Results: Gimap5 deficient Lewis rats develop T lymphopenia in the periphery and show an altered TCR repertoire. Whereas the V beta chain usage in the thymus is unchanged, some V beta chains are overrepresented on peripheral T cells of Gimap5 deficient Lewis rats as compared to controls. However, the affected V beta chains are not identical to the ones altered in BB rats. The few remaining T cells in the Gimap5 deficient Lewis rats exhibit an activated phenotype as indicated by high levels of CD134 and CD11a expression and low levels of CD62L. Furthermore, the relative number of IFNγ and IL-17 producing T cells is increased while the frequency of regulatory T cells is not affected. Although up to now we did not observe any spontaneous disease development, Gimap5 deficient rats suffer from a fulminant disease course after active EAE induction.
Conclusions: Collectively, our data indicate that Gimap5 is important for T cell survival and adjustment of the different T cell subsets and that its absence results in an altered TCR repertoire and a disproportionally high frequency of Th1/Th17 cells.

New approach in EAE treatment, part I: the application of dendritic cells stimulated with Trichinella spiralis antigens results in dose dependent effect

N. Ilic, A. Gruden-Movsesijan, I. Radovic, J. Cvetkovic & L. Sofronic-Milosavljevic
Institute for the application of nuclear energy – INEP, Immunology and immunoparasitology, Belgrade, Serbia

Purpose/Objective: Helminth infection has a potent systemic immunomodulatory effect on the host immune response, which also affects the development of autoimmune diseases. Our model of combined *Trichinella spiralis* (*T. spiralis*) infection and experimental autoimmune encephalomyelitis (EAE) in Dark Agouti (DA) rats demonstrated a significant reduction in EAE severity in infected animals. The results indicated that the final muscle stage of parasite infection can affect the outcome of a particular autoimmune disease in a manner beneficial to the host. Recently, we have achieved to create immune status characteristic for the live infection by *in vivo* application of dendritic cells (DCs) stimulated with excretory secretory (ES L1) products of *T. spiralis* muscle larvae. The aim of current research was to investigate the effect of DCs educated with ES L1 on the development and course of EAE.
Materials and methods: Different doses of DCs (0.5×10^6, 1×10^6, 5×10^6) stimulated with ES L1 were administered i.p. into naïve DA rats 7 days before EAE induction. The clinical signs of the disease were monitored for 25 days. We examined the production of IFN-γ, IL-17, IL-4, IL-10 and TGF-β, as well as the presence of $CD4^+$ CD25+Foxp3+ cells at the end of the observation period, both at the level of spinal cord and at systemic level.
Results: The applied doses differently influenced the disease development. The recipients of 0.5×10^6 DCs had similar clinical sings as control animals (received DCs cultivated in medium only before EAE induction). Doses of 1×10^6 and 5×10^6 DCs reduced the severity of EAE as judged by lower maximal clinical score (1.8 ± 1.3 and 1.6 ± 1.5 both versus control 2.4 ± 0.6), cumulative index (0.26 ± 0.2 and 0.22 ± 0.2 both versus control 0.55 ± 0.2), duration of illness (4.2 ± 2.4 and 3 ± 3.1 both versus control 9.4 ± 3.7) and degree of mononuclear cell infiltration in central nervous system (CNS). The production of IL-17 was significantly decreased, while the production of IL-10 and TGF-β was greatly increased in animals treated with ES L1 stimulated DCs compared to controls. The proportion of regulatory T cells was significantly higher in recovered recipients of ES L1 stimulated DCs.
Conclusions: Novel approach in treatment of EAE by educated DCs gave promising results and brought us closer to the establishment of a new therapy.

P0918

New approach in EAE treatment, part II: Mechanisms underlying the beneficial effects of dendritic cells stimulated with Trichinella spiralis antigens

A. Gruden-Movsesijan, N. Ilic, I. Radovic, J. Cvetkovic & L. Sofronic-Milosavljevic
Institute for the application of nuclear energy – INEP, Immunology and immunoparasitology, Belgrade, Serbia

Purpose/Objective: Parasitic nematode *Trichinella spiralis (T. spiralis)* exert immunomodulatory effect on the host immune response through excretory-secretory products (ES L1) released from the encysted muscle larvae. Rat bone-marrow derived dendritic cells (DCs) stimulated with ES L1 antigens acquire semi-matured status and induce Th2 and regulatory responses when applied into naïve Dark Agouti (DA)

rats. Moreover, these cells were able to ameliorate experimental autoimmune encephalomyelitis (EAE) when applied 7 days before EAE induction. This study is focused on the mechanisms underlying observed beneficial effects of DCs stimulated with ES L1 antigens on the development and course of EAE.

Materials and methods: DCs stimulated with ES L1 antigens (5×10^6) were applied to DA rats 7 days before the induction of EAE. We analyzed the kinetics of production of IL-4, IL-10, TGF-β, IFN-γ and IL-17 by cells harvested from spleens and CNS throughout the disease, ie in inductive (day 8 p.i.), effector (day 15 p.i.) and recovery phase (day 25 p.i.). The proportion of Foxp3+ T cells at each time point was estimated.

Results: Our results indicated that educated DCs altered the immune response responsible for the development of EAE via increased production of IL-4, IL-10 and TGF-β, and decreased production of IFN-γ and IL-17, both on systemic level and the level of target organ. Significant increase in the proportion of $CD4^+$ CD25+Foxp3+ cells was found among spleen cells and CNS infiltrates from DA rats treated with ES L1 stimulated DCs before EAE induction compared to immunized, non-treated controls.

Conclusions: Our results show that ES L1 antigen stimulated DCs are able not only to provoke, but also to sustain anti-inflammatory and regulatory responses regardless of EAE induction, which results in amelioration of EAE, or even protection from the disease.

Novel Ap4A second messenger signaling in Bone Marrow-derived Dendritic Cell (BMDC) differentiation, maturation and function

A. Lee,* C. Yang,* P. Y. Low,* I. Carmi-Levy,† Y. Ophir,† E. Razin† & D. M. Kemeny*

**Microbiology, National University of Singapore, Singapore, Singapore, †Biochemistry, Hebrew University of Jerusalem, Jerusalem, Israel*

Purpose/Objective: Diadenosine tetraphosphate, Ap4A acts as a second messenger in the Lysyl-tRNA synthetase (LysRS) signaling pathway. It is produced by Phosphorylated LysRS and in turn it activates a family of microphthalmia-associated transcription factors (MITF). Tartarate-resistant acid phosphatase 5 (TRACP5) expressed in osteoclasts and dendritic cells (DC) is transcriptionally regulated by MITF. We aim to characterize the Ap4A second messenger signaling pathway in BMDC.

Materials and methods: BMDCs were isolated and cultured with Granulocyte Macrophage Colony-Stimulating Factor (GM-CSF) and activated with lipopolysaccharide (LPS), GM-CSF and Receptor Activator for Nuclear Factor kappa B Ligand (RANKL). Whole cell lysate was collected for analysis by SDS-PAGE. Total RNA was isolated, converted to cDNA and analyzed by SYBR-green real-time PCR. Ap4A levels were analyzed by hydrolysis of Ap4A in an ATP assay. The Dendritic cell line, JAWS II, was used as an *in vitro* model to study the effects of LysRS overexpression in DC. Mutation of Serine 207 into aspartate mimics the phosphorylated state of LysRS on residue 207, thus JAWS II was transfected with 3 different constructs, LysRS WT, S207A that act as a control and S207D which represents overexpression.

Results: We observed that mRNA expression of IL-23p19 in BMDC stimulated with LPS, GM-CSF and RANKL resulted in a 1000-fold increase. DC activation also induced a 27-fold rise in intracellular Ap4A levels and a 3-fold rise in MITF mRNA. TRACP5 gene and protein expression were also up regulated in LPS/GM-CSF/RANKL activated BMDCs. We found that upon activation with LPS, GM-CSF and RANKL, JAWS ll cell line transfected with LysRS S207D show similar IL23p19 mRNA and TRACP5 expression profile to BMDC when activated.

Conclusions: Our results show that activation of BMDC by LPS/GM-CSF/RANKL results in MITF-specific gene activation, suggesting that the Ap4A signaling pathway functions in DC as a mechanism for gene regulation, and may serve as a novel DC signaling pathway. Further investigations in functional significance of the pathway are currently underway.

P0920

Phenoypical characterization and isolation of a subpopulation of myeloid cells from swine peripheral blood: new method to isolate plasmacytoid dendritic cells

P. Martinez-Orellana,* M. Cortes,* C. Rodriguez-Cariño,† L. Córdoba,* R. Maeso,* E. Crisci,* S. Chamorro,‡ P. Martínez de la Riva,§ J. Dominguez§ & M. Montoya*

**Centre de Recerca en Sanitat Animal (CReSA), Immunology, Barcelona, Spain, †Facultad de Ciencias Veterinarias Campus Maracay de la Universidad Central de Venezuela, Veterinary Pathology, Maracay, Venezuela, ‡Centro de Investigaciones Biológicas (CIB), Immunology, Madrid, Spain, §Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria (INIA), Biotechnology, Madrid, Spain*

Purpose/Objective: Our study aims to isolate a subpopulation phenotypically identified as $CD11R3^-$ $CD172a^{lo}$ and investigate a possible relationship with pDC subset.

Materials and methods: PBMC from healthy pigs were collected and a magnetic depletion using negative selection for $CD3^-$ $CD163^-$ cells was performed, discarding a major part of the lymphocytic and monocytes in the population. Secondly, the subpopulation obtained was characterized for different surface markers and further isolated through sorting with FACSAria Sorter (BD Becton, Dickinson). The subpopulation obtained was evaluated by electron microscopy (EM) Jeol 1400. Also, a functional analysis was performed to test the ability of these cells to be stimulated either with TLR agonist (Poly:IC, R837 or CpG) or infected with H3N2 at MOI 0.01. Activation was quantified for IFNa production by ELISA.

Results: Cells under study revealed a defined rounded to oval shape with a centered nucleus by EM. These cells were $CD3^-$, $CD163^-$, $CD172a^{lo}$, $CD11R3^-$ and $CD4^+$. Functional assays also suggest that this population could be pDC.

Conclusions: The subpopulation $CD172a^{lo}$ $CD11R3^-$ isolated through sorting showed morphological and phenotypical characteristics of the pDC subpopulation.

P0922

Preferential HLA-DRB1*11 dependent presentation of ADAMTS13 derived peptides in autoimmune thrombotic thrombocytopenic purpura

N. Sorvillo, S. Van Haren, P. Kaijen, A. B. Meijer & J. Voorberg

Sanquin, Plasma Proteins, Amsterdam, The Netherlands

Purpose/Objective: Autoantibodies directed against ADAMTS13, a plasma metalloproteinase, prohibit the processing of VWF multimers initiating a rare and life-threatening disorder called acquired thrombotic thrombocytopenic purpura (TTP). At present the cause of antibody formation in these patients is unknown. Recently HLA-DRB1*11 has been identified as a risk factor for the development of acquired TTP. This finding indicates that ADAMTS13 derived peptides are presented to CD4+ T cells by antigen presenting cells. We have recently identified that ADAMTS13 is endocytosed by immature monocyte derived dendritic cells in a mannose receptor dependent manner. The aim of the current study is to directly identify naturally ADAMTS13-derived peptides presented on MHC class II alleles.

Materials and methods: Dendritic cells from a panel of both HLA-DRB1*11 positive and negative donors were pulsed with antigen.

Subsequently the HLA-DR-peptide repertoire was analyzed by means of affinity-purification and mass spectrometric peptide sequencing.
Results: Interestingly, at low antigen concentration only DR11-positive donors presented CUB1-2 derived ADAMTS13 peptides. Increasing the concentration of the antigen lead to the identification of a higher number of ADAMTS13 derived peptides by both HLA-DRB1*11 positive and negative donors. Although the presented peptides belonged to several ADAMTS13 domains, inspection of the peptide-profiles revealed that antigenic 'core' peptides, originated from the CUB1-2 domains of ADAMTS13, were presented with a higher efficiency compared to other peptides.
Conclusions: These findings show that antigen presenting cells, in particular HLA-DRB1*11 positive cells, preferentially present antigenic 'core' peptides derived from the CUB1-2 domains of ADAMTS13. We hypothesize that functional presentation of these peptides on HLA-DRB1*11 contributes to the onset of acquired TTP by stimulating low affinity self-reactive CD4+ T cells that have escaped negative selection in the thymus.

P0923

Protective HLA Molecules Determine Infection Outcome by Preferential Presentation of Peptides From Conserved Hepatitis C Proteins

C. Kesmir,* I. Hoof,* R. A. O. Xiangyu* & D. van Baarle†
*Biology, Utrecht University, Utrecht, The Netherlands, †Immunology, University Medical Center, Utrecht, The Netherlands

Purpose/Objective: Hepatitis C virus infections (HCV) affect worldwide more than 170 million people. While the majority of these individuals are chronically infected, some clear the infection rapidly. Host factors seem to play a key role in the clearance of HCV, among them the human leukocyte antigen (HLA) class I molecules. Particular HLA molecules, e.g. B*27 and B*57, are associated with viral clearance.
Materials and methods: To get a better understanding of the mechanisms behind these associations, we analyzed the HLA-restriction of both experimentally verified and *in silico* predicted HCV epitopes with respect to the sequence variability of HCV proteins, which was estimated using publicly available HCV sequences.
Results: Core, NS5B and NS3 are the most conserved proteins of HCV, while E1 is the most variable. HLA molecules associated with HCV clearance preferentially present cytotoxic T cell (CTL) epitopes from conserved HCV proteins: especially NS5B is significantly enriched in epitopes presented by HLA-B*57 and HLA-B*27. In contrast, none of the known susceptible HLA molecules, i.e. HLA molecules associated with HCV persistence, have a similar preference.
Conclusions: Our analysis suggests that by targeting the most constrained – and thereby conserved – proteins of HCV, ÒprotectiveÓ HLA molecules reduce the potential of HCV to escape the cytotoxic T cell response of the infected host.

P0925

Quantifying the contribution of polymorphic residues to peptide binding of HLA molecules

H. W. M. van Deutekom & C. Kesmir
Utrecht University, Theoretical Biology/Bioinformatics, Utrecht, The Netherlands

Purpose/Objective: HLA genes are known to be the most polymorphic genes in the human genome. Almost all polymorphic residues are located in the peptide binding groove, resulting in different binding preferences. Using the structural data it is possible to infer the proximity of the polymorphic site to the peptide, and thus determine which sites might be in contact with the peptide However, to date it has not been possible to quantify the contribution of each polymorphic residue to the actual peptide binding.
Materials and methods: We make use of an in silico peptide-MHC binding predictor, netMHCpan-2.4. This method combines the information on the polymorphic sites in the binding groove (the so called HLA pseudo-sequence) with the measured peptide-HLA binding affinities, and was shown to be a highly accurate predictor of peptide-HLA binding affinity. We first predict the binding affinity of 100.000 natural peptides for the common HLA molecules. Next, we simulate point mutations in the HLA molecules by generating new sequences that differs only one position with a 'real' HLA molecule, and predict the binding affinity of the natural peptides the same way. We then focus on the top 1% best binding peptides as most likely binders, and calculate the repertoire overlap between the 'real' HLA molecule and the mutated one.
Results: The repertoire overlap, as defined here, allows us to quantify the functional effect of polymorphic residues. Our results show that mutations in a few positions, e.g. 116, effect the HLA peptide repertoire much more than the in other positions, and that the contribution of the polymorphic residues to the peptide binding is very different. Moreover, our analysis show clear differences between HLA-A and HLA-B molecules, which might shed light into the functional differences between these two HLA loci.
Conclusions: Both the position and the amino acid substitution are important for changing the binding motif. The HLA-B backbone is more sensitive to substitutions, i.e. a substitution could make a new binding preference. Next to recombination this could be a reason why we see more polymorphism in the B locus compared to the A locus.

P0926

Rapamycin prevents the onset of EAE by modulating proliferation and migration of pathogenic effector T-cells

H. L. Gooding* & S. M. Anderton†
*Edinburgh Bioquarter, Aquila Biomedical Ltd, Edinburgh, UK, †Centre for Inflammation Research, The University of Edinburgh, Edinburgh, UK

Purpose/Objective: Rapamycin is an immunosuppressant drug used to prevent allogenic transplant rejection. Due to its powerful immunosuppressive effects, it has been suggested that rapamycin may be effective in treating autoimmune diseases such as MS. Utilising the animal model of MS, experimental autoimmune encephalomyelitis (EAE), studies have shown that rapamycin is able to ameliorate the clinical signs of EAE, in both rats and mice. Standard EAE models provide limited information as to the mechanism of potential therapeutic drugs such as rapamycin. To overcome this we have developed an 'MBP tracker' CD4+ve T cell transfer EAE model which allows us to specifically track pathogenic T cells and therefore help us to determine the mode of action of a particular drug, *in vivo*. Using the MBP Tracker model, we have shown that rapamycin appears to prevent the clinical signs of EAE by preventing proliferation and migration of pathogenic effector cells.
Materials and methods: Traceable, TCR transgenic CD4+ve cells specifically responsive to a myelin basic protein (MBP) peptide epitope were transferred to non-transgenic host mice by i.v injection prior to immunisation with MBP peptide in adjuvant. Tissues were harvested and processed for subsequent analysis of cells by flow cytometry or ELISA.
Results: Rapamycin was able to prevent the onset of disease in MBP tracker model. Analysis by flow cytometry shows that there are fewer CD4+, pathogenic donor cells present in both the spleen and CNS of mice treated with rapamycin, compared to vehicle. There are also changes in the expression of cell surface markers such as CD62L.
Conclusions: Our data suggest that the main mode of action by which rapamycin is able to suppress the clinical signs of EAE is by modulating the clonal expansion of pathogenic T cells and their ability to migrate

into the CNS. This newly developed MBP-tracker EAE model not only provides efficacy data, but by allowing us to specifically track the cells capable of causing disease, we are able to obtain mode of action data on potential therapeutic targets.

P0927

Reactive carbonyl adduction of proteins primes TH2 responses by enhanced MHCII/peptide complexes on dendritic cell surface

A. E. Moghaddam, K. H. Gartlan, S. Mukhopadhyay, S. Gordon & Q. J. Sattnetau
The Sir William Dunn School of Pathology, University of Oxford, Oxford, UK

Purpose/Objective: Oxidation has been linked to altered protein immunogenicity, possibly by chemical adductions that can serve as ligands for pattern receptors of innate immunity. We have previously demonstrated that reactive carbonyls (RCs), commonly generated on proteins during oxidation, serve as a common group of damage associated molecular patterns (DAMPs) to enhance TH2 type immune responses. However, no molecular mechanism(s) has yet been put forward. This work explores pathways through which RCs may confer their immunomodulation.
Materials and methods: Proteins were carbonylated using biologically relevant aldehydes, and the modifications were characterized using carbonyl essays, mass spectrometry, chromatography, and electrophoresis. Antigen presenting cells, as well as reporter cell lines, was pulsed with modified and unmodified antigens and antigen uptake and presentation, along with signs of stimulation, were assayed in the presence of specific blockers. Wild type and knock-out mice for key immune molecules were immunized and their B and T cell responses analysed.
Results: *In vitro* pulsing and *in vivo* cell transfer experiments established that dendritic cells (DCs) are sufficient to confer immunomodulatory effects of RC-modified antigens. While pulsed DCs showed no signs of conventional activation, they expressed higher density of MHCII-peptide on their cell surface leading to enhanced priming of T cells *in vitro* and *in vivo*. This effect was blocked by pan-blockers of scavenger receptors (e.g. dextran sulphate), but was increased by blocking or knocking down two RC-binding scavenger receptors, SRA and CD36.
Conclusions: RC adduction of antigens increases their uptake/processing/presentation, without a marked activation of DCs, leading to enhanced T cell priming with a TH2 polarization effect. While the exact PRR(s) responsible for this effect is still under investigation, our data confirms the two main candidate scavenger receptors SRA and CD36 as binding but rules out their involvement in the observed immune enhancing effects of RC adduction. Given the prevalence of carbonylated self and non-self antigens in autoimmune, inflammatory, and allergic conditions, characterization of their putative receptor(s) and mode of immune enhancement is of universal importance.

P0928

Regulation of Flt3-L availability for dendritic cell development

T. Miloud,* N. Fiegler,* T. Holland,† G. J. Hämmerling* & N. Garbi†
**Department of Molecular Immunology, German Cancer Research Center (DKFZ), Heidelberg, Germany, †Department of Molecular Immunology, Institutes of Molecular Medicine and Experimental Immunology (IMMEI), Bonn, Germany*

Purpose/Objective: Flt3-L is a key cytokine instructing development of conventional DCs (cDCs). Although it is know that the size of the DC compartment regulates the availability of Flt3-L, very little is understood regarding tissue distribution and regulation of Flt3-L. The aim of this study was to characterise the source of Flt3-L required for cDC differentiation and to define the molecular mechanisms by which cDCs regulate Flt3-L availability.
Materials and methods: Flt3-L expression was investigated using BAC transgenic reporter mice in which eGFP and luciferase are expressed under the control of the *flt3l* promoter (FL-GL mice).
Results: Using a novel Flt3-L reporter-mouse strain, we found ubiquitous Flt3-L expression. All cells and organs investigated expressed Flt3-L, likely ensuring optimal cDC generation across different organs. Restricting Flt3-L expression to the hematopoietic or non-hematopoietic compartments did not result in a significant alteration in the frequency of DC precursors (MDPs, CDPs, pre-cDCs). However, we observed organ-specific differences in the contribution of different cellular compartments to final cDC differentiation. Flt3-L in all non-lymphoid organs was largely derived from non-hematopoietic cells and, accordingly, this source was mandatory and sufficient for the $CD103^+$ cDC compartment in lung, kidney and pancreas. Liver was exceptional in that hematopoietic and non-hematopoietic sources of Flt3-L were both required for normal cDC generation. The requisite of Flt3-L for generating $CD103^-$ $CD11b^{hi}$ cDCs was variable depending on the non-lymphoid organ investigated, possibly reflecting heterogeneity in this cDC compartment. Regarding cDC development in lymphoid organs, hematopoietic and non-hematopoietic cells equally contributed to splenic Flt3-L, although production by the former was necessary and sufficient for normal splenic cDC development indicating that the source rather than the total amount of splenic Flt3-L is dominant for splenic cDC development. In addition, data on regulation of Flt3-L expression by cDCs will be presented.
Conclusions: Flt3-L is ubiquitous across mouse organs and cells. The cellular source of Flt3-L instructing cDC development varies significantly depending on the organ in question. These results highlight different strategies adopted to optimise cDC development across organs presenting such different microenvironments.

P0929

Remodeling of lipid metabolism by IL-17A in human dendritic cells

G. Salvatore
CNRS UMR5239-Laboratoire de Biologie Moléculaire de la Cellule, Cellules Dendritiques & Plasticité Immunitaire (Pr. C. Delprat)-, Lyon, France

Purpose/Objective: Our laboratory has previously shown a crucial role of IL-17A in a rare disease of unknown etiology called Langerhans cell hystiocytosis (LCH). LCH is characterized by the accumulation of atypical dendritic cells resembling skin DC (LCH-DC), but also other immune cells including multinucleated giant cells (MGC) to form aggressive granulomas that destroy the tissues. In LCH, IL-17A is synthesized by LCH-DC and MGC. IL-17A induces survival of DC and their fusion leading to MGC *in vitro*, as observed in granuloma *in vivo*. Exogenous recombinant IL-17A shows the same effects on DC from healthy donors which do not produce autocrine IL-17A (Coury *et al.* Nat Med, 2008). The objective of this study was to further understand the molecular mechanisms underlying IL-17A-mediated biological effects on DC.
Materials and methods: We used Affymetrix microarrays to compare the gene expression profile of IL-17A-treated DC and LCH-DC to that of DC from healthy donors. Transcriptome analysis suggested a complete remodelling of lipid metabolism in response to IL-17A in DC. Lipid accumulation in IL-17A-treated DC was confirmed by Oil Red-O, a lipid-soluble dye which stains neutral lipids. The exact nature of the lipids present in IL-17A-treated DC was determined by high performance thin layer chromatography after lipid extraction.
Results: Transcriptome analysis, validated at the mRNA level by qPCR, showed that expression of enzymes, transporters and other proteins involved in lipid storage and metabolism, were profoundly

affected in IL-17-treated DC and LCH-DC compared to DC from healthy donors. In agreement with transcriptome data, we found that both DC from LCH patient and IL-17A-treated DC from healthy donors accumulated huge amounts of lipid droplets in their cytoplasm. Interestingly, levels of phospholipids, triglycerides, cholesteryl esters and cholesterol were all increased in IL-17A-treated DC.
Conclusions: We have shown for the first time a link between IL-17A and lipid metabolism in DC. This is of major interest, not only in LCH but also in other chronic inflammatory diseases.

P0932
Secretory leukocyte proteinase inhibitor (SLPI) competent DNA deposits are potent stimulators of plasmacytoid dendritic cells in psoriasis

J. Cichy,* J. Skrzeczynska-Moncznik,* A. Wlodarczyk,* K. Zabieglo,* M. Kapinska-Mrowiecka,† E. Marewicz,* A. Dubin‡ & J. Potempa§
**Faculty of Biochemistry Biophysics and Biotechnology, Immunology, Jagiellonian University, Krakow, Poland, †Dermatology, Zeromski Hospital, Krakow, Poland, ‡Faculty of Biochemistry Biophysics and Biotechnology, Analytical Biochemistry, Jagiellonian University, Krakow, Poland, §Faculty of Biochemistry Biophysics and Biotechnology, Jagiellonian University, Microbiology, Krakow, Poland*

Purpose/Objective: Secretory leukocyte proteinase inhibitor (SLPI) is a well-established inhibitor of serine proteases such as human neutrophil elastase (HNE) and a NF-κB regulatory agent in immune cells. Here, we report that SLPI plays a previously uncharacterized role in regulating activation of plasmacytoid dendritic cells (pDCs). As the main source of interferon type I (IFNI), pDCs are crucial contributors to inflammatory and likely wound healing responses associated with psoriasis. The mechanisms responsible for activation of pDCs in psoriatic skin are therefore of substantial interest.
Materials and methods: Immunohistochemistry, flow cytometry, magnetic cell sorting, ELISA.
Results: We demonstrate that in lesional skin of psoriasis patients, SLPI together with its enzymatic target HNE and DNA, is a component of neutrophil extracellular traps (NETs). Whereas SLPI-positive neutrophils and NETs were found to colocalize with pDCs in psoriatic skin, a mixture of SLPI with neutrophil DNA and HNE induced a marked production of IFNI by pDCs. IFNI synthesis by stimulated pDCs was dependent on intracellular DNA receptor TLR9.
Conclusions: SLPI may contribute to psoriasis by enabling pDCs to sense extracellular DNA and produce IFNI.

P0934
Skin pathology in Wiskott-Aldrich syndrome mice is caused by hyperactive CD8$^+$ T cells and increased cross-presentation by DCs

M. Baptista,* C. Dahlberg,* A. Liedén,† I. Kuo,‡ K. K. S. Sunahara,* C. K. Yan,‡ M. N. E. Forsell,* S. B. Snapper,§ L. Eidsmo,* A. Scheynius,* M. C. Karlsson,* S. Nylén¶ & L. S. Westerberg*
**Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden, †Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, ‡Department of Paediatrics, National University of Singapore, Singapore, Singapore, §Division of Gastroenterology, Children's Hospital Harvard Medical School, Boston, MA, USA, ¶Department of Microbiology and Tumor Biology, Karolinska Institutet, Stockholm, Sweden*

Purpose/Objective: Wiskott-Aldrich syndrome (WAS) is a primary immunodeficiency caused by loss-of-function mutations in the WAS protein (WASp). WASp coordinates upstream receptor signaling to changes in the actin cytoskeleton in hematopoietic cells. A major clinical complication for WAS patients is development of eczema. Because WAS is considered a 'cell-trafficking disease' in which all hematopoietic cells show decreased migratory, adhesive, and receptor-mediated responses, it remains elusive why WAS patients develop eczema, caused by an over-active immune system.
Materials and methods: Wildtype and WAS protein-deficient (WASp KO) mice were epicutaneously challenged with the allergen Der p 2 to induce eczema or infected intradermally in the ears with *Leishmania major* to induce a robust skin inflammation. To investigate the capacity to cross-present, wildtype and WASp-deficient dendritic cells were isolated from spleen and pulsed with OVA and stimulated with LPS, and afterwards co-cultured with OT-I CD8$^+$ T cells.
Results: Der p 2 challenge of wildtype mice induced eczema with increased epidermal hyperplasia and egress of Langerhans cells from the skin. WASp KO mice had increased accumulation of mature DCs in the skin and, in contrast to wildtype cells, Der p 2 induced expansions of WASp KO CD8$^+$ T cells that produced IFNγ.

Wildtype and WASp KO mice responded vigorously to infection with *L. major* with massive cellular infiltration in the infected ear. Similar to challenge with Der p 2, WASp KO mice infected with *L. major* showed an altered immune response with increased expansion of IFNγ-producing CD8$^+$T cells in the draining lymph node.

Finally, we provide an explanation for increased number and activation of CD8$^+$ T cells in WASp deficiency by showing that WASp KO DCs had increased capacity to cross-present exogenous antigen and activate CD8$^+$ T cells.
Conclusions: How can immunodeficiency be associated with increased immune cell activation to seemingly harmless substances such as allergens? Our findings reveal that even though WASp deficiency leads to a compromised immune response, WASp KO cells can respond to allergens and parasite infiltration in the skin. However, skin inflammation in WASp KO mice causes a skewed immune response with DC mediated CD8$^+$ T cell responses at incorrect sites.

P0936
Substrates of the MHC-I antigenic pool derives from DRiPs rather than from mature protein

B. M. Fiebiger,* A. Moosmann,* U. Behrends† & J. Mautner*
**Helmholtz Zentrum München, Abteilung Genvektoren, München, Germany, †Technische Universität München, Kinderklinik Schwabing, München, Germany*

Purpose/Objective: Defective ribosomal products (DRiPs) are a subset of newly synthesized proteins which are rapidly degraded by the proteasome. The observation that antigen presentation on MHC class I is detectable immediately after antigen expression led to the conclusion that peptides presented on MHC class I molecules mostly derive from DRiPs. However it still remains unclear whether and to what extent mature proteins are used as antigenic substrates.
Materials and methods: In our study we designed a conditional antigen expression system that enables to investigate antigen presentation from mature proteins by inducing their rapid proteasomal degradation in the absence of ongoing antigen synthesis.
Results: Target cells in which expression of two Epstein-Barr virus antigens was induced were rapidly recognized by antigen-specific CD8+ T cells in a time and dosage dependent manner, demonstrating that antigen presentation was linked to antigen synthesis. As opposed to this finding, T cell recognition of antigen presenting cells that contained large amounts of mature protein was not detectable even after rapid proteasomal degradation.
Conclusions: Based on these results we could demonstrate that protein synthesis is essential for MHC-I antigen presentation. More importantly we could exclude that mature proteins enter the antigenic pool for MHC-I antigen presentation. These results have implications

for the design of immunotherapeutic strategies that aim at targeting proteins with increased half-lives and hence overexpressed in tumors.

P0938
The cold-shock protein YB-1 controls T-cell proliferation and survival

S. Gieseler,* P. R. Mertens† & M. C. Brunner-Weinzierl*
**Medical Faculty of Otto-von-Guericke University Magdeburg, Experimental Pediatrics, Magdeburg, Germany, †Medical Faculty of Otto-von-Guericke University Magdeburg, Nephrology and Hypertension Diabetes and Endocrinology, Magdeburg, Germany*

Purpose/Objective: The cold-shock protein YB-1 is an oncogene highly expressed in tumor cells and associated with increased cell survival, proliferation and migration. Its localization within the nucleus and enhanced expression of mRNA has been shown to correlate with poor prognosis for tumor patients. Although it has a central role in tumor cells such as breast, ovarian, and lung cancer, its role in T cell responses has not been appreciated, yet.
Materials and methods: $CD4^+$ T cells isolated from PBMCs or Jurkat T cells were stimulated either with anti-CD3 and isotype or with anti-CD3 and anti-CD28 coupled sulfate latex beads at the ratio 1:1 and subcellular fractions were analyzed by Western blot, expression of mRNA by real-time PCR, and expression of intracellular molecules and surface receptors by FACS analysis. YB-1 was manipulated by lentiviral transduction of YB-1shRNA.
Results: YB-1 protein was unambiguously expressed in naïve and effector/memory human $CD4^+$ T cells. In contrast to $CD4^+$ T cells, the T-ALL cell line Jurkat showed an enhanced localization of YB-1 in the nucleus independently of stimulation. To evaluate YB-1 mRNA expression in T cells as a diagnostic marker for unintentional T cell responses, stimulated $CD4^+$ T cells were analyzed under inflammatory conditions using IFN-γ and TGF-β. Expression of YB-1 mRNA revealed rather decreased expression of YB-1 mRNA in stimulated cells in the presence ofcytokines. Quantification of YB-1 mRNA expression is not suited as diagnostic marker for excessive T cell responses, as shown for tumor growth. However, shRNA-mediated knockdown of YB-1 resulted in abrogated proliferation and increased apoptosis of $CD4^+$ T cells and Jurkat cells that was rescued by IL-2 administration. Upon stimulation of human $CD4^+$ T cells with anti-CD3 and anti-CD28, YB-1 protein was highly expressed in the cytoplasm and the nucleus of T cells starting 16 h after initiating stimulation. The accumulation of YB-1 within the nucleus was inhibited in stimulated $CD4^+$ T cells when RSK1/2 was inactivated with a specific inhibitor and to a lesser extent when Akt and PKCa were inactivated thus, identifying the MEK-ERK-RSK signalling pathway in YB-1 S^{102} phosphorylation in T cells as a prerequisite for YB-1 translocation in the nucleus.
Conclusions: Altogether, our data demonstrate that YB-1 is tightly controlled in T cells and is centrally involved in T cell proliferation.

P0939
The Crucial Role of ICOS Driving the Onset of Lupus in Sle1 Mouse Model

G. Carlesso,* N. Mittereder,* E. Kuta,* D. Taylor,* K. Dacosta,† L. Cheng† & R. Herbst*
**MedImmune LLC, Respiratory Inflammation and Autoimmunity (RIA), Gaithersburg, MD, USA, †MedImmune LLC, Translational Sciences, Gaithersburg, MD, USA*

Purpose/Objective: The pathophysiological hallmark of lupus is the production of antibodies (Abs) against self-antigens. Studies in both human and animal models have reported increased expression of Inducible T cell Costimulator (ICOS) on T follicular helper (T_{FH}) cells in several autoimmune conditions, including lupus. T_{FH} cells are critical players in the formation of germinal centers (GCs) and under pathological condition can contribute to skewing the differentiation of B cells into hyperactive germinal center (GC) B cells and autoAbs producing plasma cells (PCs). Increased numbers of T_{FH}-like cells have been associated with high levels of autoAbs and have correlated with disease activity in patients with active lupus. Furthermore, several autoimmune animal models, including B6.Sle1 mice have suggested that abnormalities in T_{FH} cell homeostasis may represent one of the mechanisms of breaking tolerance resulting in the production of autoAbs.

The aim of this study is to explore the role of ICOS in the differentiation of T_{FH} cells on B6.Sle1 mice and thus decipher the function of T_{FH} cells during the onset of murine lupus.
Materials and methods: B6.Sle1 were crossed with B6.$ICOS^{-/-}$ animals to generate B6.Sle1 × $ICOS^{-/-}$ mice. Secondary lymphoid tissues and peripheral blood from B6.Sle1 × $ICOS^{-/-}$, B6.Sle1, B6.$ICOS^{-/-}$ and C57Bl/6 (B6) mice were collected for phenotypic analysis of T and B lymphocytes along with serum immunoglobulins (Igs) and autoAbs analysis.
Results: Immunophenotypic analysis revealed that *Icos* deficiency in B6.Sle1 mice restored the ratio of naïve/memory of CD4 T cells compared to B6.Sle1 animals. Moreover, lack of ICOS in B6.Sle1 mice statistically influenced the numbers of T_{FH} cells, which affected the numbers of GC B cells and PCs. Importantly, these changes diminished significantly the levels of Igs and autoAbs [ANA, double strand (ds) DNA and histone] in B6.Sle1 × $ICOS^{-/-}$ mice as compared to B6.Sle1 animals. Finally, while notably expanded in B6.Sle1, the numbers of T regulatory $Foxp3^+$ cells in B6.Sle1 × $ICOS^{-/-}$ animals returned to levels comparable to B6 mice.
Conclusions: Our results suggest that ICOS regulates the homeostasis of T_{FH} cells and influences the function of T_{FH} during GC B cell responses. Therefore, therapies targeting the ICOS signaling pathway may offer new opportunities to reduce disease activity in patients with lupus.

P0940
The immunopathogenesis of ankylosing spondylitis: a dendritic cell perspective

P. B. Wright,* L. Utriainen,* A. McEntegart,† D. McCarey,† I. B. McInnes* & S. W. F. Milling*
**Centre for Immunobiology, Institute of Infection Immunity and Inflammation, Glasgow, UK, †Centre for Rheumatic Diseases, Glasgow Royal Infirmary, Glasgow, UK*

Purpose/Objective: Ankylosing Spondylitis (AS), a member of the Spondyloarthritis family, is a chronic systemic inflammatory disease primarily affecting the axial skeleton. Despite the fact that 95% of AS patients express the MHC Class I molecule HLA-B27, the pathogenic role of this molecule remains elusive. Dendritic cells (DCs) are essential for directing and inducing immune responses. Studies in our laboratory using HLA-B27 transgenic (TG) rats, an animal model of spondyloarthropathy, have uncovered deficiencies in DC populations. We hypothesised, therefore, that DC populations in AS patients would be altered, contributing to chronic inflammation. We set out to characterise and functionally compare DC populations between AS patients and healthy controls, aiming to understand the role of DCs in AS pathogenesis.
Materials and methods: AS patient peripheral blood samples were obtained from the AS clinic at Glasgow Royal Infirmary. Healthy donors were recruited from Glasgow University. Peripheral blood mononuclear cells (PBMCs) were isolated using a ficoll gradient and analysed for T cells and DC subsets using 7-colour flow cytometry. Flow sorted DCs were co-cultured with allogeneic T cells, where T cell proliferation was measured by CFSE dilution and chemokine expres-

sion was analysed by flow cytometry. Circulating plasma cytokines were measured by Luminex.
Results: Our initial experiments have successfully identified all known blood DC subsets in both healthy controls and AS patients. AS patients have an increased proportion of blood $CD16^+$ $CD11c^+$ DCs, in addition to an increased proportion of circulating $CD4^+$ $CCR6^+$ activated T cells. Using mixed lymphocyte reactions, we observe a tendency for AS $CD16^+$ DCs to induce greater levels of CCR6 on responding naïve T cells compared to those isolated from healthy controls. In addition, this subset preferentially induced secretion of a variety of pro-inflammatory cytokines including TNFα from these co-cultures.
Conclusions: Our results demonstrate differences in the proportions of several DC subsets, between AS patients and healthy controls. Specifically, in AS patients the pro-inflammatory $CD16^+$ $CD11c^+$ DC subset is expanded, and this subset induces a larger proportion of naïve T cells to express CCR6. These data, combined with the observed increase in the proportion of $CCR6^+$ $CD4^+$ activated T cells in AS patient blood may suggest a pathogenic role for these DCs.

P0942
The proteasome system in infection: Impact of ß5 and LMP7 on composition, maturation and quantity of active proteasome complexes

T. Joeris,* N. Schmidt,† D. Ermert,‡ P. Krienke,† A. Visekruna,§ U. Kuckelkorn,¶ S. H. E. Kaufmann† & U. Steinhoff§
**Experimental Medical Sciences – Immunology, Lund University, Lund, Sweden, †Immunology, Max Planck Institute for Infection Biology, Berlin, Germany, ‡Department of Laboratory Medicine – Medical Protein Chemistry, Lund University, Malmö, Sweden, §Institute for Microbiology and Hygiene, Philipps University Marburg, Marburg, Germany, ¶Institute for Biochemistry, Charité Berlin, Berlin, Germany*

Purpose/Objective: Proteasomes are involved in MHC class I antigen presentation, inflammation and defense against oxidative stress. Mammals express two sets of catalytic proteasome subunits: the constitutive subunits $\beta1$, $\beta2$ and $\beta5$ and the immunosubunits LMP2, MECL-1 and LMP7. According to the rules of cooperative proteasome assembly, the LMP7-propeptide (proLMP7) is required for maturation of LMP2/MECL-1-containing precursors to immunoproteasomes, while the $\beta5$-propeptide (pro$\beta5$) promotes integration into $\beta1/\beta2$-containing precursors, resulting in the formation of constitutive proteasomes. However, these rules have been defined in steady state cell lines and thus we raised the question, whether they are also valid under inflammatory conditions. Further, it has been described that LMP7 accelerates the rate of proteasome assembly and we address, how this function of LMP7 affects the proteasome composition, maturation and quantity in infection.
Materials and methods: To analyse the function of proLMP7 and pro$\beta5$ under inflammatory conditions, $lmp7^{-/-}$ MEFs were reconstituted with full length LMP7 or $\beta5$ or chimeric subunits, in which proLMP7 was fused to $\beta5$ (proLMP7m$\beta5$) or pro$\beta5$ was fused to LMP7 (pro$\beta5$ mLMP7). The integration of the full-length or chimeric subunits into proteasomes was analysed by co-immunoprecipitation in IFNγ-stimulated $lmp7^{-/-}$ MEFs. The impact of LMP7 on proteasome composition, maturation and quantity in infection, was determined in $lmp7^{-/-}$ and wild-type mice infected with *Listeria monocytogenes*..
Results: We found that pro$\beta5$ mediates predominant integration into LMP2/MECL-1-containing precursors in IFNγ-stimulated $lmp7^{-/-}$ MEFs and infected $lmp7^{-/-}$ mice. Further, we identified the propeptides as the critical factors determining the efficiency of proteasome maturation, with proLMP7 displaying a higher chaperone activity as compared to pro$\beta5$. In infection, induction of LMP7 not only results in rapid formation of immunoproteasomes, but also increases the proteasome quantity within the infected tissue.
Conclusions: Since $\beta5$ mediates predominant integration into mixed LMP2/MECL-1/$\beta5$ proteasomes in IFNγ-stimulated cells and infected mice, the rules of cooperative proteasome assembly do not appear to be valid under inflammatory conditions. Moreover, we identify a LMP7-dependent mechnism, which increases the proteasome quantity in infected tissues and is based on the high chaperone activity of proLMP7.

P0943
The protective role of interferon gamma in EAE, is not due to effects on dendritic cells

F. Wanke,* W. Müller,† A. Waisman‡ & F. Kurschus‡
**Institute for Molecular Medicin, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany, †Faculty for Life Sciences, University of Manchester, Manchester, UK, ‡Institute for Molecular Medicin, University Medical Center of the University of Mainz, Mainz, Germany*

Purpose/Objective: Interferon gamma has been shown to play an essential role in the immune response towards intracellular pathogens. However recent publications point to an additional, regulatory function, as mice deficient for either IFNγ or the receptor are highly susceptible for induction of EAE and show a severe outcome of the disease. We analyzed the role of IFNγ signaling in dendritic cells (DCs) in EAE by using a conditional receptor knock-out model.
Materials and methods: We crossed mice with floxed *Ifngr2* to CD11c-Cre mice (CD11c/IFNγR2 KO). EAE was induced by immunization with MOG_{35-55} in emulsion with CFA and mice were analyzed for effector and regulatory T cells, as well as for expression of CD80, CD86 and PDL-1/-2 on DCs. Additionally, we generated BMDCs and analyzed their capability for *in vitro* T cell differentiation and expansion.
Results: We found, that loss of IFNγ signaling in DCs, led to a slightly more severe outcome of EAE, but did not enhance the infiltration of effector T cells in the CNS and did not alter the number of regulatory T cells in the periphery. Culture of LPS and IFNγ stimulated and MOG_{35-55} pulsed control BMDCs with $CD4^+$ T cells from 2D2 mice, led to significantly more $FoxP3^+$ T cells, which were additionally more expanded.
Conclusions: Our results suggest that the protective effect of IFNγ in EAE is not due to effects on DCs, as we could not see a difference in the number of effector T cells or the expression of stimulatory/inhibitory molecules on DCs. However, our *in vitro* data propose a role of IFNγ signaling in the generation and expansion of regulatory T cells.

P0945
The role of lysosomal trafficking regulator LYST in antigen presentation

L. Nath, W. Cheng & K. Lee
Leibniz Research Center for Medicine and Biosciences (FZB), Molecular Immunology, Borstel, Germany

Purpose/Objective: Chediak -Higashi syndrome (CHS) is a genetic disorder caused by mutations in the lysosomal trafficking gene, LYST. Patients with this disorder suffer from partial albinism, excessive bleeding, and recurrent bacterial infections. The murine equivalent of CHS, *beige* mice exhibits a similar phenotype. A prominent feature of this disease is the accumulation of enlarged lysosome-related granules in a variety of cells. In order to generate appropriate $CD8^+$ T cell-mediated immune responses to viral, bacterial, or tumor associated protein antigens, professional antigen-presenting cells acquire these antigens from the extracellular milieu;

process them at the cell surface. This process of 'cross-presentation'is known to occur most efficintly in dendritic cells (DCs). However, the underlying mechanistic and molecular details have remained largely unclear. Here we investigated the role of LYST in the regulation of dendritic cell function, particularly in the process of antigen cross-presentation.

Materials and methods: Utilizing a genetic system of LYST-deficient mice our study followed a multidisciplinary approach, which involved bio-chemical, cell biological and immunological methods to analyse the impact of lysosomal trafficking regulator LYST on antigen presentation and other functional aspects of dendritic cells.

Results: Our studies revealed that LYST is critically involved in cross-presentation in DCs. LYST MUTANT DCs from *beige* mice showed a significantly impaired ability to present ovalbumin (OVA)-peptide on the cell surface upon uptake of OVA-protein coupled beads. As a consequence, LYST mutant DCS only poorly activate OT-1CD8^{+} T cells which specifically recognize OVA-peptide presented by MHC-1molecules. The observation that the uptake of apoptotic cells through phagocytic processes appears to be intact in LYST mutant DCs suggests that the impaired ability to present antigen on the surface likely is due to defects in antigen processing at endosomal compartments.

Conclusions: Our studies reveal a so far unrecognized function of LYST as a novel effector molecule in antigen cross -presentation in dendritic cells.

P0948
Vav1 regulates transcription and transport of MHCII molecules

B. Jux,* A. Staratschek-Jox,† J. M. Penninger,‡ J. L. Schultze† & W. Kolanus*

**Life&Medical Sciences Institut (LIMES), Molecular Immunology, Bonn, Germany, †Life&Medical Sciences Institut (LIMES), Genomics and Immunoregulation, Bonn, Germany, ‡Institute of Molecular Biotechnology of the Austrian Academy of Sciences, Bones immunity and cancer, Vienna, Austria*

Purpose/Objective: Vav1 is a guanine nucleotide exchange factor (GEF) for Rho GTPases which is exclusively expressed in cells of the hematopoietic system. In addition to its well-documented GEF-activity it was suggested to have other functions, due to the presence of multiple domains and nuclear localization signals in its protein structure. Although GEF-dependent and GEF-independent functions of vav1 have been implicated in T cell development and T cell receptor signaling, the different roles of vav1 in antigen-presenting cells (APC) are poorly understood.

Materials and methods: To evaluate differential phenotypes and functions of APC from vav1$^{-/-}$ mice in comparison to WT mice, we performed experiments with resting and stimulated primary B cells, dendritic cells (DC) and macrophages as well as bone marrow-derived (BM) DC and macrophages.

