mice by ELISA and real-time PCR. We compared viral titers (by plaque assay) and T cell responses (by FACS) of LCMV-infected infant/adult wild-type and infant/adult IFNAR $^{-/-}$ mice. Activation and function of plasmacytoid and conventional dendritic cells were analyzed by FACS and real-time PCR. The effect of supplementing recombinant IFN-alpha on viral control and T cell responses was investigated in infant mice.
Results: Our data showed an insufficient immediate-early IFN-alpha production in infant mice, which fails to support early viral control and the expansion of LCMV-specific T cells: disrupting IFNAR signaling in adult mice mimicked a protracted LCMV infection. Plasmacytoid dendritic cells (pDCs) which are the main source of type I IFNs in LCMV infection failed to acquire an activated phenotype in infant mice and displayed defective function *in vivo* upon LCMV infection reflected by the low expression of the central pDC transcription factor E2-2 and related genes (TLR7/9, IRF-7 and IRF-8), MyD88 and NF-KappaB. In contrast, the *in vitro* function of early life pDCs was normal suggesting an *in vivo* negative regulation of infant pDCs. Direct evidence of the contribution of type I IFNs for early life infection control was demonstrated by given exogenous IFN-alpha which restored virus control and CTL functionality in infant mice.
Conclusions: In this study, we identify an age-specific down-regulation of multiple factors which are critical for the activation and function of pDCs and demonstrate that it is orchestrated by the E2-2 pDC regulator. We show that this down-regulation prevents the immediate-early burst of type I IFN and the early viral control and permanently impairs T cell responses. This defect was overcome by giving exogenous IFN-alpha which restored virus control and T cell responses in infant mice. The results suggest that early life pDC responses are tightly regulated *in vivo*, possibly to avoid potentially harmful inflammatory or autoimmune reactions.

P0885
Effect of Th17/Th1/Treg balance and microRNA expression in *A. actinomyctemcomitans* – accelerated atherosclerosis

R. Jia, T. Ochiai & M. Yamamoto
Nihon University School of Dentistry at Matsudo, Oral Immunology, Matsudo Chiba, Japan

Purpose/Objective: Recent studies have shown that there is an association between periodontal disease and cardiovascular disease. We

previously reported that the TLR signaling pathway plays an important role in *Aggregatibacter actinomyctemcomitans (A. a.)* mediated atherosclerosis in apolipoprotein E-deficient spontaneously hyperlipidemic ($Apoe^{shl}$) mice. However, it is not known whether the causal or primary immune mechanism is involved in periodontopathic bacteria-associated atherosclerosis. Atherosclerosis is a chronic inflammatory disease regulated by T lymphocyte subsets. In this study, we investigated whether the functional imbalance between Th17, Th1, and regulatory T (Treg) cells, and Th17-related microRNA expression existed in *A. a.*-challenged $Apoe^{shl}$ mice.

Materials and methods: The mice were intravenously treated with live *A. a.* HK1651 or vehicles. Histomorphometric features of atheromatous lesions, serum IFN-gamma, IL-17 and IL-10 levels, and gene expression of Th17-related molecules and microRNA (miR) were examined.

Results: We observed that *A. a.* challenge induced a Th17/Th1 shift in $Apoe^{shl}$ mice. *A. a.*-challenged splenic Th17 cells greatly increased during early stages of bacteria-challenge, compared to Th1 cell increase accompanied with Th17 cell reduction during later stage of challenge. In contrast, splenic Treg cell-changes in the *A. a.*-challenged group were almost similar with the control group. Similarly, differentiation factors (TGF-βplus IL-6, TL-17RA and IL-21), growth and stabilization factor (IL-23), and transcription factor (STAT3) involved in the development of Th17 cells, as well as Th1-related IFN-γ were also detected in *A. a.*-challenged mice. Furthermore, we found that miR-326 expression was upregulated in the hearts of *A. a.* − challenged mice.

Author	Department and Institute	City	Country
1. Ru Jia	Oral Immunology of Nihon University School of Dentistry at Matsudo	Matsudo, Chiba	Japan
2. Tomoko Kurita-Ochiai	Oral Immunology of Nihon University School of Dentistry at Matsudo	Matsudo, Chiba	Japan
3. Masafumi Yamamoto	Oral Immunology of Nihon University School of Dentistry at Matsudo	Matsudo, Chiba	Japan

Conclusions: These results suggest that Th17/Th1/Treg imbalance and Th17 cell-associated miR-326 expression exists during early atherosclerosis in *A. a.*-challenged $Apoe^{shl}$ mice, suggesting a potential role of Th17/Th1/Treg imbalance in the progression of *A. a.*- accelerated atherosclerosis.

P0888
Enhanced CD8 T cell priming in DAP12 and FcR-gamma deficient mice

G. B. Gmyrek, D. B. Graham, H. M. Akilesh, G. S. Blaufuss & W. Swat
Washington University School of Medicine, Pathology and Immunology, St. Louis, MO, USA

Purpose/Objective: The disruption of the immunoreceptor tyrosine-based activation motif (ITAM) signaling in mice with combined deficiency in DAP12 and FcR-gamma (DF mice) was shown to have either positive or negative effects on dendritic cell function. However, the exact role of dendritic cell ITAM (DC ITAM) signaling in CD8 T cell priming was not explored so far.

Materials and methods: To determine the requirement of DC ITAMs in CD8 T cell priming, we performed a series of immunization experiments with MHC class I restricted peptide ($OVA_{257-264}$) to evaluate CD8 T cell priming followed by analysis of dendritic cell subsets and evaluation of IFN type I and cytokine responses.

Results: We found sharply increased CD8 T cell priming in DF mice, as indicated by increased frequency of IFN-gamma producing cells after re-call response with $OVA_{257-264}$ peptide (SIINFEKL) *in vitro*. Given that many DC subsets contribute to modulation of T cell responses *in vivo* we hypothesized that the difference in CD8 T cell priming could be related to activation of specific DC subsets resulting in polarization of the T cell response. In this line of investigation we found an increased number of monocyte-derived- and plasmacytoid dendritic cells in the draining lymph nodes of DF mice after immunization with SIINFEKL. We tested if there was a cell autonomous defect due to ITAM signaling deficiency, and noted no difference in the ability of sorted CD8α DCs from DF and WT mice to prime exogenous CD8 T cells *ex vivo*. Subsequently, given that IL-12 significantly contributes to increased IFN-gamma production, we noted that monocyte-derived DCs (moDC), from bone-marrow of DF mice, expanded after GM-CSF culture produced increased amounts of IL-12, along with up-regulation of transcription factor IRF-8. Consistent with this scenario the treatment of DF mice with IFNAR1-specific MAR1-5A3 mAb followed by the immunization with SIINFEKL, showed dramatically decreased IFN-gamma production.

Conclusions: Collectively, we showed that DC ITAMs negatively regulate IFN type I responses and IL-12 production controlling CD8 T cell priming.

P0889
Enteropathogenic *Escherichia coli* engages in temporal regulation of the inflammasome by interaction with NLRC4 and NALP3

N. Pramanik,* M. Lucas,* C. Bryant,† M. Bajaj Elliott* & N. Klein*
**UCL Institute of Child Health, immunology and infectious disease, London, UK, †Department of Veterinary Medicine, Cambridge University, London, UK*

Purpose/Objective: Enteropathogenic *Escherichia coli (EPEC)* is a leading cause of acute and chronic diarrhoea in developing nations, principally affecting children <2 years of age. The interaction of EPEC with the gastrointestinal (GI) mucosal immune system remains largely uncharacterised. A recent study by Lebeis *et al.* 2011 indicated a critical role for IL-1 receptor signalling in Citrobacter rodentium (murine model for EPEC) mediated disease pathogenesis. In the present study we investigate the signalling events that regulate IL-1β production in murine dendritic cells in response to EPEC infection. Better understanding of this complex pathway may highlight novel therapeutic targets for infection control and highlight strategies for vaccine development for this major enteropathogen.