Results: We found that vav1 is an important regulator of MHCII expression and transport. Microarray analysis of un-stimulated BM-macrophages revealed a role of vav1 in the transcription of the MHCII locus, which was not based on changes in CIITA expression. Primary immune cells from vav1-deficient mice as well as BM-APC had a significantly lower constitutive and inducible surface expression of MHCII molecules resulting in a diminished capacity for T cell activation. Using 6-thio-GTP, a specific inhibitor of vav1-GEF function, we were able to show that the GEF-activity is required for MHCII up-regulation after stimulation with LPS and IL-4/anti-CD40, respectively, but were dispensable for basal MHCII expression in un-stimulated cells. Furthermore, our data show that vav1 does not only control transcription of the MHCII locus, but is also an important regulator of MHCII protein transport to the cell surface.

Conclusions: Collectively, we show that vav1 regulates transcription and intracellular transport of MHCII molecules in antigen-presenting cells and indicates that inhibition of vav1 might be useful for the therapy of inflammatory diseases.

Poster Session: Fundamental Inflammatory Processes

A potential role for the X chromosome in the gender differences observed in the innate immune response

N. Lefèvre,* F. Corazza,† J. Duchateau,‡ J. Désir,§ J. Valsamis¶ & G. Casimir*

*Pulmonology Allergology and Cystic Fibrosis, Hôpital Universitaire des Enfants Reine Fabiola, Brussels, Belgium, †Laboratory of Immunology, Hôpital Brugmann, Brussels, Belgium, ‡Laboratory of Pediatrics, Hôpital Brugmann, Brussels, Belgium, §Medical Genetics, Hôpital Erasme, Brussels, Belgium, ¶Laboratory of Hormonology, Hôpital Brugmann, Brussels, Belgium

Purpose/Objective: Gender influences the severity and evolution of various inflammatory conditions. Many studies have demonstrated the important role of sex hormones in modulating the inflammatory response. However, recent clinical studies showed gender differences in inflammatory markers of prepubertal children, suggesting a genetic contribution.

Materials and methods: We determined some leukocyte parameters depending on X-linked genes in 24 healthy adults of both sexes and 8 patients with sex chromosome aneuploidy: 4 patients with Klinefelter syndrome (XXY) and 4 patients carrying an extra Y chromosome (XYY). We measured neutrophil respiratory burst by chemiluminescence, leukocyte expression of CD11b and CD99 and cytokine production (IL-1β, IL-6, IL-8, IL-10, IFN-γ and TNF-α) in whole blood.

Results: The neutrophil respiratory burst was not different between groups ($P > 0.05$) although the main NADPH oxydase subunit gp91phox is linked to the X chromosome. Median CD99 monocyte and lymphocyte expressions were higher in patients with sex chromosome aneuploidy compared to healthy adults in the basal state as after stimulation with fMLP and LPS ($P < 0.05$). This indicates a sex chromosome dose effect on CD99 expression. CD99 plays a major role in the migration of leukocytes through endothelial junctions. Its gene is located on the pseudoautosomal region PAR1, close to the boundary with X-linked regions where it can accidentally be silenced in the inactivated X chromosome of female cells. Additionally, men with Klinefelter syndrome (XXY) produced significantly less TNF-α compared to healthy men (XY) ($P < 0.01$) and had a tendency to produce less IL-6 ($P = 0.07$) in response to LPS. We did not observe any difference in the levels of 17β-estradiol and testosterone between these two groups ($P > 0.05$) suggesting an influence of the X chromosome numbers rather than the sex steroids levels.

Conclusions: Although performed in a small number of patients, our study highlighted important differences in men carrying an extra X chromosome in terms of the innate immune response to endotoxin through expression of a diapedesis marker and secretion of inflammatory cytokines depending on the TLR activation. These differences suggest a role for the X chromosome in the sex-specific response to acute inflammatory challenge, independently of hormonal impregnation.

P950

ABR-215757, an immunomodulatory compound, reduces the accumulation of cells during acute peritonitis

A. Deronic, T. Leanderson & F. Ivars

Lund University, Experimental Medical Science, Lund, Sweden

Purpose/Objective: The quinoline-3-carboxamides (Q compounds) are a group of chemical immunomodulators that have shown efficacy in several mouse models of human autoimmune disease. Currently, one such compound, ABR-215757 (5757), is in clinical trial for scleroderma. However, the mechanism behind the immunomodulating capacity of the Q compounds is largely unknown. The aim of this study was to evaluate the effect of 5757 on cell recruitment, as this is one potential mechanism for the Q compounds.

Materials and methods: For this purpose, we used a mouse model of acute peritonitis induced either by intraperitoneal injection of heat-shocked necrotic cells or Imject alum. Also, monocyte recruitment was induced by the injection of monocyte chemoattractant protein-1 (MCP-1).

Results: Upon induction of peritonitis using heat-shocked necrotic cells, treatment with 5757 reduced the number of cells accumulated in the peritoneum. This was mainly due to a reduction in the number of inflammatory monocytes, but also neutrophils and eosinophils. Similar results were obtained during the early phase of inflammation induced by immunization with Imject alum. Also, the recruitment of inflammatory monocytes to the omentum, by intraperitoneal injection of MCP-1, was abolished by treatment with 5757. Seven-day treatment with 5757 during steady state conditions similarly reduced the influx of inflammatory monocytes, neutrophils and eosinophils to the omentum as well as peritoneum, suggesting an effect on the homeostatic migration of cells as well.

Conclusions: Our results indicate that 5757 reduces the accumulation of cells in the peritoneum during acute inflammation, as well as during steady state. Future studies include performing transmigration assays using Boyden chambers, allowing monocytes to migrate across either a resting or activated endothelial cell layer pretreated with 5757. This will help us understand if the effects of 5757 observed in this study are due to an impact on endothelial cells and if cells in the blood stream, as a consequence, are unable to migrate across the endothelial cells of the blood vessels. The information obtained in this study could help us clarify the mechanism of the Q compounds in relation to cell recruitment during autoimmune disease.

P951

Altered distribution of neutrophils and NK cells in collagenase-induced osteoarthritis

O. Rasid,* V. Milanova,† G. Bernardini,‡ C. Stavaru,* M. Cippitelli,‡ L. Banica,* G. Benigni,‡ N. Ivanovska,† A. Santoni‡ & P. Dimitrova†

*'Cantacuzino' National Institute of Research-Development for Microbiology and Immunology, Cellular Receptors Laboratory Department of Research Development Innovation, Bucharest, Romania, †Department of Immunology, Institute of Microbiology Bulgarian Academy of Sciences, Sofia, Bulgaria, ‡Molecular Medicine-Institute Pasteur Cenci Bolognetti Foundation, University of Rome 'La Sapienza', Rome, Italy

Purpose/Objective: Osteoarthritis (OA) is a degenerative joint disease associated with high disability and pain. The aim of the present study is to evaluate the distribution and trafficking of neutrophils and NK cells in an experimental model of osteoarthritis.

Materials and methods: SCID mice received an intra-articular (i.a) injection of collagenase at the knee joint (CIOA mice). In order to compare the progression of OA with an acute inflammatory process, a group of SCID mice were i.a. injected with zymosan (ZIA mice). The degree of joint damage were determined after H&E and toluidine blue staining. The distribution of neutrophils and NK cells and the expression of surface CXCR2, 4 and galectin-9 were evaluated in lymphoid organs and bodily fluids by flow cytometry at day 7 of the disease model.

Results: Two populations of neutrophils, LY6G^{high} and LY6G^{low} were found in bone marrow (BM) and spleen. While BM LY6G^{high} cells expressed CXCR 2 and galectin-9, LY6G^{low} cells were negative for CXCR 2 and 4 but positive for galectin-9. Down-regulated expression of CXCR 2, 4 and galectin-9 on LY6G^{high} cells at day 7 of CIOA may correlate with the mobilization of these cells from the BM. CIOA NKp46 cells expressed CXCR4 and lost the surface CXCR2 in BM but

in a lesser extent than ZIA population. In spleen, CXCR2 and 4 decreased on CIOA LY6G^{high} cells similarly to ZIA cells. LY6G^{low} population negative for CXCR2, 4 up-regulated galectin-9 only in CIOA mice suggesting its specific role in the osteoarthritic process. CIOA NKp46 cells in spleen down-regulated surface CXCR2 and 4. The percentages of CXCR 4+ cells in blood were strongly reduced in CIOA (for NK cells) and ZIA (for NK cells and neutrophils) groups suggesting that the cells with decreased expression of CXCR 4 can enter the circulation. A lot of the cells in ZIA synovial fluid were CXCR2+ and had down-modulated CXCR4 while CIOA phenotype was more similar to control.

Conclusions: Our investigations shed a new light on the mechanism of LY6G neutrophils and NK cell trafficking in OA. Different modulations observed on these populations, suggest that the exploration of these mechanisms in OA could lead to the development of novel therapeutic strategies for the disease.

CCR7 deficiency causes manifestation of spontaneous autoimmune gastritis and chronic diarrhea in mice

S. Winter,* M. Schumann,† K. Wichner,* A. Kühl,† A. Rehm,‡ A. Batra,† B. Siegmund,† J. D. Schulzke,† M. Lipp* & U. E. Höpken*
**Department of Tumor- and Immunogenetics, Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany, †Department of Medicine I, Charite Medical University, Berlin, Germany, ‡Department of Hematology Oncology and Tumorimmunology, Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany*

Purpose/Objective: The chemokine receptor CCR7 is a central regulator in the maintenance of cellular homeostasis of mucosal tissues. CCR7 deficiency in mice leads to massive accumulation of lymphocytes within the gastric mucosa along with the development of tertiary lymphoid organs (TLOs) and histomorphological changes including cystic hyperplasia. We investigated if gastrointestinal aberrant lymphoid aggregates in CCR7-deficient mice were functionally linked with the development of autoimmune gastritis (AIG) and intestinal inflammation.

Materials and methods: Gastrointestinal pathogenesis was monitored using immunohistochemistry, flow cytometry analysis, and ELISA. Sonic hedgehog, H^+K^+-ATPase alpha, cystic fibrosis transmembrane conductance regulator (CFTR), and epithelium sodium channel (ENAC) expression was quantified by quantitative PCR or by immunoblot analysis. Colonic chloride secretion and electronic sodium transport was analysed in Ussing chambers.

Results: CCR7-deficient mice developed an early AIG accompanied by metaplasia of the gastric mucosa and the formation of gastric TLOs. Moreover, we found that CCR7-deficient mice displayed enhanced formation of intestinal lymphoid follicles in the colon and frequently suffered from chronic diarrhea and the development of severe anorectal prolapse. We found an elevated proportion of activated T cells within the gastric and colonic mucosa and an increased local production of the cytokines IL-1beta and IL-17. The induction of a defined inflammatory microenvironment in the stomach led to increased gastric pH via suppression of the gastric morphogenic factor sonic hedgehog. In the colon, IL-1beta production reduced ion channel-mediated sodium absorption and cloride secretion in colonocytes which led to altered net ion flux and a Na^+-malabsorptive-type of diarrhea.

Conclusions: In conclusion, CCR7-deficient mice reveal an immune-mediated condition which causes a dosed immune response of pro-inflammatory cytokines resulting in the development of autoimmune gastritis and chronic diarrhea.

This work was funded by the Priority Program SFB 633 of the German Research Foundation (DFG).

Effects of fibroblast co-culture on the response of immature porcine cartilage explant tissue to erythropoietin and interleukin-1 beta in explant models of arthritic disease

C. Fanutti,* S. Baig,† S. Hussain,‡ R. Davidson,‡ I. Clark,‡ R. Grant† & P. Coussons§
**Norwich Medical School, The University of East Anglia, Norwich, UK, †Faculty of Science, Kingston University, Kingston Upon Thames, Surrey, UK, ‡School of Biological Sciences, The University of East Anglia, Norwich, UK, §Department of Life Sciences CP&MG, Anglia Ruskin University, Cambridge, UK*

Purpose/Objective: To characterise the responsiveness of immature porcine nasal explant tissue to the inflammatory mediator interleukin-1 beta (IL-1β) and the human recombinant cytokine hormone erythropoietin (rHuEPO) in the absence and presence of fibroblast cells.

Materials and methods: Explant discs from 1 to 2 month old piglets were pre-cultured for 24 h in the absence or presence of 3T3 fibroblasts, prior to addition of optimum concentrations of rHuEPO (25 μU/ml), either alone or in combination with IL-1β (20 ng/ml). Media and treatments were replenished every 24 h and supernatants were tested for nitric oxide (NO) release and glycosaminoglycan (GAG) breakdown.

Results: The effects of rHuEPO on explant tissue were comparable to that of IL-1β treatment, and were greater in combined rHuEPO/IL-1β treatments than in individual treatments; fibroblast co-cultures significantly further increased NO and GAG release. Interestingly, while the nitric oxide synthase (NOS) inhibitor NG-nitro-L-arginine methyl ester hydrochloride (L-NAME) reduced NO and GAG release to baseline levels in controls lacking fibroblasts, the NOS inhibitor had no effect on fibroblast co-cultures.

Conclusions: The results confirm earlier studies, which showed that independent of its established erythropoietic role, pleiotropic rHuEPO can induce NO and GAG release in immature cartilaginous explant tissue to a level similar to that observed with IL-1β treatment. The amplifying effect of fibroblast co-cultures implies a synergistic interaction between immature explant cells and fibroblasts in the stimulation of GAG breakdown and NO release, possibly mimicking the role of pannus tissue on cartilage tissue breakdown in rheumatoid arthritis. Further support for a direct role of rHuEPO in matrix remodelling comes from preliminary experiments, which have confirmed that the mRNA for EPO receptor is expressed in 3T3 fibroblasts and that changes in MMP-1 and MMP-13 expression appear to occur in a dose-responsive manner in primary cultures of human synoviocyte-like fibroblasts, following rHuEPO and/or IL-1β treatment. Collectively, these results support the contention that immature fibroblast co-cultures are a suitable model for the study of erythropoietin in the pathogenesis of arthritic diseases.

P0956

High MMP-2, MMP-9 and low TIMP-1 expression in the spinal cord of rats correlate to CNS autoimmunity resistance

M. Momcilovic,* J. Blazevski,* F. Petkovic,* M. Mostarica Stojkovic† & D. Miljkovic*
**Institute for Biological Research "Sinisa Stankovic" University of Belgrade, immunology, Belgrade, Serbia, †Institute of Microbiology and Immunology School of Medicine University of Belgrade, immunology, Belgrade, Serbia*

Purpose/Objective: Experimental autoimmune encephalomyelitis (EAE) is a model of multiple sclerosis (MS), an inflammatory, demyelinating and neurodegenerative disease of the CNS. We have previously shown that Dark Agouti (DA) rats immunized with spinal cord homogenate (SCH) and Complete Freund's adjuvant (CFA) develop

severe form of EAE, while Albino Oxford (AO) rats remain fairly unaffected. Although initial infiltrates of immune cells were detected within the CNS of both strains, they multiplied in DA rats during the course of EAE, but remained low in AO rats. The restricted infiltration in AO rats imply that regulatory mechanisms within the CNS contribute to their resistance to EAE. Among various molecules within the CNS, matrix metaloproteinases (MMP) play significant role in initiation, progression and resolution of inflammation in MS and EAE. Our aim was to investigate gene expression of MMP-2 and MMP-9 and their inhibitor TIMP-1 in AO and DA rats CNS during the course of EAE.

Materials and methods: EAE was induced in rats by immunization with SCH + CFA. Spinal cords of both strains were isolated from untreated rats and from immunized rats at the time of onset, peak and recovery of EAE in DA rats. SC immune cells (SCIC) were isolated using Percoll gradient (30%/70%). Gene expression in SCH and SCIC was measured by real-time RT-PCR.

Results: Immunized, DA rats, but not AO rats, developed clinically manifested EAE. The expression of the examined genes in untreated rats was low in both strains. After immunization, MMP-9 and TIMP-1 gene expression was increased in SCH of both strains, while MMP-2 was increased only in AO rats. MMP-2 and MMP-9 gene expression was higher and TIMP-1 gene expression was lower in AO rats than in DA rats SCH and SCIC.

Conclusions: Resistance of AO rats to EAE correlated to high gene expression of MMP-2 and MMP-9 and low expression of TIMP-1. Such a pattern of MMP-2, MMP-9 and TIMP-1 expression imply that these molecules might have additional roles in EAE besides previously described promotion of neuroinflammation.

Purpose/Objective: Interleukin-6 (IL-6) is vital for competent antimicrobial host defence. Mice deficient in IL-6 are unable to control bacterial peritoneal infections and show increase dissemination and reduced bacterial clearance. Although the mechanism underlying this response is currently unknown, we propose that this is linked to the ability of IL-6 to govern the pattern of leukocyte recruitment that directs transition from neutrophils to monocytic cells.

Materials and methods: Real time quantitative PCR of human peritoneal mesothelial cells (HPMC) and mouse peritoneal membrane was used to examine IL-6 mediated expression of enzyme systems implicated in antimicrobial host defence. A Peritonitis model of *Staphylococcus epidermidis* (*S. epi*) assessed the host response to infection in wild type, IL-$6^{-/-}$ and IL-$6R^{-/-}$ mice. Flow cytometry characterised neutrophil effector function in response to live bacteria. Bioactive lipids and inflammatory cytokines in peritoneal lavage and tissue culture supernatants were quantified by mass spectrometry and ELISA.

Results: Bacterial clearance within the IL-6 deficient mouse is compromised; the time frame in which this occurs suggests a defective innate component. Although the antibacterial effector characteristics of patrolling neutrophils from IL-6 deficient mice was not compromised, once recruited to the peritoneal cavity following bacterial challenge, these neutrophils show impaired respiratory burst and phagocytic activity. Analysis of inflammation related genes in HPMC showed an IL-6 dependent COX2 activation, suggesting a role for PGE2 in the IL-6 control of acute infection. PGE2 (1 μM) treatment significantly reduced mouse neutrophil respiratory burst and bacterial phagocytosis when stimulated with live *S. epi*. IL-6 deficient mice show poor control of membrane derived COX2 and increased levels of at baseline compared to wild type mice.

Conclusions: These studies indicate that IL-6 control of non-haemopoietic stromal cells is important for regulating the innate effector characteristics of infiltrating neutrophils. In this regard, IL-6 control of COX2 may govern this response, with the production of COX2 derived PGE2 (and other COX2 related lipids), impacting the innate response to bacterial challenge.

P0958

Lesional IL-21 expression correlates with functional germinal center formation and T follicular helper cell infiltration in the salivary glands of Sjögren's syndrome

W. Murray-Brown,* C. Croia,* N. Sutcliffe,* A. Tappuni,† S. Vartoukian,† F. Fortune,† C. Pitzalis* & M. Bombardieri*

**Experimental Medicine and Rheumatology, William Harvey Research Institute, London, UK, †Department of Oral Medicine, Institute of Dentistry, London, UK*

Purpose/Objective: IL-21 is a pro-inflammatory cytokine that plays a key role in the activation and differentiation of B cells. B cells infiltrate the salivary glands (SG) of Sjögren's syndrome (SS), an autoimmune disease characterized by immune infiltration in the lacrimal and salivary glands leading to exocrine dysfunction. In SS SG, B cells are organized as functional ectopic germinal centers (GC) and are pivotal in SS pathogenesis. Follicular helper T cells (Tfh) abundantly express IL-21 and contributes to GC B cell affinity maturation via induction of AID, somatic hypermutation and class switching. We aimed to investigate IL-21 and TFh expression in SS SG and their relationship with the development of functional ectopic GC.

Materials and methods: IL-21 and IL-21R mRNA expression was assessed by Taqman PCR in 22 labial SG of patients with SS and 17 with non-specific chronic sialadenitis (NSCS). Expression levels were correlated with genes regulating ectopic GC formation such as CXCL13 and Ltb and B cell function such as BAFF, AID, Pax5 and Blimp1. In addition, GC formation in the SG was assessed by IHC for B/T cell segregation and follicular dendritic cell (FDC) networks. Finally, Tfh cells infiltration in the SG was assessed by IF for CD3/CD45RO/ICOS and PD1.

Results: SG of SS patients displayed higher expression of IL-21 and IL-21R mRNA compared to NSCS (mean fold increase ± SEM 38 ± 12 versus 5 ± 4, $P = 0.02$ for IL-21 and 59 ± 13 versus 12 ± 2, $P = 0.01$). In SS, IL-21 mRNA strictly correlated with the levels of CXCL13 (Spearman's $r = 0.697$, $P < 0.0001$) and Ltb ($r = 0.478$, $P < 0.001$) which were closely associated with the formation of CD21L+ ectopic GC. Furthermore, IL-21 expression was associated with functional B cell activation as shown by its correlation with AID ($r = 0.540$, $P < 0.0001$) and Pax5 ($r = 0.456$, $P < 0.002$). Finally, a subset of CD45RO/ICOS/PD1+ T cells highly resembling Tfh were invariably observed in the presence of ectopic GC characterised by FDC networks but not in FDC- or NSCS SG.

Conclusions: Here we show that IL-21 expression is significantly increased in the SG of SS patients and strongly correlate with ectopic GC formation, functional B cell activation and accumulation of Tfh. These data strongly implicate IL-21 and Tfh cells in the development and maintenance of functional ectopic GC in the SG and could represent novel therapeutic targets in SS.

P0959

Leukocyte associated Ig-like receptor-1 is a novel receptor for the immunomodulatory surfactant protein D

M. J. M. Olde Nordkamp,* M. van Eijk,† R. T. Urbanus,‡ H. P. Haagsman† & L. Meyaard*
*UMC Utrecht, Immunology, Utrecht, The Netherlands, †Division of Molecular Host Defence, Department of Infectious Diseases and Immunology, Faculty Veterinary Medicine, Utrecht University, Utrecht, The Netherlands, ‡UMC Utrecht, Clinical Chemistry and Haematology, Utrecht, The Netherlands

Purpose/Objective: The collagenous C-type lectin surfactant protein D (SP-D) is an immunomodulatory multi-trimeric protein. Its collagenous triple helices are linked via its neck domains to distinct carbohydrate recognition domains (CRD). Most putative SP-D receptors interact with the CRDs of SP-D. Leukocyte Associated Ig-like Receptor-1 (LAIR-1) is an inhibitory immune receptor that binds collagen. We hypothesize that the immunomodulatory functions of SP-D can be mediated via binding to LAIR-1.
Materials and methods: We investigated binding of SP-D to LAIR-1 by using a cell-free, protein-based system and with surface plasmon resonance experiments. By using mannan-coated plates, we determined whether LAIR-2 binding to SP-D interferes with the sugar-binding properties of SP-D. In addition, we used LAIR-1 expressing reporter cells to investigate the capacity of SP-D to trigger the receptor.
Results: We showed binding of SP-D to LAIR-1 and its family member LAIR-2. Furthermore, we determined that this binding was mediated via the collagen domain of SP-D. Binding of SP-D to LAIR-2 did not alter the binding of SP-D to mannan, indicating that the opsonin function of SP-D was not affected by binding to LAIR. Binding of SP-D to LAIR-1 expressed on cells triggered the receptor, thereby showing the functionality of this interaction and adding further evidence for a potential functional role of SP-D/LAIR-1 interactions.
Conclusions: We demonstrate that SP-D is a functional ligand for the immune inhibitory receptor LAIR-1. Thus, we have identified a novel pathway for immunomodulatory functions of SP-D.

P0961

Neutrophils are the key initiators of early osteoclastogenic events in experimental arthritis model

V. Milanova, N. Ivanovska & P. Dimitrova
Department of Immunology, Institute of Microbiology Bulgarian Academy of Sciences, Sofia, Bulgaria

Purpose/Objective: The potential of neutrophils to take part in inflammatory events in arthritis were recently highlighted. Herein we studied the neutrophils ability to promote destruction and bone resorption. We evaluated the RANKL expression, IL-17 and IFNγ production of peripheral and synovial neutrophils isolated from mice with zymosan-induced arthritis (ZIA).
Materials and methods: BALB/c mice were injected i.a. with zymosan. The organ distribution of neutrophils was evaluated by flow cytometry at day 7 of disease. Peripheral and synovial neutrophils were purified by Percoll gradient. Surface RANKL expression and intracellular production of IL-17 and IFNγ were determined by flow cytometry. Peripheral neutrophils were co-cultured with osteoclast bone morrow precursors and the number of mature osteoclasts was evaluated after TRAP staining. In a set of experiments we eliminated neutrophil population in SCID mice by i.p. administration of etoposide for 3 days prior zymosan injection.
Results: We found elevated number of Ly6G/CD11b cells in synovial fluid, blood and bone morrow of ZIA mice. Arthritic peripheral neutrophils showed up-regulated RANKL expression and increased IL-17 production in comparison to naïve mice. This ability of neutrophis was additionaly amplified *in vitro* by exogenous IL-17. In ZIA mice most of the synovial neutrophils were double IL-17/IFNγ producers. The elimination of neutrophils in periphery by etopiside resulted in a significantly decreased IL-17 synovial levels and joint destruction. *In vitro* experiments demonstrated that neutrophils promoted IL-17-induced osteoclastogenesis.
Conclusions: We propose that neutrophils receive signals for emerging inflammatory process in the bone morrow. Migrating to the periphery they acquire activated phenotype, express RANKL and IL-17 and thus contribute to early destructive events in arthritic synovium. Our results open new perspective for design of novel treatment strategy to inhibit abnormal bone destruction in arthritis.

P0962

NOD2/CARD15, IL-17A and IL-23R gene polymorphisms in sarcoidosis

K. Bogunia-Kubik,* B. Wysoczanska,* A. Wojtowicz* & A. Lange†
*L. Hirszfeld Institute of Immunology and Experimental Therapy Polish Academy of Sciences, Clinical Immunology, Wroclaw, Poland,
†L. Hirszfeld Institute of Immunology and Experimental Therapy Polish Academy of Sciences/Lower Silesian Center for Cellular Transplantation and National Polish Bone Marrow Donor Registry, Clinical Immunology, Wroclaw, Poland

Purpose/Objective: Sarcoidosis is a multiorgan granulomatous disease with clinically apparent inflammatory lesions of different activity. Our former results highlight the influence of HLA-associated factors on the extent of inflammation. In the present study we focused on the polymorphisms within the NOD2/CARD15 (SNP8: rs2066844, 2104C>T; SNP12: rs2066845, 2722G>C; SNP13: rs2066847, insC), IL-17A (rs2275913, 197G>A) and IL-23R (rs11209026, 1142G>A) encoding genes, which products promote Th17 response.
Materials and methods: Two hundred and thirty one individuals were studied, including 48 Polish patients with sarcoidosis, 13 of which presented with Löfgren's syndrome (LS) and 83 control subjects. *NOD2/CARD15* genotyping was performed by PCR-RFLP technique. Real-time PCR amplification with LightSNiP or TaqMan SNP Genotyping Assay was used for detection of *IL-17A* and *IL-23R* alleles, respectively.
Results: There was no significant difference in the distribution of *NOD2/CAR15, IL-17A and IL-23R* alleles and genotypes in sarcoidosis patients and controls. However, a tendency was observed towards the lower representation of *IL-23R* mutation among patients when compared to controls (1/47 versus 9/83, RR = 0.25, $P = 0.091$). LS patients more frequently presented with the *SNP13* variant (insC) when compared to healthy individuals (4/13 versus 6/80, RR = 5.43, $P = 0.031$). The prevalence of the *SNP13* variant (insC) was also seen when LS patients were compared to those lacking LS symptoms (4/13 versus 3/34, $P = 0.080$). It is postulated that the presence of any of 3 *NOD2/CARD15* SNPs influence the transcription potential of this gene. Also in the present study patients with the presence of any studied *NOD2/CARD15* mutations significantly prevailed among LS as compared to non-LS cases (7/13 versus 6/34, $P = 0.026$) and controls (7/13 versus 14/80, RR = 5.29, $P = 0.008$). In the studied group, majority of LS patients were carrying DRB1*03 (8/13 versus 8/34, $P = 0.020$) as compared with non-LS cases. Interestingly, HLA-DRB1*03-positive LS patients were more frequently carrying *NOD2/CARD15* variants (5 out of 8; 62.5%) and the concomitant presence of these 2 genetic factors was more frequent among LS as compared to non-LS patients (5/13 versus 1/34, $P = 0.004$).
Conclusions: Therefore, the contribution of the factors associated with DRB1*03 and *NOD2/CARD15* SNPs contribute to LS – highly inflammatory variant of sarcoidosis.

P0963

p110gamma PI3K deletion in LDL receptor-deficient mice reduces macrophage proliferation but not M1/M2 polarization in atherosclerotic lesions

T. M. Zotes,* C. F. Arias,* J. J. Fuster,† S. Pérez-Yagüe,* R. Spada,* E. Hirsch,‡ M. Wymann,§ A. C. Carrera,* V. Andrés† & D. F. Barber*
**Department of Immunology and Oncology (DIO), Centro Nacional de Biotecnología (CNB-CSIC), Madrid, Spain, †Department of Epidemiology Atherothrombosis and Imaging, Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain, ‡Department of Genetics Biology and Biochemistry, Center for Molecular Biotechnology University of Torino, Torino, Italy, §Department of Clinical and Biological Sciences, Institute of Biochemistry and Genetics, University of Basel, Basel, Switzerland*

Purpose/Objective: Atherosclerosis is an inflammatory disease driven by atherogenic lipids that accumulate in arterial walls. It is regulated by the immune system and shares characteristics with other inflammatory diseases, such as tissue infiltration of activated monocyte/macrophages and T cells. Macrophage number in atherosclerotic lesions is controlled by monocyte migration to plaque and by *in situ* macrophage proliferation. Differentiation to an inflammatory (M1) or anti-inflammatory phenotype (M2) is also implicated in atherosclerosis progression. We studied the role of phosphoinositol-3-kinase (PI3K) p110γ in the regulation of macrophage proliferation and polarization towards pro-inflammatory (M1) or anti-inflammatory (M2) phenotypes in atherosclerotic lesions.
Materials and methods: We analyzed atherosclerosis development in LDLR$^{-/-}$ p110$\gamma^{+/-}$ and LDLR$^{-/-}$ p110$\gamma^{-/-}$ mice, and performed expression and functional assays in tissues and primary cells from these and from p110$\gamma^{+/-}$ and p110$\gamma^{-/-}$ mice.
Results: Atherosclerotic plaques in fat-fed LDLR$^{-/-}$ p110$\gamma^{-/-}$ were smaller and had reduced immune cell infiltration compared with LDLR$^{-/-}$ p110$\gamma^{+/-}$ controls. This coincided with decreased macrophage proliferation in atherosclerotic lesions of LDLR$^{-/-}$ p110$\gamma^{-/-}$ mice. This proliferation defect was also observed in p110$\gamma^{-/-}$ bone marrow-derived macrophages (BMM) stimulated with macrophage colony-stimulating factor (M-CSF), and was associated with accumulation of the growth suppressor p27^{Kip1}. In contrast, proliferation of infiltrating T cells was unaffected in LDLR$^{-/-}$ p110$\gamma^{-/-}$ mice. p110γ deficiency did not affect macrophage polarization towards the M1 or M2 phenotypes in atherosclerotic plaques and cultured BMM.
Conclusions: Our results suggest that p27^{Kip1} accumulation and the ensuing inhibition of macrophage proliferation contribute to atheroprotection in LDLR-null mice lacking p110γ. Nonetheless, p110γ deletion does not appear to be involved in infiltrating macrophage polarization or in infiltrating T cell proliferation.

Paracrine Interactions in neuroinflammation

N. Patel, M. R. H. White & P. Paszek
Faculty of Life Sciences, University of Manchester, Manchester, UK

Purpose/Objective: Neural progenitor cells (NPCs) are potent immunomodulatory agents, capable of promoting tissue repair in cases of neurodegenerative disease. As yet, the mechanisms by which they aid regeneration in disease conditions are unknown. Here, we investigate the interactions between NPCs and the main drivers of neuroinflammation, microglia. By studying the dynamics of a gene transcription factor, and major neuroinflammatory mediator, Nuclear Factor kappaB (NF-kB), we aim to elucidate paracrine interactions that may provide therapeutic effects in the diseased brain.
Materials and methods: We have adopted a systems level approach to study NF-kB dynamics in a mouse model of neuroinflammation. Modified murine microglial (BV.2) and NPC (C17.2) lines were used to make single cell- and dual cell-cultures, which were stimulated with different doses of a potent inflammatory agent [either tumor necrosis factor-a (TNF-a) or lipopolysaccharide (LPS)]. Population-level NF-kB activation was observed, using cells expressing NF-kB promoter-driven luciferase and live cell luminometry. This was complimented with quantitative single cell analysis of NF-kB dynamics, using cells expressing fluorescently- tagged NF-kB and confocal microscopy.
Results: Our results demonstrate interactions between microglia and NPCs in a neuroinflammatory environment. NF-kB response in these cell lines show distinct stimulus-dependant and dose-time activation profiles. Interestingly, some cells within an NPC population demonstrate NF-kB unresponsiveness to inflammatory stimuli, even at saturating doses.
Conclusions: Quantitative, multi-scale analysis of NF-kB dynamics reveals complex NF-kB-mediated interactions between microglia and NPCs. These interactions require further investigation to determine whether they serve to orchestrate a regenerative phenotype in the inflamed brain.

P0965

Required contribution of IL-6, IL-17 AND IL-23 to control the paracoccidioidomycosis

F. A. Rocha, J. S. Silva & M. A. Rossi
Imunology, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil

Purpose/Objective: *Paracoccidioides brasiliensis* (Pb), a thermally dimorphic fungus, is the causative agent of paracoccidioidomycosis (PCM), one of the most frequent systemic mycosis that affects the rural population in Latin America. T helper cells type 17 (Th17) are described as an arm of the immune system that enhances host protection against several infections, including mycosis. Considering the better understanding of the mechanisms involved in resistance to *P. brasiliensis* infection is necessary, our aim was to evaluate the Th17 and related cytokines participation during the PCM.
Materials and methods: We worked with male C57BL/6 (WT) and IL-6, IL-17 receptor (R) and IL-23 knockout (KO) mice that were intravenously inoculated with 1×10^6 yeast forms of Pb18, a highly virulent *P. brasiliensis* strain. We measured cytokines mRNA and production from lung homogenate, besides, followed the fungal growth by recovering of colony forming units (CFU) and verified the inflammatory process and granulomas formation during de Pb experimental infection by cytometry and histopathology analysis.
Results: Our results show that Pb-infection induces increased IL-6, IL-17 and IL-23 mRNA lung expression and production compared with uninfected mice. Evaluating the susceptibility to the infection, the IL-6^{KO} mice showed the highest mortality rate. At 15 and 30 dpi, the CFU recoveries from the lung, liver and spleen of all KO mice were increased in relation to WT group. Histopathological analysis showed that IL-6 and IL-17 deficiency assisted absence of compact granulomas due to impaired formation of reticulin fibers accompanied of disorganized CD4$^+$ T cell infiltration at lung tissue, favoring an increased fungal load. The absence of IL-6, IL-17R or IL-23 induced lower production of IFN-g and IL-10 compared with WT lung. Additionally, the frequency of CD4$^+$IL-17$^+$ T cells also this cytokine production were decreased in the absence of IL-6 or IL-23.
Conclusions: Taken together, these results demonstrate that IL-6, IL-17 and IL-23 contribute to control of experimental Pb-infection through an efficient granulomatous organization.

P0966

Role of microglia and macrophages on retinal pigment epithelial cells degeneration and the factors influencing these in age related macular degeneration

G. Devarajan, J. Forrester & I. Crane
Division of Applied Medicine, University of Aberdeen, Aberdeen, UK

Purpose/Objective: Age related macular degeneration (AMD) is one of the common causes of blindness in elderly population. Retinal pigment epithelial (RPE) degeneration is one of the early events in AMD and these RPE cells mainly die through apoptosis. Maintaining a normal and functional RPE layer is vital for healthy vision. Therefore understanding the factors that induce RPE cell death in AMD would help identify a therapeutic approach. Inflammation is one of the key factors that influence the development of AMD. Infiltrating macrophages and resident microglia are associated with AMD and may influence RPE degeneration. Therefore we sought to identify the effects of cytokines, microglia and macrophages on RPE degeneration.
Materials and methods: An *in vitro* system to model *in vivo* conditions was set up by co-culturing murine macrophages derived from bone marrow cells or microglia from central nerves system on a confluent murine RPE cell layer under different conditions for 48 h at a ratio of 1:2 respectively. These conditions include RPE cells and macrophages or microglia pre-treated for 24 and 18 h respectively before the co-culture in the presence of pro inflammatory mediators, oxLDL, IL-1β, TNF-α, IL-6, and IFN-γ that are present in the microenvironment in which AMD develops. After co-culture the apoptotic cells were detected using annexin V staining by flow cytometry.
Results: Co-culture of un-treated RPE cells and un-treated BMDM or microglia does not increase apoptosis in RPE cells. However co-culture of un-treated RPE cells with pre-treated macrophages increased apoptosis in RPE cells but pre-treated brain microglia failed to increase apoptosis in RPE cells. Co-culture of pre-treated microglia and macrophages were able to increase apoptosis in treated RPE cells. These macrophages/microglia increase apoptosis in RPE cells through cell contact. In addition to macrophages and microglia, combination of cytokines and oxLDL also increases apoptosis in RPE cells.
Conclusions: The above findings provide a greater understanding of the pathogenesis of AMD, specifically the role played by microglia/macrophages in RPE degeneration and how oxidative stress and cytokines act together to bring about RPE degeneration. Better understanding of the pathogenesis of AMD will provide better therapeutic strategies.

P0967

S100B in the ocular inflammatory response; cytokine and chemokine modulation

J. Niven, J. Hoare, P. Teismann & I. Crane
Division of Applied Medicine, Institute of Medical Sciences, University of Aberdeen, Aberdeen, UK

Purpose/Objective: S100B is a Ca^{2+} binding protein which can potentially act as a pro-inflammatory mediator via the receptor for advanced glycation end products (RAGE); however its involvement in inflammation is still unclear. In the human condition, Endogenous Posterior Uveitis, retinal inflammation with autoimmune aetiology is associated with loss of sight. Both S100B and RAGE are reported to be present in the retina and the purpose of the study was to determine whether S100B is involved in retinal inflammation.
Materials and methods: Using the mouse model, experimental autoimmune uveitis, Topical Endoscope Fundal Imaging allowed disease progression to be followed post-immunization (pi) with uveitogenic peptide, in S100B-deficient and wild type mice. Eyes were snapping frozen for histological grading and immunohistochemistry. Real-time PCR array analysis was used to confirm changes in cytokine and chemokine expression in diseased matched retinas from S100B-deficient and wild type mice. This method was also used to investigate the response of a murine macrophage cell line RAW 264 to treatment with S100B, with cytokine production confirmed by ELISA.
Results: We have shown using clinical grading, that disease is significantly reduced in S100B deficient mice compared to wild type, at days 15 and 21. At day 24 pi this disease reduction was also shown by histological grading of the infiltrate, although the composition of the infiltrate remained unchanged. In S100B knockout mice compared to wild-type, at day 24 pi there was an overall reduction in expression of proinflammatory cytokines and chemokines in diseased matched retinas. We confirmedthat the macrophage cell line express RAGE and that this expression increases upon activation with PMA. Treatment of the macrophages with S100B resulted in an increase in proinflammatory cytokines and chemokines, in particular IL-1β and CCL22. ELISA analysis confirmed a significant increase in CCL22 with 2 and 5 μM S100B compared to un-treated cells.
Conclusions: These results suggest that S100B may be involved in augmenting the inflammatory response in uveitis and this may be via a direct effect on macrophages.

P0968

The conformational significance of hinge region glycosylation on the solution structure of monomeric IgA1 in IgA nephropathy

O. Vennard,* K. Molyneux,* L. Rayner,† S. J. Perkins† & J. Barratt*
**Infection Immunity and Inflammation, University of Leicester, Leicester, UK, †Structural Immunology Group, University College London, London, UK*

Purpose/Objective: Intrinsically characterised by the deposition of IgA1 in the renal mesangium, IgA nephropathy (IgAN) remains the most common form of glomerular inflammation worldwide. Within 20 years of diagnosis, up to 30% of patients progress to end stage renal disease. It is widely accepted that IgAN is caused by an inherent abnormality in the IgA1 molecule. Aberrant IgA1 hinge O-glycosylation, presenting as undergalactosylation, is observed in patients and is strongly implicated in the pathogenesis of IgAN.

Analytical ultracentrifugation (AUC) represents a powerful technique in the study of macromolecular size and shape in biologically relevant conditions. This study focuses upon the complex relationship between structurally induced changes in the IgA1 molecule through hinge region glycosylation, and its potential effects in the causation and prognosis of IgAN.
Materials and methods: Serum IgA1was isolated using jacalin affinity chromatography from a healthy control and 2 progressive IgAN patients. Monomeric IgA1 was separated by FPLC. The relative hinge region O-galactosylation was determined using a helix aspersa (HA) lectin binding assay including a standard curve containing serum samples with decreasing lectin binding. High lectin binding relates to low galactosylation.

AUC sedimentation velocity experiments were performed at 20°C with rotor speeds of 20 000 and 30 000 rpm for 16 h in PBS. Data was analysed using size-distribution plots c(s) using SEDFIT to determine monodispersity and establish sedimentation coefficients (S).
Results: The HA lectin binding values of the healthy subject and the patients 1 and 2, expressed as arbitrary units from a standard curve, were 22, 32 and 31, the sedimentation coefficients were 6.85 S, 6.7 S and 6.55 S respectively.
Conclusions: Sedimentation coefficient, a measure of molecular elongation increases when a molecule becomes more compact. The decrease in s value with increased HA binding and therefore decreased galactosylation, suggests a change in shape associated with the undergalactosylation of serum IgA1 in IgAN patients.

These results show that the conformational state of monomeric IgA may be directly altered via hinge glycosylation, potentially providing an implication to the increased deposition of IgA in IgAN.

P0969

The effect of interleukin-15 on inflammatory bone metabolism

A. Mitani, H. Takeda, T. Kikuchi, K. Soboku, S. Fujita, Y. Ishihara & T. Noguchi
Aichi Gakuin University, Periodontology Sch Dentistry, Nagoya, Japan

Purpose/Objective: Interleukin-15 (IL-15), mainly induced by macrophage or epithelium cell, is important for early response to compensate the time difference between innate immunity and adaptive immunity and deeply involved the initial immune response at local inflammatory site. However, it is still unclear about the effect on inflammatory bone metablism like periodontitis and peri-implantitis. Thus, we examine the effect of IL-15 on osteoblast and osteoclast differentiation.
Materials and methods: Bone marrow cells (BMCs) were collected from femurs of 4-week-old ddy mice. Osteoblasts from 2-day-old ddy mice were isolated from the calvaria. Osteoclast formation using primary cells was determined in co-cultures of osteoblasts (1.6×10^4 cells/well) and BMCs (4×10^6 cells/well). They were co-cultured for 7 days in a 24-well plate in the presence or absence of 10^{-6} M prostaglandin E_2 (PGE_2) and/or IL-15 (10, 100 ng/ml). To detect osteoclasts, the cells were stained for Tartrate-Resistant Acid Phosphatase (TRAP). TRAP-positive multinucleated cells containing three or more nuclei were counted as osteoclasts. Osteoclast formation using cell line was determined in RAW 264 cells (6×10^3 cells/well). They were cultured for 5 days in a 48-well plate in the presence or absence of receptor activator of nuclear factor-κB ligand (RANKL) at 10, 25, 50 ng/ml. Osteoclast detection was carried out as described above.
Results: The number of osteoclasts in co-culture was decreased by IL-15 in a dose-dependent manner. The osteoblasts in co-culture seemed to disappear and be apoptotic cell death. This phenomenon was attenuated when T-cells and NK-cells were removed from BMCs. The number of osteoclasts in RAW 264 cells was increased by IL-15 in a dose-dependent manner.
Conclusions: IL-15 might promote inflammatory bone destruction by both promoting osteoclast differentiation and osteoblast apoptotic cell death. It is possible for IL-15 to be immunological therapeutic target for local inflammatory bone resorption like periodontitis and peri-implantitis.

P0970

The genes of AP-1 transcription complex as the potential factors which have an influencing on atherosclerosis development

M. Sautin
Faculty of Medicine, Peoples' Friendship University of Russia, Moscow, Russia

Purpose/Objective: Searching and research of the expression of the genes, which are connected with the risks of atherosclerosis development.
Materials and methods: It was used material of 34 autopsies taken from patients who were suffered from the ischemic attacks of the brain and acute heart failure. Mean age of the patients was 77.6 years old. It was used PubMed and UniGene bases during preparing the list of the genes. According to this list maps gene interactions were prepared. We looked throw the genes whose expression was changed more than 2 times. According to the maps key gene complexes are transcription factors AP-1 and NF-kB. NF-kB factor is not specific for the atherosclerosis process; therefore we have excluded it from research. Transcription factor AP-1 (Activating protein 1) is including proteins of Fos-, Jun- and ATF- families. Expression level of the components of AP-1 transcription factor at the blood vessel intimae was determined by Real-time PCR. Expression of the JunB, c-Jun, JunD, cFos genes was studied. Expression of the genes was normalized on the housekeeper gene GAPDH.
Results: cFos expression at the affected intimae of the blood vessel in comparison with the not affected intimae was increased in more than two times. JunB expression at the affected intimae was increased too. JunD expression in two patients was increased less than 2 times. In the case of 3 patients gene expression was increased more than 10. c-Jun expression decreased in 1 case. In the case of 2 patients' it was increased in more than 10 times. Thus, expression of the cFos, JunB, JunD, c-Jun genes in the in the most cases was increased.
Conclusions: Our data relate to those of other authors that the expression of the certain genes of the AP-1 transcription factor may vary in different pathological processes. Increasing of the level of cFos gene expression in 3 or more times is observed in patients, who were developed complications of atherosclerotic damage of the arteries which are supplying the tissue of the brain.

Our data suggest that the genes of AP-1 transcription factor are playing key role at the atherosclerosis processes.

P0971

The right dose determines a poison – influence of benzo(a)pyrene on the infection with *Salmonella enterica*

C. Fueldner, S. Riemschneider, K. Zoldan, J. Knauer & J. Lehmann
Cell Engineering/GLP unit, Fraunhofer Institute for Cell Therapy and Immunology, Leipzig, Germany

Purpose/Objective: Polycyclic aromatic hydrocarbons (PAHs) such as benzo(a)pyrene (BaP) are environmental contaminants exerting deleterious effects towards the immune system, ranging from immunosuppression to fatal inflammatory disease. Since exposure to BaP is ubiquitary, risk assessment was conducted to determine upper limits for tolerable daily intake doses (subtoxic concentrations). However, most studies demonstrating hazardous effects of BaP used concentrations in the toxic range. Therefore, the aim of this study was to investigate the influence of subtoxic BaP-concentrations on the outcome of an infection with *Salmonella enterica* (*S. e*) in a murine model.
Materials and methods: Mice were infected with *Salmonella enterica* and simultaneously exposed to subtoxic doses of BaP..
Results: Importantly, exposure to BaP in subtoxic concentrations markedly increased survival of mice after infection with *S. e.* However, BaP-treated animals developed a long-term infection with higher bacterial burden in spleen and liver when compared to vehicle controls. The number of B lymphocytes was significantly increased at day 90 post infection in BaP-exposed mice, which was accompanied by higher serum titers of *S. e.*-specific IgG1 and IgG2c antibodies. Furthermore, IL-17 and IL-22 mRNA levels in splenocytes were significantly up-regulated after long-term infection in BaP-treated mice.
Conclusions: Although BaP-treatment in subtoxic concentrations increased survival of mice during *S. e.* infection, it also promoted the survival of bacteria with a consequent increase in inflammatory responses. Our data suggest that constant BaP-exposure in subtoxic concentrations during an infection favours a bacteria-driven chronic inflammation.

Unravelling the causes of inflammatory steroid resistance via a systems biology approach

N. Valeyev* **& G. Welsh†**

**College of Engineering Mathematics and Physical Sciences, University of Exeter, Exeter, UK, †School of Clinical Sciences, University of Bristol, Bristol, UK*

Purpose/Objective: Steroid resistance is a generic problem which occurs in a number of autoimmune diseases. Treatment failure occurs in up to 30% of patients treated with steroids for inflammatory diseases. While it has been shown that there are significant homeostatic differences in cytokine and growth factor production profiles of interacting cell populations between steroid resistant and steroid sensitive cases, the mechanism of the steroid resistance is not understood. Recent evidence has implicated a steroid resistant CD4+ T cell subpopulation in the perpetration of steroid resistant disease.

Materials and methods: In order to investigate the inflammatory causes of steroid resistance we combined available experimental information into an extended systems model of our earlier work on interdependent cellular interactions. This project applies a systems based approach to the problem of steroid resistance using Steroid Resistant Nephrotic Syndrome (SRNS) as an example and is applicable to other steroid resistant cases.

Results: Using our unique cultured human glomerular cells and glomerular cell models we have measured cytokine and growth factor production in reponse to steroids using ELISA and mass spectrometry. These results allowed us to develop a model of the response of the kidney glomerulus to steroids. The model allowed the generation of a new hypothesis by predicting the appearance of pathological conditions as a result of altered cytokine and growth factor production rates and/or degradation rates in the glomerulus.

Conclusions: Our model predicts that glucocorticoids can modulate the cytokine concentrations and as a result of feedback loop interactions between cytokines and chemokines in a number of case may lead to the shift from pathologic conditions to healthy homeostasis. At the same time, we show that there can be cases when steroids can aggravate the disease and even introduce new disease etiologies.

Beneficial effects of Ocimum gratissimum aqueous extract on rats with CCl4-induced acute liver injury

T. C. Hsu,* B. S. Tzang,† C. C. Chiu* & Y. W. Wang†
*Institute of Microbiology and Immunology, Chung Shan Medical University, Taichung, Taiwan, †Institute of Biochemistry and Biotechnology, Chung Shan Medical University, Taichung, Taiwan

Purpose/Objective: Ocimum gratissimum (OG) is known as a food spice and traditional herb, which has been recommended for the treatment of various diseases. Herein we investigated the effects of OG leaf aqueous extract (OGAE) on reducing hepatic injuries in rats after CCl4 challenging.
Materials and methods: To investigate the hepatoprotective effect of OG aqueous extract (OGAE), male Wistar rats challenged by carbon tetrachloride (CCl4) were used as the animal model of chronic hepatic injury. Catalase assay (CAT) and DPPH assay was assessed in CCl4-administrated rats. Expression and phosphorylation of protein was determined and quantitated by immunoblotting using specific antibodies and densitometric analysis.
Results: Significantly increased serum catalase and DPPH levels were detected in CCl4-administrated rats that were treated with OGAE or sylimarin as compared to those rats that were treated with saline or CCl4. In contrast, significantly decreased stress proteins including HSP70 and iNOS were observed in livers of CCl4-administrated rats that were treated with OGAE or sylimarin as compared to those rats that were treated with saline or CCl4. Moreover, significant decreases of MMP-9/MMP-2 ratio, uPA, phosphorylated ERK (p-ERK) and NF-κB (p-P65) were detected in livers of CCl4-administrated rats that were treated with OGAE or sylimarin as compared to those rats that were treated with saline or CCl4.
Conclusions: These findings imply that OGAE can efficiently inhibit CCl4-induced liver injuries in rats and may therefore be a potential food or herb for preventing liver injuries.

CCR5-32 and UGT1A1 28− mutations in HCV patients

L. Sadovska,* L. Piekuse,* M. Kreile,* J. Keiss† & A. Krumina‡
*Riga Stradins University, Laboratory of Molecular Genetics, Riga, Latvia, †Latvian Infectology Center, Liver disease department, Riga, Latvia, ‡Latvian Biomedical Research and Study Center, Genetics, Riga, Latvia

Purpose/Objective: The role of CCR5-Δ32 and UGT1A1 28* mutations in HCV patients is not entirely clear, but it is known that CCR5-Δ32 contributes to immunology and UGTA1A 28* mutations cause Gilbert's syndrome which affects the liver. Presumably, a patient homozygous for both of these mutations is more likely to be at risk group for HCV infection. The objective to this study was to determine whether the occurrence of mutations CCR5-Δ32 and UGT1A1 28* is higher in HCV patients than in normal healthy group.
Materials and methods: To achieve our goal, we performed PCR for the genes in question and visualized the results in 6% polyacrylamide gel electrophoresis and by sequencing the PCR products. In this study we analyzed 262 individuals infected with hepatitis C and 187 healthy donors from general population, in total*243 male and 206 female individuals. For statistical analysis we used PLINK software, for biomedical association we used linear regression using additive model.
Results: Allelic frequency for CCR5-Δ32 mutation was 0.239 in HCV patient group and 0.176 in control group ($P = 0.0399$); for $(TA)^7$ allele it was 0.546 in HCV patient group and 0.355 in general population ($P = 0.00000005$.

For 79 patients there was more detailed information about their infection − viral RNA levels before and after therapy, viral genotype, iron, ferritin, ALT before and after therapy, viral clearance right after and 3 months after therapy. We found no significant association between patient's genotypes and RNA levels, ALT and iron levels ($P > 0.05$). Almost significant association was found between CCR5-Δ32 mutation and ferritin level by additive model (BETA -120.4, $P = 0.077$). Moreover, there was no association with viral clearance right after therapy, but 3 months after therapy for positive RNA CCR5-Δ32 allele frequency was 0.297, for negative − 0.0714 ($P = 0.0363$).
Conclusions: Patients with mutations in CCR5 and UGT1A1 are more likely to be infected with HCV, as their immune response is altered and their liver is weakened. It seems that UGT1A1 28* can affect liver function also in heterozygous state, but that way it does not cause Gilbert's syndrome. Presumably, the CCR5-Δ32 mutation correlates with unresponsiveness to therapy.

P0976

$CD39^+$ CD4+ T cells display a pro-inflammatory signature in patients with autoimmune hepatitis

C. Grant, R. Liberal, B. S. Holder, Y. Ma, G. Mieli-Vergani, D. Vergani & M. S. Longhi
King's College London, Institute of Liver Studies, London, UK

Purpose/Objective: Autoimmune hepatitis (AIH) is associated with numerical and functional regulatory T cell (Treg) defects. A recently described Treg subset expresses the ectonucleotidase CD39, which renders Tregs capable of suppression by initiating an ATP/ADP hydrolysis cascade culminating in the production of immunomodulatory adenosine. $CD39^+$Tregs exert preferential control over Th17 cells, an effector subset involved in AIH liver damage. CD39 is also present on a proportion of CD4 memory lymphocytes with effector function. Regulatory and pro-inflammatory features of $CD39^+$ $CD4^+$ cells in AIH are untested. We therefore sought to provide a phenotypic signature of $CD39^+$ $CD4^+$ cells in AIH.
Materials and methods: Of the 14 AIH patients and 6 healthy subjects (HS) were studied. Circulating $CD39^+$ $CD4^+$ cells were phenotyped by flow cytometry using monoclonal antibodies to CD4, CD39, CD25, FOXP3, Granzyme B, CD62L, CTLA-4 and RORC. The frequency of TGFβ and IL17A-producing cells was assessed by intracellular cytokine staining after incubation with Leukocyte Activation Cocktail (LAC).
Results: Compared to $CD39^-$ $CD4^+$ cells, a higher proportion of $CD39^+$ $CD4^+$ cells expressed Treg and Th17 markers in AIH and health. Compared to HS, $CD39^+$ $CD4^+$ cells in AIH patients contained fewer cells positive for the Treg-associated markers CD25, FOXP3, and Granzyme B, while CD62L or CTLA-4 positive cell frequencies were similar. After LAC stimulation, the frequency of TGFβ-producing cells among $CD39^+$ $CD4^+$ cells was lower in AIH patients compared to HS. In contrast to Treg markers, $CD39^+$ $CD4^+$ cells from AIH patients contained a higher proportion of cells positive for the Th17 transcription factor RORC than those from HS. There was no difference in the proportion of IL17A-producing cells within $CD39^+$ $CD4^+$ cells between AIH and HS.
Conclusions: The $CD4^+$ population expressing the ectoenzyme CD39 contains a high proportion of cells expressing Treg and Th17 markers. In AIH the lower frequency of cells positive for conventional Treg markers and the higher number of cells positive for RORC indicates that the $CD39^{++}$ $CD4^+$ population is skewed towards a pro-inflammatory phenotype. Whether the effector potential of Th17 committed lymphocytes is mitigated by the presence of CD39 awaits investigation.

P0977

CD8ßlow – a novel differentiation marker and a prominent population in chronic hepatitis B infection

L. Walker, E. Marrinan, E. Barnes & P. Klennerman
Nuffield Department of Medicine, University of Oxford, Oxford, UK

Purpose/Objective: Failure of antigen-specific CD8 T cells is a recognised feature of chronic hepatitis B (HBV) infection, however the bulk CD8 T cell population is also characterised by low expression of CD28 and poor IL-2 production and proliferation capacity (Hoare D *et al.* 2008) in keeping the phenotype of late differentiated CD8 T cells. We have previously observed a prominent CD8 T cell population in chronic HBV to be CD8α+β^{low} (Kang W *et al.* 2009) – this is most obvious in the cells which either lack (CD161-) or have low expression of CD161 (CD161+) (a molecule associated with liver homing). In this study we aimed to explore the relationship between these two observations in chronic HBV, chronic Hepatitis C (HCV) and healthy controls (HC).

Materials and methods: Peripheral blood mononucleocytes were obtained from patients with chronic HBV (n = 37), chronic genotype 1HCV (n = 24) and healthy controls (n = 15). All patients were treatment naïve. FACS analysis was performed on both cell surface antibody staining using a panel of activation/exhaustion/differentiation markers (CD25, CD38, CD69, HLA-DR, PD-1, CD8α, CCR7, CD62L, CD45RA, CD45RO, CD28, CD27, CD57) and intracellular cytokine staining following PMA/ionomycin stimulation.

Results: Prominent populations of CD161$^-$ and CD161+ CD8α+β^{low} T cells can be identified in healthy individuals as well as those with chronic viral hepatitis, however a significantly greater population of CD161-/CD161$^+$ CD8α^+ CD8β^{low} T cells is seen overall in chronic HBV compared to healthy controls (mean 39.5% HBV, mean 24.74% HC, P = 0.05). The CD8α+β^{low} T cells have the CD28$^-$ CD27$^-$ CD57$^+$ CD62L$^-$ CCR7$^-$ CD45RA$^-$ phenotype of late differentiation in both healthy controls and patients with chronic HBV and HCV and express high levels of the late activation marker HLA-DR. CD161- CD8α+β^{low} CD8 T cells produce significantly more IFN-γ and TNF-α on stimulation with PMA/ionomycin than their CD161$^-$ CD8α+β^{high} counterparts and express greater levels of Ki67 and perforin.

Conclusions: CD8β^{low} status represents a novel marker for late differentiated CD8+ T cells and may alter the ability of CD8+ T cells within this population to respond to CD8$\alpha\beta$ dependent epitopes. The prominence of CD8α+β^{low} T cells in chronic HBV infection is likely to profoundly influence the immune environment, with important implications for the development of immunotherapy and treatment.

Cell-targeting gold nanorods critically affect the outcome of liver inflammation *in vivo* by modulating macrophage polarization

M. Bartneck,* T. Ritz,* H. A. Keul,† M. Wambach,† J. Bornemann,‡ U. Gbureck,§ J. Ehling,¶ T. Lammers,¶ F. Heymann,* N. Gassler, T. Lüdde,* C. Trautwein,* J. Groll§ & F. Tacke***
**Department of Medicine III, Medical Faculty RWTH Aachen, Aachen, Germany, †RWTH Aachen, DWI e.V. and Institute of Technical and Macromolecular Chemistry, Aachen, Germany, ‡Medical Faculty RWTH Aachen, Electron Microscopic Facility (EMF), Aachen, Germany, §Department and Chair of Functional Materials in Medicine and Dentistry, University Hospital Würzburg, Würzburg, Germany, ¶Department of Experimental Molecular Imaging (ExMI), Helmholtz Institute for Biomedical Engineering, Aachen, Germany, **Medical Faculty RWTH Aachen, Institute of Pathology, Aachen, Germany*

Purpose/Objective: Hepatic macrophages critically promote liver inflammation and fibrogenesis. Thus, hepatic macrophage-specific immunomodulatory nanoparticles represent a promising therapeutic option in liver diseases. We reported recently that human primary macrophages are strongly polarized by nanoparticle surface chemistry *in vitro*. Here, we investigated the toxicity, distribution, and therapeutic effects of gold nanorods (AuNR) in acute and chronic liver injury *in vivo*, aiming to develop novel therapeutic strategies for the treatment of liver disease.

Materials and methods: We studied the concentration-dependent organ distribution of AuNR coated with either CTAB, PEG, or with the tripeptides GLF, or RGD *in vivo* in C57BL/6J mice using inductively coupled plasma-mass spectrometry, electron microscopy, and *in vivo* imaging (micro-CT). The therapeutic effects of the AuNR were studied in Concanavalin A (ConA)-mediated acute hepatitis as well as in carbon tetrachloride (CCl_4)-induced fibrosis, using biochemistry (ALT, AST, hydroxyproline), histology, immunohistochemistry, and flow cytometry. Macrophages were isolated from liver and analyzed for polarization by qPCR-based assays.

Results: We found that the AuNR predominantly accumulate in liver *in vivo*, specifically in hepatic macrophages. At high concentrations (1200 μg/kg), CTAB-coated AuNR slightly increased infiltrating inflammatory CD11b$^+$F4/80$^+$Gr1^{high} macrophages in the liver without evidence of hepatotoxicity *in vivo*. Interestingly, upon ConA-induced hepatitis, RGD-peptide-modified AuNR significantly deteriorated liver damage, decreased the frequency of resident CD11b$^-$ F4/80$^+$Gr1^{low} Kupffer cells accompanied by strong changes in the expression of surface markers and function-related genes expressed by classically or alternatively activated macrophages, compared to untreated controls. Similar observations were found in chronic liver injury, with a trend towards increased liver fibrosis development by RGD-coupled AuNR.

Conclusions: AuNR efficiently target hepatic macrophages, and modifications of nanoparticle surface chemistry affect the phenotype and functionality of both liver infiltrating and resident macrophages, thereby impacting the hepatic response towards acute or chronic injury.

P0979

Characterization of two human monoclonal anti-E2/HCV antibodies for potential application in prevention and treatment of HCV infection

R. A. Diotti, G. Sautto, E. Criscuolo, N. Mancini, L. Solforosi, M. Clementi & R. Burioni
Università Vita-Salute San Raffaele, Microbiology, Milano, Italy

Purpose/Objective: HCV is a major cause of chronic liver disease worldwide and the current antiviral therapies results successful in approximately half of treated patients. Liver disease caused by HCV infection is a common indication forliver transplantation but graft re-infection is universal and often results in graft loss. Immunotherapies employing neutralizing antibodies, able to inhibit HCV infection, directed against the HCV viral glycoproteins E1 and E2, involved in cell viral entry, have the potential to control or prevent graft reinfection. Moreover, anti-HCV neutralizing antibody can find a potential application for the treatment of chronically infected patient.

Here we characterized two potent neutralizing anti-E2/HCV human monoclonal antibodies (mAbs).

Materials and methods: We previously characterized two anti-HCV E2 human mAbs as Fab fragments, e20 and e137. To obtain molecules more suitable for therapeutic purposes, we generated whole IgG e20 and e137. Both mAbs were tested in ELISA and immunofluorescence assay (IF) to study the affinity and the reactivity on different genotypes. To determine the capacity of these antibodies to interfere with E2-CD81 binding, we performed an inhibition of binding (IOB) of CD81 to recombinant E2 glycoprotein by ELISA. For studying biological activity of e20 and e137, neutralization assay against HCVpseudo-

particles of five genotypes and cell culture infectious HCV system based on genotype 2a was performed.
Results: The antibodies showed high affinityfor E2 recombinant glycoprotein (genotype 1a) and were able to recognize HEK293T cells expressing HCV E1-E2 from the principal HCV genotypes. Both IgGs showed dose dependent IOB activity and at the maximum tested concentration the inhibition was about 97%. Neutralization assay showed that these antibodies are strong neutralizers of the tested genotypes with IC50 ranging from 0.02 to 2 μg/ml.
Conclusions: e20 and e137 are potent cross-reactive and cross-neutralizing mAbs able to inhibit E2-CD81 binding. These data suggests that both antibodies are directed against conserved and critical residues for viral infectivity on E2 glycoproteins. Based on their features, both IgGs may assist in the development of an effective passive immunotherapy for the prevention of viral reinfection of the liver graft and treatment of chronically infected patients.

P0980
Chemokine presentation by liver sinusoidal endothelial cells as therapeutic target in murine T cell-mediated hepatitis

K. Neumann,* N. Kruse,* K. Wechsung,* M. Schumann,* A. Kühl,† U. Erben,* M. Zeitz* & K. Klugewitz*
**Charité Universitätsmedizin Berlin, Medizinische Klinik I, Berlin, Germany, †Charité Universitätsmedizin Berlin, Institut für Pathologie, Berlin, Germany*

Purpose/Objective: Leukocyte adhesion and transmigration is one of the central paradigms of inflammation. Within the liver sinusoids, chemokines initiate the first crucial step of lymphocyte migration into the parenchyma. Especially liver sinusoidal endothelial cells (LSEC) present chemokines to T cells increasing their biological activity. We here investigated mechanisms of chemokine transport by LSEC and whether inhibition of endothelial chemokine presentation influences autoimmune hepatitis.
Materials and methods: In the murine model of Concanavalin (Con) A-induced T-cell mediated hepatitis chemokine expression was determined. Chemokine uptake, transcytosis and presentation by LSEC were visualized by confocal microscopy and functionally investigated in transmigration assays. Effects of reduced endothelial chemokine presentation on the development of hepatic inflammation were monitored by alanine transaminase and histology.
Results: During Con A-induced hepatitis, liver mRNA expression of the pro-inflammatory CXC chemokine ligand (CXCL)9 and CXCL10 was significantly increased. Furthermore, CXCL9 was particularly shown within LSEC. LSEC internalized basolateral CXCL9, CXCL10 and CXCL12 via clathrin-coated vesicles and provided these chemokines immobilized on the glycosaminoglycans heparan sulphate and chondroitin sulphate to $CD4^+$ T cells, thereby increasing transmigration *in vitro*. Blockage of the clathrin-dependent cellular transport pathway significantly reduced endothelial chemokine internalization and consequently chemokine-dependent $CD4^+$ T-cell transmigration across LSEC. Administration of a clathrin inhibitor *in vivo* suppressed Con A-induced autoimmune hepatitis and decreased accumulation of activated $CD4^+$ T cells expressing the CXC chemokine receptor 3.
Conclusions: Intervention in endothelial chemokine provision *in vivo* affects chemokine-dependent migration of pro-inflammatory $CD4^+$ T cells into the liver, thereby counteracting development of autoimmune hepatitis. Thus, chemokine presentation by LSEC during liver inflammation might be a promising therapeutic target in hepatitis.

P0981
Corticosteroids affect hepatitis C infection by modulating plasmacytoid dendritic cells but not interferon-a signaling

J. Kwekkeboom,* P. E. de Ruiter,† P. P. C. Boor,* Q. Pan,† J. de Jonge,† H. J. M. Metselaar,* H. W. Tilanus† & L. J. W. van der Laan†
**Erasmus MC – University Medical Centre, Gastroenterology and Hepatology, Rotterdam, The Netherlands, †Erasmus MC – University Medical Centre, Surgery, Rotterdam, The Netherlands*

Purpose/Objective: Chronic hepatitis C virus (HCV) infection is one of the leading indications for liver transplantation, but outcomes are often compromised by re-infection of the graft. Several studies have indicated that the use of corticosteroid-based immunosuppression is a risk factor for severe HCV recurrence. The mechanism for the steroid-mediated effect on HCV is not fully elucidated, but recent studies using *in vitro* HCV models found no direct effect on viral replication. The success rate of interferon-a (IFN-α) based antiviral therapy is significantly lower post-transplantation than in the non-transplant HCV population; however the impact of steroids on the antiviral activity of IFN-α is unknown. Therefore, the aim of this study is to investigate the effect of steroids on the antiviral activity of IFN-α and the impact on the primary IFN-α-producing cells, the plasmacytoid dendritic cells (PDCs).
Materials and methods: As a model for HCV replication we used the Huh7 hepatoma cell line, stably transfected with the non-structural coding sequence of HCV directly coupled to a luciferase reporter gene (Huh7-ET), and treated with IFN-α in the presence or absence of different doses of prednisolone or dexamethasone. A Huh7 cell line stably transfected with a luciferase gene under the control of an interferon response element (Huh7-ISRE-Luc) was used to investigate effects on IFN-α signal transduction. To investigate the effects of steroids on PDCs, Huh7-ET cells were co-cultured with human PDCs in the presence or absence of steroids.
Results: HCV replication was inhibited by 10 IU/ml IFN-α by more than 99% of control levels. Treatment with increasing doses of dexamethasone or prednisolone did not significantly affect HCV replication. When combining IFN-α with dexamethasone or prednisolone, no interference with the inhibition of HCV replication by IFN-α was observed. Moreover, dexamethasone and prednisolone had no effect on IFN-α signal transduction as measured in Huh7-ISRE-Luc cells. However, when Huh7-ET cells were co-cultured with PDCs, a significant reduction of HCV replication was observed, which was almost completely reversed by treatment with steroids.
Conclusions: We found no evidence that corticosteroids interfere with signal transduction and antiviral action of IFN-α. However, steroids may affect HCV replication post-transplantation by reducing the antiviral capacity of PDCs.

P0982
Differential migration patterns of CD8 T cells primed in the liver and gut

I. Eickmeier,* D. Seidel,* J. R. Grün,† A. A. Kühl‡ & E. Schott*
**Charité – Universitätsmedizin, Hepatology and Gastroenterology, Berlin, Germany, †German Arthritis Research Center (DRFZ), Bioinformatics, Berlin, Germany, ‡Charité – Universitätsmedizin, Immunopathology/RCIS, Berlin, Germany*

Purpose/Objective: Patients with inflammatory bowel disease (IBD) are frequently affected by autoimmune liver diseases, suggesting that these anatomical distinct diseases may share pathogenic features. Since IBD is T-cell mediated, it is possible that T cells activated in the gut migrate to the liver where they cause inflammation. In earlier experiments we have shown that gut- as well as liver-activated T cells

accumulate in the liver, but only gut-activated CD8 T cells are licensed to migrate to the small intestine. In contrast liver-activatedCD8 T cells retain the capacity to migrate through lymph nodes. Here we analysed the expression of activation and adhesion molecules of these differentially activated T cells, which may explain their migration behaviour.
Materials and methods: Antigen-specific naïve OT-I CD8 T cells were adoptively transferred into mice, in which ovalbumin is expressed in the liver (TF-OVA mice) or in the small intestine (iFABP-OVA mice). Effector T cells were isolated from liver and mesenteric lymph nodes after three days. Activation assays as well as microarray analysis and flow cytometry were used to examine distinct or shared imprinted patterns of these cells.
Results: Transcriptome analysis of naïve, liver- and gut-activated CD8 T cells identified 10 326 differentially regulated IDs. Hierarchical clustering clearly discriminated naïve, liver- and gut-activated T cells. Activation in the gut induced the typical gut-specific CCR9/$\alpha4\beta7$ T cells. In contrast liver-activated T cells displayed increased expression of $\alpha4\beta1$, $\alpha6\beta1$, Ly6C, PD-1 and CD62L, whereas activation markers as well as $\alpha L\beta2$ were upregulated in both cell types. The adhesion molecules ICAM-1 and VCAM-1 are constitutively expressed in the liver and were upregulated upon inflammation, whereas MAdCAM-1 expression could not be detected in the liver.
Conclusions: Liver-activated CD8 T cells display a unique phenotype compared to naïve and gut-activated T cells. High expression of CD62L and Ly6C may be responsible for their migration through lymph nodes. Only gut-activated T cells show gut-specific migration, but they also accumulate in the liver. This accumulation probably results from their adhesion to VCAM-1 and ICAM-1 in the liver. The migration of activated CD8 T cells is a one way route from the gut to the liver and may be responsible for the development of liver disease in patients with IBD.

P0983

Estudy of LDL influence in the interaction between HCV E2 protein and the surface receptors of ECV304 cell

A. C. Urbaczek,* W. C. Generoso,† A. Tansini,* L. M. Fonseca,* F. Henrique-Silva† & P. I. Costa*
**UNESP, Clinical Analysis, Araraquara, Brazil, †UFSCAR, Genetic and Evolution, São Carlos, Brazil*

Purpose/Objective: The HCV presents a world-wide prevalence of 3%, being the Hepatitis C one of the most important public health problems. The virus is enveloped and presents 10 different structural and non-structural proteins, amongst them the envelope 2 glycoprotein (E2). The E2 protein presents a strong association with the LDL receptor, suggesting that the HCV may use it to invade cells. An association between HCV and LDL from human serum was demonstrated in preliminary studies which report that lipoproteins may increase HCV infectivity. The aim was to produce a recombinant protein similar to HCV E2 protein, codified by partial E2 protein gene (without TM domain) and not glycosylated, to analyze its binding to the surface receptors of ECV304 cells, in the presence and absence of human LDL, in order to verify the influence of LDL in this binding process.
Materials and methods: The coding gene of the E2-like protein fused to the GST was cloned in the pET-42a vector and transformed into *E. coli* bacteria strain Rosetta, which was induced to protein expression with IPTG, at 37°C, 300 rpm for 3 h. The proteins were purified by glutathione column. ECV304 cells were incubated at 4°C for 90 min with 20 μg of E2 protein only and with 20 μg of E2 protein added of 40 μg of human LDL. The cells were washed with PBS pH7.2 and incubated at 4°C for 30 min with anti-his antibodies conjugated with APC. The cells were washed with PBS pH7.2 and submitted to analysis in *FACS Canto BD* cytometer, *software Diva FACS*..
Results: The flow cytometry results showed that the E2 recombinant protein bound to 20% of the cells and the proteins with human LDL bound to 35% of the tested cells.
Conclusions: The flow cytometry revealed that the addiction of human LDL to E2 recombinant proteins provided an increase of 75% in the binding to surface receptors of ECV304 cells, phenomenon that may increases the HCV infectivity.

Expression and function of Toll-like receptors in human hepatic stellate cells

J. Zeromski,* A. Mania,† M. Kaczmarek,* I. Mozer Lisewska,‡ B. Brzezicha,* M. Frydrychowicz,* R. Safadi§ & A. Kowala Piaskowska‡
**Clinical Immunology, University of Medical Sciences, Poznan, Poland, †Pediatrics, University of Medical Sciences, Poznan, Poland, ‡Infectious Diseases, University of Medical Sciences, Poznan, Poland, §Hadassah Medical Center, Liver & Gastroenterology Unit, Jerusalem, Israel*

Purpose/Objective: Human hepatic stellate cells (HHSC) play pivotal role in chronic liver diseases. They are involved in the induction and progression of hepatic fibrosis leading to liver cirrhosis. Toll-like receptors (TLRs) are known to be expressed on/in HHSC and some of them, such as TLR4 have been claimed to promote liver fibrosis. Presence and function of other TLRs in HHSC remains totally inknown. The aim of the current study was to to get some information about the expression and function of these structures in the cells in question.
Materials and methods: Established cell line of HHSC, LX2 was used. Cell cytospins were searched by immunocytochemistry (ICH) and cell suspensions by flow cytometry (FC) for TLR1-10 expression, as a per cent of positive cells and mean fluorescent intensity (MFI). RNA was isolated from cells and tested for mRNA specific for respective TLRs. Cells were subjected to short time culture with appropriate TLR ligands and afterwards assessed by FC for TLR expression. Culture supernatants were searched for a number of released cytokines by Flexnet (BD) cytometric assay.
Results: LX2 cells were shown to express all TLR1-10, both, tested by ICH and FC, but the per cent of positive cells varied. TLR mRNA was evidenced also for all TLRs tested. Culture with ligands resulted usually in lower MFI expression than in medium alone. SSpolyU, TLR8 ligand was the only one, that provided slightly higher MFI value of LX2 cells as compared to medium alone. The only cytokine, or rather chemokine, produced by LX2 cells in reasonable amounts (up to 800 pg/ml) was stromal cell-derived factor-1 (SDF-1a also known as CXCL12). Its production however appeared to be constitutive feature of LX2 cells, because it was also secreted by cells cultured without any TLR ligands. Another cytokine, being also a chemokine, that was secreted by cells in tiny but measurable range (53 pg/ml) was IL-8. It was the case, when cells were cultured in medium supplemented with FLA-BS, ligand of TLR5. Besides, cells cultured in medium (without any ligand) secreted TGF β_1, in amounts of 96 pg/ml.
Conclusions: Expression of TLRs (1−10) appears to be common phenomenon on/in LX2 cells. Their activation by TLR ligands has relatively modest effect on TLR expression and function. Presumably, in the case of HSC *in vivo*, these cells are boosted by other, hitherto unknown receptors or agents to manifest their profibrotic activity.

P0985

HCV Core protein induced immune disordre via oxidative stress and thiol redox alteration

K. Ben Larbi Zarki, M. Rodri′guez Iglesias, M. C. Duran Ruiz & F. F. Garcia Cozar
Biomedicine Biotechnology and Public Health, Universidad de Cádiz, Cádiz, Spain

Purpose/Objective: The network linking HCV infection, inflammation, free radical production, and carcinogenesis applies very well to HCV-mediated chronic liver damage, just as it applies to any chronic inflammatory condition. Research into the role of structural and nonstructural proteins of HCV and the changes induced in cytokine expression oncogenes, antioncogenes, and intracellular kinases shows that HCV is by itself and not only through inflammation able to induce ROS, an effect specific to this virus. This free radical production, accompanied by oxidative genomic injury, constitutes the first step of a cascade of genomic and postgenomic events that play an important role in HCC. More information is necessary from recently introduced technologies for proteomics that will hopefully close the gap between hypothesis and understanding. In the present study, we provide further evidence in support of this postulate. The technique used in our search, combining proteomics and proteine redox modification by S-glutathionylation, can help identifying proteins specifically modified under HCV Core pathological conditions.
Materials and methods: In the present work, we have engineered lentiviral vectors expressing the HCV core to determine how the pattern of protein oxidation is affected by disrupting thiol reduction pathways in CD4 Jurkat cells expressing HCV core protein. As a step towards characterizing relative susceptibilities of cell proteins to oxidation and identifying what changes can altere signalling or metabolic regulation, we have taken a proteomic approach (mono and two-dimensional electrophoresis; and MALDI-TOF MS) to identifying thiol proteins that become oxidized in both CD4 Jurkat cells expressing HCV Core and JKT cells exposed to oxidative stress (H_2O_2); This model was previously reported to cause extensive S-thiolation of cellular proteins. we also monitored oxidized thiols *in situ* by a technique that involves labelling with the fluorescent probe and analyzed by flow cytometry in a CyanADP-MLE (DakoCytomation) using an UV enterprise laser set at 30 Mw.
Results: Core protein increased S-glutathionylation in CD4 Jurkat cells. These results suggest that expression of core protein and subsequent oxidation of the glutathione pool and oxidative cysteine modifications inducing glutathiolation may be an important cause of the Alteration of immune cell function and the progression from chronic hepatitis C to HCC.
Conclusions: This new insight into the mechanisms for HCV mediated immune evasion and lymphocyte homeostasis alteration may offer novel therapeutic targets for one of the most devastating human malignancies in the world today

P0987

Hepatocytes mediate Notch dependent immune regulation in response to inflammation in the regenerating mouse liver

S. Burghardt, A. Erhardt & G. Tiegs
Institute of Experimental Immunology and Hepatology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Purpose/Objective: A single injection of concanavalin A (ConA) to mice induces acute Th1-mediated hepatitis. Tolerance against ConA rechallenge develops within 8 days and is mediated by IL-10 predominantly produced by $CD4^+$ $CD25^+Foxp3^+$ regulatory T cells (Tregs) and Kupffer Cells. This study was intended to identify the role of hepatocytes (HC) in ConA-induced immunoregulation.
Materials and methods: HC or splenic DC were isolated from saline- or ConA-pretreated wt, IL-10-, IFNγ-, or interferon regulatory factor (IRF)-1-deficient mice. Subsequently, HC or DC were co-cultured with splenic $CD4^+$ T cells from wt, DEREG or IL-10 KO mice and stimulated with anti-CD3 for 60 h. Cytokine release was measured by ELISA. Frequencies of $CD4^+Foxp3^+$ Tregs and $Notch1^+$ T cells were quantified by FACS analysis.
Results: Naive $CD4^+$ wt T cells co-cultured with wt HC from ConA-tolerant mice showed significantly increased IL-10 levels indicating a tolerant phenotype. T cells were identified as major source of IL-10. In contrast, splenic DC from ConA-tolerant mice failed to induce IL-10 release in naïve wt T cells. $CD4^+$ wt T cells co-cultured with ConA-primed IFNγ- or IRF-1-deficient HC released significantly lower levels of IL-10 compared to co-cultivation with wt HC from ConA-tolerant mice. Moreover, the γ-secretase inhibitor DAPT, which blocked Notch activation, prevented IL-10 secretion. Interestingly, HC from ConA-tolerant mice increased the frequency of $CD4^+Notch1^+$ T cells as well as receptor density of Notch1 on $CD4^+$ T cells. Furthermore, Foxp3 expression was elevated in co-cultures containing T cells from DEREG mice and ConA-tolerant HC compared to non-primed HC. Moreover, HC from ConA-tolerant mice promoted the TGFβ-driven conversion of naïve wt T cells to $Foxp3^+$ Tregs which was again abrogated by DAPT.
Conclusions: We showed that HC from ConA-tolerant mice induce an IL-10-secreting regulatory phenotype in naïve T cells and convert these cells into $Foxp3^+$ Tregs in the presence of TGFβ. The conversion depends on an intact IFNγ-dependent Th1 response and on Notch signalling. The failure of splenic DC to induce IL-10 expression indicates that the generation of an IL-10 producing T cell subset is restricted to liver-resident non-professional APCs favouring the 'liver tolerance effect' as well as regeneration in response to inflammation.

P0989

Human cytomegalovirus infection of human hepatic sinusoidal endothelial cells promotes CD_4 T cell recruitment and post-transmigrational activation

T. Bruns,* H. Zimmermann,* A. Pachnio,† P. A. Moss† & D. H. Adams*
NIHR Biomedical Research Unit and Centre for Liver Research, University of Birmingham, Birmingham, UK, †School of Cancer Sciences, University of Birmingham, Birmingham, UK

Purpose/Objective: Animal studies suggest that endothelial cells and not hepatocytes are the site of cytomegalovirus (CMV) latency and reactivation in the liver and the source of secondary viral spread. Furthermore, murine CMV infection of sinusoidal endothelium is able to break immunotolerance and induce a strong CD8 T cell effector response. The aim of this study was to investigate, whether CMV infection of human hepatic sinusoidal endothelial cells (HSEC) modulates the ability of the liver to recruit and activate CD4 lymphocytes.
Materials and methods: Recombinant endotheliotropic eGFP-labeled CMV was propagated in RPE-1 cells and purified by ultracentrifugation in tartrate/glycerol gradients. Primary HSEC were isolated from explanted livers, grown to confluence and infected with CMV over 2 h. Infection was confirmed by fluorescence microscopy and plaque assay on fibroblasts. Expression of adhesion molecules and costimulatory on infected HSEC were analyzed by flow cytometry and cell-based elisa. Resting CD4 T cells, regulatory T cells and CMV-specific CD4 clones were perfused over HSEC monolayers 24 h after infection under constant flow simulating physiological shear stress and adhesion and transmigration recorded using phase contrast microscopy. Static transmigration assays through HSEC into collagen were used to study phenotype and cytokine production of transmigrating lymphocytes using flow cytometry.

Results: Human sinusoidal endothelial cells were permissive to CMV infection. CMV infection of HSEC resulted in an increase of ICAM-1 and a decrease of ICAM-2, PD-L1 and CD40 and secretion of CXCL10 and CCL5. Under flow, transendothelial migration of CD4 T cells was increased through CMV-infected endothelium and predominantly mediated by ICAM-1. Transmigrated allogeneic CD4 effector memory T cells from CMV-seropositive and seronegative donors displayed a strongly increased expression of CD69 at 24 h and CD25 after 48 h after transendothelial migration through CMV-infected HSEC into collagen and demonstrated a Th1 phenotype (T-bet+, IFNg+, TNFa+) independently from HSEC MHC class II expression.
Conclusions: CMV infection of HSEC facilitates the up-regulation of cell-adhesion molecules and chemokines resulting in increased adhesion, transmigration and activation of CD4 T cells. This may explain how human CMV infection not only provokes significant hepatitis but also increases hepatic immune activation in graft rejection.

P0990

IL-33 exacerbates liver ischemia-reperfusion injury in mice

P. Zhu,* L. Xie,† L. Yang,* L. Duan,‡ M. Fang,‡ F. Gong‡ & J. Yang*
**Department of Internal Medicine, Institution of Immunology, the First college of Clinical Medical Science, Yichang city, China, †Department of Surgery the First college of Clinical Medical Science, Institution of Immunology, China Three Gorges University Yichang China, Yichang city, China, ‡Department of Immunology, Institution of Immunology, Tongji Medical College Huazhong University of Science and Technology Wuhan China, Yichang city, China*

Purpose/Objective: The aim of this study was to examine the role of IL-33 on liver I/R injury in mice.
Materials and methods: A partial lobar liver warm ischemia model was performed. The expression of IL-33 and ST2 were analysed in sham mice and liver I/R injury mice, using real-time polymerase chain reaction, western blotting, immunohistochemisry staining and confocal microscope approaches. The liver function, the level of cytokines and TLR4 and the infiltration of neutrophils were measured in sham, anti-IL-33 antibody, rIL-33 protein and saline group by ELISA, flow cytometry, immunohistochemisry staining, respectively.
Results: Our results show that both mRNA and protein levels of IL-33 were overproduced in I/R injury mice but not sham mice ($P < 0.05$). The major sources of IL-33 during liver I/R injury were injury hepatocytes and the vascular endothelial cells. Those mice pre-treated with anti-IL-33 antibody 1 h before ischemia showed decreased serum alanine aminotransferase levels, inhibited production of proinfiammatory cytokines such as IL-1β, IL-18, TNF-a, and IL-6 as well as decreased of infiammatory cell infiltration by down regulation of TLR4 on kupffer cell, leading to the prevention of liver I/R injury, when compared with controls ($P < 0.05$). Histology revealed that pre-treated with anti-IL-33 antibody significantly ameliorated hepatocellular damage ($P < 0.05$). At the same time, those mice pre-treated with rIL-33 protein revealed more serious liver injury than control mice ($P < 0.05$).
Conclusions: our study confirms that IL-33/ST2 signalling is involved in liver I/R and that inhibition of IL-33 can protect the liver from I/R injury by reducing IL-1β, IL-18, TNF-a, IL-6 release and infiammatory cell infiltration through down regulation of TLR4 expression on kupffer cell.

P0991

Immune cell CD39 and CD73 expression in autoimmune hepatitis and health

C. Grant, R. Liberal, B. S. Holder, Y. Ma, G. Mieli-Vergani, D. Vergani & M. S. Longhi
Institute of Liver Studies, King's College London, London, UK

Purpose/Objective: CD39 is an ectoenzyme that works in tandem with CD73 to degrade ATP and ADP into AMP and immunosuppressive adenosine. In mice, $CD4^+$ $CD25^{high}$ regulatory T cells (Tregs) express both CD39 and CD73. In humans $CD39^+$ Tregs have potent immunomodulatory capabilities, despite variable CD73 expression. Autoimmune hepatitis (AIH) is an inflammatory liver disorder characterised by reduced Treg frequency and function. CD39 and CD73 expression by different immune cell subsets has not been fully characterised. Our objective was to determine the frequency of circulating $CD39^+$ and $CD73^+$ immune cells in AIH and health.
Materials and methods: Twenty AIH patients and 10 healthy subjects were studied. The frequency of $CD19^+$ (B cells), $CD11c^+$ (dendritic cells), $CD8^+$, $CD56^+$ (natural killer cells), $CD4^+$ $CD25^-$ and Treg cells expressing CD39 and CD73 was measured by flow cytometry.
Results: $CD19^+$ and $CD11c^+$ populations contained the highest frequency of $CD39^+$ cells in both AIH patients and HS. CD39 was expressed to a lesser extent by Tregs, and the frequency of $CD39^+$ Tregs was lower in AIH than in HS. The frequency of $CD39^+$ cells within the $CD4^+$ $CD25^-$, $CD56^+$ and $CD8^+$ subsets was low in both groups, but $CD39^+$ $CD8^+$ lymphocytes were fewer in AIH than in HS.

The $CD19^+$ and the $CD8^+$ subsets contained the highest frequencies of $CD73^+$ cells in both groups, with $CD73^+$ $CD8^+$ lymphocytes being more numerous in AIH than in health. A lower proportion of Tregs from both groups were positive for CD73. The frequency of $CD73^+$ cells within $CD11c^+$, $CD56^+$ and $CD4^+$ $CD25^-$ populations was low in both AIH and health, but AIH patients displayed higher frequencies of $CD73^+$ $CD56^+$ and $CD73^+$ $CD4^+$ $CD25^-$ lymphocytes than HS.
Conclusions: Circulating immune cells display differential CD39 and CD73 expression patterns. In AIH, the low proportion of $CD39^+$ cells within Tregs and $CD8^+$ lymphocytes may account for impaired immune-regulation. Both in AIH and health, only a small proportion of Tregs are positive for CD73, suggesting that completion of the ectonucleotidase cascade is performed by $CD19^+$ and $CD8^+$ cells, the higher frequency of $CD73^+$ cells in AIH possibly reflecting an inflammatory state. Since $CD19^+$ cells express the highest frequency of both CD39 and CD73, their possible role as regulatory B cells needs to be investigated in future studies.

P0992

Immunohistochemical study of Toxocara-induced hepatic inflammation: characterizing the immune response players

A. Othman, D. Ashour & D. A. Mohamed
Parasitology Faculty of Medicine, Tanta University, Tanta, Egypt

Purpose/Objective: The aim of this study was to characterize the key immune cells and the rate of apoptosis in hepatic inflammation during the course of experimental infection by Toxocara canis.
Materials and methods: Mice experimentally infected with Toxocara canis were divided into two groups: mice with primary infection by Toxocara, and those infected after sensitization by Toxocara excretory-secretory antigen. CD4+, CD8+, andBcl-2-expressing T lymphocytes were identified in the liver by immunohistochemistry at different durations post-infection.
Results: We observed recruitment in both CD4+ and CD8+ T lymphocytes with difference in count and localization within the liver. These cells were detected within and around Toxocara-induced granulomas as well as in isolated inflammatory foci in the portal tracts

or within the hepatic parenchyma. The antiapoptotic protein Bcl-2 showed no significant change at different periods post-infection. On the other hand, immunization of mice with Toxocara excretory-secretory antigen prior to experimental infection caused earlier and more pronounced recruitment of CD8+ T cells to the liver and enhanced expression of Bcl-2.

Conclusions: These results suggest a dynamic change in key immune cells according to duration of infection as well as the immune status of the host.

P0993

Induction and functionality of hepatic regulatory CD4+ T cells

C. Rudolph,* N. Kruse,* K. Neumann,* U. Erben,* A. Kühl,* A. Derkow,† E. Schott,† M. Zeitz,* A. Hamann‡ & K. Klugewitz*

**Charité University-Medicine Berlin, Medical Clinic I, Berlin, Germany, †Charité University-Medicine Berlin, Medical Clinic Hepatology and Gastroenterology, Berlin, Germany, ‡Deutsches Rheuma-Forschungszentrum, Berlin, Germany*

Purpose/Objective: Liver sinusoidal endothelial cells (LSEC) play an important role in shifting local immune responses to tolerance in major histocompatibility complex (MHC) I-restricted models of antigen presentation. Their impact in MHCII-mediated antigen presentation in the context of tolerance and immunity is still under investigation. Recently, in a bone marrow chimeric mouse model expressing MHCII exclusively on non-hematopoietic cells like LSEC, the induction of $CD4^+$ $CD25^{low}$ forkhead box protein (FoxP)3$^-$ regulatory T cells by LSEC has been described.

Materials and methods: In a model of T cell-mediated autoimmune hepatitis, we adoptively transferred OVA-specific $CD8^+$ and $CD4^+$ T cells alone or in combination with LSEC-primed $CD4^+$ T cells (T_{LSEC}) into TF-OVA mouse, expressing OVA exclusively in the liver. The suppressive capacity of T_{LSEC} was analyzed by CD8 T cell suppression assay *in vitro*. We further investigated the mechanisms involved in induction of T_{LSEC} phenotype. Transfer colitis model was used to gain insights into the ability of regulatory T_{LSEC} to suppress the development and progression of intestinal inflammation.

Results: T_{LSEC} suppress a T cell-mediated autoimmune hepatitis *in vivo*. *In vitro* T_{LSEC} have the capacity to suppress proliferation, activation and development of effector molecules of $CD8^+$ T cells. We investigate mechanisms involved in the induction and function of regulatory $CD4^+$ T cells by LSEC. Especially retinoic acid seems to play an important role during induction of T_{LSEC} phenotype. Surprisingly, T_{LSEC} do not only home into the liver but also migrate into the gut, enabled by expression $\alpha_4\beta_7$ integrin and CC chemokine receptor (CCR)9. Initial experiments showed an inhibitory effect of T_{LSEC} on intestinal inflammation by reduced lamina propria lymhocyte cell counts and a slightly reduced clinical colitis score.

Conclusions: The suppressive capacity and gut-homing properties of T_{LSEC} open for the intriguing possibility that recruitment of liver-primed $CD4^+$ T cells into the intestine might modulate the immunological balance of the gut.

Induction of human CD14+HLA-DR- Myeloid Derived Suppressor Cells by Hepatic Stellate Cells

B. Höchst,* F. A. Schildberg,† M. Ballmaier,‡ P. Sauerborn,* J. Schilling,* I. Müller,§ F. Gieseke,§ P. Knolle† & L. Diehl*

**Institutes of molecular Medicine and experimental Immunology, AG Diehl, Bonn, Germany, †Institutes of molecular Medicine and experimental Immunology, AG Knolle, Bonn, Germany, ‡Department of Pediatric Hematology, Medizinische Hochschule Hannover, Bonn, Germany, §Forschungsinstitut Kinderkrebs-Zentrum, AG Müller, Hamburg, Germany*

Purpose/Objective: Tumors have evolved different mechanisms to evade the host immune response and generate a suppressive network. In addition to regulatory T cells (Tregs) and tumor-associated macrophages (TAMs), myeloid-derived suppressor cells (MDSCs) are of great importance and are becoming a focus of interest.

The only possibility to overcome this problem will be a careful phenotypical and functional analysis of all potential MDSC subsets in different clinical settings and different immunological compartments. Identification of better markers will facilitate these studies. More in-depth analysis of the interaction of MDSC with other cell types will help understanding the biological function and finally, the specific targeting of human MDSCs will enhance the effect of immune-based therapies in cancer.