Materials and methods: Bone marrow derived dendritic cells (BMDC) from inflammasome knockout mice $NLRC4^{-/-}$, $NALP3^{-/-}$, $ASC^{-/-}$, $CASPASE^{-/-}$ were isolated and infected with EPEC Wild Type (WT) strain (E69) and isogenic mutants deficient in structural and effector protein of T3SS (Type III secretion system) and flagella to determine inflammasome activation. Inflammasome activation was assessed by gene and protein expression, flow cytometry and florescent microscopy.

Results: WT strain induced marked increase in bioactive IL-1β in a caspase dependant manner in $NLRC4^{-/-}$ BMDC. This effect was dependant on the presence of T3SS component in EPEC. In contrast to published work by Miao *et al.* (2010), we found a minimal role of flagella mediated IL-1β as ΔFliC elicited IL-1β to similar levels as WT in $IPAF^{-/-}$ DC. ASC speck formation an essential adaptor required for regulating mature caspase by the inflammasome showed a significant decrease in both $NLRC4^{-/-}$ and $NLRP3^{-/-}$ suggesting temporal regulation of both in ASC mediated caspase activation.

Conclusions: An intact T3SS was found to be necessary for optimal IL-1β release. Our experiments indicate potential role of ASC in EPEC-mediated IL-1β release especially in the presence of the inflammasome NLRC4. Our study is the first to show the effect of both NLR (Nod-like Receptors) in a time dependant manner.

P0891

Expression of HLA-B27 causes loss of migratory dendritic cells in a rat model of spondyloarthritis

L. Utriainen, D. Firmin, P. Wright, V. Cerovic, I. McInnes & S. Milling

Institute of Infection Immunity and Inflammation, Centre for Immunobiology, Glasgow, UK

Purpose/Objective: The Spondyloarthritides (SpAs) are a group of related inflammatory disorders that share common clinical features and a genetic predisposing factor, the MHC class I gene HLA-B27. Rats transgenic for human HLA-B27 and b2-microglobulin (B27-TG rats) spontaneously develop colitis and peripheral inflammation, and thus provide a model of SpA. Because inflammation in the animals requires $CD4^+$ T lymphocytes and involves intestinal pathology, we hypothesized that the dendritic cells (DCs) that migrate from the intestine and control $CD4^+$ T cell differentiation would be aberrant in B27-TG animals.

Materials and methods: Migrating intestinal lymph DCs were collected by thoracic duct cannulation from B27-TG and control (HLA-B7 transgenic or non-transgenic) rats. The phenotypes of these DCs, and of mesenteric lymph node DCs, were assessed by flow cytometry. Also, the ability of DCs to differentiate from bone marrow precursors *in vitro* was assessed.

Results: Strikingly, B27-TG animals lack one of the three subsets of migrating lymph DCs, the $MHCII^{hi}$ $CD103^+$ $CD172a^{lo}$ cells, in the pseudo-afferent lymph. This '$CD172a^{lo}$' DC subset has been implicated in the induction and maintenance of intestinal tolerance, and thus lack of this subset could lead to breakdown in tolerance and to systemic disease. In addition, the remaining B27-TG L-DCs express more CD25, indicating an increase in their activation. The $CD172a^{lo}$ subset was also proportionally reduced in the B27-TG mesenteric lymph nodes. Furthermore, *in vitro* culture of DCs from bone marrow precursors with Flt3L revealed a reduced survival of B27-TG DCs, suggesting a systemic defect in B27-TG DC differentiation. In spite of the reduced viability of B27-TG BMDCs, the DCs that were generated *in vitro* induced enhanced IL-17 production from naïve $CD4^+$ T cells.

Conclusions: We describe two different mechanisms by which HLA-B27 may contribute to inflammatory disease: increased apoptotic death of B27-TG DCs that normally function to maintain immunological tolerance; and enhanced IL-17 production from $CD4^+$ T cells stimulated by the surviving B27-TG BMDCs.

P0892

Granzyme B produced by human plasmacytoid dendritic cells is regulated by anti-viral vaccines

D. Fabricius*, A. Vollmer,* B. Nußbaum,* D. Busch,* V. Panitz,* B. Jahrsdörfer,† O. Lunov,‡ U. Nienhaus§ & K. M. Debatin§

**Pediatrics, University Medical Center, Ulm, Germany, †Transfusion Medicine, University Medical Center, Ulm, Germany, ‡Institute of Pharmacology of Natural Products and Clinical Pharmacology, Ulm University, Ulm, Germany, §Applied Physics and Center for Functional Nanostructures, University of Karlsruhe, Karlsruhe, Germany*

Purpose/Objective: Plasmacytoid dendritic cells (pDC) are decisive modulators of adaptive T cell responses. Recently we showed that human pDC can produce large amounts of granzyme B (GrB) and that such GrB^+ pDC potently suppress T cell proliferation in a GrB-dependent, perforin-independent manner, reminiscent of regulatory T cells. The relevance of this phenomenon for anti-viral immune responses is not clear.

Materials and methods: The study was performed with pDC isolated from healthy volunteers treated with commercially available anti-viral vaccines *in vitro*. GrB and IFN-alpha production was measured using glow cytometry and ELISA, induction of T cell proliferation was analyzed in pDC- T cell cocultures. In a subset of experiments, pDC were derived from healthy subjects before and after vaccination with tick-borne encephalitis (TBEV) vaccine.

Results: We demonstrate that commonly used anti-viral vaccines against infections including TBEV, poliomyelitis and measles potently suppress pDC-derived GrB production and secretion, thereby paving the way for a more efficient capacity of vaccine-treated pDC to induce T cell proliferation. PDC derived from recently TBEV-vaccinated donors produce less GrB after than before vaccination. TBEV, the most potent enhancer of pDC-induced T cell proliferation, inhibits GrB transfer from IL-3-stimulated pDC to T cells and leads to marked IFN-alpha production in pDC.

Conclusions: Alteration of GrB-secreting pDC activity may be a mechanism by which anti-viral immune responses are regulated. Our results provide novel insights into pDC-T cell interactions and may contribute to an advancement of prophylactic and therapeutic vaccinations.

P0893

HLA class II tetramer detection of a-enolase specific T cells in rheumatoid arthritis

V. Malmström,* J. Pieper,* M. Rieck,† E. James,† C. Sandin,* L. Klareskog* & J. H. Buckner†

**Karolinska Institutet, Medicine rheumatology unit, Stockholm, Sweden, †Virginia Mason, Benaroya Research Institute, Seattle, WA, USA*

Purpose/Objective: Antibodies against different citrullinated proteins are highly specific for RA and α-enolase is one candidate autoantigen towards which antibodies are found. These autoantibodies are strongly associated with the RA risk factor HLA-DRB1*0401. Here, we have studied a set of novel HLA-DRB1*0401 restricted T cell epitopes from α-enolase and constructed and utilized HLA class II tetramers to determine the frequency of α-enolase-specific T cells in blood and synovial fluid of DRB1*0401 RA patients.