Materials and methods: MDSCs have gained a lot of attention in recent years, mainly in mouse models. However, the results from murine studies indicate that human MDSCs will need to be analyzed in more detail in cancer patients in order to understand the induction and function of these cells in patients. One major hurdle remains the heterogeneity of these cells. humans, MDSC are inadequately characterized because of the lack of uniform markers. The described phenotype includes CD33+, CD11b HLA-DR- cells (immature phenotype) CD14+, HLA-DR- cells (monocytic like) and CD15+, HLA-DR- cells (granulocytic like). They negatively regulate the immune response by effecting NK and T cells. Potential mechanisms, which underlie this inhibitory activity range from those requiring direct cell-cellcontact. The only possibility to overcome this problem will be a careful phenotypical and functional analysis of all potential MDSC subsets in different clinical settings and different immunological compartments. Identification of better markers will facilitate these studies. More in-depth analysis of the interaction of MDSC with other cell types will help understanding the biological function and finally, the specific targeting of human MDSCs will enhance the effect of immune-based therapies in cancer.

Results: Here we show that human Hepatic Stellate Cells have the capability to induce Myeloid derived Suppressor Cells from circulation Monocytes in a cell-cell contact dependent mechanism.

Conclusions: Further investigation of the exact mechanism will provide opportunities to prevent the induction of Myeloid Derived Suppressor Cells. This represents a potential target for immunotherapy.

P0995

Induction of sustained tolerance towards experimental ConA hepatitis depends on CD4+ T and NKT cells

B. Claass, A. Erhardt & G. Tiegs

Institute for Experimental Immunology and Hepatology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Purpose/Objective: In mice, a single i.v. injection of the T cell mitogen Concanavalin A (ConA) leads to severe acute T cell and Kupffer Cell (KC) dependent hepatitis. Following a sublethal treatment of ConA, mice develop resistance towards hepatitis after additional

ConA injections within 8 days. This resistance is characterized by regulatory T cell and KC derived IL-10 dependent immunoregulation. However, IL-10 production was less regulated during sustained tolerance observed between 14 and 42 days. Here we investigated the role for B cells, $CD4^+$ T and NKT cells, Tregs and KCs in the induction of long-lasting liver tolerance during the first ConA treatment.

Materials and methods: Liver damage was quantified by plasma transaminase activities and/or by histology 8 h after a single ConA injection or after ConA restimulation 14 days after the first ConA treatment. Tregs were depleted from DEREG (DEpletion of REGulatory T cells) mice by diphtheria toxin i.p. treatment 1 day before first ConA injection. KCs were depleted by i.v. injection of Cl_2MDP liposomes 2 days before the first ConA stimulation. A role for antibody mediated protection was investigated by ConA restimulation in Jh/Jk double knock-out mice 42 days after the first ConA treatment. To investigate if induction of liver resistance depends on $CD4^+$ T cells, $RAG1^{-/-}$ mice were reconstituted with liver $CD4^+$ T cells and treated with ConA.

Results: Liver injury was detectable 8 h after a single ConA injection but was completely absent 14 days after ConA restimulation. However, neither absence of Tregs nor absence of KCs during the first ConA treatment abrogated liver tolerance in response to ConA restimulation on day 14. Also, B cell deficiency did not abrogate liver tolerance towards ConA. ConA treatment of $Rag1^{-/-}$ mice reconstituted with $CD4^+$ T cells induced hepatic injury. ConA tolerance upon restimulation was inducible in these reconstituted mice. However, ConA pretreatment of $RAG^{-/-}$ mice 14 days prior to reconstitution failed to induce tolerance.

Conclusions: $CD4^+$ T and NKT cells seem to be involved in induction of sustained liver tolerance towards ConA observed from day 14 onwards. Involvement of Tregs and KCs during the first ConA treatment might play a minor role in the induction of long-lasting liver tolerance towards ConA.

P0997

Innate and adaptive control of immunity to *Salmonella* in the liver

J. R. Hitchcock, E. A. Ross, A. Flores-Langarica, J. Marshall, C. Cook, M. Khan, S. Bobat, R. Coughlan, G. Reynolds, D. H. Adams & A. F. Cunningham

Immunity and Infection, University of Birmingham, Birmingham, UK

Purpose/Objective: Non-typhoidal *Salmonella* e (NTS) such as *Salmonella* Typhimurium (STm) can cause invasive and often fatal disease in children and HIV-infected adults in developing countries. The liver is a major target of this infection yet how immunity is regulated in this site is incompletely understood. Whilst important for understanding how STm can kill, examining hepatic immune function also allows the study of how innate and adaptive responses co-ordinate to control infection in non-lymphoid sites.

Materials and methods: Microscopy, FACS and biochemical techniques were used to assess the impact of systemic STm infection on the murine liver in a resolving model of NTS infection.

Results: There was a profound and rapid impact of infection on the liver. Inflammatory lesions formed from day 2 of infection, peaked as T cells effected STm clearance and had resolved when bacteria had been cleared. Despite the striking inflammatory response and substantial necrosis, liver function was largely normal. Lesions mostly contained multiple myeloid $CD11c^+$ and $F4/80^+$ subsets, with small numbers of CD4 and CD8 T cells, but not B cells. Before infection, Kupffer cells were the dominant monocyte population but this changed rapidly after infection. T cells orchestrated foci development. In particular, T-bet in T cells was required for optimal T cell migration and T cell IFNγ, but not TNFα, expression. In addition, loss of T-bet increased numbers of hepatic $FoxP3^+$ T cells but did not alter the early inflammatory response. In contrast, infected IFNγ KO livers resembled those of non-infected mice despite having substantial bacterial burdens.

Conclusions: This work details the complex phenotype and organization of hepatic lesions after STm infection and the discrete roles of IFNγ in this response. Moreover, it identifies a central role for T-bet in balancing T cell phenotype in the liver post-infection. Exploiting these findings will help identify how best to promote bacterial clearance whilst minimizing the collateral cost of immune responses to the host.

P0998

LLT1 engages CD161 at the immunological synapse between T cells and hepatocytes

M. Purbhoo, N. Kumar & S. Ashraf

Imperial College London, Section of Hepatology, London, UK

Purpose/Objective: CD161+ CD8+ T cells are liver resident and associated with chronic hepatitis C virus infection. However, little is known about how CD161+ T cells engage target cells at a molecular level. CD161 is a co-stimulatory molecule that engages Lectin Like Transcript 1 (LLT1) on target cells and potentiates IFNγ production by T cells. It may thus be important in generating an effective anti-viral immune response. We have investigated the expression of LLT1 by hepatocytes, and the partitioning of CD161 and LLT1 at the immunological synapse between T cells and hepatocytes.

Materials and methods: LLT1 expression was investigated by flow cytometry and semi-quantitative RT-PCR in (1) Huh7 cells, (2) Huh7 cells containing the JFH-1 subgenomic replicon, and (3) Huh7/replicon cells cured with IFNα. CD161 and LLT-1 were fluorescently tagged and expressed in immortalized T cells (Jurkat) or Huh7 cells, and their distribution at the T cell/hepatocyte immune synapse determined by confocal microscopy.

Results: Huh7 cells constitutively expressed low levels of LLT1. The JFH-1 subgenomic replicon cells upregulated LLT1 at both surface protein and mRNA levels. Huh7 cells stimulated with TLR3 and TLR 7/8 agonists known to upregulate LLT1 on hematopoietic cells, did not show increased levels of LLT1. CD161 and LLT1 colocalised at T cell/hepatocyte immune synapses. These molecules formed microdomains which gradually coalesced into extended, perforated accumulations which represent a novel, atypical spatial arrangement for costimulatory molecules in T cells.

Conclusions: This study demonstrates that HCV may upregulate LLT1 on infected hepatocytes, independent of TLR-mediated recognition of virus. Hepatocytes expressing LLT1 form a stable immunological synapse with T cells expressing CD161, which forms independent of the presence of antigen. Within the synapse, CD161/LLT1 show a unique spatial distribution, and such patterning may underpin the molecular mechanism of how CD161 enhances T cell activation.

P0999

Loss of chemokine receptor CCR6 diminishes recruitment of IL-17-producing gamma/delta T cells to the liver leading to increased liver inflammation and fibrosis

L. Hammerich,* F. Heymann,* H. W. Zimmermann,* S. Huss,† S. A. Lira,‡ C. Trautwein* & F. Tacke*

**Medical Clinic III, University Hospital Aachen, Aachen, Germany, †Institute of Pathology, University Hospital Cologne, Cologne, Germany, ‡Immunology Institute, Mount Sinai School of Medicine, New York, NY, USA*

Purpose/Objective: The chemokine receptor CCR6 is known to be expressed on some T helper cells and $\gamma\delta$ T cells, monocyte derived dendritic cells and B cell subsets. It plays an important role in mucosal

immunity, but its role in liver disease is largely unknown. In this study we investigated its functional relevance in chronic liver disease and hepatic fibrosis.

Materials and methods: Wildtype (wt) and CCR6$^{-/-}$ mice were treated with the hepatotoxic agent carbon tetrachloride (CCl_4) thrice weekly over a period of 4 weeks. Liver damage, inflammation and fibrosis development were assessed by biochemical methods, histology, immunostaining, flow cytometry and qPCR. Human liver samples from patients with chronic liver disease ($n = 50$) were analysed by qPCR.

Results: CCR6 and its ligand CCL20 are strongly upregulated upon chronic liver injury in mice and in human patients with cirrhosis. CCR6$^{-/-}$ mice develop more severe hepatic fibrosis compared to wt mice when treated with CCl_4. They also show higher liver inflammation compared to wt mice, as indicated by increased overall infiltration of immune cells to the liver. We could not detect changes in infiltrating macrophages or composition of T helper cell subtypes between wt and CCR6-deficient mice, but expression of interleukin-17 (IL-17) was significantly reduced in livers of CCR6$^{-/-}$ mice. While wt mice showed an accumulation of IL-17-producing $\gamma\delta$ T cells in the liver upon CCl_4 treatment, this cell type was markedly reduced in livers of CCR6$^{-/-}$ mice. The adoptive transfer of wt $\gamma\delta$ T cells into CCR6$^{-/-}$ mice restored hepatic inflammation and fibrosis in the chronic injury model.

Conclusions: We propose a CCR6-dependent pathway for recruitment of IL-17-producing $\gamma\delta$ T cells in chronic liver injury, that protects the liver from excessive inflammation and fibrogenesis.

P1000
Metformin aggravates Con A induced liver injury

V. Volarevic,* M. Milovanovic,* B. Simovic Markovic,* M. Stojanovic,* M. Misirkic,† L. J. Vucicevic,† V. Trajkovic,† N. Arsenijevic* & M. L. Lukic*

**Center for Molecular and Stem Cell Research, Immunology, Kragujevac, Serbia, †Faculty of Medicine, Immunology, Belgrade, Serbia*

Purpose/Objective: Several cases of liver injury related to hepatotoxicity of metformin, the most commonly prescribed oral antidiabetic medication, have been reported recently but mechanism of metformin induced liver injury remains unclear. We tested metformin hepatotoxicity and its effects in Con A induced hepatitis in mice.

Materials and methods: Con A hepatitis was induced in susceptible C57BL/6 and CBA mice, relatively resistant BALB/c mice as well as in CBA iNOS$^{-/-}$ mice. Liver enzymes, histology, mononuclear cell (MNC) infiltration, cytokine production, expression of Akt, NF-kB, p38, AMPK, apoptosis of MNCs and autophagy were analyzed.

Results: Single injection (400 mg/kg dissolved in saline, i.p) metformin did not induce liver damage, but the same dose of metformin significantly enhanced Con A (12 mg/kg dissolved in saline i.v) induced liver injury in BALB/c C57Bl/6 and CBA mice as evaluated by liver enzymes and histology. We found an increased level of TNF-α, IFN-γ in the sera and an increased number of TNF-α, IFN-γ and IL-17 producing CD4+ T cells, IFN-γ producing NK and IL-4 producing NKT cells, activated CD80$^+$ CD86+ IL-12 producing F4/80+ macrophages and CD11c+ dendritic cells (DCs) and aggressive B2 cells all of which are involved in disease process. Liver specific (CD4$^+$ CXCR3+ Tbet+IL-10+ and CD4$^+$ CD69$^+$ CD25-) T regulatory cells were downregulated by metformin. Metformin significantly increased expression of both Akt and NF-kB in the liver as well as influx of activated CD4$^+$ CD27+ cells, CD4+ and CD8+ CD62L$^-$ CCR7$^-$ effector memory cells.

We also noticed significantly increase of iNOS expression both in the liver and spleen by metformin. Deletion of iNOS attenuated both Con A induced disease and the effects of metformin: there was no difference in percentage of liver specific T regulatory cells, total number of liver infiltrated effector T cells, macrophages and DCs.

Conclusions: Metformin aggravates Con A induced liver injury by enhancing activation of immune cells in Akt/NF-kB dependent and p38 and AMPK independent manner affecting influx of effector and liver specific regulatory cells and NO production. These data suggest that in the inflamed liver metformin have deleterious effects.

P1001
MHC class I transfer from stellate cells to LSEC allows for enhanced immune surveillance in the liver

K. Schölzel, F. A. Schildberg, P. A. Knolle & D. Wohlleber

Insitute of Molecular Medicine and Experimental Immunology, University of Bonn, Bonn, Germany

Purpose/Objective: The liver is known for its unique immunological properties. Besides liver parenchymal cells, the hepatocytes, also non-parenchymal cells like dendritic cells (DC), liver-resident macrophages, the Kupffer cells, and liver sinusoidal endothelial cells (LSEC) interact with passenger leukocytes and modulate immune responses. However, little is known about the contribution of stellate cells, known to be responsible for contraction of the vessel diameter and storage of vitamin A.

Here, we addressed the question, if stellate cells contribute to immune surveillance by (cross-) presenting exogenous antigen to circulating naïve or effector CD8 T cells and the consequences of such antigen presentation during viral infection of the liver.

Materials and methods: We employed a transgenic mouse model with stellate cell-specific expression of the MHC class I molecule H2-K^b under the control of the GFAP-promoter (GFAP-K^b mouse). Mice were infected with 5×10^8 pfu of Adenovirus expressing the model antigen ovalbumin (AdOVA) followed by adoptive transfer of activated OT-I T cells which recognize SIINFEKL, a H2-K^b restricted peptide of ovalbumin. Stellate cells and liver sinusoidal endothelial cells were isolated as described previously.

Results: Using this model system, we found that H2-K^b-restricted CD8 T cells were stimulated *in vivo* to proliferate and express cytokines suggesting that stellate cells could directly interact with circulating naïve CD8 T cells.

Further, we found that stellate cells play a role in generating antiviral CD8 T cell response to viral infection of the liver.

However, a detailed characterization of the GFAP-K^b mouse revealed that stellate cells transferred MHC-I molecules to other hepatic cell populations like LSEC, DCs and Kupffer cells. We excluded erratic gene expression driven by GFAP-promoter in LSEC by RT-PCR.

Rather, we directly demonstrate transfer of H2-K^b molecules from stellate cells to H2-K^b-negative LSEC. Such molecule-transfer rendered LSEC capable of stimulating H2-K^b-restricted CD8 T cells in an antigen-specific fashion.

Conclusions: Our results provide insight into new mechanisms of how local immune regulation in the liver can be achieved, i.e. by transfer of MHC-I molecules from stellate cells to LSEC. This phenomenon may contribute to the unique immune functions of the liver.

Modification of a single lysine in a CYP2E1 epitope induces immune-mediated DILI in BALB/c mice

D. Njoku,* J. Cho,† L. Kim,† L. Strouss,† E. McCarthy,† K. Gilbert,† M. Amzel‡ & N. Rose§

*Johns Hopkins University, Anesthesiology Pathology Pediatrics, Baltimore, MD, USA, †Johns Hopkins University, Anesthesiology, Baltimore, MD, USA, ‡Johns Hopkins University, Biochemistry, Baltimore, MD, USA, §Johns Hopkins University, Pathology Molecular Microbiology and Immunology, Baltimore, MD, USA

Purpose/Objective: Key steps in the pathogenesis of immune-mediated drug-induced liver injury (Im-DILI) have not been identified. After receiving halogenated anesthetics, anti-seizure medications, antibiotics or non-steroidal anti-inflammatory drugs, susceptible patients develop Im-DILI thereby increasing their morbidity and often their mortality. In anesthetic Im-DILI patients, granulocytic hepatitis, trifluoroacetyl chloride (TFA) and IL-4-mediated cytochrome P4502E1 (CYP2E1) IgG4 antibodies support the diagnosis, while CYP2E1 epitopes responsible for the pathogenesis of Im-DILI are unknown. We previously demonstrated a CYP2E1 epitope [Gly^{113}-Leu^{133} (JHDN5)] containing a single lysine that was recognized by sera from anesthetic DILI patients with specific MHC II haplotypes. We showed that JHDN5 was recognized by splenocytes from mice with experimental Im-DILI induced by immunizations with liver proteins covalently altered by TFA, a drug hapten formed during metabolism of halogenated anesthetics. We hypothesize that covalent modification of a single lysine in JHDN5 induces IL-4-mediated, Im-DILI in BALB/c mice.
Materials and methods: JDN5 was modified by TFA (TFA-JHDN5) using the methods of Goldberger and Anfinisen. We confirmed 81.5% modification of JHDN5 using the method of Habeeb. BALB/c mice were immunized with 100 μg of an unrelated CYP2E1 epitope or JHDN5 ± TFA emulsified in CFA or CFA alone on days 0 and 7 and killed on day 21. IL-4 deficient (KO) mice were similarly treated with CFA ± TFA-JHDN5. Histology scores, antibodies and cytokine levels were analyzed using Mann−Whitney *U*-test. A P value <0.05 was significant.
Results: TFA-JHDN5 induced more granulocytic hepatitis ($P < 0.01$) as well as anti-TFA and anti-CYP2E1 antibodies ($P < 0.05$) than CFA-immunized BALB/c or KO mice. Granulocyte and macrophage attractants KC, MIP-2, G-CSF, M-CSF, MCP-1, MIP-1a, MIP-1b and VEGF as well as IL-7 and IL-9 were elevated in BALB/c but not KO livers ($P < 0.05$). Unmodified epitopes did not induce Im-DILI.
Conclusions: We confirm that covalent modification of a single lysine in a CYP2E1 epitope induces Im-DILI in BALB/c mice with features reminiscent of anesthetic Im-DILI in patients. Future studies of this epitope may uncover unidentified mechanisms of Im-DILI from other drugs and help to develop targeted agents to either treat or prevent this disease.

P1004

Overexpression of SMAD7 protects liver from TGFb/Smad-mediated fibrogenesis

N. Argentou,* G. Germanidis,† E. Apostolou,‡ T. Vasiliadis,§ P. Sideras,‡ A. E. Germenis* & M. Speletas*

*Medical School, University of Thessaly, Larissa, Greece, †AHEPA Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece, ‡Biomedical Research Foundation, Academy of Athens, Athens, Greece, §Hippokration Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece

Purpose/Objective: SMAD7 is a negative regulator of TGFb/activin pathway. Recently, animal studies have shown that SMAD7 induction ameliorates TGFb/Smad-mediated fibrogenesis, suggesting a protective mechanism against liver injury. This study was scheduled to examine the role of SMAD7 in liver inflammation, fibrosis and the possible effect of antiviral treatment.
Materials and methods: Liver biopsies from 67 patients with hepatic diseases were studied: (1) 18 with chronic HCV hepatitis (CHC); (2) 19 with chronic HBV hepatitis at diagnosis (CHB/d); (3) four with CHB after antiviral treatment and relapse (CHB/non-r) (4) 14 with CHB after antiviral treatment response and remission for >5 years (CHB/r); (5) 12 with non alcoholic fatty liver disease (NAFLD). Three liver samples with a mild increase of aminotransferases but without histological changes, served as controls. Histological activity index and staging of fibrosis were also assessed. RNA was extracted and cDNA was synthesized using standard protocols. mRNA expression of TGFb isoforms (*TGFB1, 2, 3*), activins (*A, B, C, E*), *ALK4*, *ALK5*, SMAD molecules (*SMAD2, 3, 4, 7*), and *CTGF*was examined using quantitative real time PCR. Statistical analysis was performed using SPSS and P values < 0.05 were considered significant.
Results: Patients with CHB/r exhibited a significant increase of *SMAD7* and *ALK4* mRNA expression compared to CHB/d patients, and reduced levels of *TGFB1, SMAD2, SMAD3*, and *CTGF*. A significant increase of *SMAD7* was also found in NAFLD patients compared to untreated viral hepatitis patients and those who did not respond to any treatment. Moreover, NAFLD patients were presented with elevated levels of *TGFB1, TGFB3, INHβC, ALK5*, and *SMAD4.* Considering the intensity of inflammation, *SMAD7, ALK5*, and *INHβC* exhibited a significant increased expression from absent to minimal inflammation with a gradual reduction as inflammation exacerbates.
Conclusions: Our data indicate that in cases with low grade fibrosis, as NAFLD (characterized by a lower incidence of severe liver complications and fibrosis progression) and CHB/r, *SMAD7* overexpression might be a mechanism limiting the fibrogenic effect of TGFb suggesting that its induction may provide a target for novel therapeutic approaches.

This research has been co-financed by the ESF and Greek national funds through the Operational Program ''Education and Lifelong Learning'' of the NSRF − Research Funding Program: Heracleitus II. Investing in knowledge society through the European Social Fund.

Peritoneal macrophage inflammatory profile in cirrhosis is dependent on the etiology and is related to ERK phosphorylation level

M. Martínez-Esparza,* A. Tapia-Abellán,* A. J. Ruiz-Alcaraz,* T. Hernández-Caselles,* C. Martínez-Pascual,† M. Miras-López,† J. Such,‡ R. Francés‡ & P. García-Peñarrubia‡

*Biochemistry and Molecular Biology (B) and Immunology, University of Murcia, Murcia, Spain, †Hospital Universitario Virgen de la Arrixaca, Unidad de Trasplante Hepático, Murcia, Spain, ‡Hospital Universitario, Unidad Hepática, Alicante, Spain

Purpose/Objective: The aim of this work is to identify functional differences in the inflammatory profile of monocyte-derived macrophages (M-DM) from ascites in cirrhotic patients of different etiologies, alcohol- and hepatitis C virus (HCV)-related cirrhosis, trying to extrapolate studies from liver biopsies to immune cells in ascites.
Materials and methods: We studied 45 patients with cirrhosis and non-infected ascites, distributed according to disease etiology, HCV ($n = 15$) or alcohol ($n = 30$). Cytokines and cellular content in ascites were assessed by ELISA and flow cytometry, respectively. Cytokines and ERK phosphorylation level from peritoneal monocyte-derived macrophages isolated and stimulated *in vitro* were also determined.
Results: A different pattern of leukocyte migration to peritoneal cavity and primed status of macrophages in cirrhosis is observed depending on the viral or alcoholic etiology. Whereas no differences in peripheral

blood cell subpopulations could be achieved, T lymphocyte, monocyte and polymorphonuclear cell populations in ascites were more abundant in HCV versus alcohol etiology. Cirrhosis of HCV etiology is associated to a decreased inflammatory profile in ascites compared with alcoholic etiology. Higher levels of IL-10 and lower levels of IL-6 and IL-12 were present in ascitic fluid from HCV group. Isolated peritoneal monocyte-derived macrophages kept their primed status *in vitro* for the extent of 24 h culture. Increased phosphorylation of ERK1/2 was observed in ALC peritoneal macrophages at baseline compared with those from HCV patients, although addition of LPS induced higher phosphorylation increases of ERK1/2 in macrophages from HCV than from ALC patients.
Conclusions;An increased macrophage inflammatory status is present in ascites of alcohol-related cirrhotic patients compared with that of HCV-related. This fact could be related to differences in bacterial translocation episodies or regulatory T cell populations. These findings would contribute to identify potential prognostic and/or therapeutic targets for chronic liver diseases of different etiology.

P1006
Positive M2-ELISAs with negative anti-mitochondrial antibodies (AMA) on IFT: a diagnostic dilemma?

C. Weiler-Normann,* A. W. Lohse* & F. Haag†
*1st Medical Clinic, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, †Institute of Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Purpose/Objective: Immune fluorescence testing (IFT) combined with ELISA techniques to determine the specificity of autoantibodies have refined and facilitated the diagnosis of primary biliary cirrhosis (PBC) over the past years. Positive AMA with specificity for the M2 antigen have become an established diagnostic criterion. However, in our liver clinic we encountered a substantial number of patients with negative AMA who nevertheless showed positive ELISA results for M2 antibodies. The aim of the present study was to evaluate the significance of positive M2-ELISA- results with discordant negative IFT Results.
Materials and methods: Patient sera were screened using Hep2-cells (Inova), rat kidney, liver, and stomach sections (Menarini) and the M2 EP (MIT3)-ELISA (Inova). All sera screened for M2 antibodies in 2011 were included.
Results: Of 278 patients tested for M2 antibodies in 2011, 112 (40.3%) were positive. Surprisingly, 26 of these (23.2%) were judged negative for AMA on tissue sections. In nine of these cases (34.6%) PBC was diagnosed on the basis of clinical/histological criteria. In AMA/M2-discordant patients, ELISA Titers were significantly higher in patients suffering from PBC according to the guidelines (69.68 ± 41.22 units) than in ānon-PBC' patients (31.85 ± 8.332 units; $P = 0.0011$). Nine AMA/M2-discordant patients showed untypical cytoplasmic staining patterns in Hep2 cells, of whom 4 (44.4%) were diagnosed as having PBC. Of the 17 patients without cytoplasmic staining, 5 (29.4%) were diagnosed with PBC.
Conclusions: Some patients with PBC can present with negative testing for AMA, but react positive in the M2-ELISA. Conversely, patients with conditions other than PBC can exhibit positive M2-ELISAs. Most of these latter patients have elevated immunoglobulins on analysis, and M2-ELISA-levels in these patients are usually low. In conclusion, if clinical suspicion of PBC exists, M2 testing should be performed even in the absence of positive AMA.

P1008
Recruitment mechanisms for primary and malignant B cells to the human liver

S. Shetty,* T. Bruns,* C. J. Weston,* Z. Stamataki,* G. M. Reynolds,* H. M. Long,† S. Jalkanen,‡ S. G. Hubscher,† P. F. Lalor* & D. H. Adams*
*Centre for Liver Research, University of Birmingham, Birmingham, UK, †School of Cancer Studies, University of Birmingham, Birmingham, UK, ‡Department of Microbiology and Inflammation, University of Turku, Turku, Finland

Purpose/Objective: B cells are present within chronically inflamed liver tissue and recent evidence implicates them in the progression of liver disease. In addition a large proportion of hepatic lymphomas are of B cell origin. The molecular signals that regulate normal and malignant B cell recruitment into peripheral tissue from blood are poorly understood leading us to study human B cell migration through hepatic sinusoidal endothelial cells (HSEC) in flow-based adhesion assays.
Materials and methods: We used isolated human HSEC in flow assays with purified peripheral blood B cells to elucidate the molecular mechanisms of B cell recruitment via HSEC. The contribution of conventional adhesion molecules, ICAM-1 and VCAM-1 and unconventional molecules VAP-1 and CLEVER-1/stabilin-1 was assessed by using function blocking antibodies. We repeated our experiments with two B cell lymphoma cell lines, CRL-2261 and Karpas 422, and primary malignant B cells. We assessed the contribution of chemokines by performing transwell assays and adding chemokines to our flow assays. We also tracked the motility of B cells and lymphoma cell lines on HSEC using tracking software.
Results: In flow assays B cells were captured from shear flow without a prior rolling phase and underwent firm adhesion mediated by VCAM-1. Unlike T cells, which displayed vigorous crawling behaviour on the endothelium, B cells remained static before a proportion underwent transendothelial migration mediated by a combination of ICAM-1, VAP-1, CLEVER-1/stabilin-1 and the chemokine receptor CXCR3 and CXCR4. B cell lymphoma cell lines and primary malignant B cells from patients with chronic lymphocytic leukaemia and marginal zone B cell lymphoma also underwent integrin-mediated firm adhesion involving ICAM-1 and/or VCAM-1 and demonstrated ICAM-1 dependent shape-change and crawling behaviour. Unlike primary lymphocytes the malignant cells did not undergo transendothelial migration which could explain why lymphomas are frequently characterised by intravascular accumulation of malignant cells in the hepatic sinusoids.
Conclusions: Our findings demonstrate that distinct combinations of signals promote B cell recruitment to the liver suggesting the possibility of novel targets to modulate liver inflammation in disease. Certain features of lymphocyte homing are maintained in lymphoma recruitment to the liver suggesting that therapeutic targets for lymphocyte recruitment may also prevent hepatic lymphoma dissemination.

P1009
Relationship between synthesis of alpha2-macroglobulin and changes in serum cytokine in rats

T. Kuribayashi,* T. Seita,* E. Momotani† & S. Yamamoto*
*Azabu University, Immunology, Sagamihara, Japan, †National Institute of Animal Health, Research Team for Paratuberculosis, Tsukuba, Japan

Purpose/Objective: The α_2-macroglobulin (α2M) is a typical acute phase protein in rats. We have investigated the kinetics of α2M after inflammatory stimulation. Furthermore, we estimated that interleukin (IL)-6 and cytokine-induced neutrophil chemoattractant-1 (CINC-1) were contributed the synthesis of α2M. However, little is available on the time-dependent changes on synthesis of α2M in hepatocytes. In

this study, synthesis of α2M in hepatocytes was estimated by immunohistochemistry and correlations between synthesis of α2M and cytokines (IL-6, CINC-1) were investigated.
Materials and methods: Sprague-Dawley rats (age, 9 weeks) were used. Turpentine oil was intramuscularly injected at 0.4 ml/rat to induce acute inflammation. Three rats at each time point were scarified under anesthesia with pentobarbital before treatment and at 6, 12, 18, 24, 36, 48 or 72 h after injection of turpentine oil. Blood was collected from the aorta and the liver was removed. The presence of α2M in the liver was investigated by immunohistochemistry, and serum levels of α2M, IL-6 and CINC-1 were measured by ELISA.
Results: α2M was not detected in the liver before injection of turpentine oil. α2M was detected in whole lobules of liver after 12 h after injection of turpentine oil, when high serum levels of IL-6 or CINC-1 were observed. α2M was distributed around the central vein at 36 h. However, small amounts of α2M were detected in the liver at 48 h, when peak serum levels of α2M were observed. α2M was apparently synthesized in response to stimulation by IL-6 and CINC-1, and synthesis of α2M in hepatocytes peaked long before peak α2M serum levels were seen.
Conclusions: In conclusion, synthesis of α2M appears to be correlated closely with serum levels of IL-6 and CINC-1.

P1010

Role of mitogen activated protein kinases and PI3K-Akt on the cytokine inflammatory profile of peritoneal macrophages from ascites of cirrhotic patients

A. Tapia-Abellán,* A. J. Ruiz-Alcaraz,* T. Hernández-Caselles,* R. Francés,† P. Garía-Peñarrubia* & M. Martínez-Esparza*
**Biochemistry and Molecular Biology (B) and Immunology, University of Murcia, Murcia, Spain, †Hepatic Unit, Hospital General Universitario, Alicante, Spain*

Purpose/Objective: To compare the role played by several Mitogen Activated Protein Kinases (MAPKs) and PI3K-Akt pathways on the release of cytokines in monocyte-derived macrophages (M-DM) obtained from the ascites of cirrhotic patients to identify novel targets for pharmaceutical intervention to prevent hepatic damage.
Materials and methods: M-DM were isolated from ascites of cirrhotic patients and stimulated *in vitro* with LPS and heat killed *Candida albicans* in the presence or absence of the inhibitors for MEK1, p38 MAPK, JNK and PI3K. Ascites and cell culture supernatants were assayed by ELISA for TNF-a, IL-6 and IL-10. MAPK phosphorylation levels were determined by Western blot.
Results: We found that release of the pro-inflammatory cytokines, IL-6 and TNF-alpha at baseline was more effectively reduced by the MAPK inhibitors, while basal IL-10 anti-inflammatory cytokine secretion, was only, but strongly (91.6%) affected by inhibition of PI3K. The incubation of peritoneal M-DMs in the presence of LPS and heat killed *C. albicans* increased the release of IL-6, TNF-alpha and IL-10. LPS-induced pro-inflammatory secretion was more sensitive to MAK inhibitors, while that induced by *C. albicans* was more susceptible to inhibition of PI3K. Finally, inhibition of PI3K almost completely suppressed secretion of IL-10 in stimulated M-DM.
Conclusions: These results demonstrate pro-inflammatory cytokines release depends on MAPK signalling pathways and differ depending of microbial stimulus in this clinical setting, and confirm the prominent role of PI3K-Akt pathway in the modulation of IL-10 mediated anti-inflammatory function.

P1011

Salmonella infection promotes cross reaction of gut activated t cells to liver antigen leading to immune-mediated cholangitis in mice

D. Seidel,* I. Eickmeier,* A. Kühl,† B. Wiedenmann* & E. Schott*
**Medizinische Klinik m. S. Hepatologie und Gastroenterologie, Charité – Universitätsmedizin Berlin, Berlin, Germany, †Medizinische Klinik m. S. Rheumatologie und Klinische Immunologie, Charité – Universitätsmedizin Berlin, Berlin, Germany*

Purpose/Objective: A dysregulated immune response against components of the gut flora may be involved in the pathogenesis of inflammatory bowel diseases (IBD). Infections with pathogens could further trigger cross reactions against extraintestinal autoantigens in genetically susceptible individuals. Primary sclerosing cholangitis (PSC) is strongly associated with IBD. T cells infiltrating the livers of patients with PSC display an $\alpha 4\beta 7^+$ $CCR9^+$ phenotype, indicating their provenance from the gut-associated lymphatic tissues (GALT). This finding led to the hypothesis that activation of the adaptive immune system in the GALT could initiate an aberrant reaction against antigens in the liver.
Materials and methods: Naive antigen-specific CD8 OT-I T cells were transferred *i.v.* into transgenic mice, which express their nominal antigen ovalbumin (OVA) in enterocytes of the small intestine (iFABP-tOVA) or in the bile duct epithelia (ASBT-OVA), or into double transgenic mice (iFABPxASBT-OVA). To evaluate whether *Salmonella* promotes immune-mediated liver disease, mice were infected orally with *S. typhimurium* SL7207 (Sm) or *S. typhimurium* SL7207 expressing the MHC-I epitope $OVA_{257-264}$ (SmOVA). The effector function of OT-I T cells was evaluated by measuring IFN-g production and by an *in vivo* cytotoxicity assay. Inflammation in the liver was assessed by measuring plasma ALT and by histologic analysis.
Results: Adoptively transferred OT-I T cells acquired effector function characterized by production of IFN-γ and *in vivo* cytotoxicity in iFABP-tOVA as well as in double transgenic iFABPxASBT-OVA mice, while only a minority of OT-I T cells became activated in ASBT-OVA mice. Activated OT-I T cells migrated into the liver, but caused cholangitis only in the presence of OVA in the biliary epithelia. ALT-levels were elevated in the plasma of double transgenic iFABPxASBT-OVA mice, but not in the single transgenic lines. Infection with Sm or SmOVA enhanced the activation of OT-I T cells in the GALT and exacerbated cholangitis in iFABPxASBT-OVA mice.
Conclusions: The activation of T cells in the gut led to cross reactivity in the liver when the same antigen was expressed in both compartments. The severity of cholangitis was increased by oral *Salmonella* infection. Our findings suggest that cross reactivity of gut-derived T cells to endogenous antigens may be involved in the pathogenesis of PSC.

P1012

SepSecS-induced TH17-associated autoimmune hepatitis in mice

J. Rauch, F. Schulte, M. Sebode, A. Carambia, A. W. Lohse, C. Weiler-Normann & J. Herkel
Departmend of Medicine I, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Purpose/Objective: Autoimmune Hepatitis (AIH) is a chronic inflammatory liver disease of unknown pathogenesis; its characteristics include intrahepatic periportal lymphocytic infiltrates and circulating autoantibodies. Autoimmunity to the SepSecS molecule may be of pathogenetic relevance, since SLA/LP autoantibodies that recognize the SepSecS molecule are highly specific for AIH. Here we explored the role of SepSecS immunity in AIH.
Materials and methods: Mice were immunised with recombinant murine SepSecS protein in complete Freund's adjuvant (CFA).

Primary immune responses were analysed by *in vitro* re-stimulation of draining lymph node cells. Liver inflammation and cytokine response of liver infiltrating lymphocytes were determined.

Results: SepSecS-immunised C57BL/6 mice and IL-$10^{-/-}$ mice on C57BL/6 background developed SLA/LP autoantibodies. However, SepSecS-immunised C57BL/6 mice did not develop liver inflammation; in contrast, IL-$10^{-/-}$ mice manifested histological liver inflammation with periportal lymphocytic infiltrates, reminiscent of human AIH. In response to saline/CFA, IL-$10^{-/-}$ mice showed mild parenchymal liver inflammation of a granulomatous type, but not the characteristic periportal inflammation seen in response to SepSecS/CFA. Lymphocytes from SepSecS-immunised IL-$10^{-/-}$ mice, but not from C57BL/6 mice could transfer histological hepatitis both to C57BL/6 or IL-$10^{-/-}$ mice. In response to CD3 antibody stimulation *in vitro*, lymph node cells of IL$10^{-/-}$ mice secreted more IL-17 than those of C57BL/6 mice (1230 versus 460 pg/ml), indicating a general tendency of IL$10^{-/-}$ mice for T_H17 differentiation. In response to SepSecS re-stimulation, lymph node cells of IL-$10^{-/-}$ mice secreted considerably more IL-6 (480 versus 65 pg/ml) and IL-17 (550 versus 15 pg/ml) than lymph node cells of C57BL/6 mice. Accordingly, liver-infiltrating lymphocytes, notably CD4 T cells, isolated from SepSecS/CFA immunised IL-$10^{-/-}$ mice secreted significantly higher amounts of IL-17 (524 versus 72 pg/ml) and IFNγ (7590 versus 1234 pg/ml) in response to SepSecS re-stimulation, than IL-$10^{-/-}$ mice immunised with saline/CFA.

Conclusions: Immunity to SepSecS can cause hepatitis in susceptible IL-$10^{-/-}$ mice. Periportal liver inflammation was associated with a T_H17 response of SepSecS-primed lymphocytes.

P1013

Serum HLA-G is associated with liver damage rather than with liver graft acceptance

J. Kwekkeboom,* V. Moroso,* B. van Cranenbroek,† F. Fai-A-Fat,* L. J. W. van der Laan,‡ H. J. M. Metselaar* & I. Joosten†

**Gastroenterology and Hepatology, Erasmus MC – University Medical Centre, Rotterdam, Netherlands, †Laboratory Medicine, Radboud University Medical Centre, Nijmegen, Netherlands, ‡Surgery, Erasmus MC – University Medical Centre, Rotterdam, Netherlands*

Purpose/Objective: HLA-G is a non-classical HLA class I molecule which expression in healthy individuals is restricted to invading trophoblasts in placenta, which is thought to contribute to protection of the fetus from immunological attack by the mother. On basis of cross-sectional studies it has been suggested that increased serum HLA-G levels after liver transplantation (LTX) are associated with graft acceptance. The aim of this study was to determine whether longitudinal variations in serum HLA-G concentrations after LTx are associated with signs of graft acceptance.

Materials and methods: Serum HLA-G levels were quantified by ELISA in a cohort of 32 patients with end-stage liver diseases, both before transplantation and at several time points during the first year after transplantation, and for comparison in 24 age- and gender-matched healthy subjects. In addition, HLA-G was quantified in T-tube bile collected during the first few weeks after LTx.

Results: Pre-LTX serum HLA-G levels in the patients were significantly higher compared to those in healthy individuals, suggesting that soluble HLA-G is released from diseased livers. Pre- and post-LTx serum HLA-G levels were positively correlated with serum transaminases and bilirubin, indicating release during liver damage. Patients with an early acute rejection episode displayed significantly elevated serum HLA-G concentrations compared to non-rejectors during the first 2 weeks after LTx. Starting at 1 month after LTX, serum HLA-G levels gradually decreased. Interestingly, bile secreted by the liver graft during the first few weeks after LTx contained HLA-G, suggesting that HLA-G is produced in the liver graft early after LTx.

Conclusions: Our data do not support the hypothesis of a tolerogenic role for HLA-G after LTX, but rather suggest that serum HLA-G levels are associated with liver (graft) damage.

P1014

Synergistic effect of HLA-class II DRB1*1301 and activating full length KIR2DS4 in the susceptibility to type I autoimmune hepatitis

L. Fainboim,* N. Paladino,* A. Podhorzer,* G. Theiler,* S. Paz,† H. A. Fainboim† & M. Cuartirolo‡

**Inmunogenética, INIGEM, Ciudad Autónoma de Buenos Aire, Argentina, †Hepatología, Hospital F. J. Muniz, Ciudad Autónoma de Buenos Aire, Argentina, ‡Hepatología, Hospital Nacional de Pediatría J. P. Garrahan, Ciudad Autónoma de Buenos Aire, Argentina*

Purpose/Objective: A previous study from our center revealed a difference in the genetic predisposition to type I autoimmune hepatitis (AH) between children (PAH) and adults (AAH). The haplotype HLA-DRB1*1301-DQB1*603 is strongly associated with PAH in most pediatric populations studied worldwide. Because some activating KIR genes were associated with autoimmune diseases, in the present study we investigated the possibility of a combined effect of these two highly polymorphic systems.

Materials and methods: The study included 233 healthy controls, 81 type I PAH and 44 AAH patients. Genomic DNA was used to identify the presence or absence of each 16 KIR genes, by two PCR amplifications: PCR-1 for domains D1and D2 combined and the PCR-2 for the TM/cytoplasmic region. Nineteen 5«-digoxigenin-labeled probes were used in a sequence-specific oligo-nucleotide probing (SSOP) approach. The KIR2DS4 gene was amplified by PCR with primers to analize the full-length and the deleted version of KIR2DS4. HLA class I and class II alleles were typed by PCR amplification and hybridization with SSOP for the analysis of exon 2 and 3 (class I), or exon 2 polymorphisms (class II).

Results: The frequency of all 16 tested KIR genes were similar when we compared controls with AAH or PAH patients. In Argentinian Caucasoid healthy population, the frequency of KIR2DS4-alleles containing the 22 bp deletion in exon 5 account for 81% versus a frequency of the full-length gene of 39%. In contrast, in PAH patients the full-length 2DS4*001 allotype was present in 68% ($P < 0.0001$) and in 53% of AAH. We followed the method of Svejgaard and Ryder to find out whether class II allele or KIR full-length allele represent the primary association. The combined presence of both factors provided an OR value of 40.3, higher than the product of the RR of the two independent factors. The presence of the truncated form of KIR2DS4, showed a protector effect with an OR of 0.22. In AAH, only the combined presence of HLA-DRB1*1301 and functional KIR2DS4 showed an increased susceptibility (O $r = 5.8$) not observed by these two factors independently.

Conclusions: These results represent the first evidence of a synergistic effect between a class II allele and an activator KIR gene in the susceptibility to develop autoimmune hepatitis.

P1015

The ABCs of viral hepatitis – defining biomarker signatures for acute viral hepatitis

D. Duffy,* R. Saleh,† M. Laird,* L. Le Fouler,‡ M. El-Daly,§ A. Casrouge,* M. Abdel Hamid,§ M. Mohamed,§ M. Rafik,† A. Fontanet‡ & M. Albert*

*Institut Pasteur, ICD, Paris, France, †Faculty of Medicine, Aim Shams University, Cairo, Egypt, ‡Emerging Disease Epidemiology, Institut Pasteur, Paris, France, §Liver Disease Research Unit, National Hepatology & Tropical Medicine Research Institute, Cairo, Egypt

Purpose/Objective: Viral hepatitis is the leading cause of liver disease worldwide and can be caused by several agents, including: Hepatitis A, B and C. The host response to liver infection has been an area of intense study. We exploited recent advances in the assessment of biomarker signatures in order to define unique and common responses during three acute infections, all sharing the same tissue tropism. Patients were recruited as part of a hospital based surveillance program in two 'fever hospitals' specialized in infectious diseases in Cairo, Egypt.

Materials and methods: We performed multi-analyte profiling (MAP) measuring the concentrations of 182 molecules in the serum of acute Hepatitis A, Hepatitis B, and Hepatitis C infected individuals, as well as healthy controls. Patients with negative anti-HCV Ab and positive HCV-RNA were considered as acute hepatitis C cases. Acute Hepatitis B was defined by a positive IgM anti-hepatitis B virus core and circulating levels of hepatitis B surface antigen. Acute Hepatitis A was defined as positive anti-HAV IgM Ab.

Results: Statistical analysis revealed an analyte signature based upon eight proteins, which applied to Principle Component Analysis distinguished HCV patients from HAV/HBV-infected individuals and healthy controls. Notably, the signatures of HAV and HBV host response were indistinguishable in a hierarchical cluster analysis of all samples; suggesting that these RNA and DNA viruses share a similar mode of pathology in contrast with Hepatitis C. However when HAV and HBV patients were directly compared, six differentially expressed serum proteins were identified. Within the Hepatitis C cohort we could separate cleared and non-cleared patients based on just five molecules. One of these was IP-10, which we and others have previously highlighted as a predictive biomarker of Hepatitis C clearance, thus validating the approach used here.

Conclusions: This medium throughput discovery approach has revealed previously unrecognized virus host interactions. The identification of hepatitis virus specific biomarkers will lead to novel functional insights of disease mechanisms.

P1016

The lymphotoxin-ß receptor and its role in hepatocyte-mediated liver regeneration

K. Behnke, U. R. Sorg & K. Pfeffer

Institute for Medical Microbiology & Hospital Hygiene, Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany

Purpose/Objective: The liver retains a capacity for regeneration in response to injury. Loss of at least 30% of liver mass leads to synchronized proliferation of mature hepatocytes (compensatory hyperplasia). It has previously been shown that mice deficient in LTβR (LTβR$^{-/-}$) exhibit reduced survival after partial (70%) hepatectomy (PHx). Therefore, liver regeneration was analyzed in LTβR$^{-/-}$ mice compared to wild-type (WT) mice.

Materials and methods: 70% PHx was performed in WT and LTβR$^{-/-}$ (KO) mice. Using microarray (MA) analysis, the gene expression profile of liver tissue was analyzed 12 h post PHx and, where appropriate, verified by realtime RT-PCR. H/E-staining of liver sections and cytokine ELISAs were performed 0, 12, 24, and 48 h post PHx. Serum protein levels (GPT, GOT, Bilirubin, pancreatic amylase, alkaline phosphatase, glucose) were analyzed 0, 12, 24, and 48 h post PHx. At similar time points H/E-staining of liver sections and cytokine ELISAs were performed.

Results: It was confirmed that LTβR-deficient mice have a decreased survival rate compared to WT mice (62% versus 90%, respectively). Interestingly, surviving LTβR$^{-/-}$ animals show no delay in liver regeneration compared to WT animals. MA analysis identified a panel of differentially expressed genes; most prominent among these was a markedly decreased expression (in LTβR$^{-/-}$ mice) of murinoglobulin-2, a proteinase inhibitor of the α2-macroglobulin family. Also, TNF expression was increased twofold in the LTβR$^{-/-}$ cohort (confirmed by ELISA). Levels of the liver transaminases GPT and GOT were similar in both cohorts, while levels of pancreatic amylase were significantly decreased in LTβR$^{-/-}$ animals 24 h post PHx. In contrast, alkaline phosphatase was significantly increased in KO animals 24 and 48 h post PHx, and surprisingly, still elevated 10 days after PHx. Liver sections of LTβR$^{-/-}$ animals showed a higher number of hemorrhagic/necrotic areas and more vacuolisation of hepatocytes 24 and 48 h post PHx.

Conclusions: After PHx, LTβR$^{-/-}$ mice show a massive change in their gene expression profile compared to WT animals. In addition, their cytokine expression profile is altered and several serum proteins appear to be deregulated. This clearly demonstrates the importance of LTβR signaling in liver regeneration and its exact role in will be elucidated in further studies.

P1017

The role of Foxp3+ regulatory T cells in the development of an adaptive immune response in a persistent HBV mouse model

Y. A. Gäbel,* L. R. Huang,* N. Garbi,* U. Protzer† & P. A. Knolle*

*Molecular Medicine, Institutes of Molecular Medicine and Experimental Immunology, Bonn, Germany, †Virology, Institute of Virology Technische Universität München/Helmholtz Zentrum München, Munich, Germany

Purpose/Objective: Worldwide around 2 billion people are infected with the Hepatitis B Virus (HBV), from whom approximately 350 million people are chronically infected. They are at high risk of developing liver cirrhosis and hepatocellular carcinoma (HCC). To facilitate the development of therapeutic strategies against chronic Hepatitis B infection, it is mandatory to have a better understanding of the detailed mechanism responsible for the induction of HBV persistence.

The forkhead box P3 transcription factor (Foxp3) has been shown to influence several adaptive immune responses, for example in the context of LCMV, where protective roles for regulatory T cells (Treg) have been uncovered (Rowe *et al.*, Immunology 2012). Here we analyze the role of Foxp3$^+$ Treg on the induction of HBV-specific CTL responses upon HBV infection in a novel mouse model.

Materials and methods: As *in vivo* studies of HBV are hampered by the lack of a suitable animal model, we here take advantage of our recently developed mouse model for the induction of HBV persistence in mice (Huang *et al.*, Gastroenterology 2012).

These mice were infected with a low-dose (1×10^8 i.u./mouse) adenoviral vector carrying a 1.3-fold overlength human HBV genome (AdHBV) to cross the species barrier.

To deplete Foxp3$^+$ Treg, we used Foxp3.LuciDTR-4, which display 95% Treg depletion following injection of diphtheria toxin (DT) (Suffner *et al.*, J. Immunology 2009).

Results: In AdHBV infected Foxp3.LuciDTR-4 mice we observed a dramatic decline of the serum HBsAg but not HBeAg level, which dropped below detection limit at d10, whereas the control groups remained positive for HBsAg. Additionally, the serum ALT level of those mice peaked at day 7 by fourfold. Further, we analyzed the HBV-specific CTL response among total CD8$^+$ T cells. We found that after

depleting Foxp3$^+$ cells there is an increase in HBs$_{190-97}$ -specific, but not HBc$_{93-100}$ -specific CD8$^+$ CTLs in the liver and spleen.
Conclusions: During persistent HBV infection, Foxp3$^+$ Treg plays a role in the suppression of HBV-specific CTL response, especially for the development of an HBs-specific adaptive immunity. Further analysis for revealing the detailed mechanism of tolerance induction towards HBV has to be investigated.

P1018

The secretion of cytokines has a greater influence on the severity of acute hepatitis than the survival of infiltrating CD8 T cells

M. Vo,* L. E. Holz,* V. Benseler,* S. S. Tay,* C. McGuffog,* A. Andreas,* D. Hilton,† G. McCaughan,‡ D. G. Bowen* & P. Bertolino*
**Liver Immunology, Centenary Institute, Sydney, Australia, †WEHI, Molecular Medicine, Melbourne, Australia, ‡Liver Immuobiology, Centenary Institute, Sydney, Australia*

Purpose/Objective: Acute hepatitis is often mediated by CD8 T cells that kill target cells or secrete hepatotoxic cytokines. Although it is known how cytotoxic T cells mediate liver damage, the parameters that regulate acute hepatitis are not well understood. To determine whether some intrinsic T cell parameters might play a role in this regulation, we used the well-characterized Met-K^{b}Tg mouse model of autoimmune mediated hepatitis (AIH).
Materials and methods: Acute liver injury in Met-K^b mice is induced by the adoptive transfer of TCR Tg CD8 T cells activated in lymph nodes and recognizing their cognate antigen in the liver. Tg CD8 T cells transferred into Met-K^b typically induced a severe but self-limiting autoimmune hepatitis (AIH). To investigate whether cytokine regulation and apoptosis of CD8 T cells were critical in limiting the acute damage induced by CTLs, we performed transfer experiments using TCR transgenic T cells deficient for either suppressor of cytokine signaling (SOCS-1) or the pro-apoptotic molecule Bim.
Results: Bim$^{-/-}$ Tg cells accumulated in liver of recipient mice at sixfold higher levels compared to wt Tg cells. Despite this substantial accumulation, the outcome of hepatitis remained unchanged, neither prolonged nor more severe. This data suggest that although T cells died in a Bim-dependent process, T cell survival was not a critical parameter in limiting liver damage.

In contrast, SOCS-1-deficient Tg T cells induced a more severe hepatitis than their wt counterparts. SOCS-1$^{-/-}$ Tg isolated from the liver displayed upregulated IL-2Ra chain, required to form the high affinity IL-2R. Upregulated IL-2Rawas associated with higher IFNg, CTL activity, and proliferation rates, consistent with enhanced effector function and supporting a critical role for cytokines in CTL function.
Conclusions: These data demonstrate that the propensity of CD8 T cells to mediate acute hepatitis is determined by the quality, rather than the quantity of CTLs infiltrating the liver. In the long term, both Bim and SOCS deficiency led to the accumulation of CD8 T cells that were unable to cause chronic liver damage. These findings reveal the existence of mechanisms that are able to silence potentially autoreactive T cells surviving acute hepatitis. Such mechanisms might explain why immune infiltrates do not always correlate with ALT levels in patients chronically infected with HCV or with autoimmune hepatitis.

P1019

TREM-1 expression is elevated on monocytes in cirrhotic patients

S. Gurney,* C. Graham,† R. Metcalf,† L. Greathead,† M. Foxton,‡ S. Singh,* N. Soni* & P. Kelleher†
**Chelsea and Westminster Hospital, Intensive Care Unit, London, United Kingdom, †Imperial College London, Immunology, London, United Kingdom, ‡Chelsea and Westminster Hospital, Hepatology, London, United Kingdom*

Purpose/Objective: Sepsis and spontaneous bacterial peritonitis (SBP) are common sequelae in patients with cirrhosis. There is increasing interest in the role of monocytes in bacterial infection in cirrhotics. Triggering Receptor Expressed on Myelocytes 1 (TREM-1) modulates the immune response via an intracellular signalling cascade with resultant production of pro-inflammatory cytokines. It has been used as a biomarker in the diagnosis of bacterial infection but its role in patients with cirrhosis is unknown. We aim to evaluate TREM-1 as a biomarker in the diagnosis of SBP.
Materials and methods: Venous blood samples were obtained from 11 healthy controls (HC) and 14 patients with advanced cirrhosis (CA), as defined by clinico-radiological criteria. Simultaneous ascitic fluid samples were taken from seven patients in the CA group. Cirrhosis severity was graded using Child-Pugh score (median: 10) and Model for End-Stage Liver Disease score (MELD) (median: 14). The CA group had no clinical or laboratory evidence of sepsis at the time of sampling. Flow cytometry was used to quantify the expression of TREM-1 on three monocyte subsets: CD14$^+$CD16-, CD14$^+$CD16+, CD14dimCD16+ and CD16$^+$CD15+ neutrophils in blood and CD14+ monocytes and CD16$^+$CD15+ neutrophils in ascitic fluid.
Results: Results to date show that TREM-1 expression is significantly higher in the CA group compared to HC in the monocyte subsets CD14$^+$ CD16- [median geometric mean fluorescent intensity (GMFI): 6250 versus 2663 ($P = 0.0067$)] and CD14$^+$CD16$^+$ [GMFI: 4666 versus 9280 ($P = 0.0148$)] but not CD14dimCD16$^+$ or CD16$^+$ CD15$^+$ neutrophils. There is no correlation between TREM-1 expression and severity of cirrhosis by Child-Pugh or MELD score. There is no significant difference in TREM-1 expression on monocytes in ascitic fluid compared with CD14$^+$ CD16$^+$ monocytes in blood.
Conclusions: Blood monocyte TREM-1 levels are elevated in the CA group compared to the HC group in the absence of infection. There was no difference in TREM-1 expression between blood and ascitic fluid monocytes in culture negative and non-neutrocytic ascites (PMN count <250 cells/mm^3). On-going studies are evaluating the use of a biomarker panel comprising TREM-1, CD11b, CCR2 and CD64 in the diagnosis of SBP.

P1020

Tumor necrosis factor plays a vital role in mediating acetaminophen hepatotoxicity

C. J. Chen, C. L. Liu, S. Y. Huang & W. T. Li
Biochemical Science and Technology, National Taiwan University, Taipei, Taiwan

Purpose/Objective: Acetaminophen (APAP) is a widely used analgesic, and overdose of APAP may cause acute liver failure. APAP induces direct hepatotoxicity, and the necrotic hepatocytes further trigger an acute inflammatory response in the liver. Whether the inflammatory response and recruited leukocytes contribute to APAP-induced liver injury is still controversial. In this study, we investigated the role of the pleiotropic proinflammatory cytokine tumor necrosis factor (TNF) in APAP-induced liver injury.
Materials and methods: Overdoes of APAP (300 mg/kg) was administered to C57BL/6, TNF$^{-/-}$ and TNFR1$^{-/-}$ mice intraperitoneally, and serum levels of ALT, TNF, IL-6, and IL-1β and liver myeloperoxidase

activity were determined at various times after APAP challenge. To evaluate the effect of pharmacological TNF blockade, mice were given etanercept (Enbrel®) prior to APAP challenge.
Results: APAP-induced liver injury and hepatitis were markedly attenuated in $TNFR1^{-/-}$ and $TNF^{-/-}$ mice, and wild-type animals treated with the TNF blocker etanercept were also protected from APAP hepatotoxicity, indicating that TNF plays an important role in mediating AAP-induced hepatitis. Using the bone marrow chimeric mouse model, we further identified that TNFR1 function was required on radiosensitive non-parenchymal cells.
Conclusions: The production of TNF and its action on the TNFR1 of non-parenchymal cells play a vital role in mediating APAP hepatotoxicity.

P1021

Xenobiotics induced mouse model of human primary biliary cirrhosis develop PDC-E2 specific autoreactive T and B cells

Y. Chuang, C. Chang, H. Jen & S. Wu
Department of Clinical Laboratory Sciences and Medical Biotechnology, College of Medicine, National Taiwan University, Taipei, Taiwan

Purpose/Objective: Primary biliary cirrhosis (PBC) is a liver specific autoimmune disease characterized by antimitochondrial autoantibodies (AMAs), infiltration of lymphocytes in portal tracts and progressive destruction of intrahepatic bile duct. The major autoantigen in human PBC is the E2 subunits of the pyruvate dehydrogenase complex (PDC-E2). Increased serum levels of anti-PDC-E2 antibodies and liver T cells against PDC-E2 have been observed in patients with PBC, suggesting that autoreactive T cells and B cells play roles in the pathogenesis of PBC. We have developed the mouse PBC based upon immunization with xenobiotics 2-OA-BSA and a-galactosylceramide (a-GalCer), an invariant natural killer T cell activator. Such mice, similar to human PBC, develop high titer AMAs, autoimmune cholangitis and fibrosis. However, there has not been attempted at defining the presence of autoreactive T cells and B cells and, in particular, whether such cells are directed against PDC-E2.
Materials and methods: To address this issue, T cells and B cells against PDC-E2 from 2-OA-BSA/a-GalCer immunized mice were analyzed. For autoreactive T cells, liver mononuclear cells were stimulated with recombinant mouse PDC-E2 (rmPDC-E2) and cytokine production and proliferation of the antigen-stimulated T cells were examined. For autoreactive B cells, splenocytes were stimulated with rmPDC-E2 and anti-PDC-E2 antibodies in the culture supernatants were examined.
Results: Our results showed that there was no detection of reactive T and B cells in naïve mice when either control protein or rmPDC-E2 was used as antigens. Moreover, there was low detection of reactive T cells and B cells in 2-OA-BSA/a-GalCer immunized mice when cells were stimulated with no protein or control protein. However, significant increases of IFN-g and IL-17 production and proliferation of T cells as well as supernatant anti-PDC-E2 antibodies in rmPDC-E2 stimulated B cells in 2-OA-BSA/a-GalCer immunized mice were noted.
Conclusions: These data highlight not only the relevance of 2-OA-BSA/a-GalCer immunized mice as a model of human PBC, but also further imply that PDC-E2 is a major autoantigen and likely to be the antigenic driver of this disease.

P1022

Anti-retroviral drugs used in the management of HIV down-regulate PPAR-gamma binding, adipokine production and triglyceride storage in 3T3-L1 adipocytes

C. Loonam, S. O'Dell & A. Mullen
Diabetes and Nutritional Sciences Division, King's College London, London, UK

Purpose/Objective: Anti-retroviral therapy (ART), used in the management of HIV, is associated with a lipodystrophy syndrome characterised by peripheral fat wasting, central obesity, dyslipidaemia, insulin resistance, inflammation and endothelial dysfunction. Peroxisome proliferator-activated receptor-γ (PPAR-γ) binding and downstream signalling have been shown to be down-regulated by ART. We hypothesise that anti-retroviral drugs decrease PPAR-γ binding to its gene response element, decrease adiponectin, increase leptin and resistin, and decrease triglyceride storage.
Materials and methods: 3T3-L1 pre-adipocytes were differentiated in the presence of zidovudine (1 μM), stavudine (10 μM), tenofovir (1 μM), ritonavir (20 μM) and indinavir (10 μM). We investigated triglyceride storage using Oil Red O staining, gene expression using real-time RT-PCR, protein secretion using a multiplex ELISA and PPAR-γ binding using a DNA-binding ELISA. Statistical analysis was performed using ANOVA (SPSS, v15).
Results: Triglyceride storage was significantly reduced in adipocytes treated with ritonavir relative to the vehicle (ethanol) control (29%; $P = 0.001$). Ritonavir significantly decreased PPAR-γ binding and gene expression relative to vehicle control (39%; $P = 0.03$ and 51%; $P = 0.004$, respectively). Ritonavir significantly decreased secretion of PPAR-γ target gene product, the anti-inflammatory cytokine adiponectin (97%; $P < 0.001$). Indinavir and tenofovir significantly decreased adiponectin secretion relative to vehicle control (21%; $P = 0.001$ and 30%; $P < 0.001$, respectively). Significant increases in expression of pro-inflammatory resistin ($P = 0.001$), leptin ($P < 0.001$) and IL-6 genes ($P < 0.001$) were caused by tenofovir, in leptin by zidovudine ($P = 0.005$) and in IL-6 by indinavir ($P = 0.017$).
Conclusions: These data indicate the detrimental effect of ART on triglyceride storage, PPAR-γ signalling, adiponectin secretion and expression of pro-inflammatory genes. Ongoing work is investigating whether long-chain polyunsaturated fatty acids, as activating ligands for PPAR-γ, can mitigate the effects of ART on adipocyte function, gene expression and inflammation by up-regulating PPAR-γ and adiponectin and down-regulating resistin, leptin and IL-6.

Association between HLA-B*40 and lipodystrophy in a population of HIV-infected patients from South of Spain

M. J. Bravo,* R. Lavado-Valenzuela,† J. M. Miranda-Sayago,‡ M. I. Queipo-Ortuño,§ J. D. Colmenero,¶ M. Delgado,¶ F. Orihuela,¶ A. Alonso, A. Caballero** & N. Fernández-Arcás****
**Biochemistry and Molecular Biology Department, University of Malaga, Málaga, Spain, †Oncology Section, Carlos Haya University Hospital, Málaga, Spain, ‡Department of Biological Sciences, University of Essex, Colchester, UK, §Investigation Laboratory, Virgen de la Victoria University Hospital, Málaga, Spain, ¶Infectious Disease Service, Carlos Haya University Hospital, Málaga, Spain, **Carlos Haya University Hospital, Immunology Service, Málaga, Spain*

Purpose/Objective: Some HIV-infected patients undergoing highly active antirretroviral therapy (HAART) develop adipose tissue redistribution and metabolic abnormalities called lipodystrophy syndrome (LD). The frecuency of lipodystrophy is approximately between 35–50% and host genetic factors might confer particulary susceptibility. The aim of this study was to determine the clinical risk factors and HLA-B* alleles associated with stavudine or zidovudine-associated lipodystrophy.
Materials and methods: A case-control study was conducted for HIV-patients receiving stavudine or zidovudine containing antirretroviral regimens. Clinical assessments for lipodystrophy by phisical examination and DEXA (dual-energy X-ray absorptiometry) were obtained. The patients were calssified into 2 groups: patients with lipodystrophy and patients without lipodystrophy (control group). We compared the HLA-B* allelic frequency between the case and the control group to determine the possible association with stavudine or zidovudine associates lipodystrophy.

DNA was isolated from anticoagulated peripheral blood mononuclear cells using standard techniques. The locus B HLA class I typing was made for all subjects by Luminex PCR-SSO (One Lambda). The data were analyzed using the chi-square test or Fisher exact test, the magnitude of associations was estimated by odds ratio by the Woolf-Haldane method.
Results: We studied 127 patients with HIV infection diagnosed in the infectious Diseases Service of Carlos Haya University Hospital in Malaga, south of Spain. Seventy three of them had lipodystrophy and fifty four were considered as controls. Frequencies distribution analysis of the alleles at the B locus showed a statistically significant increase in the frequency of HLA-B*40 in the group of patients with LD compared to those with no LD (13.6% versus 1.8%) $P = 0.01$.
Conclusions: Although greater numbers of patients are needed the HLA-B*40 allele seems confer susceptibility for lipodystrophy in patients with HIV in a population from south of Spain.

P1024

Atopic-like dermatitis as expression of post-kala-azar dermal diffuse leishmaniasis in HIV infection

A. Zampetti, M. Gnarra, C. Feliciani, F. Giurdanella, D. Caposiena, C. De Simone & R. Capizzi
Dermatology Department, Catholic University of the Sacred Heart, Rome, Italy

Purpose/Objective: To describe the case of post-kala-azar dermal diffuse leishmaniasis in HIV infection.
Materials and methods: A 52 yo. man with B3 HIV infection from 10 years, came for a 3-week history of dyspnoea, cough and diffuse itch. He was submitted 7 years before to splenectomy for a visceral leshamniosis (VL), treated by antimony therapy. He was suffering from hyperthyroidism, hyperuricemia and dilatative cardiomyopathy. He received multidrug treatment for the HIV infection, and specific therapies for the concomitant diseases. At the physical examination hepatomegaly and diffuse severe xerosis with fine scales on the face and on the body, especially on the flexor surfaces, were observed. Routine blood and urine tests, lymphocyte typing, Ig E serum level, stool cultures were requested. Although afebrile, he was submitted to pulmonary TC scan and sputum cultures for mycobacteria were performed. Skin biopsies for histologic examination and PCR analysis were obtained.
Results: The lab tests revealed severe anemia (Hgb 7.5 g/dl) with macrocytosis, lymphocytopenia (0.82×10^9/l; 11.7%), CD3 641 ml, CD4 327 ml, CD4/CD8 ratio of 1.08. Ig E level was normal and stool cultures negative. The CT showed signs of pneumonitis but sputum cultures did not reveal mycobacteria. Skin histology showed diffuse dermal mucinosis and oedema, massive infiltrate of lymphocytes, histiocytes fulfilled by intracytoplasmatic parasites. The bone marrow biopsy showed severe infiltration by amastigotes. PCR confirmed a Leshamania Donovani infection. Liposomal amphotericine B (5 mg/kg), given as a five-day course, induced 100% cure rate and was tolerated.

Conclusions: Post-kala-azar dermal leishmaniasis (PKDL) is a complication of VL in a patient who has recovered from visceral form and who is otherwise well. There is increasing evidence that the pathogenesis is largely immunologically mediated. Increased interleukin 10 in the peripheral blood of VL patients predict the development of PKDL. During VL, interferon γ is not produced by peripheral blood mononuclear cells (PBMC). After treatment of VL, PBMC start producing interferon γ, which coincides with the appearance of PKDL lesions? Interferon-γ-producing cells cause skin inflammation, as observed in classical atopic lesions, as a reaction to persisting parasites in the skin.

Cellular immune responses after a dendritic cells (DC)-based therapeutic vaccine in cART treated chronic hiv-infected patients

A. C. Guardo,* F. García,† M. J. Maleno,‡ L. Papagno,§ M. E. Bargalló,* N. Climent,* B. Autran,§ J. M. Gatell,¶ T. Gallart & M. Plana***

**HIV research group IDIBAPS H. Clinic HIVACAT., Retrovirology and viral Immunopathology, Barcelona, Spain, †HIV research group IDIBAPS H. Clinic HIVACAT, Infectious diseases, Barcelona, Spain, ‡Hospital Clinic-IDIBAPS HIVACAT University of Barcelona, Retrovirology and viral Immunopathology, Barcelona, Spain, §Laboratoire d'Immunologie Cellulaire et Tissulaire INSERM U543 — Université Paris VI Pierre et Marie Curie., Infectious diseases, Paris, France, ¶Hospital Clinic-IDIBAPS, HIVACAT, Infectious diseases, Barcelona, Spain, **HIV research group IDIBAPS H. Clinic HIVACAT., Infectious diseases, Barcelona, Spain*

Purpose/Objective: We have performed a blinded placebo-controlled study immunizing antiretroviral (cART) treated chronically HIV-1 infected patients with autologous Myeloid-Derived Dendritic Cells (MD-DCs) pulsed with heat inactivated autologous HIV-1.

Materials and methods: Of the 36 patients with $CD4^+$ >450 cells/mm^3 were randomized (2:1) to receive three immunizations every 2 weeks with DC pulsed with autologous heat-inactivated HIV-1 (Cases, $n = 24$) or with non-pulsed DC (Controls, $n = 12$). Changes in viral load (VL) as well as changes in CD4 cell counts have been evaluated. Additionally HIV specific responses were measured in PBMC samples from different time-points by LPR and by IFN-g-Elispot against gag, nef and gp41 HIV overlapping peptide pools, respectively.

Results: VL rebounded to detectable level in all the patients. At week 12 and 24, a decrease of VL ≥ 1 log was observed in 12/22 (55%) versus 1/11 (9%) and in 7/20 (35%) versus 0/10 (0%) in cases and controls, respectively ($P = 0.02$, $P = 0.03$). CD4 drop to baseline value before any cART without differences between groups. Although only transient positive responses to HIV p24 were observed, the median change in LPR to HIV p24 at week 24 from baseline was 0.96 versus -0.50 ($P = 0.02$) in cases versus controls, respectively. Baseline median values of the total sum of HIV specific responses against HIV peptide pools were similar in both arms (2625 versus 2283 SFC/10^6 PBMC, $P = 0.462$). After vaccination, the median change of total sum of SFC/10^6 PBMC at week 24 was 3567 versus 838 SFC/10^6 PBMC ($P = 0.0459$) in cases and controls, respectively. This difference was more evident when analyzing responses against gag p17 and Nef peptide pools ($P = 0.0288$ and $P = 0.03615$, respectively). No statistically significant correlations between immune responses and VL were found.

Conclusions: These results indicate that HIV-1 specific immune responses elicited by therapeutic DC vaccines could significantly change pVL set-point after cART interruption in chronic HIV-1 infected patients.

P1027

Chemokines CCL3, CCL4 and chemokine receptor CCR5 in HIV-1-infected women with complicated anamnesis

V. P. Chernyshov,* V. V. Podolsky,† B. V. Dons'koi,* A. A. Kostyuchyk* & V. V. Podolsky†

**Laboratory of Immunology, Institute of Pediatrics Obstetrics& Gynecology National Academy of Medical Sci, Kiev, Ukraine, †Department of Gynecology, Institute of Pediatrics Obstetrics& Gynecology National Academy of Medical Sci, Kiev, Ukraine*

Purpose/Objective: Chemokine receptor CCR5 plays a key role inhuman immunodeficiency virus (HIV) entry into CD4+ T lymphocytes. Chemokines CCL3 and CCL4 have been shown to possess antiviral effects by binding to the HIV-1 co-receptor CCR5. We evaluated activity of these mechanisms in HIV-infected women that used drugs, alcohol and additionally had sexual transmitted diseases.

Materials and methods: Eighty three HIV-1-infected women were divided in four groups: drug edicts (DE) — 20, prostitutes (P) — 21, sexual transmitted diseases (STD) — 23, chronic alcoholism (CA) — 19. Non-infected 30 women with chronic alcoholism and 30 women with acute alcohol intoxication served as control groups. Lymphocyte subsets and expression of CCR5 on CD4+ T lymphocytes were examined by flow cytometry. CCL3, CCL4, IL-8 in blood serum were detected by ELISA.

Results: Levels of CD4+ T lymphocytes, especially CD4/CD8 ratios were decreased dramatically in four groups of HIV+ women. Expression of CCR5 inCD4+ lymphocytes was decreased in all groups of HIV+ women too. Levels of CCL4 in groups DE, P and STD were decreased, but not in CA group. Changes in CCL3 were not significant in all groups of HIV+ women. Levels of IL-8 were elevated in all groups ofHIV+ women. In non-infected women with acute alcohol intoxication levels of CCL4 were decreased.

Conclusions: Drugs using and sexual transmitted diseases in HIV-1-infected women are related with suppressed CCR5 expression in CD4+ lymphocytes and levels of CCL4 in blood serum. Chronic alcoholism has not so great suppressive influence. Acute alcohol intoxication relates with lower levels of CCL4 in non-infected women and one should think about weaker resistance of organism against HIV in such women.

P1028

Co-infection of human immunodeficiency virus and hepatitis B surface antigen among pregnant women in Kaduna, Nigeria

H. O. ABA, C. M. Z. Whong & M. Aminu

Department of Microbiology, Faculty of Science, Ahmadu Bello University, Zaria, Nigeria

Purpose/Objective: Human immunodeficiency virus (HIV) and Hepatitis B virus (HBV) share overlapping transmission routes and some risk factors. The HIV-infected pregnant cohort represents a unique population and infection with HBV is considered a public health problem worldwide. This study was conducted to determine the sero-prevalence of HIV and Hepatitis B Surface Antigen (HBsAg) and co-infection in pregnant women in Kaduna, Nigeria.

Materials and methods: Eight hundred pregnant women attending ante-natal care in four selected hospitals were recruited for the study. Blood samples were collected and examined for the presence of HIV and HBsAg using test kits. The positive HIV blood samples were analyzed for $CD4^+$ counts, while the positive HBsAg plasma samples were confirmed using ELISA and tested for various markers of HBV.

Results: Human immunodeficiency virus was detected in 5.9% (47/800) and HBsAg was detected in 3.9% (31/800) of the blood samples of the pregnant women. Four (0.5%) of the women were co-infected with both viruses. Mean $CD4^+$ count in the HIV positive pregnant women

was 396 cells/μl of blood while the mean $CD4^+$ count in HIV and HBsAg co-infected women was 299 cells/μl of blood. Test for markers of HBV indicated Anti-HBc as the most predominant (58.1%:18/31) while Anti-HBs was the least (3.2%:1/31). The highest prevalence of 13% (7/54) and 4.4% (10/229) were recorded for HIV and HBsAg among women in age groups 36−40 years and 21−25 years respectively ($P > 0.05$). There was a statistically significant association between the presence of both viruses and women in polygamy and those who have undergone blood transfusion and surgery ($P < 0.05$).
Conclusions: The results obtained in this study showed a considerably higher sero-prevalence rate of HIV and HBsAg amongst the pregnant women. Hepatitis B virus infection is a dynamic disease and co-infection with HIV impacts directly on the outcome of HBV infection, considerably complicating its natural history, diagnosis, and management, Therefore screening for HIV and HBsAg co-infection during pregnancy is essential to improve ante-natal care and inform clinical management.

P1030
Different prognostic value of cell-associated total HIV-1 DNA and integrated HIV-1 DNA for virological outcome in ART naïve and treated HIV-1 chronically infected patients

I. Martínez Río, J. Modrego-Ruiz, E. Fernández-Cruz & C. Rodríguez-Sáinz
Clinical Immunology, Hospital Gregorio Marañón, Madrid, Spain

Purpose/Objective: It has been demonstrated that total HIV-1 DNA levels associated to peripheral blood mononuclear cells (HIV-1 DNA_T) has prognostic value for virological outcome in HIV-1 infected patients. HIV-1 DNA_T includes both integrated and unintegrated forms of HIV-1 DNA. During natural infection the majority of HIV-1 DNA exists in an unintegrated state, compared with treated patients where the majority DNA is integrated. We evaluated whether the integrated forms of HIV-1 DNA (HIV-1 DNA_I) could provide a different prognostic value compared to HIV-1 DNA_T for virological outcome in ART naïve chronically HIV-1^+ individuals.
Materials and methods: In 107 ART naïve HIV-1^+ patients who have been previously analyzed for HIV-1 DNA_T we have retrospectively measured integrated DNA_I using real time PCR and relative quantification by $\Delta\Delta$Ct. Patients had participated in a multicenter, randomised, double-blinded, placebo-controlled phase II clinical trial of ART combined with an HIV-1 immunogen (STIR-2102). We analyzed the prognostic value of HIV-1 DNA_T and HIV-1 DNA_I as categorical variables using bivariate Cox regression models and stratifying by the medians at baseline PRE-ART and POST-ART (6 weeks after initiation ART). In STIR-2102 trial the endpoint was defined as time to the first increase of HIV-1 RNA > 5000 copies/ml.
Results: HR for virological failure in PRE-ART patients, introducing in the Cox model HIV-1 DNA_T and HIV-1 DNA_I were: HR 1.69 (95% CI, 1.02−2.79, $P = 0.04$) and HR 1.83 (95% CI, 1.11−3.03, $P = 0.019$), respectively. In POST-ART HR for HIV-1 DNA_T and HIV-1 DNA_Iwere: HR 2.36 (95% CI, 1.39−4.02, $P = 0.001$) and HR 1.68 (95% CI, 1.01−2.80, $P = 0.046$), respectively.
Conclusions: Both HIV-1 DNA_T and HIV-1 DNA_Ishowed different independent prognostic value. In ART naïve patients integrated HIV-1 $DNA_I$was the strongest variable associated with virological failure independently of HIV-1 DNA_T. In treated patients, HIV-1 DNA_T showed the strongest prognostic value for virological outcome, probably reflecting residual replication.

Dissecting HIV-1 clade C − specific antibody responses

D. Gallerano,* M. Focke,† I. Makupe,‡ E. N. Sibanda§ & R. Valenta†
**Division of Immunopathology, Inst. of Pathophysiology and Allergy Research, Vienna, Austria, †Christian Doppler Laboratory for Allergy Research, Inst. of Pathophysiology and Allergy Research, Vienna, Austria, ‡Allergy Asthma and Immunology Clinic, Gamma City Laboratory, Harare, Zimbabwe, §Asthma Allergy and Immune Dysfunction Clinic, Parirenyatwa University Teaching Hospital, Harare, Zimbabwe*

Purpose/Objective: Out of the different HIV strains, HIV-1 clade C is the one which is expanding more rapidly, above all in the southern states of Africa. Though, little is known about the immune response elicited by this strain in HIV infected individuals. In order to dissect the clade C HIV-1-specific antibody response in HIV-infected individuals we produced recombinant proteins and synthetic peptides.
Materials and methods: For a precise mapping of epitopes lying on the HIV envelope proteins (gp120 and gp41) overlapping peptides covering the entire amino acid sequence of the two proteins of a South African HIV-1 clade C strain were synthesized by solid phase synthesis. In order to indentify epitopes on non-surface antigens the HIV-1 clade C structural, functional and accessory proteins have been expressed in *Escherichia coli*. In preliminary experiments 85 sera from Zimbabwe were tested for HIV-specific IgG reactivity to the produced antigens in a dot blot immunoassay.
Results: The envelope epitope mapping allowed identifying immunogenic regions of gp120 and gp41. Interestingly HIV-specific IgG antibodies have been found to be elicited by both the domains which are conserved among HIV-1 strains as well as by variable domains (i.e. C1, V3 and V4 regions). On the other hand, we detected strong IgG reactivity also to proteins and peptides which have not been reported to be exposed on the surface of the virion (i.e. gp41 C-terminal region, matrix protein, Vif).
Conclusions: This suggests that also proteins contained within viral particles are exposed to the immune system in an immunogenic form.

P1032
Effectiveness of herbal remedy in 6 HIV patients in Nigeria

A. Jewell,* B. Okesina,† T. Ajadi,‡ S. Rahamon§ & O. Ogunrin¶
**Health & Social Care Sciences, Kingston University, London, UK, †Chemical Pathology, University of Ilorin, Ilorin, Nigeria, ‡Radiology, LAUTECH Teaching Hospital, Osogbo, Nigeria, §Chemical Pathology, College of Medicine University of Ibadan, Ibadan, Nigeria, ¶NAFDAC, Drug R & R, Lagos, Nigeria*

Purpose/Objective: The uncurable nature of HIV infection compelled many people living with the virus to seek alternative therapy. This pilot study determined effectiveness (clinical and laboratory responses) of an herbal remedy (A-Zam) used by patients seeking herbal remedy for HIV infection in Nigeria.
Materials and methods: Six patients taking herbal concoction as alternative therapy for HIV infection were recruited into the study and monitored for 4 months. All the (6) patients were confirmed for presence of HIV infection using Western blot technique in the nearest teaching hospital before commencing preliminary clinical and laboratory examinations using WHO and CDC criteria. The patients were contacted daily and visited regularly after commencement of herbal medications to assess side effects, drug toxicity, compliance and effectiveness.
Results: The symptoms and signs associated with HIV infection disappeared within 20 days of commencement of herbal therapy. The body weight increased from average 52.8kg to 62.7kg (9.9 ± 3.2), viral (HIV-RNA) load decreased from average 42 300 copies/ml to undetectable level (≤50 copies/ml) and CD4 T cell count increased

from average 226–680 $mm^3/\mu l$ (454 ± 106 $mm^3/\mu l$) at 4-month post therapy.
Conclusions: This pilot study concluded that the herbal remedy (A-Zam) is effective in HIV infection based on dramatic improvement in both clinical features and laboratory results of HIV infection. However, a longer period is suggested to ensure that the observed improvement is sustained. Also, a large population study is needed to confirm our observation in this cohort of people

P1033
Evaluation of the presence of the compound KIR:HLA-C genotypes in the virologic outcome of individuals with HIV-1 chronic infection

C. Rodríguez-Sainz, L. Herraiz, D. C. Hernández, L. Valor, I. Martínez & E. Fernández-Cruz
Servicio de Inmunología Clínica, Hospital General Universitario Gregorio Marañón, Madrid, Spain

Purpose/Objective: An effect of certain HLA-C genotypes in combination with KIR2DL3 has been implicated with HCV clearance previously. However, to date neither individual HLA-C alleles nor combinations or HLA-C groups with KIR have shown a protective effect against HIV-1 infection. The objective of this work was to study whether the presence of different compound KIR:HLA-C genotypes (KIR2DL1 and its ligand the HLA-C2 allotype; KIR2DS1:HLA-C2; KIR2DL2:HLA-C1; KIR2DL3:HLA-C1; and KIR2DS2:HLA-C1) could influence the virological outcome of chronically HIV-1 infected individuals initiating antiviral-therapy.
Materials and methods: Of the 187 patients with asymptomatic HIV-1 chronic infection who had participated in a multicenter, randomised, double-blinded, placebo-controlled phase II clinical trial of ART combined with an HIV-1 immunogen (STIR-2102), were retrospectively genotyped for HLA-C allotypes and KIR genes using sequence-specific primer PCR (Olerup SSP KIR Genotyping kit). Kaplan–Meier curves and Cox proportional-hazard models were used for survival analysis.
Results: Kaplan–Meier analyses, stratifying by the different genotypes showed that HLA-C1 allotype and KIR2DL3 were strongly associated with virological failure (χ^2 value for the Log-Rank test was 8.46; $P = 0.004$): The mean time to virological failure (first increase of HIV-1 RNA above 5000 copies/ml) was 31.60 months (95% CI, 29.29–33.92) for the group KIR2DL3:HLA-C1 and 20.74 months (95% CI, 19.07–27.06M) for the group of patients lacking the KIR2DL3:HLA-C1 genotype. In a Cox regression model, the HR for virological failure was significantly higher for individuals without the compound KIR2DL3:HLA-C1 genotype [HR, 1.90 (95% CI, 1.20–2.97, $P = 0.006$)].
Conclusions: The compound KIR2DL3:HLA-C1 genotype has been associated to a protective effect in a cohort of chronically HIV-1 infected individuals initiating antiviral-therapy.

P1035
High numbers of M-DC8+ monocytes and TNFa+ cells within the marginal zone of spleens from HIV-1 infected patients

S. A. Degrelle,* C. A. Dutertre,* S. Amraoui,* J. P. Jourdain,* E. Oksenhendler,† J. P. Viard,‡ L. Garderet,§ Y. Richard,* R. Cheynier* & A. Hosmalin*
**Inserm U1016 Institut Cochin Paris France. CNRS UMR8104 Paris France. Univ Paris Descartes Paris France., Immunology Department, Paris, France, †Assistance Publique-Hôpitaux de Paris (AP-HP)/Hôpital Saint Louis, Service d'Immunologie Clinique, Paris, France, ‡Centre de Diagnostic et de Thérapeutique/Hôpital Hotel Dieu, Unité fonctionnelle de Thérapeutique en Immuno-infectiologie (T2i), Paris, France, §Assistance Publique-Hôpitaux de Paris (AP-HP)/Hôpital Saint-Antoine, Hématologie Anatomie Pathologique, Paris, France*

Purpose/Objective: We found recently that circulating M-DC8+ monocyte numbers were significantly higher in viremic, HIV-1 infected patients than in non-viremic patients or in healthy controls. *In vitro*, peripheral blood mononuclear cells from viremic patients produced more TNFα in response to LPS than those from non-viremic patients or from controls, and M-DC8+ monocytes were mostly responsible for this overproduction. We quantified and localized these monocytes in spleens from HIV-1 infected patients with idiopathic thrombopenic purpura (ITP).
Materials and methods: Samples were obtained after therapeutic splenectomy from HIV-infected or uninfected patients. Numbers of M-DC8+ monocytes were evaluated by 11-color flow cytometry in spleen mononuclear cells from 10 patients (six HIV-infected, four uninfected). Localization and quantification of M-DC8+ and TNFα+ cells were performed by immunohistofluorescence on spleen cryosections from 17 patients (eight uninfected, nine HIV-infected including four untreated by antiretrovirals).
Results: Spleens from HIV-infected patients displayed significantly higher numbers of M-DC8+ monocytes than those from uninfected patients. M-DC8+ cells were localized in the red pulps from all patients, but were present within the marginal zone only in HIV-infected, untreated patients. Numbers of TNFα+ cells were also significantly higher in HIV-infected patients than in controls, irrespective of treatment. Some were found within the marginal zone, whereas in uninfected patients, they localized strictly in the red pulp. TNFα did not colocalize with M-DC8+ cells, but with other cell types currently being characterized.
Conclusions: High numbers of M-DC8+ monocytes were not only found in the blood from HIV-infected patients, but also in the spleen. In untreated patients, these cells localized abnormally within the marginal zone. TNFαexpression was higher in spleens from HIV-infected patients than in uninfected patients, and was found within the marginal zone, but did not colocalize with MDC8 labeling. We will test further the kinetics of proinflammatory monocyte homing in a simian model over different stages of SIV infection.

P1036
Highly Active Antiretroviral Therapy (HAART) can restore the decrease of CD20+ T cell numbers in HIV-1 patients

F. Förster,* A. Singla,† S. K. Arora,† R. E. Schmidt* & R. Jacobs*
**Department of Clinical Immunology & Rheumatology, Hannover Medical School, Hannover, Germany, †Department of Immunopathology, PGIMER, Chandigarh, India*

Purpose/Objective: CD38 expression on $CD8^+$ T cells is a valuable prognostic marker for disease progression in HIV infection. Like CD38, CD20 is functionally involved in calcium mobilization and coexpressed by a subpopulation of human T cells. Here we wanted to elucidate if $CD20^+$ T cells are affected by HIV-1 infection and may have a prognostic value for the course of disease.

Materials and methods: Numbers of $CD20^+$ T cells were determined in healthy controls, untreated and HAART-treated HIV-1 patients. Coexpression patterns of CD4, CD8, and CD38 as well as IFN-γ production were analysed in $CD3^+$ $CD20^+$ and $CD3^+$ $CD20^-$ T cells by multi color flow cytometry.
Results: We found a significant decrease of $CD20^+$ T cell numbers in untreated HIV-1 patients (1.4%) as compared to healthy controls (2.5%) which recovered under HAART (1.9%). Particularly, the $CD8^+$ T cell compartment was affected revealing significant differences between healthy controls (3.4%) and both treated (1.7%) and untreated (1.1%) patients. CD38 was expressed on a few $CD20^+$ T cells but preferentially on $CD20^-$ cells in all three groups.

IFN-γ production was measured upon cell activation using PMA alone or in combination with ionomycin in order to assess functional capacities of the cells. PMA alone was much more effective in $CD20^+$ cells regardless of CD38 coexpression, indicating a supportive role of CD20 but not CD38 in T cell activation.
Conclusions: Here we present data showing that $CD3^+$ $CD20^+$ T cells are decreased in untreated HIV-1 patients and normal numbers are restored under HAART. Expression of CD20 and CD38 is independently regulated on T cells and it is not clear by now if CD20 expression is of prognostic value. Contrary to CD38, CD20 can substitute ionophores for Ca^{2+} flux in early T cell activation and also strongly amplifies cell stimulation in the presence of Ca^{2+} ionophores, indicating that CD20 contributes to T cell activation.

The study was supported by the Federal Ministry of Education and Research (BMBF, Germany) and by the Indian Council of Medical Research (Ministry of Health and Family Welfare, Govt. of India).

P0137
HIV impairs avidity maturation to EPI vaccines in children

D. M. Muema,* E. Nduati,* J. Berkley* & B. Urban†
**KEMRI-Wellcome Trust Research Programme, Immunology, Kilifi, Kenya, †Liverpool School of Tropical Medicine, Molecular and Biomedical parasitology, Liverpool, UK*

Purpose/Objective: HIV-infected adults and children have reduced quantities of antibodies and memory B cells to non-HIV antigens. On the other hand, avidity of antibodies to vaccine antigens is not affected by HIV in adults, probably because they have already experienced avidity maturation to most routine vaccine antigens prior to infection. Little is known regarding avidity maturation in children infected with HIV. Here, we analysed the avidity of antibodies against tetanus toxoid and diphtheria toxoid in children who acquired HIV vertically. We also measured the quantities of circulating antibodies and frequencies of memory B cells to vaccine antigens.
Materials and methods: Memory B-cell frequencies were determined using cultured B-cell ELISpot. ELISA was used to determine the antibody levels while a modified ELISA was used to determine the antibody avidities. In the modified ELISA, Guanidine Hydrochloride was used to elute the antibodies after incubating the plasma (sample) with the antigen-coated plates. The ratio of the remaining antibody levels in the eluted wells to that in the control (PBS eluted) wells was taken as the avidity index.

The children were then classified based on their viral loads and compared with community controls.
Results: HIV-infected children, regardless of level of viremia, had significantly lower avidity indices when compared with the community controls. As previously reported, they also had lower titres of circulating antibodies as well as lower frequencies of antigen specific memory B cells.
Conclusions: HIV affects not only the magnitude but also the quality of antibody response to vaccine antigens in vertically infected children.

P0138
HIV triggers interleukin 21-mediated induction of granzyme B-secreting B cells with antiviral properties

C. Kaltenmeier,* A. Gawanbacht,† S. Hofmann,* K. Dahlke,‡ T. Beyer,* G. Härter,§ B. Grüner,§ P. Kern,§ F. Kirchhoff,† H. Schrezenmeier* & B. Jahrsdörfer*
**Institute of Clinical Transfusion Medicine and Immunogenetics, University of Ulm, Ulm, Germany, †Institute of Molecular Virology, University of Ulm, Ulm, Germany, ‡Institute of Clinical Pharmacology, University of Ulm, Ulm, Germany, §Comprehensive Infectious Diseases Center, University of Ulm, Ulm, Germany*

Purpose/Objective: Certain lymphocyte subsets including plasmacytoid dendritic cells and regulatory T cells can secrete granzyme B (GrB), thereby suppressing T cell expansion. Recently, we found that B cells can also produce GrB in response to interleukin (IL-) 21. Since HIV has been shown to be associated with elevated serum IL-21 levels, we hypothesized that GrB-expressing B cells may be induced during HIV infection.
Materials and methods: Cell culture, HIV infection of cells in cell culture, FACS, laser-scanning confocal microscopy, Wetern Blotting.
Results: Here, we demonstrate for the first time, that infection of $CD4^+$ T cells with HIV 1 (NL4-3), but not mock infection, induces strong expression of IL-21. We further demonstrate that such T cells induce GrB in co-cultured B cells in an IL-21-dependent fashion. In support of these data, serum levels of both IL-21 and GrB are significantly higher in HIV-infected patients before HAART as compared to healthy controls. Up to 60% of B cells ($36.2 \pm 12.9\%$) from patients infected with HIV, but not normal B cells, express GrB. Importantly, co-culture of HIV-infected $CD4^+$ T cells with GrB^+ B cells resulted in GrB transfer, and strongly suppressed both, proliferation of T cells and virus replication as indicated by significantly reduced p24 levels in the supernatants. The observed effects were enhanced by IL-21, and reduced by GrB inhibition.
Conclusions: In summary, we demonstrate that HIV infection induces IL-21 in $CD4^+$ T cells, thereby indirectly triggering the development of GrB-secreting B cells with antiretroviral properties. GrB-secreting B cells may play a so far unappreciated role in decelerating HIV expansion, particularly in the early phase of infection. On the other hand, induction of GrB in B cells may interfere with their terminal differentiation into plasma cells, which may explain the lack of an efficient anti-HIV humoral immune response in HIV-infected patients.

Immunogenicity of a universal HIV-1 vaccine vectored by DNA, MVA and ChAdV-63 in a phase I/IIa clinical trial

T. Hanke,* N. Borthwick,* T. Ahmed,* E. J. Hayton,* U. Ebrahimsa,* A. Rose,* A. Black,* H. Yang,* G. Hancock,* S. Colloca,† A. Nicosia,† A. J. McMichael‡ & L. Dorrell‡
**The Jenner Institute, University of Oxford, Oxford, UK, †Okairos, company, Rome, Italy, ‡Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, UK*

Purpose/Objective: The develop a safe and effective vaccine against HIV-1/AIDS.
Materials and methods: The major challenge that both antibody and T cell-eliciting vaccines against HIV-1 face is the extreme variability of the HIV-1 genome: a successful vaccine has to effectively target diverse HIV-1 strains circulating in the population and then must deal with ongoing virus escape in infected individuals. To address these issues, we assembled vaccine immunogen HIVconsv from the functionally most conserved regions (not epitopes) of the HIV-1 proteome with the underlying working hypothesis that early focus of vaccine-elicited immune responses on these regions will lead to a better recognition

and control of transmitting viruses. A gene coding for the HIVconsv immunogen was inserted into plasmid DNA (D), modified vaccinia virus Ankara (MVA; M) and non-replicating adenovirus of a chimpanzee origin ChAdV-63 (C). Currently, combined heterologous prime-boost regimens of these vaccines, namely CM, DDDCM and DDDMC, are being evaluated in a phase I/IIa trial HIV-CORE002 in healthy HIV-1/2-negative volunteers in Oxford.
Results: Preliminary data indicate that the vaccines are very well tolerated and show high immunogenicity. Following the CM regimen, vaccine-induced T cell frequencies reached a median of 5150 (range 1475−16495) SFU/10^6 PMBC *ex vivo* specific for multiple, conserved, therefore in natural infection mostly subdominant HIV-1 epitopes (in contrast to 136 and 686 SFU/10^6 PMBC in the STEP study). Similar immunogenicity was observed for the DDDCM regimen. Results from DDDMC, epitope mapping, and phenotypic and functional characterization of these responses will be presented.
Conclusions: Thus so far, the unique HIVconcv immunogen and unique vector delivery have induced T cell responses superior to other HIV-1 vaccine candidates tested in humans to date, HIVconsv is the first of the second-generation immunogens addressing the HIV-1 diversity that reached clinic and ChAdV-63 is the first adenovirus of chimp origin delivering an HIV-1-derived immunogen that reached clinic.