Materials and methods: HLA-binding assays were performed for putative T cell epitopes. After verifying positive HLA-DRB1*0401 binding of the candidate peptides, PBMC were cultured with peptides to determine intracellular production of IFN-γ, IL-17A and TNF. Furthermore, we constructed HLA class II tetramers loaded with the peptides to screen mononuclear cells from peripheral blood (PBMC) and synovial fluid of CCP+ HLA-DRB1*0401 RA patients for α-enolase specific T cells. T cells recognizing the α-enolase peptides were visualized using direct *ex vivo* multi-color flow cytometry analysis including phenotypic surface markers.

Results: Novel T cell epitopes in α-enolase were identified; one where only the citrullinated form bound HLA-DRB1*0401 and another where both the native and citrullinated version formed pMHC complexes (with similar affinity). Upon *in vitro* culturing of PBMC with each of the three T cell epitopes, intracellular production of proinflammatory cytokines was apparent and could be prevented by addition of an HLA-DR blocking antibody. Next, HLA class II tetramers were constructed and utilized for the detection of α-enolase specific T cells; in peripheral blood 7/12 RA patients displayed α-enolase specific cells while 9/12 synovial fluids were positive. The *ex vivo* frequency of influenza HA-specific T cells were similar in both peripheral blood and synovial fluid, while the frequencies of α-enolase positive T cells varied greatly between individuals and compartments. Still, the highest frequency of α-enolase specific T cells was found in synovial fluid. Overall, most tetramer positive cells (both HA and in particular α-enolase) where of memory CD45RO phenotype and did not express CD25.

Conclusions: We have identified novel α-enolase T cell epitopes that bind HLA-DRB1*0401. T cells specific for these pMHC's were commonly found in RA patients and produced proinflammtory

cytokines. These α-enolase specific T cells may participate in disease driving immune responses and potentially serve as candidates to immune modulatory strategies.

P0894
HLA-B and HLA-DRB1 associations with henoch-schönlein purpura

O. Montes Ares,* A. Torio Ruíz,* I. Melian Dominguez,† M. Granados Aguirre,† I. Gonzalez Henriquez,* C. Trejo Benitez* & E. Gónzalez Díaz†
*Complejo Hospìtalario Universitario Insular Materno Infantil, Immunology, Las Palmas de Gran Canaria, Spain, †Complejo Hospìtalario Universitario Insular Materno Infantil, Pediatry, Las Palmas de Gran Canaria, Spain

Purpose/Objective: Henoch-Schönlein purpura (HSP) is the most common vasculitis in children with an estimated incidence of 20 in 100 000 children. The pathogenesis of the disease still remains unknown and its genetic susceptibility has been mainly associated to the HLA system. Increased prevalence of some HLA-DRB1 and HLA-B alleles has been previously described and also associations with nephritis and its severity. The aim of this study was to investigate HLA-B and DRB1 genotype frequencies in HSP patients of our area (Gran Canaria, Spain).
Materials and methods: Twenty-four children diagnosed with HSP (9 female, 15 male; Age range 4−16 years) and 121 controls (Blood donors) were enrolled in the study. HLA-B and DRB1 DNA typing was performed with PCR-SSP commercial kits (Innotrain). Differences in frequencies were assessed by the chi-square test.
Results: HLA-B51 was found to be significantly increased in patients compared to controls (14.6% versus 5.8%, $P = 0.04$). Previously described associations from some other areas in Europe such as B35 were not found in our area (8.3% versus 9.9%) HLA-DRB1*04 was increased in patients (25% versus 12.1%, $P = 0.01$) and DRB1*13 was decreased (10.4% versus 23.7%, $P = 0.04$). We did not find differences regarding the severity of the nephritis among the patients.
Conclusions: In this preliminary study HLA-B51 seems to be a factor for susceptibility to the disease as previously described in a cohort from Madrid (Spain). Regarding HLA-class II, HLA-DRB1*04 is also increased in patients while HLA-DRB1*13 was found to be negatively associated with HSP. These results differ from studies carried out in Italy, Northwest Spain and Turkey.

P0896
IgG-opsonization of HIV attenuates the CTL-stimulatory capacity of dendritic cells

D. Wilflingseder,* C. Hamimi,† G. Pancino,† A. Moris,‡ M. P. Dierich,* C. Lass-Floerl,* A. Saez-Cirion† & W. Posch*
*Division of Hygiene and Medical Microbiology, Innsbruck Medical University, Innsbruck, Austria, †Pasteur Institute, Unité de Régulation des Infections Rétrovirales, Paris, France, ‡UPMC, INSERM UMRS-945, Paris, France

Purpose/Objective: Control of HIV is suggested to depend on potent effector functions of the virus-specific $CD8^+$ T cell response. Antigen opsonization can modulate the capture of antigen, its presentation and the priming of specific $CD8^+$ T cell responses. We have previously shown, that opsonization of retroviruses acts as endogenous adjuvant for DC-mediated induction of specific CTLs. However, in some HIV-positive individuals, high levels of antibodies and low levels of complement fragments coat the HIV surface.
Materials and methods: Thus, we analyzed the impact of IgG-opsonization on the antigen-presenting capacity of dendritic cells (DC) by $CD8^+$ T cell proliferation assays following repeated prime-boosting with loaded DC, by measuring the antiviral activity against HIV-infected autologous $CD4^+$ T cells, and by IFN-γ secretion from HIV-specific CTL clones.
Results: We found, that IgG deposition on the viral surface was associated with a loss of the CTL-stimulatory capacity by DC as represented by reduced proliferation, a weak antiviral activity and significantly lower activation of HIV-specific CTL clones compared to HIV covered with high amounts of C and low IgG concentrations.
Conclusions: Our results illustrate the impact of the opsonization pattern of HIV in DC-induced expansion and differentiation of specific CTLs.

P0897
Immune complexes enhance uptake of blood coagulation factor VIII by antigen presenting cells

A. Wroblewska,* E. Herczenik,* A. ten Brinke† & J. Voorberg*
*Sanquin Blood Supply, Plasma Proteins, Amsterdam, The Netherlands, †Sanquin Blood Supply, Immunopathology, Amsterdam, The Netherlands

Purpose/Objective: The X-chromosome-linked bleeding disorder hemophilia A is caused by the absence or dysfunction of blood coagulation factor VIII (FVIII) which can be corrected by regular intravenous administration of FVIII. Development of antibodies directed against FVIII (referred to as FVIII inhibitors) is common complication in hemophilia care. Immune tolerance induction (ITI) comprising frequent administration of high doses of FVIII is the treatment of choice for hemophilia A patients with inhibitors. Thus far, the molecular mechanisms contributing to tolerance induction have not been defined. Here we sought to study the role of immune complex (IC) formation in endocytosis and functional presentation of FVIII by antigen presenting cells.
Materials and methods: Bone marrow-derived dendritic cells (DC) were used as model antigen-presenting cells, as DCs are known for their ability to take up and process immune complexes via FcγR. Purified recombinant FVIII was labeled using the Microscale Alexa Fluor 488 protein-labeling kit. For T-cell proliferation assays, $FVIII^{-/-}$ mice were injected intravenously 5× weekly with 1 μg of recombinant FVIII. Subsequently, spleens collected after weekly injections were processed into single-cell suspensions and used as a source of FVIII-specific T cells.
Results: Bone marrow-derived murine DCs were able to efficiently take up FVIII pre-complexed with anti-FVIII antibodies (FVIII-IC) in a dose-dependent manner. Endocytosis of FVIII-IC was 5- to 10-fold more efficient when compared to equimolar concentrations of soluble FVIII. Uptake of FVIII-IC, but not FVIII alone, could be inhibited with 2.4G2 antibody indicating functional involvement of FcγRI/III in this process. Moreover, antibodies used for IC formation were analysed based on isotype IgG2a antibodies were most efficient in mediating IC endocytosis. Experiments performed with FVIII-specific T cells showed that in the low concentration range (<1 nM), FVIII-IC induced stronger T cell proliferation when compared to soluble FVIII.
Conclusions: Collectively, these data provide further insight and understanding of modulation of anti-FVIII immune response in hemophilia A patients with pre-existing FVIII inhibitors.