P1042
Immunomodulation of antigen-specific T cells by HIV gp41 transmembrane envelope protein

A. Ashkenazi,* O. Faingold,* N. Kaushansky,† A. Ben-Nun† & Y. Shai*
**The Department of Biological Chemistry, The Weizmann Institute of Science, Rehovot, Israel, †The Department of Immunology, The Weizmann Institute of Science, Rehovot, Israel*

Purpose/Objective: Modulation of T-cell responses by human immunodeficiency virus (HIV) occurs via distinct mechanisms, one of which involves down-regulation of T cells already at the stage of virus-cell fusion. The membrane-bound T-cell receptor (TCR) complex is located in the vicinity of the HIV fusion site. Thus, it is conceivable that hydrophobic portions of the gp41 protein of the viral envelope that contributes to membrane fusion may interact with membrane-embedded portions of the TCR and modulate T-cell responsiveness.
Materials and methods: To address this hypothesis, we investigate the ability of HIV gp41 derived peptides to modulate T-cell proliferation *in-vitro* by examining their effect on T cells, which were stimulated at different steps of the TCR complex signal transduction. Furthermore, imaging, biochemical and biophysical approaches are implemented to identify the target protein of the HIV peptides. *In-vivo* studies are carried out in mice models of autoimmune disease.
Results: We demonstrate inhibition of antigen-specific T-cell proliferation by peptides derived from membranotropic regions of HIV gp41. We will address the mode of action of the peptides on the transmembrane domains of the TCR complex. Furthermore, administering the peptides to an animal model of autoimmune disease mediated by pathogenic T-cells significantly reduces the severity of the disease. This seems to be associated with down-regulation of Th1 pro-inflammatory cytokines.
Conclusions: Thus, our data imply that T-cell inactivation during HIV-cell fusion lie in part in hydrophobic portions of gp41. Disassociated from HIV, however, these HIV peptides may act as novel reagent for down-regulating undesirable immune responses.

P1044
Inhibition of HIV-replication by cell-membrane crossing oligomers (CMCOs)

W. Posch,* T. Lindhorst,† B. Werner,† H. Bock,† C. Lass-Floerl* & D. Wilflingseder*
**Division of Hygiene and Medical Microbiology, Innsbruck Medical University, Innsbruck, Austria, †Ugichem GmbH, Innsbruck, Austria*

Purpose/Objective: Although rapidly becoming a valuable tool for gene silencing, regulation or editing *in vitro*, the direct transfer of siRNAs into cells is still an unsolved problem for *in vivo* applications.
Materials and methods: For the first time, we show that specific modifications of antisense oligomers allow autonomous passage into cell lines and primary cells without further adjuvant or coupling to a cell-penetrating peptide. For this reason, we termed the specifically modified oligonucleotides '*cell-membrane crossing oligomers*' (*CMCOs*).
Results: CMCOs targeted to various conserved regions of HIV-1 were tested and compared to non-targeting CMCOs. Analyses of non-infected and infected cells incubated with labeled CMCOs revealed that the compounds were enriched in infected cells and some of the tested CMCOs exhibited a potent antiviral effect. Finally, the CMCOs did not exert any cytotoxicity and did not inhibit proliferation of the cells.
Conclusions: *In vitro*, our CMCOs are promising candidates as biologically active anti-HIV reagents for future *in vivo* applications.

P1045
Interferon alpha induced acceleration of thymic production during acute SIV infection

J. Dutrieux,* V. Fabre-Mersseman,* B. Charmeteu-De Muylder,* M. Rancez,* R. Ponte,* S. Rozlan,† A. Bernard,* S. Morgado-Figueiredo,* A. Couëdel-Courteille* & R. Cheynier*
**Cochin Institute Inserm U1016, Immunology, Paris, France, †Cytheris SA, Immunology, Paris, France*

Purpose/Objective: The processes involved in the inhibition of thymic function usually observed during primary HIV-infection are poorly understood. In humans, the acute phase of HIV-infection, that certainly drives pathogenesis, remains barely studied. The aim of this study was to define the mechanisms impacting thymopoiesis during the acute phase of SIVmac251-infection in rhesus macaques.
Materials and methods: Blood samples were taken every other day for 2 weeks in 15 SIV-infected macaques. T-cell subsets were followed by flow cytometry. Plasma interferon alpha (IFNa) levels were measured by ELISA. Thymic function was evaluated by qPCR quantification of T-cell Receptor Excision Circles (TRECs) and estimation of intrathymic precursor T-cell proliferation (sj/§TREC ratio). Eight animals were autopsied at day 3, 7, 10 and 14 post-infection. Thymic expression of IFNa was evaluated by qRT-PCR and the proportion of the 12 IFNa subtypes estimated by heteroduplex tracking assay. The expression of chemokines involved in thymopoiesis was studied by qRT-PCR on thymus samples. Finally, the effect of IFNa subtypes on thymocyte differentiation was tested on simian DN cells cultured on OP9-hDL1 cells.
Results: Combined analysis of the evolution of recent thymic emigrants (CD31+ naïve CD4+ T-cells) in blood and TRECs pointed to the fact that, by day 7 of infection, the RTE compartment mostly contains newly exported cells with a reduced proliferation history. This change in thymocyte behavior coincided with both increased plasma IFNa levels and production of IFNa 1, 2, 3, 5 and 7 in the thymus. In culture, 6 IFNa subtypes, including IFNa3 and 7, induced strong inhibition of thymocyte proliferation, as demonstrated by lower cell counts, DP frequencies and sj/bTREC ratio at day 14. Finally, in the SIV-infected thymuses CXCL12 transcription was significantly increased while CCL19 and CCL25 expression was reduced.

Conclusions: Altogether, our data demonstrate that, during acute SIV-infection, modified chemokine expression patterns in the thymus and inhibition of thymocyte proliferation by locally produced IFNa subtypes lead to an acceleration of thymocyte differentiation thus to massive export of newly maturated T-cells. In the long term, such modification of thymopoiesis may lead to the observed reduction of naïve T-cell counts and diversity.

M-DC8+ monocyte expansion and TNFa overproduction in response to LPS during HIV-1 infection

A. Hosmalin,[*,†,‡,§] S. Amraoui,[*,†,‡,§] A. L. DeRosa,[*,†,‡,§] J. P. Jourdain,[*,†,‡,§] L. Vimeux,[*,†,‡,§] C. Goujard,[¶] P. Loulergue,[**] O. Launay,[**] Y. Richard[*,†,‡,§] & C. A. Dutertre[*,†,‡,§]
[*]*Inserm U1016 Institut Cochin Paris France,* [†]*CNRS UMR8104, Paris, France,* [‡]*Univ Paris Descartes, Paris, France,* [§]*Immunology, Paris, France,* [¶]*Hôpital de Bicêtre AP-HP INSERM U1018, Univ Paris Sud, Le Kremlin-Bicêtre, France,* [**]*Inserm CIC BT505 CIC de Vaccinologie Cochin Pasteur Paris France, Vaccinology, Paris, France*

Purpose/Objective: HIV infects activated CD4+ T cells and induces their depletion. Progressive HIV infection is fueled by chronic immune hyperactivation, mediated by inflammatory cytokines like TNFα, and related to intestinal epithelial damage and microbial LPS translocation into the circulation.
Materials and methods: Using 11-color flow cytometry and cell culture after sorting, we investigated the numbers and TNFα production of fully defined myeloid populations during HIV-1 infection.
Results: In 15 viremic patients, compared to 8 virologically suppressed patients or to 13 controls, circulating CD141 (BDCA-3)$^+$ and CD1c (BDCA-1)$^+$ dendritic cell counts were reduced. Conversely, non-classical CD14^{dim}CD16$^+$ monocyte counts were increased, particularly those expressing M-DC8. These M-DC8$^+$ monocytes were mostly responsible for the LPS-induced TNFα overproduction found in viremic patients. *In vitro*, CD16$^+$M-DC8$^+$ monocytes differenciated from classical, CD16$^-$ M-DC8$^-$ monocytes using M-CSF and GM-CSF, which is increased in viremic patient's plasma.
Conclusions: This M-DC8$^+$ population, which is involved in the pathogenesis of chronic inflammatory diseases, might thus be considered as a major actor in the vicious circle of immune hyperactivation fueling HIV infection progression.

P1047

mCMV infection can be beneficial or harmful in retrovirus infection dependent on the order and time-point of infections

J. Duppach, S. Francois, J. Peng, U. Dittmer & A. Kraft
Virology, University Hospital Essen, Essen, Germany

Purpose/Objective: Suppression of the immune system e.g. transplantation or HIV infection can result in reactivation of cytomegalovirus (CMV). In general, CMV reactivation can be life-threatening and therefore it should be avoided especially in transplantation patients. However, recently it was shown that CMV reactivation early after bone marrow transplantation in human adult myeloid leukemia can also be beneficial by reducing tumor relapse, indicating that CMV infection can be beneficial for the host. Different to CMV reactivation studies in AIDS patients, only limited studies are done to investigate if a primary or persistent CMV might be beneficial or harmful in HIV patients.
Materials and methods: In this study we used the two well established infection models in mice, the Friend leukemia Virus (FV), as a model for retroviral infections and the murine cytomegalovirus (mCMV), as a model for human cytomegalovirus infections.
Results: A primary mCMV infection resulted in enhanced FV replication in mice persistently infected with FV and enhanced numbers of functional FV-specific CD8 T cells. However these cells become dysfunctional suggesting that expanded Treg cells might dampen the 'newly' generated FV-specific T cell response and inhibit the clearance of persistent FV infection.

In contrast to these findings, we found that persistent mCMV limited a primary FV infection. Significantly reduced FV titers were found during a primary FV infection in persistently mCMV infected mice compared to primary FV infected naïve mice. The reduced FV titers were mediated by an augmented FV-specific CD8 T cell response. In persistent mCMV infection we found that FV-specific CD8 T cells had a significant earlier and stronger *in vivo* killing capacity during primary FV infection compared to only primary FV infected mice.
Conclusions: In conclusion, our data showed that a primary mCMV infection is harmful in persistently retrovirally infected mouse, but a persistent mCMV infection is beneficial by reducing viral titers of a primary retrovirus infection. Our data demonstrated that the mCMV mediated effect onto a retroviral infection is dependent on the sequence order and the time-point of mCMV infection.

P1048

Modifications of the redox intracellular environment during the Human Immunodeficiency Virus type I (HIV-1) infection associated with the Src kinase activation

M. Curcio,[*] H. P. Monteiro,[†] A. Sartori,[†] S. Strumilo,[‡] W. Maia,[*] E. Castro,[†] S. Andrade,[§] L. Simão,[*] M. Soane[‡] & M. Janini[*]
[*]*Federal University of São Paulo, Microbiology Immunology and Parasitology, São Paulo, Brazil,* [†]*Federal University of São Paulo, Biochemistry, São Paulo, Brazil,* [‡]*Federal University of São Paulo, Infectology, São Paulo, Brazi,* [§]*Federal University of São Paulo, Ginecology and Charitable Association of Blood Collection – COLSAN, São Paulo, Brazil*

Purpose/Objective: Human Immunodeficiency Virus (HIV) and other structurally simple retroviruses developed, as a defense mechanism, numerous replication strategies to escape from apoptotic mechanism triggered by host cells. HIV maintains a persistent infection by stimulating intracellular (host) production of cytokines and of reactive oxygen and nitrogen species (ROS and RNS) (1). Levels of ROS and RNS and of their antioxidant counterparts determine the redox environment. Alterations on the redox environment are sensed by raising levels of the antioxidant enzyme Cu/Zn and Mn Superoxide dismutase (SOD). Such alterations are potentially associated with the regulation ofHIV-replication signaling pathways (2).
Materials and methods: In the present study we used isolated human CD4 T lymphocytes submitted to a protocol of *in vitro* infection with purified HIV viral particles. Levels of the antioxidant enzymes, Cu/Zn and Mn-SOD, Glutathione peroxidase (GPx), Glutathione reductase (GR), and of the tri-peptide Glutathione (GSH) were measured in infected and non-infected CD4 T lymphocytes.
Results: There was an increase on the activities of the antioxidant enzymes followed by a decrease on intracellular GSH levels. In addition we followed the temporal pattern of activation of Src kinase. Src is a cytoplasmic protein tyrosine kinase which has been shown to play an important role in HIV-1 replication (3).
Conclusions: Our findings suggest a possible relationship between the alterations in intracellular redox environment and the activation pattern of Src kinase in HIV-infected human CD4 T lymphocytes. These results also emphasize the importance of the intracellular redox environment in regulating the Src-mediated signaling pathway associated with HIV infection.

P1050

Natural T regs recently emigrated from the thymus; consist of two subsets, differently impaired during HIV infection

V. Terzieva,* J. Dutrieux,† V. Fabre-Mersseman,† M. Rancez,† B. Charmeteau-de Muylder,† S. Logerot,† M. Andrieu,‡ K. Labroquère§ & R. Cheynier†

*INSERM U567 CNRS UMR 8104 Paris France Université Paris Descartes Faculté de Médecine René Descartes UMR-S 8104 Paris France BAS IBIR Sofia Bulgaria, Immunology, Paris, France, †INSERM U567 CNRS UMR 8104 Paris France Université Paris Descartes Faculté de Médecine René Descartes UMR-S 8104 Paris France, Immunology, Paris, France, ‡INSERM U1016 CNRS UMR 8104, Immunology, Paris, France, §INSERM U1016 Paris France, Immunology, Paris, France

Purpose/Objective: The hallmark of HIV infection is the sustained deterioration of the CD4 T cell compartment accompanied by the exhausted thymic function. The role of different Treg populations in the course of HIV infection remains imprecisely determined with nTregs being less characterized than iTregs due to the lack of a clearly defined specific markers. However, it can be expected that similarly to non-Treg naïve T-cells, HIV infection impacts on *de novo* production of nTregs.

Materials and methods: Of the 26 healthy control (HC) individuals and 16 age/sex matched HIV-1+ subjects, ART-treated or therapy-free, were included. PBMCs were simultaneously stained for extra and intracellular markers. The determination of nTregs-RTE cells was done by multi-colors flowcytometry using combinations of anti-CD3, -CD4, -CD45RA, -CD31, -CCR7, -CD25 and -CD127. TREC quantification was performed by real-time PCR on FACS-sorted lymphocytes and expressed as TRECs/10^5 cells. Statistical analysis was performed using GraphPad software.

Results: In the compartment of naïve CD4+T cells ($CD45RA^+$ CCR7+) we identified two subsets of recent thymic emigrants (RTE) nTreg cells (CD31+FOXP3+ naïve CD4+ T-cells) differentially expressing CD25. These 2 subsets contained high concentrations of TRECs, confirming thymic proximity. In contrast, no difference in TREC levels was observed between CD25+ and CD25- nTregs-RTE. In HCs CD25+ nTregs-RTE were twice as numerous as CD25- nTregs-RTE ($P = 0.027$). In patients' groups an increase of RTE nTregs was observed, mostly as a consequence of CD25- nTregs-RTE expansion ($P < 0.02$). In ART-treated patients, they essentially consisted of CD127 cells ($P < 0.05$). This was not the case in the group of untreated patients ($P > 0.05$).

Conclusions: Our results show that nTregs recently emigrated from the thymus consist of two subsets differentially expressing CD25. These subsets are differently impaired during HIV-infection. Further studies are needed to clarify their respective functions and behaviors in the course of HIV infection.

Selection of sero-conversion predictive marker by serological analysis of HIV-diagnosed cases in Korea

S. H. Kim,[1] B. S. Choi,[1] H. J. Sim,[1] J. S. Lee[2] & S. S. Kim[1]

[1]Division of AIDS, Korea National Institute of Health, Cheonwon-gun, Korea, [2]Korea National Institute of Health, Center for Immunology and Pathology, Cheonwon-gun, Korea

Purpose/Objective: Even though the latest serological or molecular methods are used to diagnose HIV infection, it is still difficult to determine the HIV status of indeterminate cases. In this study, we identified HIV status of Korean sero-converter in HIV low prevalence area and chose the most relevant markers to predict the status of sero-conversion by analyzing serological characteristics of HIV sero-converters.

Materials and methods: We analyzed the results of the serological tests for HIV diagnosis in Korea from 2009 to 2011. The results of HIV diagnosis were classified as positive, indeterminate, and negative. Especially, we evaluated the predictive value of each antibody profile with presence of p24 antigen based on serological data of sero-converters who were assessed as indeterminate at first, retrospectively.

Results: From 2009 to 2011, 2429 people were diagnosed as HIV infected individuals in Korea, and 199 of those cases (8.2%) were determined as sero-converters. Among 199 sero-converters, up to 72.2% (60/83) showed Ab-/Ag+ in screening test were sero-converted. In the case of sero-conversion, the use of antigen detection and western blot analysis, such as the group of Ag+/gp160 (OR; 88.3) orAg+/p24 (OR; 17.9), had higher positive predictive value than the Ag+ group (OR; 9.3) of indeterminate cases.

Conclusions: According to our study, the HIV antigen detection and appearance of western blot profile to gp160 protein could be used as a high predictive diagnostic marker to determine the HIV status of indeterminate at first. These results would be helpful to increase the specificity of the HIV positive criteria in HIV low prevalence region without delayed interpretation of HIV status.

Polymorphisms in the HCP5 and HLA-C genes associate with time to undetectable plasma HIV RNA during highly active antiretroviral therapy (HAART)

L. W. Thørner,* C. Erikstrup,† L. H. Harritshøj,* G. Kronborg,‡ C. Pedersen,§ C. S. Larsen,¶ G. Pedersen,** J. Gerstoft,†† N. Obel†† & H. Ullum*

*Department of Clinical Immunology, Copenhagen University Hospital, Copenhagen, Denmark, †Department of Clinical Immunology, Aarhus University Hospital, Aarhus, Denmark, ‡Department of Infectious Diseases, Copenhagen University Hospital, Hvidovre, Denmark, §Department of Infectious Diseases, Odense University Hospital, Odense, Denmark, ¶Department of Infectious Diseases, Aarhus University Hospital, Aarhus, Denmark, **Department of Infectious Diseases, Aarhus University Hospital, Aalborg, Denmark, ††Department of Infectious Diseases, Copenhagen University Hospital, Copenhagen, Denmark

Purpose/Objective: Single nucleotide polymorphisms (SNPs) in the HLA complex P5 gene (*HCP5*), *HLA-C,* and near the zinc ribbon domain containing 1 gene (*ZNRD1)* have been shown to influence viral load (VL) set point in HIV-infected individuals with known time of seroconversion. We aimed to determine the influence of the *HCP5* rs2395029, the *HLA-C* rs9264942, and the *ZNRD1* rs3869068 on mean VL before HAART, on time to first VL < 51 copies/ml, and on CD4 T-cell recovery during HAART.

Materials and methods: The Danish HIV Cohort Study is a prospective, nationwide, population-based study of all HIV-infected individuals treated in Danish HIV clinics since 1 January 1995. From this cohort we genotyped 1382 Caucasian individuals for the rs2395029 (A>C), rs9264942 (T>C), and rs3869068 (C>T).

We calculated the mean viral load before HAART for each individual with a CD4 T-cell count >200 cells/μl and calculated the CD4 T-cell recovery as the weighted average of the last CD4 T-cell count before 1 year with HAART and the first CD4 T-cell count after 1 year with HAART minus the last CD4 T-cell count before HAART. General linear models were applied to evaluate the effect of SNPs on mean VL before HAART and on CD4 cell recovery during HAART. Cox proportional hazard regression analysis was applied to assess the association with time to first VL < 51 copies/ml. All models were assuming additive or dominant genetic effects and were adjusted for

sex, age, calendar period, and start of HAART (where appropriate). VL was log-transformed before analysis.
Results: The C-allele of rs2395029 was associated with lower mean VL before HAART [(mean ± SD), CC/CT: 4.1 ± 0.95 versus TT: 4.6 ± 0.83, $P = 0.0003$]. We found no significant associations with mean VL before HAART for the rs9264942 and rs3869068. The C-alleles of rs2395029 and rs9264942 were associated with a shorter time to VL < 51 copies/ml [HR (95% confidence interval) = 1.36 (1.10−1.69), $P = 0.005$; HR = 1.17 (1.07−1.28), $P = 0.0004$, respectively]. None of the SNPs predicted CD4 T-cell recovery during HAART.
Conclusions: The C-allele of rs2395029 associates with mean VL before HAART and the C-alleles of rs2395029 and rs9264942 associate with time to first VL < 51 copies/ml during HAART further emphasizing the impact of these SNPs on viral replication.

P1053
Precursor frequency of HLA-B27-restricted HIV KK10-specific CD8+ T-cells is not related to their immunodominance

O. Briceño,* A. Moris,* V. Appay,* E. Gostick,† D. Price,† A. Saenz-Cirion,‡ R. Mallone§ & C. Iglesias¶
**Hôpital Pitié-Salpetriere, U945 Infections and Immunity, Paris, France, †Cardiff University, Institute of Infection and Immunity, Wales, UK, ‡Institut Pasteur, Unité de Régulation des infections Rétrovirales, Paris, France, §Université Paris Descartes, UINSERM U986, Paris, France, ¶Hôpital Pitié-Salpetriere, UINSERM U945, Paris, France*

Purpose/Objective: It has previously been demonstrated that HLA-B27 allele is associated with the control of HIV replication and that HIV specific CD8+ T cell responses restricted by this HLA molecule are immunodominant and present superior functional attributes. Studies performed in mice have shown that the frequency of naïve precursors impacts on the quantitative and qualitative attributes of CD8+ T cells during immune responses. We therefore hypothesized that advantageous properties of HLA-B27 restricted HIV specific CD8+ T cells may be linked to the initial frequency of naïve precursors.

The objective of this study was to calculate the frequency and priming capacity of naïve CD8 T cells specific for HIV epitopes restricted by the protective (HLA-B27, KK10) and the non-protective HLA alleles (HLA-A2, S9L or HLA-B7 RL9).
Materials and methods: Our data was generated using blood samples derived from healthy HIV-seronegative subjects. HIV reactive $CD8^+$ T-cell precursors were enriched from 10^8 peripheral blood mononuclear cells (PBMCs) using cognate peptide-HLA class I tetramers and magnetic beads, and their frequency was calculated. We also expanded naïve $CD8^+$ T-cells by performing *ex vivo* priming with peptide-pulsed autologous dendritic cells, which were differentiated using GM-CSF and IL-4 and matured with a cytokine cocktail for 20 days in culture. For comparison, we performed the same assays for HLA-A2 restricted Melan-A (EV10) reactive $CD8^+$ T-cells, known for their high frequency of naïve precursors.
Results: The frequency of Melan-A reactive $CD8^+$ T-cell precursors was >100 cells per million $CD8^+$ T-lymphocytes, In contrast, the frequency of KK10 reactive precursors was approximately 1 cell per million $CD8^+$ T-lymphocytes and was not different from those measured for other HIV specificities. These findings were confirmed using the *in vitro*expansion assay.
Conclusions: Our results suggest that the frequency of naïve precursors *per se,* cannot explain the acquisition of superior functional attributes or the immundominance of KK10/HLA-B27-specific $CD8^+$ T-cell populations in individuals infected with HIV-1.

P1054
Rapid broadening of the CTL responses retards the evolution of immune escapes of HIV

H. W. M. van Deutekom, G. Wijnker & R. J. de Boer
Utrecht University, Theoretical Biology/Bioinformatics, Utrecht, The Netherlands

Purpose/Objective: During the first months of infection with HIV the virus typically evolves immune escape mutations. These escape mutations are found in epitopes from the virus and reduce the selection pressure of CD8+ T cell responses specific for these epitopes. Recent data suggest that most of these immune escape mutations evolve early and rapidly. By using a mathematical model, we try to understand why the evolution of immune escape slows down over the time of infection, and how immune escapes depend on the breadth of the immune response to the virus.
Materials and methods: We used a conventional mathematical model with the main distinguishing feature that several immune responses can together control the virus at steady state (e.g. at the viral set-point). Individual CTL responses appear at different time points during infection.
Results: We find that most escapes occur early, when the diversity of the immune response is still small. A generic feature of the model is that the contribution of each immune response at steady state declines when the number of immune responses increases. Escaping one immune response provides little advantage when the breadth of immune responses is high. The impact of the breadth of the CTL response is even stronger if some of the viral epitopes are difficult to escape and/or the virus has a poor replicative capacity.
Conclusions: The contribution of a single CTL clone decreases when the breadth of the CTL response increases. Escapes therefore tend to happen during early infection because the breadth of the CTL response is still small.

P1055
Single amino-acid change in a highly conserved motif of the gp41 elicits viral neutralization and protects against CD_4 depletion

C. Petitdemange,* A. Achour,* I. Malet,† A. Sennepin,* R. Ho Tsong Fang,‡ J. Crouzet,‡ V. Calvez,‡ P. Debré* & V. Vieillard*
**hôpital Pitié-Salpetriere, immunité et infection, Paris, France, †hôpital Pitié-Salpetriere, Virologie, Paris, France, ‡Innavirvax, innavirvax, Paris, France*

Purpose/Objective: The hallmark of most successful vaccine is the ability to induce cross-reactive neutralizing antibodies (Nabs). For HIV-1, only a handful of broadly Nabs (bNAbs) have thus far been identified. Over the ensuing years, we have shown that a highly specific and conserved motif of the gp41, called 3S, induces expression of NKp44L, the cellular ligand for an activating NK receptor on CD4 T cells render them more sensitive to autologous NK lysis. The aim of this study was to explore the possibility that substitutions inside this 3S motif could permit the development of bNAbs while preserving the capacity to block CD4 depletion.
Materials and methods: To further characterized the 3S peptide, point mutations were introduced inside the 3S motif of the gp41. We tested such effect on the capacities to infect cells and the ability of the corresponding peptides to induce production of Ab that elicit viral neutralization and/or inhibit NKp44L expression on CD4T cells and NK cell function.
Results: In this study, alanine-scanning allowed us to identify specific positions in the 3S motif that inhibit HIV entry and expose it to a broad spectrum of neutralizing antibodies. Importantly, for the first time, we show that specific amino-acid substitutions within a highly linear motif of the gp41 elicit strong neutralization capacity with

impressive magnitude, breadth and ability to durability over cross clade viruses. Furthermore, our data also show that this acquisition of neutralization capacities preserves the unique ability of anti-3S Ab to inhibit NKp44L expression on CD4+T cells and their sensitivity to NK lysis.

Conclusions: Our finding suggest that specific substations into the 3S based immunogens may lead to the generation of bNAbs directed against the 3S conserved motif of gp41 and will provide foundation for a vaccine design based on 'bi-functionals' Abs allowing both viral neutralization and CD4 protection.

P1056

Study on the Functional role of Immunoglobulin E as surrogate marker for HIV/AIDS infection

V. Baghyanathan

Molecular Virology, King Institute of Preventive Medicine & Research, Chennai, India

Purpose/Objective: IgE class of antibodies has been found in mammals and plays an important role in allergic and hypersensitivity reactions. Certain viral infections are known to produce specific IgE antibodies, to the extent that significant changes in the level of total serum IgE may occur. Study attempts to associate the Level of Ig E in HIV progression.

Materials and methods: The study involves fifty HIV seropositive patients attending Anti-Retroviral Therapy Centre, Department of Sexually Transmitted Disease, Rajaji Government Hospital, and Madurai, India subjected for the present study. The individual involves 27 HIV/AIDS Male patients, 23 HIV/AIDS Female patients. The control sample comprises 15 HIV sero negatives. The samples were collected at the informed consent of the patients. Serum sample were collected and IgE was quantified using MAGIWELL IgE quantitative solid phase Enzyme linked Immunosorbent assay (ELISA).

Results: The study documents highest percentage of deviation from the control observed in Male HIV seropositives (43.7%) and age-wise influence documents highest percentage of deviation in the age group 15–29 years (56%).

Conclusions: Serum IgE level in the present study found to be elevated from the normal range documents the existence of imbalance between Th 1 and Th 2 and associated with T-cell dysfunction and a hypergammaglobulinemia. The present results suggest that elevation of circulating IgE levels may be due, at least in part, to specific IgE directed to the HIV virus rather than as a result of a nonspecific phenomenon. HIV infected adults indicate that total IgE is also increased during the early stages of disease, and this elevation appears to be independent of CD4 counts and is not correlated with the levels of other immunoglobulins, suggesting an important role for IgE as a surrogate marker of disease progression Further research need to be exploited to bring out the exact role of IgE in HIV pathogenesis.

P1057

TB-IRIS is marked by acute phase response related elevation of LBP and IL-6

O. Goovaerts,* W. Jennes,* M. Massinga-Loembe,* A. Ceulemans,* W. Worodria,† H. Mayanja-Kizza,† R. Colebunders‡ & L. Kestens*

**Institute of Tropical Medicine, Microbiology, Antwerp, Belgium, †Makerere University College of Health Sciences, Medicine, Kampala, Uganda, ‡Institute of Tropical Medicine, Clinical Sciences, Antwerp, Belgium*

Purpose/Objective: The immunopathogenesis of tuberculosis-associated immune reconstitution inflammatory syndrome (TB-IRIS) is not well understood. The presence of elevated levels of IL-6 and C-reactive protein has been reported in TB-IRIS and are indicative of an acute phase response. Stimulation of the immune system by pathogen associated molecular patterns like lipopolysaccharide (LPS) leads to the production of IL-6 and acute phase proteins. Here we aimed to explore the acute phase response in TB-IRIS, in association with the cytokine storm and plasma markers related to LPS.

Materials and methods: We followed up 254 HIV+TB+ patients at Mulago Hospital in Kampala, Uganda of whom 53 developed TB-IRIS during antiretroviral therapy (ART). We compared 40 of these TB-IRIS patients with 45 HIV+TB+ patients from the same cohort who did not develop TB-IRIS (matched for age, gender and absolute CD4 T-cells). We analysed plasma levels of LPS, LPS-binding protein (LBP), sCD14, endotoxin core antibody (EndoCAb), intestinal-fatty acid binding protein (I-FABP, a marker of enterocyte damage), and 18 different cytokines before and after initiation of ART.

Results: LBP levels in TB-IRIS patients were significantly lower pre-ART ($P = 0.008$) and were sharply increased during TB-IRIS cases compared to HIV+TB+ controls ($P = 0.003$). No differences in sCD14, LPS, EndoCAb and cytokine levels were observed pre-ART between HIV+TB+ patients that did or did not develop TB-IRIS. During TB-IRIS however, higher levels of IL-1ra, IL-6, IL-7, IL-8, IL-10, G-CSF and IP-10 were detected compared to HIV+TB+ controls at comparable time points ($p \leq 0.027$). Surprisingly, I-FABP levels were significantly decreased during TB-IRIS and remained lower than in HIV+TB+ controls during follow-up ($P = 0.005$). No such differences were observed for LPS, sCD14 and EndoCAb. Multivariate analysis showed a central role for IL-6 in the acute phase response during TB-IRIS ($P = 0.001$).

Conclusions: Our data confirm a central role for IL-6 in the inflammation that develops during IRIS, while levels of LPS and EndoCAb suggested no additional effect of bacterial translocation from the gut. TB-IRIS is characterised by lower LBP levels pre-ART, followed by elevated levels during IRIS as part of the acute phase response. These findings suggest that LBP might be a useful marker for TB-IRIS.

P1058

The human leukocyte antigen-G 3'UTR 14-bp deletion is associated with poor survival in an HIV-1-infected Zimbabwean population

M. Larsen,* R. Zinyama,† P. Kallestrup,‡ J. Gerstoft,§ E. Gomo,¶ L. Thørner, T. Berg,** C. Erikstrup†† & H. Ullum****

**Copenhagen University Hospital, Clinical immunology/Blood bank, Copenhagen, Denmark, †Medical research council, Ministry of health and child welfare, Zimbabwe, Zimbabwe, ‡Centre for Global Health, Public Health Aarhus University, Aarhus, Denmark, §Copenhagen University Hospital, Infectious diseases, Copenhagen, Denmark, ¶Medical Laboratory Sciences, University of Zimbabwe, Zimbabwe, Zimbabwe, **Copenhagen University Hospital, Clinical Immunology/Blood bank, Copenhagen, Denmark, ††Aarhus University, Clinical Immunology, Aarhus, Denmark*

Purpose/Objective: To examine the human leukocyte antigen G (HLA-G) 14-bp deletion polymorphism (rs16375) in relation to progression and survival among HIV-1-infected Zimbabwean individuals.

Materials and methods: A treatment-naïve cohort, including 150 HIV-infected and 158-HIV uninfected individuals, was genotyped for rs16375 using a competitive allele-specific PCR system. Survival among HIV-1-infected individuals followed for up to 4.3 years was compared between carriers of the +14-bp allele and -14-bp homozygous carriers by a log-rank test allowing for trend and by Cox proportional hazards regression analysis with adjustment for age and sex.

Results: The *HLA-G* homozygous -14/-14 genotype was associated with lower CD4 cell count ($P = 0.017$) and higher HIV-1 RNA ($P = 0.005$). Furthermore, the *HLA-G* homozygous -14/-14 carriers

had a higher mortality rate compared with non-carriers (hazard ratio = 1.9; $P = 0.04$, CI: 1.033−3.522); however, this difference was not statistically significant after adjustment for CD4 cell count and HIV-1 RNA (hazard ratio = 1.4; $P = 0.29$, CI: 0.753−2.578).
Conclusions: The *HLA-G* 14-bp deletion polymorphism is associated with higher viral load, more advanced progression, and increased mortality. The data suggest that high sHLA-G expression impairs the cytotoxic control of HIV.

P1059

The MHC-II transactivator CIITA is a viral restriction factor against HIV-1 replication

G. Forlani,* E. Vicenzi,† G. Poli,‡ R. Accolla* & G. Tosi*
**General Pathology and Immunology, Surgical and Morphological Sciences, Varese, Italy, †Viral Pathogens and Biosafety, San Raffaele Scientific Institute, Milano, Italy, ‡AIDS Immunopathogenesis Units, San Raffaele Scientific Institute, Milano, Italy*

Purpose/Objective: The MHC-II transactivator CIITA inhibits HIV-1 replication in human T cells by competing with the viral transactivator Tat for the binding to Cyclin T1 of PTEF-b.

Here we analyzed the anti-viral function of CIITA in a monocyte-macrophage model of HIV-1 infection, the U937 promonocytic *Plus* and *Minus* clones characterized by efficient or inefficient capacity to support HIV-1 replication, respectively. Recently, the *Plus* and the *Minus* phenotypes have been correlated to the absence or presence of the host factor TRIM22, respectively. Our purpose was to assess the functional relationships between CIITA and TRIM22.

Materials and methods: MHC-II/CIITA expression was assessed by FACS and QRT-PCR analyses. U937 *Plus* cells were stably transfected with CIITA vector by electroporation. Tat-dependent HIV-1 LTR transactivation was assessed by gene reporter assay. Exogenous CIITA and TRIM22 were co-immunoprecipitated in 293Tcells. *Plus*, *Minus* and *Plus*-CIITA cells infected with HIV-1 IIIB were monitored for RT activity over-time.
Results: U937 *Minus* cells express MHC-II molecules on the cell surface whereas *Plus* cells do not. This phenotype correlates with the expression of CIITA protein restricted to *Minus* cells. Importantly, we show that Tat-dependent HIV-1 LTR transactivation is reduced in *Minus* cells compared with *Plus* cells. The exogenous expression of CIITA did not induce TRIM22 transcription in *Plus* cells, whereas it was sufficient to inhibit Tat activity and to change the HIV-1 permissive phenotype of Plus cells to a non-permissive *Minus* 'like' phenotype.
Conclusions: We uncoupled the role of TRIM22 and CIITA in the inhibition of HIV-1 replication in monocytes cells. The transcriptional activity of Tat and HIV-1 productive infection were inhibited not only in TRIM22/CIITA-expressing *Minus* cells but also in *Plus* cells expressing exogenous CIITA. Thus, CIITA inhibits Tat-activity independently of TRIM22.

These findings demonstrate that CIITA has a dual function against HIV-1: it triggers the adaptive immune response by promoting viral antigen presentation and it acts as an endogenous restriction factor against viral transcription.

Poster Session: Inflammatory & Atopic Skin Disease

AGF inhibited a LPS-induced inflammatory response by blocking NF-kappaB activity in raw 264.7 cells

T. J. Kim, Y. J. Kim, S. J. Park & H. H. Kim
Division of Biological Science and Technology, Yonsei University, Wonju, Korea

Purpose/Objective: Inflammation is a system used by a host to defend against the presence of bacteria, viruses, or yeasts. Toll-like receptors (TLRs) in the plasma membranes of macrophages are activated when they recognize the molecular structure of a virus or bacterium. Lipopolysaccharide (LPS), an outer cell-wall component of Gram-negative bacteria, initiates an inflammatory process *via* TLR4. We investigated the effect of the extract of *Anethum graveloens* flowers (AGFs) on LPS-mediated inflammation in RAW 264.7 cells.
Materials and methods: The amount of NO production in LPS-induced macrophages was measured using Griess reagent. If AGF has a toxic effect on cells, one must distinguish such an effect from that of NO production, which also reduces the viability of LPS-induced cells. Hence, we compared cell cytotoxicity in RAW 264.7 cells incubated with AGF for 24 h using an EZ-Cytox kit. In addition, we investigated to determine whether the suppression of NO production was due to downregulation of iNOS expression. LPS-induced mRNA expression and the protein levels of iNOS were investigated in this experiment. In order to determine the effects of AGF on cytokines, we analyzed cytokine mRNA levels by RT-PCR. We further confirmed that the capability of AGF to activate the LPS-induced signal pathway involves downstream signal molecules such as MAPKs and Akt.
Results: The extract markedly suppressed nitric oxide generation in a concentration-dependent manner in LPS-stimulated RAW 264.7 cells. It inhibited inducible nitric oxide synthase (iNOS) and the mRNA expression of cytokines such as interleukin-1 beta and interleukin-6 in LPS-stimulated RAW 264.7 cells. It also inhibited iNOS protein levels in LPS-stimulated RAW 264.7 cells. In addition, AGF decreased the LPS-induced phosphorylation of mitogen-activated protein kinases in LPS-stimulated RAW 264.7 cells. AGF inhibited the phosphorylation of Akt, an upstream molecule of the nuclear factor kappa B (NF-kB) pathway, and thus inhibited NF-kB activity in LPS-stimulated RAW 264.7 cells.
Conclusions: These results suggest that AGF exerts an anti-inflammatory effect in LPS-stimulated RAW 264.7 cells by inhibiting iNOS expression and blocking the NF-kB pathway.

Cellular phenotypes implicated in reversal reaction in co-infected HIV/leprosy patients

A. L. Oliveira, T. P. Amadeu, V. M. Menezes, A. C. F. Gomes, J. A. Nery, R. O. Pinheiro & E. N. Sarno
FIOCRUZ, Leprosy, Rio de Janeiro, Brazil

Purpose/Objective: The expanded availability of antiretroviral therapy (HAART) has added another layer of complexity to the understanding of HIV/leprosy pathogenesis. It has been reported that the initiation of HAART is associated with the development of reversal reaction (RR) in co-infected HIV/leprosy patients. However, the impact of HIV infection and HAART on the cellular immune response to *M. leprae* (ML) remains unknown. This study investigated the immunological profile of HIV/leprosy patients giving special attention to the cellular activation status and memory profile of CD4+ and CD8+ T cells.
Materials and methods: Twenty-five individuals were assessed: co-infected HIV/leprosy patients with RR (RR/HIV); leprosy patients with RR without HIV (RR); and healthy controls (HC). IFNg production in PBMC culture was analyzed by ELISPOT. T cell subsets were evaluated by flow cytometry for immune differentiation/activation markers. Skin biopsies were also evaluated for T cell subsets by immunofluorescence.
Results: IFNg production in non-stimulated (NS) cells from RR/HIV group was higher than in RR and HC groups. RR patients also presented high IFNg production in response to ML independently of HIV infection. Cellular activation in RR/HIV patients was increased in both CD4+ and CD8+ T cells in comparison to RR and HC group as reflected by the expression of CD38 and CD69. These activation markers were also increased in PBMC from RR/HIV patients after ML stimulus. Analysis of skin biopsies from RR/HIV patients also showed augmented expression of CD38 and CD69 co-localizing with CD4 and CD8 T cells. A higher frequency in central and effector memory CD8+ T cells in response to ML in RR/HIV patients was also observed. The production of granzyme B and perforin by effector memory CD8 T cells in response to ML was associated with an increase in the death of ML-infected monocyte cells.
Conclusions: These data suggest that CD38 expression in CD8 T cells might be utilized as a tool to identifying HIV/leprosy individuals at risk for RR. Besides this, an increase percentage of cytotoxic CD8 effector memory T cells could be an additional mechanism in mediating the appearance of RR in co-infected patients. Furthermore, the immune response to ML in RR/HIV patients appears to be restored during HAART therapy as indicate by the increase in IFNg production.

CINCA syndrome in an infant presenting with hydrocephalus

O. Turel,* S. Uzunel,* O. Keskin,† B. Akovali,* U. Erenberk* & B. Tatli*
**Paediatrics, Bezmialem Vakif University, Istanbul, Turkey, †Dermatology, Bezmialem Vakif University, Istanbul, Turkey*

Purpose/Objective: Chronic infantile neurological cutaneous and articular syndrome (CINCA) is a very rarecongenital autoinflammatory disease. It is characterized by neonatal onset urticarial-like rash, recurrent fever, central nervous system (CNS) involvement, and chronic arthropathy, peculiar facial and morphological features. Local and systemic manifestations of disease develop as a result of elevated IL-1b production which may be related to missense mutations within the gene encoding cryopyrin.
Materials and methods: We describe an infant with CINCA syndrome who developed hydrocephalus.
Results: A seven months old boy admitted with chronic urticaria and hydrocephalus. He was born by normal vaginal delivery following an unremarkable pregnancy. The parents were healthy and nonconsanguineous. He had attacks of urticarial rash beginning from birth, recurrent episodes of fever and progressive enlargement of head after 4 months. Blood tests showed leukocytosis, anemia, elevated acute phase reactants. Investigations for intrauterine infections and metabolic diseases were negative. Immunological workup did not reveal any congenital immunodefficiency. Cerebrospinal fluid (CSF) examination was compatible with chronic meningitis. Antibiotic treatment failed to alleviate the clinical symptoms. He wasdiagnosed as having CINCA on clinical grounds.
Conclusions: CINCA syndrome is a well-defined clinical condition but its early identification is often missed. The IL-1Ra (Anakinra) treatment has given good results in CINCA subjects. Pediatricians should be aware of this rare condition in order to detect it quickly and start the appropriate treatment as soon as possible, allowing to stop the disease progression to the severe degrees such as deafness and mental retardation.

Dermatology, College of Medicine, The Catholic University of Korea, Seoul, Korea, †Dermatology, Chung-Ang University Hospital, Seoul, Korea

Purpose/Objective: Our aim was to determine whether topically applied rapamycin and/or MPA is effective in AD-liked skin lesions of NC/Nga mice.

Materials and methods: Four per cent rapamycin and/or 1% MPA were applied to the 2-chloro-1,3,5-trinitrobenzene (TNCB)-induced AD-like skin lesions in NC/Nga mice 5 days a week for 2 weeks. The mice were divided into nine groups: non-treated, TNCB only, vehicle, 4% rapamycin, 1% MPA, 4% rapamycin and 1% MPA mixtures (Rapamycin: MPA = 2:8, 5:5 and 8:2 ratio) and 0.03% protopic. The clinical efficacy of drugs was evaluated by ear thickness and severity scores of skin lesions. Histological inflammatory changes and mast cell infiltration were evaluated by H&E and toluidine blue stain, respectively. The mRNA and protein expression level of IL-4 and IFN-γ in skin lesions was determined by quantitative RT-PCR and immunohistochemistry.

Results: Topical application of 4% rapamycin and/or 1% MPA significantly reduced the clinical skin severity and mast cell infiltration in the TNCB-induced AD-like skin lesions, compared with vehicle ($P < 0.05$). One percent MPA markedly reduced both IFN-γ and IL-4 mRNA expression level compared with vehicle ($P < 0.05$), whereas 4% rapamycin significantly reduced IFN-γ but not IL-4 mRNA expression level, compared with vehicle ($P < 0.05$). Our results demonstrate that topical rapamcyin and/or MPA suppress TNCB-induced AD-like skin lesions of NC/Nga mice by suppressing the local Th2 and Th1 response.

Conclusions: These findings suggest that rapamycin and/or MPA may be one of the promising topical therapeutic candidates for AD.

P1065

Eriodictyol inhibits mast cell degranulation through the inhibition of ceramide kinase

T. J. Kim, J. M. Yoo, H. H. Kim & S. J. Park

Division of Biological Science and Technology, Yonsei University, Wonju, Korea

Purpose/Objective: Mast cells are the principal effector cells involved in allergic response, through the release of histamine. Eriodictyol is a unique constituent of the painted maple (*Acer mono*) and yerba santa (*Eriodictyon californicum*). Pharmacological activities attributed to eriodictyol include the control of blood vessel permeability in arthralgia and fracture, as well as antioxidant and antimicrobial effects. However, the anti-allergenic activity of eriodictyol has not been evaluate We investigated the effect of eriodictyol on mast cell degranulation and on an allergic response in an animal model.

Materials and methods: *Passive cutaneous anaphylaxis (PCA) analysis.*

The PCA animal model is widely used to evaluate the localized mast cell-mediated allergic reaction *in vivo*. We tested the effect of eriodictyol on allergic response in the passive cutaneous anaphylaxis (PCA) reaction.

β-hexosaminidase release assay.

The RBL-2H3 mast cell line was established from a rat basophilic leukemia. We evaluated the release of preformed allergic mediators using β-hexosaminidase as a biomarker of degranulation in the mast cells and then measured cell viability. The release of β-hexosaminidase was first measured following stimulation of the IgE-Ag complex.

Measurement of ceramide.

We measured the ceramide levels in mast cells. Ceramide is a sphingolipid and an effector in proinflammatory processes. Accordingly, we tested the effect of eriodictyol on ceramide levels in IgE/Ag-stimulated mast cells using HPLC.

Results: We also investigated the effect of eriodictyol on expression of the CERK involved in calcium-dependent degranulation, and on ceramide activation by multiple cytokines. Eriodictyol suppressed the release of beta-hexosaminidase, a marker of degranulation, and the expression of interleukin IL-4 mRNA. Eriodictyol inhibited the expression of CERK mRNA, reduced ceramide concentration in antigen-stimulated mast cells and suppressed the passive cutaneous anaphylaxis reaction in mice in a dose-dependent manner.

Conclusions: These results suggest that eriodictyol can inhibit mast cell degranulation through the inhibition of ceramide kinase, and that eriodictyol may potentially serve as an anti-allergic agent.

P1066

Evaluation of platelet functions using impedance aggregometer

N. Isiksacan,* M. Koser,* F. Cemsitoglu,† U. C. Kucuksezer,‡ I. Bakir§ & G. Deniz‡

Biochemistry, Mehmet Akif Ersoy Thoracic & Cardiovascular Surgery Training and Research Hospital, Istanbul, Turkey, †Dermatology, Mehmet Akif Ersoy Thoracic & Cardiovascular Surgery Training and Research Hospi, Istanbul, Turkey, ‡Immunology, Istanbul University DETAE, Istanbul, Turkey, §Mehmet Akif Ersoy Thoracic & Cardiovascular Surgery Training and Research Hospital, Istanbul, Turkey

Purpose/Objective: Platelets are playing a major role in primary haemostasis. Their main functions are adhesion, secretion, aggregation and procoagulant activity. Formation of a hemostatic plug in response to vessel wall injury requires functional platelets and defects platelet functionsdefined as 'Platelet Dysfunctions'. Chronic urticaria (CU) is a relapsing disease of skin, associated with itching of swelling skin and erythema, which lasts for 6 weeks or longer. Several studies indicate coagulopathy may be involved in CU etiology. The aim of this study was to investigate the platelet functions using impedance aggregometer method in CU patients.