P0900
Immunosenescence and dendritic cells: role of TLR2 and TLR4 in phagocytosis and cytokines production against Candida albicans

M. P. P. Nascimento & V. S. Lara
Bauru School of Dentistry University of São Paulo, Stomathology and Pathology, Bauru, Brazil

Purpose/Objective: Purpose.

Dendritic cells (DC) are the most potent antigen presenters, and play a key role in the induction of both innate and adaptive immunity.

Aging is associated withprogressive decline in immune function, resulting in an increasing susceptibility to infection, taking into account the specific changes in T cells, macrophages, neutrophils and DC, usually referred to as immunosenescence. Among microorganisms, the fungus *Candida albicans* (*C. albicans*) is an important pathogen for the development of invasive infections, especially in immunocompromised individuals and elderly persons. In addition, functional alterations in DC with aging, including the role of *C. albicans* infection are poorly understood.

Objectives.

To study the phagocytic capacity and aspects of immunomodulatory function of mature DC against *C. albicans* in aged patients, through the production of TNF-α, IL-6, IL-23 and IL-10. The involvement of TLR2 and TLR4 receptors was also evaluated.

Materials and methods: Peripheral blood monocytes were isolated from healthyelderly donors ($n = 18$) and young donors ($n = 20$), and were cultured for 7 days to differentiate into DC under the influence of IL-4 and GM-CSF. Participation of receptors type TLR2 and TLR4 was assessed *in vitro* by using specific blockingantibodies. Cytokine production was measured by ELISA test and phagocytosis assays were realized for 1 h and analyzed by confocal laser scanning microscopy. The data was statistically analyzed and $P < 0.05$ was considered significant.

Results: TNF-α, IL-10 and IL-23 production by DC was higher in young than aged subjects, spontaneously or after *C. albicans* challenge. The elderly presented more DC with internalized *C. albicans* than young individuals (89.7% and 63.3%, respectively). The TLR2 or TLR4 blocking did not affect cytokine production or phagocytosis by DC.

Conclusions: Together, these data suggest an impairment of cytokine production by DC from elderly in comparison with young subjects. Moreover, the elderly presented more DC with internalized fungus than young subjects, which would mean failure in time to kill the phagocytosed microorganism. Probably, receptors other than TLR2 and TLR4 are involved in signaling to elicit phagocytosis or cytokine production by DC.

P0901
Impact of cross-linking CD161 on human T cells

K. Smith,* C. Willberg,* J. Ussher,* C. O'Callaghan,* G. J. Freeman† & P. Klenerman*

**Peter Medawar Building for Pathogen Research, Nuffield Department of Medicine, Oxford, UK, †Dana Farber Cancer Institute, Harvard Medical School, Boston, MA, USA*

Purpose/Objective: CD161 is a C type Lectin expressed on NK cells and subsets of T cells. CD161 is one of the markers used to define Th17 cells. Human mucosal associated invariant T cells (MAIT) have been shown to express high levels of CD161 ($CD161^{++}$). In chronic viral hepatitis C there are tissue infiltrating T cell populations that express high levels of CD161. The CD161 protein is known to be a marker for these important cell subsets, however we do not yet understand the impact of CD161 triggering on T cell function. Understanding the functional impact that CD161 triggering has on the function or regulation of MAIT, Th17, Tc17 and other T cell subsets in human inflammatory diseases, are potentially of relevance to their role *in vivo* and therapeutic manipulation.

Materials and methods: To study the effects of cross-linking CD161 lymphocytes, (PBMCs) were isolated from healthy volunteers, stimulated and the CD161 on cells was cross-linked. Intracellular cytokine staining (ICS) and fluorescence-activated cell sorting (FACS) were used to look at the effect of cross-linking CD161 on production of IFN-g, other cytokines and other cell surface markers. We repeated these experiments using the physiologic ligand, LLT-1 (CLEC2D), expressed as a recombinant protein or on transfected cells.

Results: We stimulated PBMCs with multiple different stimuli, including PMA/I, aCD3 and aCD28, *E. coli* stimulated THP1 cells, IL12, and IL-18. We were unable to show an effect on the production of IFNy by $CD161^{+}$ T cells using antibody cross-linking or stimulation with the physiologic ligand under any condition. However, we were able to consistently show a clear dose dependent down regulation of CD161 surface protein on cells with high levels of CD161 expression ($CD161^{++}$).

Conclusions: Cross-linking CD161 via a range of stimuli induces a dose-dependent downregulation of CD161 on $CD161^{++}$ cells without affecting cytokine production. Further investigation is needed to define the key functional impact of CD161 ligation/downregulation on these critical cell subsets.

P0902
Impact of nitration on the immunogenicity of Bet v 1.0101

C. Ackaert,* S. Kofler,* N. Zulehner,† G. Posselt,* G. Gadermaier,* C. Asam,* B. Bohle,† F. Ferreira,* H. Brandstetter,* A. Duschl,* J. Horejs-Höck* & G. J. Oostingh‡

**Molecular Biology, University of Salzburg, Salzburg, Austria, †Pathophysiology and allergy research, Medical University of Vienna, Vienna, Austria, ‡Molecular Biology, University of Applied Sciences, Salzburg, Austria*

Purpose/Objective: Nitration of Bet v 1.0101 (Bet) can occur exogenously and endogenously, and might be one explanation for the higher prevalence of allergy in industrialised countries. Previously, nitration was shown to influence processing of allergens by dendritic cells (DCs). The present study investigates effects of nitration on Bet-specific IgE reactivity, Bet-dependend DC-activation and proliferation of Bet-specific T cell lines.

Materials and methods: IgE reactivity against freshly nitrated Bet and mock-Bet was tested in 100 patient sera by ELISA. In a second setup, monocyte derived DCs were stimulated with Bet, mock-Bet and nitro-Bet, and the secreted cytokines were analyzed, as well as the surface markers. Additionally, specific T cells were isolated from allergic patients and the proliferation upon stimulation with the unmodified and the nitrated allergen was measured. To follow the biophysical changes occurring upon nitration gel electrophoresis, amino acid analysis and size exclusion chromatography were performed.

Results: No increased IgE response towards nitro-Bet versus mock-Bet could be found in the sera of allergic patients. Analysis of the cytokines secreted by monocyte derived DCs reveals high concentrations of the Th1 promoting cytokines IL-12, IL-6 and TNF-α upon stimulation with Bet, which is probably due to lipopolysaccharide bound to the allergen. Notably, this Th1 priming milieu is absent in the case of nitrated Bet. Furthermore, nitrated Bet induces a much stronger proliferation of Bet specific T cells, compared to the proliferation of T cells after stimulation with Bet or mock-Bet. The main biophysical change due to nitration was the induction of SDS resistant allergen oligomerisation of nitro-Bet.

Conclusions: The data obtained in this study demonstrate that nitration of Bet v 1.0101 results in a higher immune response, possibly due to consequent oligomerisation. These findings strongly suggest that nitration plays a role in the higher prevalence of allergy.

P0903

Increased immunogenicity of proteins modified by hypochlorous acid, may be caused by their enhanced uptake via endocytic receptors expressed on antigen presenting cells

R. Biedron, J. Marcinkiewicz & S. Jozefowski
Department of Immunology, Jagiellonian University Medical College, Krakow, Poland

Purpose/Objective: During respiratory burst, neutrophils, eosinophils and monocytes produce hypochlorous acid (HOCl) which, apart from contributing to killing of pathogens, may also oxidize different proteins at sites of inflammation. It was previously reported that *in vitro* presentation of HOCl-modified ovalbumin (OVA-Cl) to ovalbumin (OVA)-specific lymphocytes by dendritic cells (DCs) was more effective than that of native OVA. Moreover, mice immunized with OVA-Cl produced higher amounts of OVA-specific antibodies that mice immunized by native OVA. We reported previously that OVA-Cl is subjected to strongly enhanced uptake by macrophages and DCs. This increased uptake and intracellular processing may be the major mechanism of increased immunogenicity of OVA-Cl as OVA-Cl neither stimulated cytokine release nor modulated expression of MHC class II and co-stimulatory molecules on the surface of DCs.
Materials and methods: We examined receptors involved in OVA-Cl uptake with the use of fluorescently labeled ligands, receptor-blocking antibodies, receptor-deficient cells and recombinant receptors.
Results: We found that two types of receptors: one blocked by dextrans sulfate (DS), but not by mannan, and the second one, blocked by both DS and mannan, contributed almost equally to OVA-Cl uptake by DCs. Results of further experiments revealed that the mannose receptor (CD206) accounted at least partially for the portion of OVA-Cl uptake which is inhibited by both mannan and DS, whereas different scavenger receptors, including scavenger receptor A (SR-A), LOX-1 and SREC-I, may be responsible for the part of the uptake which is inhibited by DS only. Finely, we have demonstrated that upon chlorination other unrelated proteins and glycoproteins gain the ability to bind to the same receptors as OVA-Cl.
Conclusions: Our results indicate that increased immunogenicity of chlorinated proteins is caused by their increased uptake by DCs through several endocytic receptors, including the mannose receptor, SR-A, LOX-1 and SREC-I. We postulate that oxidation by HOCl may be a universal mechanism of increasing immunogenicity of proteins which in their native forms are not recognized by endocytic receptors present on the surface of antigen presenting cells.

P0904

Increased Th22 cells in patients with Beçhet's disease

E. Aktas Cetin,* F. Cosan,† A. Cefle† & G. Deniz*
**Department of Immunology, Istanbul University The Institute of Experimental Medicine (DETAE), Istanbul, Turkey, †Department of Internal Medicine, Kocaeli University Faculty of Medicine, Kocaeli, Turkey*

Purpose/Objective: Beçhet's disease (BD) is a systemic inflammatory disease with recurrent inflammatory mucosal ulcerations, ocular, vascular, gastrointestinal, musculoskeletal and central nervous system involvement. Although innate immune system plays the major role in the pathogenesis, previous data has shown that some T helper (Th)1 associated cytokines have role in the inflammation of BD. The $CD4^+$ Th cells can be differentiated into Th1, Th2, Th17, Th22 and regulatory T (Treg) cells and secrete different cytokines to regulate immune system. In this study cytokine secretion of Th cells in BD were investigated.
Materials and methods: Twenty-six patients with BD that have not received any immunosuppressive treatment ($n = 26$, mean age = 37.2 ± 9.7) with mucocutaneous involvement and healthy subjects ($n = 12$, mean age = 32.5 ± 8) were enrolled in this study. Lymphocyte subpopulations in peripheral blood samples and intracellular cytokine secretion including IL-5, IL-10, IL-17, IL-22 and IFN-γ of $CD4^+$ T and $FOXP3^+$ Treg cells were determined by flow cytometry. Mann−Whitney *U*-test was used for non parametric values.
Results: Although the percentages of IL-5 secreting Th2 and IL-$17A^+$IFN-γ^- Th17 cells were found similar in both groups, IL-$17A^-$ IL-22^- IFN-γ^+ Th1 and IL-$17A^-$ IL-22^+IFN-γ^- Th22 cells are significantly increased in BD patients compared to healthy subjects ($P = 0.002$ and $P = 0.028$, respectively). There was also no significant difference for the expression of CD4, CD8, CD3, CD19, however percentages of Treg ($CD4^+$ $CD25^+FOXP3^+$) cells were dramatically reduced in BD ($P = 0.000$) patients.
Conclusions: These findings revealed that increased levels of IFN-γ secreting Th1 cells as well as Th22 cells might be associated with inflammatory reactions. It has been shown that inflammatory IL-22 secreting cells are distinct from Th17 cells and Th1 cytokines inhibit IL-17 but not IL-22. In the same manner, increased levels of IFN-γ might suppress the IL-17 secretion.

P0905

Inflammatory and tissue derived dendritic cells functionally cooperate to prime Th1 skewed responses to CpG/antigen

S. De Koker,* M. Willart,† P. Bogaert,† B. De Geest,‡ B. Lambrecht† & J. Grooten*
**Ghent University, Biomedical Molecular Research, Ghent, Belgium, †VIB, Molecular Biomedical Research, Ghent, Belgium, ‡Ghent University, Pharmacy, Ghent, Belgium*

Purpose/Objective: Dendritic cells (DCs) harbour the unique capacity to prime and steer T cell responses. DCs are however a heterogeneous population, with multiple DC subsets displaying specialized functions. Under steady state conditions, lymph node resident and tissue derived migratory DCs can be discriminated. In case of inflammation, an additional population of inflammatory DCs (iDCs) arises. Gaining insights in the functional divergence and collaboration among DC subsets in priming Th1 responses to antigens combined with the TLR9 ligand CpG constitutes the main objective of this study.
Materials and methods: Lymph nodes of mice subcutaneously injected with OVA-488/CpG were analysed by FACS for OVA containing DC subsets and IL-12 production. Sorted DC subsets were co-cultured with CFSE labeled OT-I/II cells to assess antigen presentation. Effector T cell responses were analysed using IFN-γ elispot.
Results: Subcutaneous injection of CpG/OVA-488 results in the fast recruitment of monocyte derived $Ly6C^{hi}$ $CD11b^{hi}$ cells, resembling the phenotype of iDCs, to the draining lymph nodes. These cells gradually upregulate CD11c and MHCII, indicating they differentiate into 'bonafide' DCs, but lack CCR7, suggesting they directly migrate from the blood to the lymph node. Being the major OVA containing DC population, sorted iDCs however fail to present OVA to OT-I/II cells *ex vivo*. Tissue derived migratory DCs instead efficiently stimulate OT-I/II proliferation, showing they are the main APCs following CpG based immunization. iDCs nevertheless are crucially involved in the Th1 skewing properties of CpG, as a dramatic reduction in the effector response was observed in CCR2 KO mice, which lack iDCs. By intracellular cytokine staining, we were able to demonstrate that iDCs were by far the predominant source of IL-12 following CpG-based immunization.
Conclusions: iDCs and migratory DCs functionally cooperate to prime IFN-γ secreting CD4 and CD8 T cells following immunization with CpG/antigen. While migratory DCs are crucial for antigen presentation, iDCs in contrast provide the Th1 skewing cytokine IL-12. This dichotomy in antigen presentation and cytokine secretion thereby appears to mimic the situation observed in priming Th2 responses, where DCs present the antigen but basophils/eosinophils represent the major source of IL-4.