Materials and methods: Patients diagnosed as 'CU' from dermatology outpatient clinic were enrolled to the study. Venous blood samples from 32 patients with CU as well as 26 healthy controls were collected. Platelet counts and functions were measured. Patients with hereditary/acquired angioedema, anaphylaxis, as well as urticaria-related or systemic vasculitis- patients were excluded from the study. It was confirmed that none of the patients received oral anticoagulant drug treatment, had any infection, thromboembolism, hepatic or cardiac disease or underwent any surgical treatment. Healthy subjects had similar age and gender distribution as well as the patient population. Statistical analysis was performed by using student's *t*-test. Platelet function analysis was performed as *in vitro* platelet activation and aggregation using impedance aggregometer method. Platelets were stimulated with ADP, ASP, TRAP and ristocetin agonists. Platelet aggregations were measured as 'Area Under Curve' (AUC).

Results: Response of platelets from CU patients to ADP ($P < 0.017$), TRAP ($P < 0.042$), ristocetin ($P < 0.028$) were decreased in comparison to healthy controls. Platelet counts ($P = 0.587$) and response to ASP ($P = 0.178$) did not differ in both groups.

Conclusions: Impedance aggregometer method is frequently used in determining prehaemostatic effects of antithrombotic therapies in clinical studies and in clinical practice. In this study platelet functions of chronic urticaria patients and healthy controls weremeasured with impedance aggregometer and different responses after stimulations of agonists were observed. The use of this methodology seems to be accurate and valuable in clinical practice.

P1067

Expression of histamine H4 receptor in human skin and amelioration of experimental acute pruritus using H4 receptor antagonist

K. Yamaura,* E. Suwa,* M. Suzuki† & K. Ueno*
*Department of Geriatric Pharmacology and Therapeutics Graduate School of Pharmaceutical Sciences, Chiba University, Chiba, Japan, †Research Center for Frontier Medical Engineering, Chiba University, Chiba, Japan

Purpose/Objective: Histamine is a potent mediator of itch in humans, yet histamine H1 receptor (H1R) antagonists have been shown to be of limited use in the treatment of pruritic diseases. Recently described histamine H4 receptors (H4R) are expressed in hematopoietic cells and have been linked to the pathology of atopic dermatitis and asthma. Recent studies have raised the possibility that H4R may be involved in pruritic responses. Here we investigated the expression of H4R in human skin and efficacy of the H4R antagonist on pruritus using experimental mice model of acute pruritus.
Materials and methods: Dermal tissue specimens were obtained from osteoarthritis patients, and immunofluoresence staining was performed to ascertain whether H4R is expressed in human epidermal tissues or dermal fibroblast cultures. Scratching behavior was induced by histamine (300 nmol), substance P (100 nmol) or serotonin (100 nmol) injected intradermally into the rostral part of the back of each mouse. Mice model of dry skin pruritus was created by topical application of distilled water following acetone/diethylether (1:1) mixture twice daily upon the shaved area for 5 days. Fexofenadine (30/60/150 mg/kg), a selective H1R antagonist and JNJ7777120 (3/10/30 mg/kg), a selective H4R antagonist were administrated orally.
Results: Immunohistochemical staining showed that K10-positive differentiated keratinocytes in the prickle cell layer and granular layer of epidermis strongly expressed H4R. In contrast, H4R expression was less in K14-positive proliferating keratinocytes in the basal layer. Cultured human dermal fibroblasts also express the H4R. The H4R antagonist JNJ7777120 significantly reduced histamine- and substance P-induced scratching behavior in a dose-dependent manner. Moreover, JNJ7777120 reduced dry skin-induced scratching behavior. However, the inhibitory effects of fexofenadine, a H1R antagonist, on pruritus of these models were much smaller than that of JNJ7777120. Neither fexofenadine nor JNJ7777120 showed reduction in serotonin-induced scratching.
Conclusions: Results of this study suggest that keratinocytes increase expression of H4R following differentiation. Moreover, as suggested in this study, histamine may have an involvement via the H4 rather than the H1R in histamine- and substance P-induced pruritus and dry skin-induced pruritus. The H4R antagonist may be useful for the treatment of H1R antagonist-resistant pruritus.

P1068

Hidradenitis suppurativa is characterized by a defect of Th17/Th22 CD4+ T cells and an infiltration of regulatory T cells in the skin

C. Hotz,* A. Guguin,* M. Surenaud,* N. Ortonne,† R. Bosc,‡ P. Wolkenstein,§ S. Hüe* & Y. Lévy*
*Faculte de médecine de Créteil, INSERM U955 team 16 UPEC, Créteil, France, †Hôpital Henri-Mondor, Pathology, Créteil, France, ‡Hôpital Henri-Mondor, Plastic surgery, Créteil, France, §Hôpital Henri-Mondor, Dermatology, Créteil, France

Purpose/Objective: Hidradenitis suppurativa (HS) is a chronic, inflammatory skin disease. Medical treatments in use for HS (antibiotics and immunosuppressive agents) point out to a deregulated immune response against microflora. *In situ* antimicrobial defense requires a balance between inflammatory and protective T cell responses and their regulation through a Th17/IL-22/Treg axis. We investigated this pathway in the blood and the skin of HS patients.
Materials and methods: Analyses of the phenotype and functional profile of T cell populations in PBMCs from HS ($n = 17$) and healthy donors (HDs; $n = 11$) were performed *ex vivo* and following *in vitro* stimulation. Production of cytokines (IL-17, IL-22, IFN-g) and expression of transcription factors (T-bet, RORgt, Foxp3) were assessed using qRT-PCR, multiparametric flow cytometry and functional assays using ELISA and luminex technologies. *In situ*, T cell populations were characterized by Histo-immunochemistry (HIC).
Results: HS patients exhibited a higher frequency of CD4+IL-17A+(median 2%) and CD4+IL-22+(1.32%) in the blood as compared to HDs (0.85% and 0.53%, respectively) ($P < 0.05$). Frequency of $CD4^+$ IL22+ expressing CCR10, a skin homing receptor, was significantly increased in HS (15.3% as compared to 8.1% in HDs) ($P = 0.033$). There was no difference between groups in the frequency of $CD4^+$ $CD25^{high}FoxP3^{high}CD127^{low}$ Treg. Stimulation of PBMC with either flagelline, *staphylococcus aureus* or *candida albicans* led to a higher production of IL-17, IL-22 and IFN-g in HS patients as compared to HDs. Expression of CD3, IFN-g, and FoxP3 mRNAs was increased in the skin of HS patients ($n = 4$) as compared to HDs ($n = 5$). In contrast IL-22 and RORgt RNA expression was decreased in HS patients. HIC analyses confirmed an infiltration of Treg, but not $IL\text{-}17^+$ T cells in the skin of HS.
Conclusions: HS patients are characterized by a high frequency of proinflammatory functional memory Th17/Th22 T cells in the blood capable to respond to bacterial products. Despite expressing homing receptors, a lower frequency of these cells was noted in the skin of patients, in contrast, to a higher infiltration of Treg. These results raise several hypotheses such as a defect of local production of antimicrobial peptides, key triggers of T cell homing, leading to the chronic perpetuation of inflammation in skin lesions.

P1071

Relationship of interleukin-13 and interleukin-33 serum concentration and selected clinical and immunological parameters in patients with atopic dermatitis

A. Pszonak,* W. Owczarek,* E. Paluchowska* & J. Olkowska-Truchanowicz†
*Department of Dermatology, Military Institute of Health Services, Warsaw, Poland, †Department of Transplantology and Central Tissue Bank, Center of Biostructure Research Medical, University of Warsaw, Warsaw, Poland

Purpose/Objective: Interleukin-13 (IL-13) coordinates the allergic inflammation process. It stimulates lymphocytes B to IgE synthesis, affects the differentiation's process and survival time of mastocytes and eosinophils. Interleukin-33 (IL-33) stimulates mastocytes, eosinophils, basophils and Th2 lymphocytes to secrete IL-13. The possible role of these cytokines in the pathogenesis of AD is indicated. To assess the relationship between serum level of IL-13 and IL-33 and severity of disease, extension of skin lesions and immunological parameters as total serum concentration of immunoglobulin E (total IgE), the amount of white blood cells and elements of leucogram in AD patients.
Materials and methods: The study involved 60 patients with AD (32 women, 28 men) aged of 18−54 years and 20 healthy volunteers of control group. AD was diagnosed according to criteria of Hanifin and Rajka. Serum concentration of interleukins was evaluated by immunosorbent assay (R&D, USA). The extension of skin lesions and SCORAD were rated in patients, total IgE in serum and the number of white blood cells with the elements of leucogram was determined.
Results: The mean concentration of IL-13 in AD patients' serum was 154.4 pg/ml (95% CI = 91−217) and IL-33 14.1 pg/ml (95% CI = 12.3−16). The mean concentration of IL-13 in healthy subjects

was 149.5 pg/ml (95% CI = 132.1−167) and was significantly lower ($P = 0.01$) and IL-33 18.4 pg/ml (95% CI = 16.2−20.7) and was significantly higher ($P = 0.01$) than in AD patients. The average extension of skin lesions was 33.4% (95% CI = 25.4−41.4) and the average severity of disease was 53.7 (95% CI = 49−58.3). The study found a statistically significant correlation between serum concentration of IL-33 and the extension of skin lesions ($P = 0.03$) and severity of disease ($P = 0.03$). The mean concentration of total IgE in serum was 2500IU/ml (95% CI = 843−4157). Relationship between serum concentration of interleukins and total IgE in serum did not show significant dependency. The evaluation of dependencies between the number of white blood cells, elements of leucogram and serum concentration of interleukins shows a statistically significant correlation with IL-13 and the percentage of lymphocytes ($P = 0.03$) and basophils ($P = 0.03$).

Conclusions: The mean concentration of IL-13 in serum is significantly higher and IL-33 is significantly lower in AD patients compared to healthy subjects. Serum concentration of IL-33 has a positive correlation with the extension of skin lesions and the severity of disease.

P1072
Role of the Aryl hydrocarbon receptor in skin inflammation

J. H. Duarte,* P. Di Meglio,* K. Hirota,* F. O. Nestle† & B. Stockinger*

**Molecular Immunology, MRC National Institute for Medical Research, London, UK, †King's College London, St. John's Institute of Dermatology, London, UK*

Purpose/Objective: The Aryl hydrocarbon receptor (AhR) recognizes polycyclic aromatic hydrocarbons (PAHs), a family of structurally related environmental contaminants. Recently, AhR ligation was shown to amplify the developmental program of Th17 cells and to induce IL-22. By being in constant contact with the environment, the skin is exposed to multiple pollutants that are potential AhR agonists. Exposure to the best known AhR ligand, dioxin, for instance, leads to a severe skin disorder in humans. Taking into consideration the broad expression of AhR in the skin, which includes lymphocytes, dendritic cells and epithelial cells, we aim at defining skin immune responses in wild-type and AhR-deficient mice in order to assess the impact and integration of AhR activation on different cells in the skin.

Materials and methods: For this end we are making use of *in vivo* models of sterile injury (mechanical skin wounding), infection (*Candida albicans* skin infection) and immune-pathology (Imiquimod-induced psoriasiform skin inflammation). Parameters analysed included histological analysis of the skin and assessment of transcriptional changes, immune cell infiltration and *ex vivo* measurement of pro-inflammatory mediator secreted by resident and recruited skin cells. Additionally, the effect of dietary, endogenous and environmental AhR ligands on different cell types and its consequences for the development of skin inflammation are being assessed.

Results: The inflammatory reaction following simple mechanical skin injury was found to be stronger in AhR-deficient mice, which displayed an increased influx of neutrophils to the injury site. Similar results were obtained in the *Candida albicans* skin infection model, where the higher inflammatory milieu of the infected skin appeared to be detrimental for the infection clearance, as mice lacking AhR had higher fungal burden. Moreover, lack of AhR resulted in a more severe phenotype induced by the TLR7/8 agonist imiquimod, with increased thickness of the epidermis, neutrophils and inflammatory macrophage infiltration, and expression of key pro-inflammatory cytokines and chemokines.

Conclusions: Taken together, our results suggest that AhR signalling has a critical role in dampening immune processes in the skin. Future work will dissect the mechanisms underlying the stronger inflammatory response observed in AhR-deficient mice using cell type-specific AhR-deficient mice, to address what effect the lack of AhR in different cell types present in the skin has in different models of skin inflammation.

P1074
Th17 cells favor inflammatory responses while inhibiting collagen production by SSc fibroblasts

N. C. Brembilla,* E. Montanari,* M. E. Truchetet,* E. Raschi,† C. B. Chighizola,‡ P. L. Meroni‡ & C. Chizzolini*

**Immunology and Allergy, University of Geneva Medical School, Geneva, Switzerland, †Immuno-Rheumatology, IRCSS Istituto Auxologico Italiano, Milan, Italy, ‡Immuno-Rheumatology, IRCSS Istituto Auxologico Italiano and Istituto G. Pini University of Milan, Milan, Italy*

Purpose/Objective: Th17 cells are augmented in Systemic Sclerosis (SSc), an autoimmune disease characterized by fibrosis of the skin and internal organs due to uncontrolled fibroblast activation. Our aim was to assess whether Th17 cells and IL-17A could modulate inflammatory and fibrotic responses in dermal fibroblasts from SSc and healthy individuals (HD).

Materials and methods: Fibroblasts were obtained from eight SSc skin biopsies and abdominoplasty pieces of 8 age/sex matched HD. Th17 cell clones were generated from the peripheral blood of HD upon enrichment of cells expressing CCR4/CCR6/CD161 and their cytokine production assessed by FACS analysis and multiplex beads immunoassay. MCP-1, IL-8, MMP-1 and type I collagen production was quantified in fibroblast supernatants by ELISA and RIA, and relative change in their transcription levels assessed by real-time PCR. IL-17 neutralizing antibody was used to confirm the specificity of the effects. Signaling events induced by IL-17A were investigated by western blotting and pharmacological inhibitors used to dissect the pathways involved.

Results: IL-17A increased MCP-1 ($P < 0.01$), IL-8 ($P < 0.01$) and MMP-1 ($P < 0.01$) production in a dose-dependent manner, while having no effect on type I collagen synthesis in 8 HD and 8 SSc fibroblasts at both protein and mRNA level. IL-17A induced the production of pro-inflammatory chemokines MCP-1 and IL-8 by triggering NF-kB and p38 signaling, while enhancing MMP-1 via activation of the JNK pathway. Supernatants of activated Th17 clones strongly enhanced MCP-1, IL-8 and MMP-1 production while inhibiting collagen synthesis. IL-17A neutralization proved the role of IL-17A in mediating Th17 effects. In clone supernatants, IL-17A had an additive/synergistic activity with TNF, as shown by IL-17A/TNF blockade. Consistently, IL-17A synergized with TNF in enhancing MCP-1, IL-8 and MMP-1 production when added to fibroblast cultures. Finally, TNF/IL-17 blockade in Th17 clone supernatants resulted in enhanced collagen production specifically in SSc fibroblasts.

Conclusions: Th17 cells elicit *in vitro* pro-inflammatory responses while limiting collagen production by fibroblasts. The increased Th17 cell number observed in SSc may impact on the inflammatory component of the disease and have rather a protective role against fibrosis.

P1075
The levels of cytokines, serum IgE and melatonin in children with atopic dermatitis with sleep disturbance

C. Yung-Sen*, L. Jyh-Hong,* S. Chi,* L. Pei-Lin,† L. Yu-Tsan,* W. Li-Chieh,* Y. Hsin-Hui,* Y. Yao-Hsu* & C. Bor-Luen*

**Department of Pediatrics, National Taiwan University Hospital, Taipei, Taiwan, †Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan*

Purpose/Objective: Patients with atopic dermatitis (AD) frequently reported disturbed sleep leading to impaired quality of life. The aims of

this study are to objectively measure the characteristics of their sleep disturbance, to determine the potential roles of scratching, cytokines, and melatonin, and to evaluate the impact of sleep disturbance on behavior.

Materials and methods: Forty-six AD patients and 32 healthy controls between 1 and 18 years old were enrolled. Subjective sleep quality is evaluated by questionnaire. Objective sleep parameters were determined by polysomnography and actigraphy. Serum levels of cytokines related to sleep (IL-1β, IL-4, IL-10, IL-6) and itch (IL-31 and INF-γ), serum total immunoglobulin E (IgE) levels, and urine melatonin sulfate levels were measured on the subsequent morning. The SNAP-IV and the Strength and Difficulties (SDQ) questionnaires were used to evaluate behavior.

Results: Subjective recognition of poor sleep quality was present in 60.9% of AD patients, compared with only 6.3% in controls. Objective measurements showed that sleep efficiency was lower in AD patients ($72.2 \pm 10.2\%$ versus $81.2 \pm 7.6\%$, $P < 0.001$). Sleep onset latency and wake time after sleep onset are longer in AD patients. Disease severity of AD was related to sleep efficiency ($r = -0.52$, $P < 0.001$) and movements in sleep ($r = 0.69$, $P < 0.001$). Total serum IgE levels were correlated with sleep efficiency ($r = -0.46$, $P = 0.001$). Morning urine melatonin sulfate level was higher in AD patients (87.7 ± 42.9 versus 71.1 ± 55.2 ng/ml, $P < 0.001$), and was correlated with sleep efficiency ($r = 0.41$, $P = 0.01$). Serum IL-1β, IL-4, IL-10, IL-6, IL-31 and INF-γ levels were not associated with sleep parameters. Lower sleep efficiency in AD patients is associated with higher oppositional defiant disorder score of SNAP-IV ($r = -0.47$, $P = 0.002$), and higher conduct problems score and total difficulties score in SDQ ($r = -0.42$, $P = 0.009$ and $r = -0.35$, $P = 0.027$, respectively).

Conclusions: Objective evaluation with polysomnography and actigraphy showed that poor sleep efficiency is common in AD patients, is associated with disease severity, and may have impact on behavior. Scratching movements, serum IgE, and melatonin might play a role in their sleep disturbance, and further studies are required to explore the mechanisms.

P1076

Truncated forms of IL-36alpha, beta and gamma cause mast cell activation and enhance the sensitivity of mast cells to stimulation via FcepsilonR1

H. Sandig, C. E. Jobbings & S. Bulfone-Paus
School of Translational Medicine, University of Manchester, Manchester, UK

Purpose/Objective: IL-36α, β and γ (previously IL-1F6, IL-1F8 and IL-1F9) are IL-1 family members that signal via the receptor IL-1Rrp2 in complex with IL-1RAcP. Levels of IL-36α are increased in psoriatic skin, suggesting that the cytokine may play a role in the disease, and in support of this over-expression of IL-36α in keratinocytes causes skin inflammation in mice. Until recently, it has been difficult to study the IL-36 cytokines *in vitro* since the full length proteins are only active at high concentrations. It is now known, however, that N-terminal processing increases their potency a thousand-fold. It seems likely that the IL-36 cytokines are processed *in vivo* in a similar manner to IL-1α and β, producing more potent agonists. The truncated proteins have been shown to activate T cells and dendritic cells to produce cytokines and upregulate co-stimulatory molecules. Since mast cells are found at high numbers in the skin and are implicated in psoriasis and skin inflammation, we investigated whether IL-36α, β and γ can activate mast cells.

Materials and methods: Experiments were carried out *in vitro* using bone marrow derived mast cells (BMMCs).

Results: We find that BMMCs express the specific receptor for IL-36, IL-1Rrp2, and that the IL-36 cytokines cause bone-marrow derived mast cells to secrete IL-6, with IL-36β and γ being the most potent of the three. IL-36 increases the response of mast cells to stimulation via FcεR1, in a similar manner to that observed to occur with IL-33. Interestingly, BMMCs deficient in another IL-1 cytokine family receptor, ST2, are significantly less able to respond to IL-36α, β and γ. It is possible that ST2 is required for the expression of IL-1Rrp2 or IL-1RAcP in mast cells, or is involved in signal transduction after stimulation with IL-36α, β and γ.

Conclusions: These findings may be of particular relevance in disease settings where IL-36 is expressed, for example in psoriatic legions. The cytokine could act to cause mast cell pro-inflammatory cytokine secretion in addition to enhancing the response of mast cells to antigen, therefore exasperating inflammation.

Poster Session: Inflammatory Bowel Diseases

Allogeneic mesenchymal stromal cells (MSC) transplant in experimental inflammatory bowel disease: modulation of gut inflammation and IL-17 dependent responses

H. Ogata,* B. C. Sousa,* V. B. F. Alves,* K. C. R. M. Farias,† J. C. Voltarelli,† V. J. D. Silva,* V. Rodrigues Junior,* J. E. L. Chica,* J. S. Silva† & C. R. B. Cardoso‡

**Department of Biological Sciences, Federal University of Triângulo Mineiro, Uberaba, Brazil, †Faculty of Medicine of Ribeirão Preto, University of São Paulo, São Paulo, Brazil, ‡Faculty of Pharmaceutical Sciences of Ribeirão Preto, University of São Paulo, São Paulo, Brazil*

Purpose/Objective: Inflammatory Bowel Diseases (IBD) is chronic inflammation of the intestinal mucosa, with uncontrolled Th1 and Th17 responses. Although there are current therapies, no treatment is at present fully effective. Since Mesenchymal Stromal Cells (MSC) is multipotent, regulatory and immunosuppressive cells, they emerge as a therapeutic option for various immune disorders. The objective was to evaluate the role of allogeneic MSC transplant in the treatment of experimentally induced IBD.
Materials and methods: IBD was induced in BALB/c mice with intrarectal injection of Trinitrobenzene Sulfonic Acid (TNBS). MSC were isolated from bone marrow of C57BL/6 mice, cultured and phenotyped for characterization. IBD mice received intraperitoneal injection of MSC 24 h after disease induction and were euthanized 3, 7 and 14 days later for sample collection, besides clinical evaluation of gut inflammation.
Results: MSC cultures in 4th passage showed characteristic markers, such as CD105, CD73, CD44, CD90, CD29, although CD45, CD31, CD34 and CD11b were also found, indicating some contamination of the MSC culture with cells of hematopoietic lineages. Even though, IBD mice treated with MSC presented gain of weight and reduced clinical score compared to not treat mice. There was an apparent increase in eosinophil and reduction in neutrophil influx in treated animals' colon. Regarding intestinal cytokines, we found an increase of IL-10 and IL-12 on day 3 together with a strong reduction in IL-17 after MSC treatment. In histological analysis, the percentage of goblet cells was higher in treated group than in not treated mice, showing restoration of intestinal morphology by MSC transplant.
Conclusions: MSC are able to modulate gut inflammation and IL-17 responses in experimental IBD model. Thus, MSC treatment of IBD may be a novel therapeutic tool aimed at modulating mucosal immune responses without apparent or undesirable adverse effects.

P1080
Anti-TNF therapy response in patients with inflammatory bowel disease is associated with T cell expression of CD25 and TNF receptor 2

M. K. Magnusson,* H. Strid,† R. Dahlén,* A. Bajor,† M. Simrén† & L. Öhman†

**Department for Microbiology and Immunology, University of Gothenburg Inst for Biomedicine, Gothenburg, Sweden, †Department for Internal Medicine and Clinical Nutrition, University of Gothenburg Inst for Medicine, Gothenburg, Sweden*

Purpose/Objective: Anti-tumor necrosis factor (anti-TNF) agents are effective treatment options for certain patients with corticosteroid dependent or refractory inflammatory bowel disease (IBD). However, the cellular mechanisms behind anti-TNF treatment leading to therapy response are still incompletely known.
Materials and methods: Blood samples were obtained before first treatment (visit 1) and 2 weeks post treatment (visit 2) from patients who commenced anti-TNF treatment. The disease activity was assessed by the validated Mayo score and Harvey-Bradshaw Index (HBI). Response was defined as a decrease in Mayo score or HBI with ≥3. The immunological effects of anti-TNF therapy were studied on freshly isolated cells and cells stimulated *ex vivo* with influenza vaccine, using flow cytometry.
Results: We have included 23 IBD patients (6 CD and 17 UC) into the study. Sixteen patients responded to the anti-TNF therapy, whereas seven patients did not respond. A reduction in the proportion of circulating $CD25^+$ CD4+ T cells [23.9 (5.3−49.6) versus 20.7 (4.4−38.5), $P = 0.003$] among freshly isolated cells was detected in responders when comparing the first visit (pre treatment) and the second visit (2 weeks post treatment). In contrast, non-responders showed an increased frequency of $CD25^+$ CD4+ T cells [14.3 (6.4−33.4) versus 25.3 (6.6−45.2), $P = 0.03$] when comparing visit 1 and 2. Levels of $FoxP3^+$ CD4+ T cells and $AnnexinV^+$ CD3+ T cells were similar between both patient groups. Also, there was no difference in expression levels of TNF receptor 1, TNF receptor 2 (TNFR 2) or membrane bound TNF on circulating T cells or monocytes. To compare the T cell phenotype of therapy responders and non-responders before anti-TNF treatment, cells from visit 1 (pre treatment) were stimulated with influenza vaccine in the presence or absence of anti-TNF antibodies. The effect of anti-TNF is shown as the reduction of CD25 and TNFR2 expression relative to cells cultured without anti-TNF. Results showed that anti-TNF induced a greater reduction of both $CD4^+$ CD25+ (35.1% (14.3−87.4) versus 21.2% (-29.6−39.4), $P = 0.03$) and CD3+TNFR2+ (51.6% (30.2−79.7) versus 20.3% (4.1−29.4), $P = 0.002$) T cells in therapy responders as compared to non-responders.
Conclusions: This study indicates that successful anti-TNF therapy induces a reduced activation of T cells *in vivo*. Moreover, the expression of CD25 and TNFR2 on *in vitro* stimulated T cells in the presence of anti-TNF antibodies before treatment start may predict the therapeutic response.

P1081
Colonic Ileus after intestinal surgery depends on CCR2

S. Gutweiler, T. Toepfer, J. Maurer, M. Schiwon, A. Job, C. Kurts & D. R. Engel

Institute of experimental Immunology, University Clinic of Bonn, Bonn, Germany

Purpose/Objective: Dendritic cells (DCs) are very potent in inducing adaptive immune responses against pathogens, but also cause intestinal autoimmune diseases like colitis. It has been shown previously that the most severe complication after abdominal operation, the post operative Ileus (POI), depends on macrophages (MPs) and memory T helper type 1 (mTh1) T cells, which are initially activated by DCs. However, the specific POI-inducing DC-subset and the role of chemokine receptors in POI-induced DC-migration is still unclear.
Materials and methods: After opening the peritoneal cavity POI was induced in $CCR2^{-/-}$, $CX3CR1^{+/-}$ and C57BL6 mice by manipulating the small bowel with moist cotton applicators once from the oral to aboral direction. After 24 h small bowel function was assessed through feeding FITC labeled Dextran and measuring its bowel progression 1.5 h later. Large bowel function was examined by inoculation of a bead into the colon and measurement of the excretion time. Cell numbers were determined using flow cytometry.
Results: We found that the presence of CX3CR1-expressing DCs after abdominal surgery was dependent on CCR2, but lack of such DCs did not improve POI in manipulated small bowel segments. However, CCR2-deficiency improved gut motility in the non-manipulated large bowel. Such improved gut motility was not due to reduced dissemination of POI by mTh1-cells, because recirculation of mTh1 cells was

not affected. Notably, F4/80$^+$ CD11c$^-$ MPs were significantly reduced in the large bowel of manipulated CCR2-deficient mice.
Conclusions: These findings indicate that CCR2-dependent DCs are dispensable for local POI-development and suggests that CCR2-dependent MPs might contribute to POI within the non-manipulated large bowel.

Deficient production of reactive oxygen species leads to a chronic DSS-induced colitis in Ncf1-deficient B10.Q mice

T. Sousa*, H. Carvalheiro,* A. F. Ladeirinha,† A. Alarcao,† A. S. Cabrita,‡ L. Carvalho† & M. Souto-Carneiro*
**Imunology, Centre for Neuroscience and Cell Biology, Coimbra, Portugal, †Pathology, Faculty of Medecine, University of Coimbra, Coimbra, Portugal, ‡Experimental Pathology, Faculty of Medecine, University of Coimbra, Coimbra, Portugal*

Purpose/Objective: Chronic Granulomatous Disease (CGD) is a genetically heterogeneous immunodeficiency disorder caused by deficiency in oxidative burst, resulting in increased susceptibility tobacterial and fungal infections. CGD is caused by mutations in the phagocyte NADPH oxidase complex, the enzyme which generatesoxygen radicals. A common clinical complication in CGD is chronic intestinal inflammation. As in humans, Ncf1 mutation leads to the lack of reactive oxygen species (ROS) in B10.Q mice, increasing their susceptibility to autoimmunity and infection. We used these mutant mice to study how the lack of ROS influences DSS-induced colitis, its transitional recovery and a second colitis induction.
Materials and methods: In the study were usedhomozygous Ncf1 mutatedand B10.Q (Wt) mice. Colitis was induced by oral administration of 3% (w/v) DSS. The induction protocol consisted of 7 days of treatment with DSS followed by 7 days of resting on normal water and finally a second cycle with DSS. Micewere sacrificed at the end of each time point. During the experiment we monitored clinical scores of colitis, collected blood for serum cytokine quantification using CBAs and phenotiping by flow cytometry. We also collected colons at each time point for HE and immunohistochemical (B220, MAC1, CD3) evaluation.
Results: The clinical and histological analyses revealed that Ncf1 mice had a more severe disease with a weaker recovery and signs of a chronic colitis. Cytokines quantification showed that both groups had similar Th1/Th17 behavior in the acute phase, but with earlier higher levels of IL-2, IL-6, IL-17, IL-21, IFNγ and IL-10 in Ncf1. In the 2nd induction Ncf1 reduced IL-21 compared to Wt. Phenotipe data show a marked Th1/Th17 response in both groups. Ncf1 had more CD4 and CD8 T cells expressing CXCR5 and CD69, NK cells expressing CD107a, Tregs expressing CTLA4 and CXCR5 and B cells expressing CXCR4. In the acute phase and at the 2nd induction Ncf1 had more central memory andeffector CD8 T cells and less Treg compared to Wt. Compared to Wt, Ncf1 circulating monocyte pool evolved from having fewer mature CD11b$^+$Ly6c^{low} at T0 towards an accumulation of CD11b$^+$Ly6c^{hi} at T1 and T2, and finally more CD11b$^+$Ly6c^{low} at T3.
Conclusions: The clinical scores, the immunohistopathology of colon biopsies, the quantification of serum cytokines and the flow cytometric analysis of peripheral blood mononuclear cells subsets suggest that ROS absent in Ncf1-deficient B10.Q mice leads to an aberrant inflammatory state leading to the development of a chronic colitis similar to seen in CGD humans.

P1084
Dissecting the disease associated functions of S1PR/SPHK axis in DSS-induced colitis in mice

P. N. Pushparaj,* M. Jayapal,* K. Narasimhan,† S. Kumar‡ & M. H. Al-Qahtani*
**Center of Excellence in Genomic Medicine Research, Faculty of Applied Medical Sciences King Abdulaziz University, Jeddah, Saudi Arabia, †Center of Excellence in Genomic Medicine Research, Faculty of Applied Medical Sciences Kingabdulaziz University, Jeddah, Saudi Arabia, ‡Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore*

Purpose/Objective: Ulcerative colitis (UC) is the most common type of inflammatory bowel disease (IBD) afflicting humans. It causes chronic inflammation and the development of ulcers of the large intestine. The aetiology of colitis is not clearly well defined. Dextran Sulphate Sodium (DSS)-induced colitis in mice is a well studied model for human UC. In the present study, we have specifically dissected the role of Sphingosine-1-Phosphate Receptor (S1PR)/Sphingosine Kinase (SPHK) axis in the development of DSS colitis using a metanalysis approach and DSS-colitis model using both SPHK1$^{-/-}$ and SPHK2$^{-/-}$ mice.
Materials and methods: Meta-analysis of high-throughput genomics data to decipher the role of S1PR/SPHK axis in DSS colitis in mice. The raw Affymetrix CEL files downloaded from the Gene Expression Omnibus (GSE22307) were analysed using the Genespring GX11.5 (Agilent, USA). The statistically significant gene list was filtered based on the standard twofold cut-off compared with the Day 0 expression values.

DSS colitis.

C57BL/6j mice were purchased from Harlan Olac. SPHK1$^{-/-}$ and SPHK2$^{-/-}$ mice were all on the C57BL/6j background. Mice were housed in specific-pathogen-free conditions in the Central Research Facility and the experiments were conducted in accordance with the respective animal experiment guidelines. For acute colitis induction, Wild-Type (WT), SPHK1$^{-/-}$ and SPHK2 $^{-/-}$ male mice were given 3.5% (weight/volume) DSS (molecular weight 36–50 kDa; ICN Biomedicals, Aurora, OH, USA) in their drinking water from day 0 for consecutive 7 days. The control mice were given only normal drinking water. The body weight, stool consistency, and rectal bleeding were monitored daily using the modified method of Cooper and colleagues. All the mice were sacrificed on day 7. The colons were dissected and properly cleaned. Sections were taken for histology and serum for multiplex cytokine assay.
Results: The meta-analysis of the high throughput genomics data showed that S1PR3 and SPHK1 were the early induced genes in the colonic epithelia of the DSS-treated WT mice. However, both SPHK1$^{-/-}$ and SPHK2$^{-/-}$ mice were protected from the DSS-induced body weight loss, pathological changes in the colon as evidenced by colon length and histological score and attenuated proinflammatory cytokine profiles when compared with DSS-treated WT mice.
Conclusions: The S1PR/SPHK axis in the colonic epithelium plays a key role in the development of DSS-colitis. Moreover, both SPHK1 and SPHK2 are important for the effective induction and exacerbation of DSS-colitis.

P1085
Elevated expression of TH17-associated cytokines in the colon of active ulcerative colitis

L. Greathead,* H. Cheeseman,* A. Steel,† R. Goldin,* M. Nelson,‡ B. Gazzard‡ & P. Kelleher*
**Medicine, Imperial College, London, UK, †Gastroenterology, Chelsea & Westminster NHS Trust, London, UK, ‡HIV Sexual Health Directorate, Chelsea & Westminster NHS Trust, London, UK*

Purpose/Objective: The functions of TH17 cytokines in IBD remain controversial. Genes involved in the downstream signaling of IL-23,

the cytokine that promotes and sustains TH17 differentiation, have been shown to mediate susceptibility to UC. However mouse models of IBD have demonstrated both protective and pathogenic effects of TH17 associated cytokines. This study measured TH17 and TH1 cytokines in matched peripheral blood and colonic biopsies to determine whether there is a detectable alteration in cytokine patterns in active UC compared to those in remission and healthy controls.

Materials and methods: Matched peripheral blood and colonic biopsies were studied in 8 patients with active UC, 8 patients with inactive UC and 10 healthy controls using multi parametric flow cytometry. Disease activity was defined by standard clinical criteria (Mayo score). Mucosal mononuclear cells (MMCs) were isolated by collagenase II digestion followed by mechanical disruption then cell straining. Cytokine staining performed on PBMCs and MMCs after stimulation with SEB. We measured the proportion of CD4 that expressed TH1 and TH17 cytokines as well as amount of cytokine secreted by CD4 T cells using the median fluorescence intensity (MFI).

Results: UC patients in remission had significantly higher CD4 percentages in the peripheral blood compared to those with active disease (81%, 55%, $P = 0.01$). The proportion of $CD4^+$ CD161+ was significantly reduced in PBMCs (active UC = 7%, control = 9%) and MMCs (active UC = 54%, control = 63%) of patients with active UC compared to controls. The MFI of IFNγ and TNF on mucosal CD4 T cells was significantly raised in active UC compared to controls ($P = 0.04$, $P = 0.01$). The MFI of IL-17a on mucosal CD4 T cells was also significantly raised in patients with active UC compared to controls ($P = 0.03$). A significantly increased number of MMC CD4 T cells were found to express IL-22 in active UC compared to controls (1.00%, 0.75%, $P = 0.01$).

Conclusions: Active UC is associated with increased expression of inflammatory TH1 and TH17 cytokines. Biological agents to inhibit inflammatory pathways may have a role in the therapy of UC.

P1086

Evaluation of the piroxicam-accelerated interleukin-10 knocks out mouse — as a model of human inflammatory bowel disease

K. Holgersen,[1,2] A. K. Hansen[†] & T. L. Holm[§]
[*]*Department of Immunopharmacology, Novo Nordisk, LIFE In vivo* Pharmacology Centre, Frederiksberg, Denmark, [†]*Department of Veterinary Disease Biology, Novo Nordisk, LIFE In vivo* Pharmacology Centre, Frederiksberg, Denmark, [‡]*Department of Veterinary Disease Biology, Faculty of Health and Medical Sciences, University of Copenhagen, Frederiksberg, Denmark,* [§]*Department of Immunopharmacology, Novo Nordisk A/S, Måløv, Denmark*

Purpose/Objective: The pathogenesis of inflammatory bowel disease (IBD) is still poorly understood, but it is believed to result from a multifactorial condition, where genetic and environmental factors play an interrelated role, leading to a breakdown of the intestinal homeostasis and an excessive immune response against the commensal microflora. The aim of this project is to evaluate whether the piroxicam-accelerated colitis interleukin-10 knock out mouse (PAC IL-10 k.o.) could function as a tool in the preclinical research and development of new therapeutics against IBD.

Materials and methods: The PAC IL-10 k.o. model was evaluated by clinical manifestations and the immune response was characterised by haematology, histopathology, colonoscopy, ELISA and FACS analysis. Qualification was performed by examining the efficacy of treatment with biological therapies for IBD (anti-TNFα and anti-IL-12/23p40). Also, the mice were treated with an antibiotic to determine the role of commensal bacteria in disease progression.

Results: The PAC IL-10 k.o. model developed a pronounced colitis immediately after the start-up of piroxicam administration, with synchronised weight loss, diarrhea and blood in stools. Clear signs of chronic colitis were present even 2 weeks after termination of piroxicam. Acute phase proteins and granulocytes were significantly elevated in the blood compared to IL-10 k.o. controls and histological evaluation revealed hyperplasia and marked infiltration of mononuclear cells and neutrophil granulocytes in the mucosa and submucosa. Disease progression was significantly reduced when treated prophylactically with neutralising monoclonal antibodies against IL-12/23p40 and TNFα, as well as ampicillin.

Conclusions: The presented data show that the PAC IL-10 k.o. mouse model may be useful as an *in vivo* model of human IBD, since the model resembles the corresponding human condition in many aspects.

P1087

GM-CSF modifies monocytes to develop anti-inflammatory properties that are beneficial in Crohn's disease

T. Weinhage, J. Däbritz, G. Varga, M. Belz & D. Foell
Institute of Immunology, University Hospital Muenster, Muenster, Germany

Purpose/Objective: Granulocyte Macrophage-Colony Stimulating Factor (GM-CSF) showed clinical response and remission in patients with active Crohn's disease (CD). Since GM-CSF has pleiotropic effects on monocytes, which represent the exclusive source of macrophages in inflamed intestinal mucosa we characterized GM-CSF-treated mouse monocytes *in vitro* and analyzed their function *in vivo* in a mouse model of chronic DSS induced colitis.

Materials and methods: Mouse bone marrow-derived monocyte precursors were treated for 48 h with GM-CSF *in vitro*. Phenotypical changes were assessed by qRT-PCR and flow cytometry. Various functional properties were evaluated: mixed lymphocyte reactions, phagocytosis, adherence, cytokine production and reactive oxygen species (ROS) production. Therapeutic effects of GM-CSF-treated monocytes were assessed in a model of chronic colitis that was induced by repeated oral administration of DSS (2%). Monocytes were administered i.v. prior to start of final DSS treatment cycle and their subsequent immunomodulatory functions were evaluated *in vivo* by clinical monitoring (e.g. body weight), histology, immunohistochemistry and expression of inflammatory markers by qRT-PCR. The distribution of injected monocytes in the intestine was measured by *in vivo* imaging.

Results: GM-CSF-treated monocytes expressed significantly higher levels of anti-inflammatory molecules on mRNA and protein levels (e.g. IL1-Ra, IL4-Ra, CD121b and ARG1) e*x vivo*. GM-CSF induces ROS production but reduces phagocytosis and adherence in monocytes. Mice treated with GM-CSF stimulated monocytes showed resistance in chronic colitis with diminished weight loss compared to control mice. (Histo-) Pathology showed less inflammatory infiltration, ulceration, and colon shrinkage. Additionally, proinflammatory mediators IL-1, IL-6 and TNF-a were decreased during the course of colitis. GM-CSF-treated monocytes enter the intestine in significantly higher number and persisted longer compared to control monocytes in DSS treated mice.

Conclusions: Our results indicate that the beneficial effects of GM-CSF in CD may be in part due to the induction of monocytes with anti-inflammatory properties.

P1088

HDAC dependent regulation of the IL-6/STAT3 pathway during T helper cells activation

R. Glauben,[*] M. Wetzel,[*] P. Mascagni,[†] M. Zeitz[*] & B. Siegmund[*]
[*]*Charité Universitätsmedizin Berlin, Research Center ImmunoSciences, Berlin, Germany,* [†]*Italfarmaco, R&D, Cinisello, Italy*

Purpose/Objective: Histone modifications represent a promising new approach in cases where cell functions are to be modulated as in

autoimmune diseases or cancer. While several histone deacetylase (HDAC) inhibitors are currently in clinical cancer studies, we demonstrated an additional anti-inflammatory potency in murine colitis models. Here we describe a possible cellular mechanism for this effect.
Materials and methods: Murine naïve T helper cells were isolated via magnetic cell sorting and macrophages were derived from bone marrow (BMMΦ). T cells were stimulated using coated anti-CD3/CD4 antibodies, macrophages via LPS. Cells were analysed using flow cytometry, cytometric bead array or western blot. Acute DSS colitis was performed.
Results: In the presence of ITF2357, the generation of FoxP3$^+$ cells from naïve T helper cells could be enhanced, the polarization to the pro-inflammatory Th17 cells suppressed. In parallel, we demonstrated a dose-dependent downregulation of the IL-6 receptor on naïve CD4 T cells treated with ITF2357. This effect could be observed on the mRNA expression level and on the protein level via flow cytometry. These results were confirmed in murine colitis models, where the IL-6R expression was diminished on naïve T cells within the lymphnodes, paralleled by a significant reduction of Th17 cells in the lamina propria of ITF2357-treated animals. Consequently, HDAC inhibition resulted in a reduced amount of activated/phosphorylated STAT3 in T cells identifying the IL-6/STAT3/IL-17 pathway as an important target of HDAC inhibitors.

In parallel, ITF2357 treatment of BMMΦ leads to a dose-dependent down regulation of TNFα, IL-6 and IL-12p70 secretion by BMMΦ. TLR4-dependent IL-6R upregulation was significantly impaired by ITF2357, while expression of the signaling transducer CD130 was unchanged. ITF2357 reduced the ability of antigen-specific, MHC-II-dependent T cell activation.
Conclusions: The present study demonstrates that inhibition of HDAC exerts an anti-inflammatory potency by modulation in T cell polarization directly, but also via affecting macrophage differentiation, leading to impaired IL-6 signalling, reduced T cell activation, thus representing a novel therapeutic approach for chronic (intestinal) inflammation.

P1089

Identification, charactarization and epitope mapping of gamma gliadin, a major wheat antigen in celiac disease

B. Srinivasan,* M. F. Tejkl,† I. Swoboda,† C. Constantin,* I. Mittermann,* S. Pahr,* H. Vogelsang,‡ W. D. Huber§ & R. Valenta†

**Division of Immunopathology, Department of Pathophysiology and Allergy Research, Centre for Pathophysiology Infectiology and Immunology Medical University of Vienna, Vienna, Austria, †Division of Immunopathology, Department of Pathophysiology and Allergy Research, Christian Doppler Laboratory for Allergy Research, Centre for Pathophysiology Infectiology and Immunology Medical University of Vienna, Vienna, Austria, ‡Department of Pediatrics and Adolescent Medicine, Medical University of Vienna, Vienna, Austria, §Department of Gasteroenterology and Hepatology, Medical University of Vienna, Vienna, Austria*

Purpose/Objective: Approximately 1% of the population suffers from celiac disease (CD), an inflammatory disease of the small intestine elicited by wheat ingestion. Affected patients mount T cell responses and IgA antibody responses to several antigens belonging to the gliadin-containing fraction of wheat but so far no recombinant wheat antigen specifically recognized by CD patients has been produced. Aim of this study was the biochemical, molecular and immunological characterization of recombinant wheat antigens specific for CD.
Materials and methods: Gliadins were fractionated into sub-fractions using ion-exchange chromatography and their antibody reactivity to patients sera was analysed by western blot and ELISA. The disease specific antigens in the sub-fractions were identified by mass spectrometry and N-terminal sequencing of the individual protein bands. Recombinant antigens were generated in bacterial expression system. Overlapping peptides covering the entire sequence of the recombinant antigen was synthesised and IgA/IgG epitope mapping was performed by ELISA. The secondary structure of the recombinant antigen was performed using circular dicroism.
Results: We developed a method for separation of gliadins by ion-exchange chromatography and identified disease specific antigens in the gliadin sub-fractions by studying their reactivity to serum IgA from clinically well defined CD and non-CD patients. Through mass spectrometry and N-terminal sequencing we identified the proteins in the sub-fractions and showed that the most relevant IgA-reactive CD-specific antigens belong to the class of gamma gliadins. Based on the sequences identified by mass spectrometry we cloned the complete cDNA sequence of a gamma gliadin (GG1) for recombinant expression and purification. Secondary structure of recombinant GG1 was analysed by circular dichroism. Recombinant GG1 was successfully purified and showed highly specific IgA reactivity with sera from CD patients. IgA and IgG epitope mapping studies with synthetic peptides revealed a major immunodominant regions located at the N-terminus of the protein. Circular dichroism analysis showed that the antigens were folded.
Conclusions: Recombinant GG1 should be useful for characterizing the immune response to wheat antigens and to develop diagnostic and therapeutic strategies for CD.

This study was supported by the DK program IAI of the Austrian Science Fund (FWF) and by a research grant from Thermofisher/Phadia, Uppsala, Sweden.

IL-1 mediates intestinal inflammation by promoting the accumulation of IL-17A secreting innate lymphoid cells and CD4+ Th17 cells

M. Coccia,* O. Harrison,* C. Schiering,† M. Asquith,* B. Becher,‡ F. Powrie† & K. Maloy*

**Sir William Dunn School of Pathology, University of Oxford, Oxford, UK, †Translational Gastroenterology Unit, University of Oxford, Oxford, UK, ‡Institute of Experimental Immunology, University of Zurich, Zurich, Switzerland*

Purpose/Objective: Although very high levels of Interleukin (IL)-1β are present in the intestines of patients suffering from Inflammatory Bowel Diseases (IBD), little is known about the contribution of IL-1β to intestinal pathology. We aimed to define the role of IL-1β in driving innate and adaptive pathology in the intestine.
Materials and methods: We assessed the roles of IL-1β in complementary mouse models of inflammatory bowel disease, mediated by either innate or adaptive immune activation.
Results: We show that IL-1β promotes innate immune pathology in *Helicobacter hepaticus*-triggered intestinal inflammation by augmenting the recruitment of granulocytes and the accumulation and activation of innate lymphoid cells (ILC). Using a T cell transfer colitis model, we demonstrate a key role for T cell-specific IL-1 receptor (IL-1R) signals in the accumulation and survival of pathogenic CD4$^+$ T cells in the colon. Furthermore, we show that IL-1β promotes 'type-17' responses from CD4$^+$ T cells and ILC in the intestine and we describe synergistic interactions between IL-1β and IL-23 signals that sustain innate and adaptive inflammatory responses in the gut.
Conclusions: Our data identify multiple mechanisms through which IL-1β promotes intestinal pathology and suggest that targeting IL-1β may represent a useful therapeutic approach in IBD.