P906
Influence of *Salmonella* on MHC class II antigen presentation

N. Jackson*, Y. H. Kang,* N. Lapaque,* H. Janssen,† J. Trowsdale* & A. P. Kelly*

**Department of Pathology, University of Cambridge, Cambridge, UK, †Division of Cell Biology, Netherlands Cancer Institute, Amsterdam, The Netherlands*

Purpose/Objective: Control of *Salmonella* infection requires MHC-II restricted $CD4^+$ T cell responses; however, development of adaptive immunity to *Salmonella* infection is delayed and inefficient. We have previously shown that cells harbouring *Salmonella enterica* serovar Typhimurium (*S.* Typhimurium) exhibit elevated MHC-II polyubiquitination and reduced MHC-II surface expression. The purpose of this study was to define the intracellular localisation of MHC-II down-regulated by *Salmonella* and the influence this has on antigen presentation to conventional Type A and unconventional Type B $CD4^+$ T cells.
Materials and methods: For EM, MelJuSo cells were infected with GFP-*S.* Typhimurium by SPI1-mediated invasion. Surface HLA-DR was labelled with L243 antibody at 12 h post-infection and then L243 endocytosis was assessed from 0 to 7 h. Cells were fixed, cryosectioned and labelled with 10 nm proteinA gold particles. For antigen presentation, BMDC were infected with opsonised *S.* Typhimurium. At 20 h post-infection, HEL protein or peptide and T hybridoma cells were added. T cell activation was quantified by measuring IL-2 concentration in supernatant by ELISA after 24 h. MHC-II surface expression was assessed by flow cytometry as mean L243 fluorescence of infected cells (GFP positive)/mean L243 fluorescence of uninfected cells (GFP negative) ×100.
Results: *S.* Typhimurium reduces surface expression of MHC-II by a mechanism that is independent of invariant chain directed trafficking and causes accumulation of MHC-II in multi-vesicular bodies. Reduced MHC-II surface expression in *S.* Typhimurium-infected BMDCs correlates with reduced presentation of antigen to conventional Type A T cells. In contrast, exposure of BMDCs to live *S.* Typhimurium enhances presentation of exogenous peptide to unconventional Type B T cells.
Conclusions: This data suggests that *Salmonella* infection specifically stabilises or enhances formation of the pMHC-II conformer recognised by Type B T cells, whilst the pMHC-II conformer recognised by Type A T cells is down-regulated. Type B T cells do not recognise peptide processed from protein in late endosomal compartments and therefore escape negative selection and are implicated in autoimmunity. These observations have implications with respect to the interplay between pathogens, the host immune response and autoimmunity.

P0907
Interference of the CD30-CD30L pathway reduces atherosclerosis development

A. C. Foks,* I. Bot,* V. Frodermann,* S. C. A. de Jager,* M. ter Borg,* P. J. van Santbrink,* H. Yagita,† J. Kuiper* & G. H. M. van Puijvelde*

**Biopharmaceutics, Leiden Amsterdam Center for Drug Research/Leiden University, Leiden, The Netherlands, †Department of Immunology, School of Medicine, Juntendo University, Tokyo, Japan*

Purpose/Objective: Costimulatory molecules tightly control immune responses by providing positive signals that promote T cell activation or by transducing inhibitory signals that limit T cell responses. CD30 and CD30L are members of the TNF(R) superfamily and are involved in activation and proliferation of T and B cells, which have been implicated in the initiation and progression of atherosclerosis. In the present study, we thus aimed to determine the role of the CD30-CD30L pathway in the development of atherosclerosis.
Materials and methods: Western-type diet fed LDL receptor deficient ($LDLr^{-/-}$) mice were treated with an anti-CD30L antibody for 8 weeks.
Results: This resulted in a reduction of atherosclerotic lesion formation in the aortic root by 35%. Reduced numbers of adventitial $CD3^+$ T cells were found in anti-CD30L-treated mice, whereas no differences were observed in collagen and macrophage content of the atherosclerotic lesions. B cell and mast cell responses were also not affected upon anti-CD30L treatment. Interestingly, splenocyte proliferation was reduced with 53%, while T cell numbers were concomitantly reduced in anti-CD30L-treated mice compared with control mice. These data thus indicate that the CD30-CD30L pathway solely exerts its function via inhibition of T cell responses.
Conclusions: In the present study, we are the first to show that interruption of the CD30-CD30L pathway reduced initial atherosclerosis development by modulating T cell function.

Intravital imaging-based analysis of thromboxane A2 receptor function during physiological T cell activation

F. Moalli, P. Halbherr, M. Pieczyk & J. V. Stein

Lymphocyte Trafficking and Activation, University of Bern Theodor Kocher Institut, Bern, Switzerland

Purpose/Objective: Thromboxane A2 (TXA2) is a prostanoid formed by thromboxane synthase using the cyclooxygenase product prostaglandin H2 as substrate. While activated dendritic cells (DCs) are able to produce TXA2, the TXA2 receptor TP is expressed by naïve T lymphocytes. *In vitro* assays have previously shown that TXA2-induced TP activation induces chemokinetic motility of T cells and decreases T cell − DC interactions, yet its *in vivo* function for controlling dynamic T cell − DC interactions in lymphoid tissue has remained elusive.
Materials and methods: The popliteal lymph node (LN) was surgically exposed in mice injected 18 h before with activated DCs, control and TP-deficient TCR tg CD4+ T cells were adoptively transferred before intravital fluorescence microscopy (IVFM) scanning. Sequences of image stacks were transformed into volume-rendered four-dimensional movies using Volocity software, which was also used for semiautomated tracking of cell motility in three dimensions and DC-T cells interactions analysis. The average track velocity and turning angles (defined as the angle between the two velocity vectors before and after a measurement time point) were calculated from the *x*, *y*, and *z* coordinates of cell centroids.
Results: Using control and TP-deficient TCR tg $CD4^+$ T cells in combination with twophoton microscopy (2 PM) of murine lymphoid tissue, we demonstrate here that TP deficiency does alter lymphocyte motility under non-inflamed conditions. In presence of activated DCs, TP-deficient T cells migrated moderately slower and with slightly larger turning angles than control T cells, although their motility coefficients remained comparable. In contrast, when activated DCs were presenting cognate peptide, the migration velocity of peptide-specific $CD4^+$ T cells was markedly reduced in the absence of TP as compared to wild type cells, irrespective of the antigenic dose. This reduction in T cell motility correlated with prolonged interactions times between TP-deficient $CD4^+$ T cells and DCs.
Conclusions: In sum, our data identify TXA2-induced TP signaling as a negative regulator of T cell − DC interactions, which may contribute to prevent excessive immune reactions and autoimmunity.

Investigating human dendritic cell localization and migrating behaviour in three-dimensional models of lung mucosa

A. Nguyen Hoang,* P. Chen,* J. Juarez,* K. Högstrand,* A. Ali,* P. Sachamitr,† L. Bosnjak,* J. Lock,‡ A. Grandien,‡ M. Coles† & M. Svensson*

Karolinska Institutet, Medicine, Stockholm, Sweden, †Biology, University of York, York, UK, ‡Karolinska Institutet, Biosciences and Nutrition, Stockholm, Sweden

Purpose/Objective: Tissue homeostasis is a dynamic process dependent on the cooperation between immune cells, such as dendritic cells (DC), and tissue specific cells, including epithelial cells and stromal cells (i.e. fibroblasts). Within lung, DC mainly associates with the epithelial layer and there is evidence of DC regulation by the epithelium and that epithelial dysfunction leads to overzealous immune cell activation. However, dissecting basic mechanisms of DC interactions with epithelial cells in human tissue is difficult. Here, we present protocols to prepare three-dimensional collagen matrices with fibroblasts, establish epithelial layers and image and quantify DC activities within lung mucosa using time-lapse fluorescence microscopy.
Materials and methods: Retroviral vectors were used to generate stable GFP epithelial cells and orange fibroblasts. DC were labelled with a far red cell tracker dye before implantation into the tissue model. The model is created on Transwell inserts to allow culture at the air-liquid interface. Monocyte-derived DC were implanted in between the fibroblasts and epithelial layer. Before imaging, models were stimulated with 100 ng/ml LPS. Live imaging analyses were performed to study DC distribution and migratory behaviour in the tissue model using both confocal and multiphoton microscopy.
Results: The tissue model recapitulates key anatomical and functional features of lung mucosal tissue, including a stratified epithelial cell layer, deposition of extracellular matrix proteins and the production of tight- and adherence- junction proteins. Labelling of fixed tissue model sections and imaging of live tissue models revealed that DC distribute in close association with the epithelial layer. Time-lapse fluorescence microscopy revealed altered distribution of DC with a more a frequent appearance of DC at the apical side of the epithelium when the model was stimulated with LPS.
Conclusions: This novel tissue model provides a tool well suited for a wide range of studies, such as elucidating incompletely defined pathways controlling homeostatic activities of human DC in mucosal tissue, as well as DC responses to pathogen-induced inflammation.

Investigating the role of cutaneous dendritic cells in T-cell mediated immunopathology

T. Conlan,* J. Sivakumaran,* F. Fallah-Arani,* L. Zhang,* T. Means,† F. Geissman,‡ R. Chakraverty* & C. Bennett*

UCL Cancer Institute, Academic Haematology, London, UK, †Massachusetts General Hospital, Immunology and Inflammatory Diseases, Charlestown, MA, USA, ‡Kings College London, Centre for Molecular and Cellular Biology of Inflammation Biology, London, UK

Purpose/Objective: Severe and chronic immunopathology mediated by T cells is common to many cutaneous diseases. An important example is graft-versus-host-disease (GVHD). In MHC-mismatched models of bone marrow transplantation, host antigen presenting cells that survive the conditioning regime have been shown to be essential for priming GVHD. We have previously shown that inflammation within peripheral tissues is critical to the recruitment and function of effector T cells (Chakraverty *et al.* JEM 2006). To assess whether Langerin+ dendritic cells (DC) have a role regulating this inflammatory checkpoint, we developed a model of cutaneous GVHD where host Langerin+ DC can be selectively depleted. Minor histocompatibility antigen mismatched models were also developed to test the role of Langerin+ DC in more clinically relevant models of GVHD.
Materials and methods: MHC-mismatched mixed chimeras (MC) were generated by reconstituting irradiated Langerin-DTR (or B6) recipients with T cell depleted bone marrow (BM) from B6 (or Langerin-DTR) and Balb/c mice. Eight weeks later, MC were injected with Balb/c T cells. Localized skin GVHD was induced by topical application of Imiquimod, a TLR7 agonist. Langerin+ DC were depleted by i.p. injection of diphtheria toxin. In another model, male Langerin-DTR mice were lethally irradiated and reconstituted with female B6 BM and either CD4 (Marilyn) or CD8 (MataHari) cells transgenic for HY-specific TCR. Depletion of Langerin+ DC was induced by i.p. DT.
Results: Depletion of Langerhans cells (LC) in MC resulted in significant reductions in cutaneous GVHD. However, the absence of host LC had no effect on the priming or frequency of donor CD8 T cells found in skin or draining lymph nodes. Rather, the capacity of epidermal CD8 T cells to generate IFN-γ, TNF-α and TRAIL was significantly reduced. When host Langerin+ dermal DC but not LC were depleted, there was no effect on the accumulation of donor CD8 cells within skin draining lymph nodes or within the epidermis and no effect on the severity of cutaneous GVHD. In the HY-mismatched model of BMT, depletion of Langerin+ DC reduced recruitment of HY-specific CD4 or CD8 cells to skin.
Conclusions: Langerin+ DC contribute to CD8 T cell mediated immunopathology in the skin. In a major mismatch model of GVHD, host LC were required to 'license' T cells for full effector function. In a minor mismatch model of GVHD, host Langerin+ DC are required for the accumulation of antigen specific CD4 and CD8 cells in the skin.

Irap is required for normal phagosome maturation in dendritic cells

M. Weimershaus, L. Saveanu & P. van Endert

INSERM, U1013, Paris, France

Purpose/Objective: Among phagocytes, dendritic cells (DCs) are characterized by mild acidification and delayed maturation of their phagosomes, features that have been demonstrated to be essential for an efficient MHC class I cross-presentation. Known molecular mechanisms contributing to delayed maturation of DC phagosomes include Sec22-mediated NOX2 mediated alkalinization of phagosomes and Sec22-mediated ERGIC recruitment to them. We have recently identified a previously unappreciated cellular compartment that is massively recruited to DC phagosomes and required for antigen cross-presentation. This compartment corresponds to regulated storage endosomes described in other cell types and contains Insulin Responsive AminoPeptidase (IRAP), which acts as a trimming peptidase for cross-presented peptides. Here we analyzed the contribution of IRAP+ storage endosomes to phagosome maturation in DCs.
Materials and methods: Phagosomes obtained from wt and IRAP deficient DCs were analyzed by confocal microscopy, immunoblot and phagoFACS with respect to the kinetics of their maturation, phagosomal cargo degradation and intra-phagosomal pathogens killing.
Results: IRAP-deficient DCs showed accelerated phagosome maturation as documented by premature loss of early endosomal markers such as EEA1 and Rab14, and accelerated acquisition of phagolysosome markers such as Lamp1 and V-ATPase. This was associated with accelerated degradation of phagocytosed antigen, enhanced acidification of endosomes and increased killing of internalized fungal cells and bacteria.
Conclusions: Our results suggest that fusion with the specific endosomal compartment containing IRAP is required for normal phagosome maturation in DCs.

Kinetics of codominant MHC protein expression and implications for disease associations

R. Busch,* A. De Riva,* C. Prevosto,* M. C. Varley,† S. McDonald,* M. F. Usmani,* S. Wassell,‡ L. A. Bluck,‡ A. Cooke,§ J. S. H. Gaston* & M. J. Deery¶

*Department of Medicine (Rheumatology), University of Cambridge, Cambridge, UK, †Department of Engineering, University of Cambridge, Cambridge, UK, ‡Stable Isotope Laboratory, MRC Human Nutrition Research, Cambridge, UK, §Department of Pathology, University of Cambridge, Cambridge, UK, ¶Centre for Proteomics, University of Cambridge, Cambridge, UK

Purpose/Objective: Genotype/phenotype relationships, such as MHC associations with autoimmune disease, remain a puzzle for biomedicine in the postgenomic era. Extensive polymorphism of codominantly expressed MHC alleles diversifies peptide presentation to T cells, but some alleles increase autoimmune disease risk. Some of these associations have been blamed on protein misfolding (HLA-B27 in ankylosing spondylitis) or increased turnover (H2-A^{g7} in NOD mice). However, little is known about how MHC polymorphism affects protein turnover. This was investigated here.

Materials and methods: A stable isotope labelling approach was developed to this end. Human APCs or mice were labelled with heavy water (^2H_2O), cells were harvested after various times, and folded MHC proteins immunoprecipitated. After SDS-PAGE and tryptic digestion, ^2H incorporation was tracked by LC/MS and used to calculate fractional protein synthesis. To control for cell proliferation, fractional DNA synthesis was quantified simultaneously by GC/MS analysis of ^2H incorporation into purine deoxyribose.

Results: The turnover rates of folded MHC proteins differed by class and isotype and were strongly affected by cellular background. In human myeloid APC lines and MoDCs, HLA-C molecules turned over faster than HLA-B; HLA-A turnover rates varied between individuals. HLA-DR, but not MHCI turnover was shut down by LPS activation of MoDCs. HLA-B and DR turnover were very slow in EBV-transformed B cells. Folded HLA-B27 molecules had similar turnover rates as other B alleles. *In vivo,* murine splenic MHCII protein turnover was faster in DCs than in B cells. Allelic differences in MHC protein turnover were slight. A^{g7} turnover differed from A^d or E^d by <20% overall, although A^{g7} exhibited kinetic heterogeneity in B cells.

Conclusions: Cell type and activation state, as well as MHC isotype, regulate the turnover rates of folded MHC proteins in physiological APCs. In contrast, the impact of allelic polymorphism in physiological APCs is minor, limiting the possible roles of MHC protein turnover in autoimmune pathogenesis. Stringent conservation of protein life span between alleles suggests critical roles in codominant expression and function of MHC proteins. The approach developed here will be generally useful for probing the impact of structural polymorphism on protein turnover, and its relevance to disease, *in vivo*.

Lactoferrin modulates immune responses induced by chemical allergens

A. Metryka,* I. Kimber,* R. Roberts† & R. Dearman*

*Faculty of Life Sciences, University of Manchester, Manchester, UK, †AstraZeneca, Safety Assessment Alderley Park, Macclesfield, UK

Purpose/Objective: Lactoferrin (LF) is an 80 kDa glycoprotein from the transferrin family. It is present in mammalian epithelial secretions and secondary neutrophil granules. LF is well known as an anti bacterial protein due to its ability to sequester iron as well as its potential to bind lipopolysaccharide. Recently LF has emerged as an immunomodulatory molecule with reports suggesting that it can exert both immunostimulatory and immunosuppressive functions. For example, in both man and mouse we have shown that the homologous LF inhibits Langerhans cell (LC) migration secondary to effects on TNF-α. The purpose of these investigations is to further characterise the action of LF *in vivo*.

Materials and methods: BALB/c strain mice were treated topically on the dorsum of both ears with 0.5 μg of human native milk LF in aqueous cream or cream alone. Two hours later the same site was treated with chemical contact allergen: either 0.5% oxazolone (Ox) or 1% 2,4-dinitrochlorobenzene (DNCB). Four to 24 h thereafter ears were excised, split into dorsal and ventral halves, epidermal sheets were prepared, and stained for LC enumeration using fluorescein isothiocyanate labelled anti-major histocompatibility complex class II antibody.

Results: The resting levels of LC in naïve BALB/c female mice were approximately 1100 LC/mm^2. Consistent with previous experience, topical exposure (4 h) to either allergen resulted in a significant decrease in LC frequency (25−30%) indicating the proportion of LC that appear to be available for rapid mobilization. Prior treatment with LF (2 h) significantly inhibited LC migration triggered by exposure to Ox (4 h) (3% and 24% migration in presence and absence of LF, respectively) but was without effect on DNCB-induced LC mobilization (17% and 21% migration in presence and absence of LF, respectively). The effects of LF on Ox-induced LC migration were reproducible but relatively transient, such that significant Ox-induced reductions in LC frequency (12% and 17%) were recorded after 6 and 24 h in the groups of animals pre-treated with LF.

Conclusions: Taken together, these results demonstrate that heterologous (human) LF functions as an immunomodulatory protein following topical exposure in mice. Furthermore, the effects of LF are allergen-specific and indicate that Ox- and DNCB-induced LC migration may have differential requirements for TNF-α.

Leishmania major lysate as source for potential immunogenic antigens

A. I. Schermann,* B. Lorenz,* S. Tenze† & E. von Stebut*

*Department of Dermatology, University Medical Center Mainz, Mainz, Germany, †Institute of Immunology, University Medical Center Mainz, Mainz, Germany

Purpose/Objective: Cutaneous leishmaniasis (CL) is caused e.g. by the parasite *Leishmania major*. It is known that healing of CL requires interferon (IFN)γ release by both antigen-specific $CD4^+$ Th1 and $CD8^+$ Tc1 cells. Nonetheless, an effective vaccine does not exist at present, even though its development is of highest interest due to increased morbidity of affected individuals with co-infections or immunosuppression. Therefore, we aim to identify and characterize *L. major*-specific immunogenic proteins from soluble *Leishmania* antigen (SLA) with proven efficacy during vaccination approaches.

Materials and methods: First, differential centrifugation was performed to partition SLA into its components (nuclei, mitochondria, membrane proteins, soluble proteins). Next, to further break-down the complexity of SLA, we focused on the soluble proteins, which we fractionated by using combinations of different anion exchange chromatography columns. Eluted fractions were tested for their T cell restimulating ability (cytokine release, proliferation) *in vitro* using draining lymph node (dLN) T cells isolated from resistant, infected C57BL/6 mice.

Results: dLN cells restimulated with SLA typically show a dominant Th1/Tc1 cytokine profile. Interestingly, all components obtained after differential centrifugation induced reactivity similar to total SLA. After combined chromatographic fractionation of the soluble proteins, we identified several fractions that induced high IFNγ levels compared to unstimulated controls. As expected for exogenous antigens, $CD4^+$ T cell reactivity played an important role, as the fraction-specific

proliferation of $CD4^+$ dominated over the expansion of $CD8^+$ T cells. IFNγ-releasing fractions will next be analyzed by label-free mass spectrometry for protein content.
Conclusions: Since immunization studies of mice showed promising results with selected recombinant *Leishmania* proteins combined with adjuvant, identification of additional immunogenic antigens *in vitro* and *in vivo* may contribute to a better understanding of T cell-mediated protection against CL; however, better antigens need to be characterized that mediate full protection.

P0916

Mutant Gimap5 derived from diabetes-prone BB rats causes selective enrichment of Th1/Th17 cells and an altered TCR repertoire in Lewis rats

H. J. Fischer, J. van den Brandt & H. M. Reichardt
Medical School, Institute of Cellular and Molecular Immunology, University of Göttingen Göttingen, Germany

Purpose/Objective: Deficiency of the *GTPase of the immunity-associated protein 5* (Gimap5) causes severe T cell lymphopenia and is responsible for the development of autoimmune Type 1 Diabetes in BB rats with the MHC haplotype $RT1^U$. Gimap5 in these rats carries a single point mutation, resulting in the expression of a truncated, non-functional protein. Consequently, peripheral CD8+ and CD4+ T lymphocyte numbers are dramatically diminished due to increased death of recent thymic emigrants. This appears to explain the selective enrichment of autoreactive T cells as indicated by an oligoclonal expansion of the remaining T cells. Interestingly, Gimap5 deficiency in PVG rats also leads to T-lymphopenia and autoimmunity, although Gimap5 deficient rats on this genetic background develop eosinophilic bowel disease rather than Type 1 diabetes. Moreover, Gimap5 polymorphisms in humans are linked to systemic lupus erythematosus and these patients are also lymphopenic.
Materials and methods: To further characterize Gimap5 function, we have backcrossed the mutant Gimap5 allele to Lewis rats harbouring the MHC haplotype $RT1^{B/D}$. By using speed congenics we were able to obtain a 99% pure Lewis background within 5 generations.