P1093

Interaction between *Trichinella spiralis* infection and inflammatory colitis: novel immunological concepts

D. Ashour,* A. Othman,* M. Shareef,† H. Gaballah‡ & W. Mayah§
**Parasitology Faculty of Medicine, Tanta University, Tanta, Egypt,*
†*Pathology Faculty of Medicine, Tanta University, Tanta, Egypt,*
‡*Biochemistry Faculty of Medicine, Tanta University, Tanta, Egypt,*
§*Tropical Medicine Faculty of Medicine, Tanta University, Tanta, Egypt*

Purpose/Objective: The aim of this study was to gain insight about time-related interaction between intestinal nematode infection and inflammatory colitis in an effort to ameliorate experimentally induced colitis using a model for ulcerative colitis, and to explore the underlying immunoregulatory mechanism of *Trichinella spiralis* infection.
Materials and methods: Mice used were divided into four groups: group I: infected with *Trichinella spiralis*; group II: infected with *Trichinella spiralis* then subjected to induction of colitis; group III: subjected to induction of colitis and group IV: subjected to induction of colitis followed by *Trichinella spiralis* infection. Mice were sacrificed at 2th and 4th weeks post-colitis. Assessment of colitis was done by histopathological examination, and determination of pentraxin 3 level in the colon. Immunohistochemistry was done for identification of T regulatory Foxp3-expressing cells.
Results: It was evident that *T. spiralis* infection ameliorated the severe inflammation induced by acetic acid. The amelioration was more pronounced when *T. spiralis* infection preceded the induction of colitis. Mean pentraxin 3 values were significantly lower in case of colitis with Trichinella infection as compared to negative control or colitis group at different experimental periods. Regarding the immunohistochemical staining of T regulatory cells, the highest score of positivity was detected in group I (*T. spiralis* alone) and the least score was in group III (acetic acid induced colitis) with the other two groups inbetween.
Conclusions: *T. spiralis* regulatory mechanism can improve the inflammation of colon through the 'inflammatory regulatory' axis. Finally, it would be of great importance to apply these results in the development of new therapeutic approaches for treatment of ulcerative colitis.

P1094

KIR-mediated NK education mediates KIR-associated Crohn's disease susceptibility

L. Lin,* C. Ma,† N. Aziz,* R. Rajalingam,* S. Targan,‡ D. McGovern‡ & J. Braun*
**UCLA, Pathology and Lab medicine, Los Angeles, USA,* †*NanoSystems Biology Cancer Center, California Institute of Technology, Pasadena, CA, USA,* ‡*Cedars–Sinai Medical Center, Medical Genetics Institute and IBD Center, Los Angeles, CA, USA*

Purpose/Objective: Natural Killer (NK) cells are innate effector lymphocytes in the host response to infections and tumors through a variety of activating and inhibitory receptors. NK cells require education by self-human leukocyte antigen (HLA) class I molecules through Killer cell Immunoglobulin-like receptors (KIRs) to gain proficient responses. Yet, it remains unknown whether and how KIR-mediated NK education contributes to chronic inflammation in humans.
Materials and methods: First, in healthy subjects bearing the simplified AA KIR haplotype, NK subsets expressing KIR2DL3 and 3DL1 were analyzed for cytokine production by single cell barcode chip [SCBC, Ma, C, *et al. Nat Med* (2011)]. Second, genetic distribution of HLA-C1 and HLA-Bw4, the respective ligands for KIR2DL3 and KIR3DL1, in AA haplotype Crohn's Disease (CD) patients were analyzed by Chi square test. Third, CD patient NK culture media was profiled for cytokine production at the bulk level using multiplex ELISA system, and at the single cell level using SCBC. Lastly, an NK coculture assay was performed to test their effect on antigenic CD4+ T cell activation and mechanism of action.
Results: In this study of subjects bearing the simplified AA KIR haplotype, we show that KIR education enables NK cells to promote $CD4^+$ T cell proliferation by eliciting expression of multiple pro-inflammatory cytokines and chemokines. Using the SCBC microfluidic platform, we show that the genetically educated NK subset was highly polarized towards robust production of cytokines at the single-cell level. The strongly-educating KIR-ligand pair (KIR2DL3 and homozygote HLA-C1) was enriched in CD patients, and NK cells from patients with this genotype had distinct secretion profiles compared to NK cells from weakly educated patients. Autologous NK-T cell co-culture demonstrated that strong KIR education permitted NK augmentation of $CD4^+$ T cell proliferation *via* secretion of pro-inflammatory cytokines.
Conclusions: Collectively, these results extend our understanding of the functional consequences of NK education, and reveal the unappreciated capacity of NK cells to produce a wide spectrum of immune mediators that modulate the $CD4^+$ T cell activation threshold. These findings offer a biologic basis for the correlation between NK education and KIR-associated susceptibility to CD and other chronic inflammatory syndromes.

P1095

Mononuclear phagocytes in steady-state and colitis

I. C. Arnold, S. Mathisen & F. Powrie
Nuffield Department of Clinical Medicine, University of Oxford, Oxford, UK

Purpose/Objective: There is increasing evidence that antigen-presenting cells are key determinants in shaping both innate and adaptive immune responses in the gut, thereby contributing to intestinal homeostasis. Recently, two major populations of intestinal mononuclear phagocytes have been identified on the basis of the differential expression of the integrin subunit CD103 and the fractalkine receptor CX_3CR1. The aim of this study is therefore to understand how these specific cellular subsets contribute to the pathogenesis of inflammatory bowel diseases.
Materials and methods: To address the function of colonic LP mononuclear phagocytes during intestinal inflammation, we utilized a mouse model of *Helicobacter hepaticus*-induced colitis combined with anti-IL10R treatment in CX_3CR1-GFP knock-in reporter mice.
Results: Upon infection, large numbers of antigen-presenting myeloid cells were rapidly detected in the colonic lamina propria and mesenteric lymph nodes, and persisted during the course inflammation. Detailed analysis of these cells revealed the primary accumulation of an activated inflammatory monocyte population expressing $MHCII^+$ $CD11c^{het}$ $Ly6C^{hi}$ CX_3CR1^{int} as well as the FCgReceptor IV (CD64), and producing TNFa, IL12p40 and iNos.
Conclusions: We therefore suggest that $CD64^+$ marks an activated subset of infiltrating CX_3CR1^{int} mononuclear phagocytes that produce colitogenic cytokines and perpetuate intestinal inflammation.

P1096

Neuronal CGRP and TNF alpha co-regulate each other in a mouse model of parasitic infection in the gut

M. Bakri,* J. Pennock* & J. Miyan†
**Immunology, University of Manchester, Manchester, UK,* †*Neuroscience, University of Manchester, Manchester, UK*

Purpose/Objective: Background: Neuropeptides have been associated with immune functions in many inflammatory models. In this study we examined the relationship between the sensory nociceptive neuropeptide calcitonin gene related peptide (CGRP) and the potent

inflammatory cytokine tumor necrosis factor alpha (TNFα) during a chronic helminth infection. CGRP has been shown to down-regulate TNFα production from macrophages *in vitro* whilst TNFα attenuates CGRP release from sensory neurons *in vitro*. Given the role for CGRP in mediating neuroinflammation, we wanted to study this interaction *in vivo* during an infectious challenge in the gut.
Materials and methods: Methods: CGRP and its receptor antagonist, hCGRP $_{8-37}$, were administered *in vivo* between days 14 and 21 post *Trichuris muris* infection in BALB/c and AKR mice. Additionally, a TNFα inhibitor, Infliximab, was administered *in vivo* in chronically infected AKR mice at day 35 p.i.
Results: Results: : During infection, an inverse correlation between CGRP and TNFa was observed. Furthermore, CGRP treatment *in vivo* reduced TNFα expression in both AKR and BALB/c mice during infection, implying a negative regulation. However, when TNFα was inhibited *in vivo* with infliximab, CGRP levels reduced in the colon, suggesting that CGRP may respond to local TNFa downregulation.
Conclusions: Conclusion: Our study shows for the first time that CGRP and TNFα inversely correlate with each other during gut inflammation *in vivo*. This demonstrates a role for CGRP in the immune response during parasite infection. Whether this happens directly or indirectly is the subject of further work.

P1097
Phagocytosis of *Escherichia coli* by human gamma delta T cells: a possible role in the pathogenesis of Crohn's disease

S. Banthiya,* N. B. Rayment,† P. Skoutari,* S. Tempest-Roe,‡ B. N. Hudspith,† J. Hermon-Taylor† & J. D. Sanderson§
**Immunology, Kings College London, London, UK, †Diabetes and Nutritional Sciences Division, Kings College London, London, UK, ‡Biomedical Sciences, Kings College London, London, UK, §Gastroenterology, Guy's & St. Thomas' Hospital, London, UK*

Purpose/Objective: The aetiology of Crohn's disease (CD), although unknown, is generally accepted as being multifactorial. One of the factors that appear to be instrumental in disease initiation/progression is the immunological response to the gut enteric microbiota. We have previously shown that in cases of CD, mucosal associated *E. coli* are able to penetrate into the lamina propria and survive within macrophages. In this present study we have not only confirmed this observation but in addition, using immunofluorescence staining (IF), identified *E. coli* associated with a population of $\gamma\delta$ T cells in biopsies of patients with Crohn's disease. This would be consistent with previous literature that has indicated the role of $\gamma\delta$ T cells as APC's.
Materials and methods: Patients with CD were identified using the Montreal criteria, none of whom were on immunosuppressive or biologic therapy at the time of study. Controls were selected from a colorectal cancer screening population who had a normal bowel habit, no abdominal pain, no rectal bleeding or bloating. Rectal biopsies were taken at colonoscopy and snap frozen in liquid nitrogen. Six micrometer sections of the biopsies were taken and fixed in acetone. Polyclonal antibodies recognising $\gamma\delta$ T cells, CD68 +ve macrophages and *E. coli* were used to stain sections by indirect immunofluorescence (IF). Spectrally distinct fluorophores were used in order to achieve co-localisation. Sections were viewed using an epi-fluorescence microscope and were quantified by counting five randomly selected high power fields.
Results: Samples were collected from 11 CD patients and 5 controls. Co-localisation of *E. coli* with $\gamma\delta$ T cells was seen in 9/11 CD patients but none in controls.$\gamma\delta$/*E. coli*/+ve T cells were observed in both colonic epithelium as well as lamina propria and where present, accounted for ~40%of the total $\gamma\delta$ T cell count.
Conclusions: This is the first study to demonstrate the uptake of *E. coli* in a population of $\gamma\delta$ T cells within the colonic tissues of CD patients but not controls. The results above suggest that the presence of *E. coli* within two immunologically distinct populations of cells may impair the host response and therefore be critical in the resolution of the chronic inflammation seen in Crohn's disease.

P1098
Regulatory role of the hypothalamic-pituitary-adrenal axis and adrenal glands in experimental colitis

P. Reis de Souza,* H. Salles-Campos,* J. S. Silva† & C. R. B. Cardoso*
**Dactb, University of São Paulo, Ribeirão Preto, Brazil, †Dpmi, School of Medicine of Ribeirão Preto, Ribeirão Preto, Brazil*

Purpose/Objective: Inflammatory immune responses may be modulated by the hypothalamic-pituitary-adrenal axis (HPA) through neuroimmunoendocrine interactions and cortisol secretion. However, even in the presence of intact adrenal glands patients may develop chronic diseases such as Inflammatory Bowel Disease (IBD), which may be caused by an imbalance between regulatory and effector responses in the intestinal mucosa. On the other hand, adrenal glands are also involved in stress response, which may predispose to uncontrolled inflammatory diseases. Then, our objective was to investigate the role of the HPA axis and adrenal glands in experimentally induced IBD.
Materials and methods: C57BL/6 mice were subjected to bilateral adrenalectomy and after a 15 day-surgery recovery period the colitis was induced by oral intake of water containing 3% (w/v) Dextran Sulfate Sodium (DSS) for 6 consecutive days. Animals were daily assessed for weight loss and clinical signs of disease. Mice were sacrificed at 6th day of colitis induction and colon samples were collected to assess cytokine production by ELISA and eosinophil peroxidase activity (EPO) by enzymatic assay. Blood samples were also obtained for evaluation of circulating leukocytes.
Results: Our results showed that colitis was more severe in animals subjected to adrenalectomy, which showed greater weight loss, increased disease clinical score and early mortality when compared to colitis group. The absence of adrenal glands was also related to an increase in pro-inflammatory cytokines such as TNF-α, IFN-γ and IL-17 in the gut, along with an augmentation of IL-10, probably in an attempt to compensate for the exacerbated inflammatory response. Moreover, these local alterations were accompanied by reduced EPO in the intestine and diminished circulating eosinophils in the blood, indicating that adrenal produced hormones and neuroimmune interactions may be involved in the maintenance of the peripheral leukocyte pool and control of exacerbated responses in the gut mucosa.
Conclusions: Taken together, our results showed HPA axis and adrenal glands play an important role in the regulation of systemic leukocytes and local inflammatory response in the gut.

P1100
Role of dendritics cells during IBD

J. Schulthess, C. Arancibia, T. Steveels & F. Powrie
NDM, University of Oxford, Oxford, UK

Purpose/Objective: Dendritic cells (DC) participate in the fine control of immune system by promoting effective immunity against invading pathogens and in the same time by preventing excessive inflammation. Even the phenotype and the function of subsets of intestinal DC are well-characterized in mice, few are known in human. Better knowledge concerning human intestinal DC at steady state allows us to understand the role of these cells during IBD.
Materials and methods: A complex panel was set up to characterize and define intestinal human DC by flow cytometry. Because of the difficulty to isolate significant number of intestinal dendritic cells from

controls and IBD patients, an *in vitro* system of intestinal-like DC was develop from monocytes-derived DC (MODC) which could provide sufficient numbers of DC to assess their function.
Results: Our human data indicate that 20% of intestinal DC expresses CD103 while this molecule is not expressed in circulating DC in the blood, suggesting that human CD103+ DC as mice CD103+ DC might be important in maintaining intestinal homeostasis. Moreover gene expression in CD103+ and CD103$^-$ DC from human colon indicates that CD103+ DC express high level of mRNA involved in TGF-β pathway or in enzyme producing retinoic acid (ALDH1A2) compared to CD103- DC. Furthermore CD103+ DC coming from IBD patient's loss the capacity to up regulate TGF-β pathway gens and ALDH1A2.

Besides the culture and the differentiation of CD14+ monocytes from blood of control donor into intestinal-like DC with in presence or in absence of RA or FLT3 ligand or TGF-β indicate that only RA is a potent inducer of CD103 on MODC. Quantitative PCR analysis shows that CD103+ MODC up regulate mRNA related to TGF-β pathway as well as ALDH1A2 compared to CD103- monocytes-derived dendritic cells.
Conclusions: Preliminary data on human intestine suggest that intestinal DC express CD103 and gene related to tolerance. When cultured with RA, MODC expressed CD103 which provide intestinal-like DC phenotype. This CD103+ DC are enriched for genes related to TGF-β activation.

P1101
Th17 related genes and celiac disease susceptibility

L. M. Medrano,* B. Dema,* C. Maluenda,† M. A. Figueredo,* M. Fernández-Arquero* & C. Núñez*
**Clinical Immunology, Hospital Clínico San Carlos, Instituto de Investigación Sanitaria HCSC (IdISSC), Madrid, Spain, †Pediatrics, Hospital Clínico San Carlos, Instituto de Investigación Sanitaria HCSC (IdISSC), Madrid, Spain*

Purpose/Objective: Celiac disease (CD) is an inflammatory intestinal disorder caused by gluten ingestion in genetically predisposed individuals. Th17 immune response has been related to different autoimmune diseases such as Crohn's disease, psoriasis or ankylosing spondylitis. Polymorphisms in genes involved in the Th17 pathway, such as *IL23R*, have been associated with susceptibility to those diseases. We aimed at exploring the role of Th17 cells in CD by studying the association of numerous single nucleotide polymorphisms (SNPs) located in Th17 genes with CD susceptibility.
Materials and methods: We initially studied 735 CD patients and 549 healthy individuals, and we used a replication sample set consisting of 294 CD patients and 475 healthy individuals. All included individuals were Spaniards and Caucasian. We selected 101 SNPs in 15 Th17 genes (*IL23R, RORC, IL6R, IL17A, IL17F, CCR6, IL6, JAK2, TNFSF15, IL23A, IL22, TBX21, SOCS3, IL12RB1* and *IL17RA*) by performing an aggressive tagging using the Haploview program. Genotyping was performed by 'Veracode' technology at the National Genotyping Center (CEGEN) or by Taqman technology in the case of the *IL6*, *IL6R* and *TBX21* genes. Genetic frecuencies were compared between cases and controls using the chi-square test. Interactions between genes were evaluated following four different approaches: logistic regression, random forests (RF), classification and regression trees (CART) and multifactor dimensionality reduction (MDR).
Results: In the case-control study, significant results were not obtained for any SNP with the excepcion of rs4969170 located in the *SOCS3* gene [$P = 0.0018$, OR (95% CI) = 0.59 (0.42−0.84)] and one haplotype conformed by the SNPs located in the *IL23R* locus. However, these results were not replicated in our validation sample set.

No significant interactions between the studied genes were found.
Conclusions: Genetic polymorphisms in Th17-related genes do not seem to be crucial for CD development.

P1102
The Gut Microbiota and Inflammatory Immune Diseases

C. MacDonald,* D. Kelly,* I. Mulder* & K. Scott†
**Gut Immunology, Institute of Medical Sciences, University of Aberdeen, Aberdeen, UK, †Gut Health, Institute of Medical Sciences, University of Aberdeen, Aberdeen, UK*

Purpose/Objective: The current work will investigate the effect of the microbiota in autoimmune disease in two disease models: inflammatory bowel disease, a local autoimmune disease within the gut, and multiple sclerosis, a systemic autoimmune disease. We aim to identify key bacterial species present in healthy animals and to investigate the presence or absence of these microbes in diseased states. The effect of the microbial composition of the gut on the function of the cells of the immune system in healthy and colitic mice will be assessed through FACS analysis. In addition, the importance of close association of the bacteria to the mucosa to elicit their effect will be studied.
Materials and methods: Denaturing Gel Gradient Electrophoresis (DGGE) has been utilised to expand our knowledge of the microbial composition of the gut. Fluorescence *In Situ* Hybridisation (FISH) was also used to provide information about the location of the bacteria within the gut tissue. A protocol to retrieve the mucosa-associated bacterial population from the gut was developed. The DNA collected from scraping the mouse gut mucosa was run on DGGE gels to visualise the differences between tissues, and between bacteria that are loosely and tightly associated to the mucosa.

Further work will involve a mouse study in which wild-type and IL-10 KO mice are treated with antibiotics. The mice are then treated with bacteria (either a single strain or a cocktail) to assess the effect of the known bacteria on microbiota composition and the host immune system. FACS analysis will investigate the effect on the differentiation of the cells in the immune system. Of the 454 Pyrosequencing and qPCR will identify the exact species present and qPCR enables the quantification of the species.
Results: Thus far, DGGE profiles have been obtained of both faecal and gut mucosa bacterial profiles. Additionally, FISH has been carried out to visualise the location of the bacteria within the gut tissue, while the protocol to retrieve bacteria associated with the gut mucosa is under-going final optimisation.
Conclusions: Our initial work shows a large difference between the bacterial DGGE profiles from faecal samples of wild type mice and IL-10 KO mice. The profiles of loosely and tightly mucosa-associated bacterial communities show a clear difference. FISH results show the technique to retrieve the bacteria from the mucosa was effective.

P1103
The impact of NOD2 3020insC mutation in microbial-driven host innate immunity

E. Milioris,* V. Iebba,* N. J. Klein,* T. Steevels,† A. Simmons† & M. Bajaj-Elliott*
**Infectious Diseases & Microbiology, UCL Institute of Child Health, London, UK, †Nuffield Department of Clinical Medicine, University of Oxford, Oxford, UK*

Purpose/Objective: NOD2 is an intracellular pattern recognition receptor of the NOD-like receptor family. Activation of NOD2 by the muramyl dipeptide (MDP) motif of the bacterial peptidoglycan drives NF-κB signaling. The NOD2 *3020insC* polymorphism is a well-established genetic risk factor for Crohn's disease. At present the impact of this mutation on enteropathogen-mediated host innate immune responses is unknown.
Materials and methods: THP-1 cells transduced with WT and *3020insC* NOD2 under both an intermediate and high expression promoter were utilized. PMA-treated cells were stimulated with TLR

(LPS & PGN) and NLR (ieDAP & MDP) ligands and infected with *Campylobacter jejuni*, *Clostridium difficille*, *Enteropathogenic E. coli* and *Salmonella enterica*. Host innate immunity was quantified by gene and protein analysis, flow cytometry and confocal microscopy.
Results: MDP reduced PGN-mediated TNFα levels in cells overexpressing wild-type NOD2 by 40%, indicating that NOD2 is a negative regulator of TLR2-driven pro-inflammatory responses. Enteropathogens led to a marked increase in TNFα, while inhibiting IL-10, during co-infection with macrophages expressing the *3020insC* mutant.
Conclusions: Our observations suggest that *3020insC* NOD2 mutant receptor responds differentially to exogenous stimuli when compared to its WT counterpart. The observed disequilibrium between the pro- and anti-inflammatory cytokine axes may contribute to bacterial-driven IBD pathogenesis in individuals carrying the *3020insC* NOD2 mutation.

P1104
The influence of cell free probiotic supernatant on bacterial macrophage interactions

Y. Seenappanahalli Nanjundaiah, Z. Ali, D. A. Wright & M. Sarker
School of Science and Engineering, Teesside University, Middlesbrough, UK

Purpose/Objective: Probiotics have been shown to be beneficial on patients suffering from inflammatory bowel diseases such as ulcerative colitis. However, the mode of action is unclear with many papers reporting contrary stimulatory or suppressive effects on immune cell activity.
Materials and methods: This study utilised a gentamicin protection assay (GPA) to assess the influence of probiotics on both the ingestion and digestion phases of phagocytosis by immune cells. The GPA was performed with *E. coli* and a murine macrophage (J774) at a multiplicity of infection of 50:1 in DMEM (Dulbecco's modified Eagle's medium) alone or DMEM supplemented with either 20 μg/ml lipopolysaccharide (LPS), 10% cell-free *Lactobacillus rhamnosus* GG (LGG) probiotic bacterial supernatant or a combination of LPS-LGG.
Results: Studies monitoring bacterial ingestion, demonstrated a significant reduction in bacterial uptake by macrophages when treated with LGG and the LPS-LGG combination ($P < 0.05$). The LPS alone had no significant effect on bacterial ingestion. In studies monitoring bacterial digestion, the LPS and the LPS-LGG combination, brought about significant increase in the digestion rate when compared to control ($P < 0.05$). LGG alone had no significant effect on bacterial digestion.

The data suggest both LGG and LPS modulate immune cells but in a contrary manner. The LGG inhibits bacterial ingestion, but does not influence digestion, whereas LPS does not influence ingestion but enhances bacterial digestion.
Conclusions: By interfering with macrophage ingestion, LGG may suppress the total microbial load associated with macrophages, and, hence, the extent to which pro-inflammatory molecules such as nitric oxide and oxygen free radicals are generated. The suppression of inflammatory promoting signals may be beneficial to the host, since overproduction of these signals may induce host damage. Future work will focus on whether the LGG driven suppression of ingestion is also associated with a reduction of pro-inflammatory molecules and can maintain this suppression in the presence of LPS, a molecule known to stimulate inflammation.

P1105
The TGF-ß activating gut-associated integrin avß8 is upregulated during DC maturation

T. Fenton,* M. Lehtinen† & M. Travis*
**Manchester, University of Manchester, UK, †Kantvik Active Nutrition, DuPont Nutrition and Health, Kantvik, Finland*

Purpose/Objective: Maintenance of homeostasis within the gut requires constitutive immune suppression to prevent inappropriate inflammation, punctuated by effective antigen-specific responses against pathogens. Breakdown of suppression, or failure to deal with infection, can result in inflammatory or allergic disease. Thus, understanding the cellular and molecular mechanisms that regulate intestinal immunity will be important in identifying potential therapies to improve immune-mediated disorders of the gut. We have previously found that high expression of integrin $\alpha v\beta 8$ on lamina propria dendritic cells (DC) results in activation of the key cytokine TGF-β, which induces either Treg or Th17 cells, depending on the immune context. This pathway is critical to gut homeostasis, as shown by CD11c-specific $\alpha v\beta 8$ knockout mice which develop severe colitis. The aim of this current study is to understand how expression of integrin $\alpha v\beta 8$ on DC is controlled, and how this affects downstream immune responses.
Materials and methods: Human monocyte derived DC was treated with intestine-associated molecules and the effect on DC maturation and $\alpha v\beta 8$ expression was measured by flow cytometry.
Results: The TLR ligand LPS upregulated expression of the TGF-β activating integrin $\alpha v\beta 8$ on human DC in a dose-dependent manner. This upregulation appeared to correlate with the activation status of the DC; however, if DC were treated with gut-associated molecules that dampen activation, LPS was still able to cause upregulation of the integrin.
Conclusions: Integrin $\alpha v\beta 8$ upregulation on DCs by danger signals in the gut may contribute to constitutive suppression of non-specific immune responses, or enhancement of Th17 responses depending on the immune milieu. We are currently determining the functional significance of this integrin upregulation in controlling gut immune responses, which may prove to be a potential pathway for modulation of intestinal immunity.

P1106
Tumour necrosis factor alpha in non-inflammatory bowel disease enterocutaneous fistulas prospective study

G. Rahbour, H. O. Al-Hassi, A. L. Hart, M. R. Ullah, S. M. Gabe, S. C. Knight, J. Warusavitarne & C. J. Vaizey
Antigen Presentation Research Group, Imperial College, St. Mark's Hospital and Academic Institute, London, UK

Purpose/Objective: The aim of this study is to assess the inflammatory activity, with a particular emphasis on tumour necrosis factor alpha (TNF-α) of non-inflammatory bowel disease enterocutaneous fistula (non-IBD ECF) when compared with IBD ECF and control small bowel terminal ileum tissue. If this study can show the presence of TNF-α in the fistula tract then there would be a potential for a novel therapy for patients with persistent ECF not associated with IBD. This would be an alternative option and benefit an already surgically challenging group of patients associated with a high morbidity and mortality where it is deemed conservative medical management has failed.
Materials and methods: Research ethics approval was granted for this study. Tissue biopsies were obtained from ECF at operation from non-IBD patients and from the terminal ileum in normal colonoscopy control patients. After 24 h incubation, intra cellular staining was performed using monensin to assess the on-going intra cellular production of cytokines. Data was acquired using FACS Canto II.

Further compensation and analysis of list-mode data were carried out subsequently using Win List software.

Results: Results are available on ten non-IBD ECF and four control patients. The student *t*-test for non-paired data was used. Production of TNF- α by dendritic cells from non-IBD ECF tissue was significantly higher than that from control terminal ileum tissue ($P = 0.0008$). All viable cells from non-IBD ECF tissue also produced significantly higher level of TNF- α compared with control tissue ($P = 0.01$). There were no significant differences in the production of TNF alpha, IL17a and IFN-g by T cells in non-IBD ECF compared with cells from control terminal ileum tissue. Ongoing production of IFN-g gamma was not significantly different in all viable cells form non-IBD ECF compared with all viable cells from control terminal ileum tissue. However, the on-going production of IL17a in all viable cells from non-IBD ECF was significantly higher compared with all viable cells from control terminal ileum tissue ($P = 0.04$).

Conclusions: Although this work is still in progress, a trend has been found in the on-going production of cytokines in non-IBD ECF compared with control tissue. Addition of a greater number of samples may show significant differences between the two groups of patients and provide validity to this trend. This data is encouraging and may provide evidence for the potential use of anti-TNF- α agent in the treatment of non-IBD ECF.

P1107
Vagal anti-inflammatory reflex in dextran sodium sulfate (DSS)-induced colitis

C. Cailotto,* B. J. Olivier,* L. M. M. Costes,* J. van der Vliet,* F. Hilbers,* W. J. de Jonge* & G. E. Boeckxstaens†

**Academic Medical Center, Tytgat Institute for Liver and Intestinal Research, Amsterdam, The Netherlands, †Department of Gastroenterology, University Hospital Leuven, Leuven, Belgium*

Purpose/Objective: The cholinergic anti-inflammatory pathway (CAIP) is a recently identified endogenous anti-inflammatory mechanism modulating the immune system. We recently established that the CAIP is endogenously activated during subtle inflammation of the small intestine in a model of postoperative ileus (POI). To what extent this neuronal pathtway is also activated during colitis remains however unknown. Therefore, we evaluated vagal activation upon DSS-induced colitis using cFos expression, a marker for neuronal activation, in the dorsal motor nucleus of the vagus nerve (DMV) at different time points of DSS exposure. Moreover, selective vagal denervation of the proximal part of the colon was performed to investigate the anti-inflammatory role of the vagal innervation of the colon.

Materials and methods: C57/Bl6 mice were exposed to DSS in drinking water for 7 consecutive days. Mice were sacrificed at day 1, 3 and 7. The group of mice exposed to 7 days of DSS was divided into 2 experimental groups: vagal denervated (Cx) and sham-operated. Brain was collected for cFos expression and colonic tissue was collected to determine the expression of inflammatory cytokines.

Results: Mice exposed to 7 days of DSS exhibited a significant increase in the disease index activity and a decreased body weight. The inflamed colons showed an increased expression of IL-6, TNFα, and IL1β compared to control mice. Colonic inflammation did not significantly increase cFos expression in the DMV. Denervation of the proximal colon induced an increase of IL6 and IL1β transcript levels in the entire colon. Strikingly, the enhanced colonic inflammation was observed only in the distal part (non-denervated) of the colon.

Conclusions: In the present study, DSS-induced colonic inflammation did not trigger endogenous activation of CAIP as described during intestinal muscularis inflammation in POI. Denervation of the vagus nerve (innervating the proximal part of the colon) enhanced colonic inflammation, confirming the role of the cholinergic anti-inflammatory pathway in mucosal immune homeostasis. Strikingly, removal of this neuronal pathway affects the innate immune response of the distal colon rather than the proximal colon. Our data demonstrated that neuronal circuitry underlying the cholinergic anti-inflammatory mechanism in colitis differs from the CAIP activated during POI.

Poster Session: Malaria

BTLA expression dampens innate as well as adaptive immunity against experimental malaria

T. Jacobs,* C. Steeg,* K. Pfeffer,† T. L. Murphy,‡ K. M. Murphy,‡ J. Langhorne§ & G. Adler*

*Immunology, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, †Institute of Medical Microbiology, Heinrich Heine University, Düsseldorf, Germany, ‡Department of Pathology and Immunology, Howard Hughes Medical Institute, Washington University School of Medicine, St. Louis, MO, USA, §Division of Parasitology, Medical Research Council National Institute for Medical Research, London, UK

Purpose/Objective: The activation of T cells during priming but also their later function is modulated by numerous surface receptors. Activation requires signals from the TCR and costimulatory signals, which determine whether antigen recognition leads to full activation or anergy. In contrast coinhibitory receptors expressed by T cells mediate the regulation of immune responses and play a pivotal role in the maintenance of peripheral tolerance. By integrating positive and negative signals excessive activation of T cells is prevented. During malaria T cells express different coinhibitory receptors, which might protect the host from an overreaction of the immune response but might contribute to an ineffective clearance of the pathogen. Recently, BTLA (B and T lymphocyte attenuator, CD272) was described as a novel negative costimulatory receptor. BTLA is predominantly expressed on T and B cells and dampens T cell activation. In this study, we analyzed the function of BTLA during experimental malaria infection.

Materials and methods: To study the function of BTLA we employed a mouse model of blood stage malaria using *P. yoelii* NL. This infection causes a high parasitemia in infected mice that is cleared within 3 weeks. By using BTLA-deficient and HVEM-deficient mice the respective function of these molecules were analysed. Using mixed bone-marrow chimera the function of BTLA on different immune cell populations was further elucidated.

Results: BTLA expression restricts the protective immune response on different levels. BTLA::HVEM interaction regulates the number and function of the responding T cells but in addition BTLA expression also dampens B cells and phagocytic cells. However, in contrast to the manipulation of the CTLA − 4 pathway, where already a transient blockade is accompanied by a massive inflammation, the lower parasitemia of BTLA- and HVEM-deficient mice is not accompanied by any signs of pathology.

Conclusions: In contrast to other negative costimulatory pathways, the HVEM::BTLA pathway dampens the function of the innate as well as of the adaptive immune system during experimental malaria and thus manipulation of this pathway is an attractive target for therapeutic interventions.

P1109

CTLA-4 expression on T effector and T regulatory cells in experimental malaria

C. Steeg,* T. Sparwasser† & T. Jacobs*

*Immunology, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, †TWINCORE/Centre for Experimental and Clinical Infection Research, Institute of Infection Immunology, Hannover, Germany

Purpose/Objective: In the course of an infection with *Plasmodium* ssp. the parasites develop via two stages: at first in the liver followed by replication in the blood. In the first phase only few hepatocytes are infected and the antigenic load is low, but in the subsequent blood stage many erythrocytes are infected which leads to a vast amount of antigenic material delivered to the immune system. This induces a strong activation of T cells followed by the production of proinflammatory cytokines that contribute to the severe complication of malaria, the cerebral Malaria (CM). Thus the immune response has to be tightly regulated to achieve on the one hand protection against the parasite but on the other hand prevent immunopathology. CTLA-4 is one of the most effective regulators of T cells and is expressed on Treg and T effector cells. We investigated CTLA-4 expression on T cells in a mouse model for the blood stage of protection against malaria and in a model for CM.

Materials and methods: We infected C57Bl/6 mice and DEREG mice (DEPletion of REGulatory T cells) with *Plasmodium yoelii* or *Plasmodium berghei* ANKA and analysed spleen cells during the development of the disease.

Results: In the course of infection with *P. yoelii* the ratio of Treg to $CD4^+$ T cells declines but the number of CTLA-4 positive T cells increases. These CTLA-4^+ cells produce IFN-g whereas the $Foxp3^+$ cells produce IL-10. After depletion of Treg in DEREG mice with Diphtheria toxin the number of CTLA-4^+ Foxp3- T cells increases rapidly and IFN-g production of $CD4^+$ T cells is also increased whereas TNF-a production is unchanged. However this has no influence on the parasitemia.

When we infected mice with *P. berghei* ANKA we observed a massive induction of CTLA-4 on $CD4^+$ as well as on $CD8^+$ with up to 30% CTLA-4 positive cells. The $CD4^+$ CTLA-4^+ cells are still functional and produce IFN-g but no TNF.

Conclusions: Our data suggest that the rapid induction of CTLA-4 on T effector cells during an infection with Plamodium is a highly dynamic counterregulatory pathway that protects the host from pathology.

P1110

P. berghei sporozoite challenge of vaccinated BALB/c mice lead to induction of humoral immunity and improved $CD8^+$ T cell memory

S. Tartz,* C. Deschermeier,† V. Heussler,‡ P. Sebo,§ B. Fleischer* & T. Jacobs*

*Immunology, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, †Parasitology, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, ‡Institute of Cell Biology, University of Bern, Bern, Switzerland, §Cell and Molecular Microbiology Division, Czech Academy of Sciences, Prague, Czech Republic

Purpose/Objective: Protection against malaria can be achieved by activation of a strong $CD8^+$ T cell response against the *Plasmodium* circumsporozoite protein (CSP). However, most subunit vaccines fail to induce a sufficient memory response. In the present study we analysed the impact of a sporozoite infection after immunization on the development of long-lasting protective immunity.

Materials and methods: BALB/c mice were immunized by a heterologous prime/boost regimen against *P. berghei* CSP. A recombinant *Salmonella typhimurium* strain and a *Bordetella pertussis* adenylate cyclase toxoid fusion molecule were used as vaccine carriers. This immunization induces a strong $CD8^+$ T cell response and complete protection upon sporozoite challenge, which is however, only short lived.

Results: A sporozoite challenge after immunization led to prolonged protective immunity. Repeated challenge infections induced sporozoite specific antibodies that showed protective capacity. On the other hand the CSP-specific $CD8^+$ T cell response was not substantially boosted by sporozoite infections and the magnitude of the $CD8^+$ T cell memory seemed not to correlate with protection. The phenotype of these memory T cells was comparable; however, CSP-specific memory $CD8^+$ T cells of challenged mice displayed stronger cytotoxic activity than

memory T cells of only immunized mice. Sterile protection was abrogated when $CD8^+$ T cells were depleted whereas $CD4^+$ T cells played a minor role.
Conclusions: Based on these data we suggest that the increase in protective immunity observed after immunization and subsequent challenge infection is the sum of different antiparasitic mechanisms including $CD8^+$ and $CD4^+$ T cells as well as neutralizing antibodies, with $CD8^+$ effector-memory T cells playing the major role. Our results indicate that a vaccine which induces a short-lived liver-stage specific immunity that prevents disease within a certain time span would allow the induction of naturally acquired immunity upon repeated sporozoite infections.

Pathogenesis and therapy of malaria-associated acute respiratory distress syndrome

P. Van den Steen, K. Deroost, N. Geurts, N. Lays, S. Verhenne, H. Heremans, J. Van Damme & G. Opdenakker
Rega Institute, Katholieke Universiteit Leuven, Leuven, Belgium

Purpose/Objective: Malaria-associated acute respiratory distress syndrome (MA-ARDS) is a lethal complication of malaria. No efficient treatment is available for this complication and its pathogenesis remains poorly understood. We studied the disease mechanisms and evaluated candidate treatments in a new mouse model.
Materials and methods: We established a novel mouse model of MA-ARDS by infection with *Plasmodium berghei NK65* (*PbNK65*). Histology, FACS analysis, RT-PCR, bronchoalveolar lavages, cell depletions and anti-inflammatory treatment with dexamethasone were performed. A new method for the extraction and quantification of hemozoin (malaria pigment) in tissues was optimized.
Results: *PbNK65* infection resulted in leukocyte accumulation, extensive edema and hemorrhage in the lungs. The pulmonary expression of several cytokines and chemokines was increased to a higher level than in mice infected with *P. chabaudi AS*, a parasite strain which does not cause MA-ARDS. $CD8^+$ T lymphocytes were shown to be pathogenic and high doses of dexamethasone (DEX) blocked MA-ARDS through inhibition of lymphocyte proliferation and expression of chemoattractants for monocytes/macrophages, even when given after appearance of the pathology. On tissue sections, we noticed the presence of hemozoin or malaria pigment in the lungs. In view of the important inflammatory potential of this hemoglobin degradation product, we optimized a novel method to quantify hemozoin in tissues and measured the Hz content in different organs of mice infected with parasites of different pathogenicity. Significantly higher amounts of hemozoin were found in the lungs of mice with MA-ARDS. Furthermore, total Hz contents (including liver and spleen levels) were significantly higher in mice infected with *P. berghei NK65* than in mice infected with *P. chabaudi AS*, despite of similar peripheral parasitemia levels. Further investigations to clarify the role of hemozoin in MA-ARDS are currently underway.
Conclusions: Our new mouse model for MA-ARDS has many similarities to human MA-ARDS. Inflammation has a prominent role in the disease, and anti-inflammatory treatment appears highly effective. High amounts of hemozoin were detected in the lungs and may contribute to the pathogenesis.

The immuno-stimulatory and protective effect of the novel nanoparticle-coated *Plasmodium yoelii* merozoite surface protein (PyMSP-1)

M. S. Cherif,* M. N. Shuaibu,† T. Kurosaki,‡ Y. Kodama,‡ H. Sasaki,‡ K. Yui,§ G. K. Helegbe,† M. Kikuchi,† T. Yanagi¶ & K. Hirayama†
**Immunogenetics, Institut National de Santé Publique, Université de Conakry (Guinea) & Institute of Tropical Medicine, Nagasaki, Japan, †Immunogenetics, Institute of Tropical Medicine, Nagasaki, Japan, ‡Hopital Pharmacy Department, Nagasaki University, Nagasaki, Japan, §Division of Immunology, Department of Molecular Microbiology and Immunology, Nagasaki University, Nagasaki, Japan, ¶Institute of Tropical Medicine, Animal Research Center for Tropical Medicine, Nagasaki, Japan*

Purpose/Objective: In malaria DNA vaccine development, for induction of an efficient and protective immunity against parasite, there exists a critical need for additional delivery vehicles. We analyzed the immuno-stimulatory effect of PEI/γ-PGA nanoparticle (NP)-coated PyMSP-1 plasmid and investigated its *in vivo* stimulatory effect on dendritic cells.
Materials and methods: Groups of C57BL/6 mice were immunized either with 100 μg/mouse of nanoparticle-coated plasmid (pVR1020-MSP-1/PEI/γ-PGA), naked (pVR1020-MSP-1) or coated control group (pVR1020/PEI/γ-PGA) using different routes of administration. Mice were prime-immunized at day 0 and subsequently, two boosters given with 3 weeks intervals. Two weeks after the last boost, specific IgG and their subtype's titres measured by ELISA. Cytokine (IL-12 and IFN-γ) levels were measured in the supernatants of antigen stimulated spleen cells and sera from immunized mice using procarta-immunoassays kit. Flow cytometric analysis of various activated DC markers was also carried out.
Results: Protection against *P. yoelii* lethal challenge, specific IgG and its subtypes and INF-γ producing cell number were observed to be significantly higher in the coated-MSP-1 group than the naked group. Also, there were a significantly increased proportion of activated DCs and their elevated CD40 expression in the NP-coated immunized group as compared to naked plasmid. In the coated group, the co-stimulatory molecule CD80 was significantly increased when immunized subcutaneously, while CD86 molecule was increased when immunized intraperitoneally. *In vivo* and ex-vivo production of IL-12 were observed in the sera and the spleen cells stimulated with recombinant MSP-1.
Conclusions: These data indicates that nanoparticle-coated PyMSP-1 DNA vaccine protected mice and induced activated DCs either with CD80 or CD86, and the activated DCs produced IL-12 when stimulated by rMSP-1.

B cell over-expression of Fc gamma receptor IIb inhibits the development of atherosclerosis

A. P. Sage,* O. Herbin,† D. Murphy,* L. Masters,* L. Baker,* J. Harrison,* M. R. Clatworthy,‡ K. Smith‡ & Z. Mallat*
*Division of Cardiovascular Medicine, University of Cambridge, Cambridge, UK, †Inserm, Centre de Recherche Cardiovasculaire, Paris, France, ‡Medicine, University of Cambridge, Cambridge, UK

Purpose/Objective: The development of atherosclerosis is significantly regulated by autoimmune and inflammatory processes involving both innate and adaptive immune systems, and is accelerated in the presence of other autoimmune diseases. The inhibitory FcyRIIb has previously been associated with regulation of atherosclerosis development, but the cells types mediating these effects are unknown. Thus, we investigated the effect of B cell-specific FcyRIIbover-expression on the development of atherosclerosis in mice.
Materials and methods: Atherosclerosis-susceptible, low density lipoprotein receptor $^{-/-}$ (ldlr) mice were irradiated and transplanted with bone marrow from B cell FcyRIIb-transgenic (BTG) mice or non-transgenic littermate controls, then fed a high-fat diet for 6 weeks. Atherosclerosis burden and plaque immune cell content was analysed histologically. Immune cell phenotypes were analysed by flow cytometry and cytokine production by intracellular flow cytometry and ELISA.
Results: Compared to normal chow, a 6 week high-fat diet, known to induce CD4+ T cell activation and increased anti-oxidized lipid antibodies, significantly increased MHC class II levels in splenic and lymph node B cells as well as increased levels of BAFF in serum and spleen, suggesting B cell activation in response to high fat feeding. In ldlr chimeras, there were no differences between control and BTG groups in total cholesterol levels, body weight or total blood cell counts. FcyRIIb overexpression suppressed purified B cell proliferation in response to anti-IgM IgG but not F'ab or LPS, and did not affect splenic B cell MHCII or CD40 expression. The level of atherosclerosis at the aortic root was significantly reduced in ldlr/BTG mice compared to littermate controls. The reduced atherosclerosis in ldlr/BTG mice was associated with reduced CD3+ T cell levels within plaques, reduced *ex-vivo* production of IFN-y by both CD4+ and CD8+ T cells, and reduced levels of CD62L*lo* CD44*hi* CD4+ T cells in the spleen, consistent with the previously proposed role of B cells in promoting T cell activation and atheroprogression.
Conclusions: FcyRIIb expression on B cells leads to reduced atherosclerosis, potentially via suppression of pro-atherogenic T cell activation and cytokine production.

Galectin-3 deficiency preserves pancreatic islets function in basal conditions and under cytotoxic stimuli

I. Nikolic,* T. Saksida,* I. Stojanovic,* M. L. Lukic† & S. Stosic-Grujicic*
*Immunology, Institute for Biological Research 'Sinisa Stankovic', University of Belgrade, Belgrade, Serbia, †Center for Molecular Medicine, Faculty of Medicine, University of Kragujevac, Kragujevac, Serbia

Purpose/Objective: Galectin-3 (Gal-3) is β-galactoside-binding lectin expressed in variety of tissues and cell types and possesses diverse functions, including promotion of inflammatory response and triggering apoptosis. Since it was established that Gal-3-deficient (Gal-3$^{-/-}$) mice are resistant to streptozotocin-induced diabetes and the precise role of Gal-3 in pancreatic islets activity has not been examined so far, our aim was to explore the influence of Gal-3 absence on insulin secretion and apoptosis of pancreatic islets.
Materials and methods: We exposed mouse pancreatic islets (isolated from Gal-3$^{-/-}$ and WT (C57BL/6) mice by collagenase digestion) to proinflammatory cytokines (IL-1β+IFN-γ+TNF-α, 10 ng/ml each) or left them untreated for 24 or 96 h and analysed their survival and function. After incubation, islet apoptosis was measured by histone-DNA ELISA. In order to assess effect of Gal-3 deficiency on insulin secretion, we performed *in vitro* insulin release assay. Isolated islets were first treated with low glucose (1.67 mM) for 1 h and then with high glucose (16.7 mM) and released insulin was measured by ELISA.
Results: Deficiency of Gal-3 promoted better survival of pancreatic islets when they were cultured in basal conditions for 96 h. In line with that, Gal-3$^{-/-}$ pancreatic islets preserved intact insulin secretion compared to WT islets. What is more, Gal-3 deficiency protected pancreatic islets from cytokine-induced apoptosis. Also, after 24 h-long cytotoxic stimulation, Gal-3$^{-/-}$ pancreatic islets retained normal insulin secretion while WT islets had lower secretion. Similarly, Gal-3$^{-/-}$ islets had better response to glucose-stimulated insulin release in basal as well in inflammatory conditions after 24 h of culture.
Conclusions: This study demonstrates that Gal-3 deficiency protects islets from cytokine-induced apoptosis and preserves their function therefore implicating the role of Gal-3 in pancreatic islets apoptosis during inflammation that occurs in diabetes pathogenesis.

This study was supported by the Serbian Ministry of Education and Science (Grants No.: 173013 and 175069).

Glucose tolerance status and hsCRP in a large population-based survey

Y. Tutuncu,* I. Satman,* S. Gedik,* B. Canbaz,* F. Turker,* N. Dinccag,* K. Karsidag,* A. Telci,† S. Genc,† B. Omer† & On behalf of TURDEP-II Study Group
*Faculty of Medicine Internal Medicine Endocrinology & Metabolism, Istanbul University, Istanul, Turkey, †Faculty of Medicine Clinical Biochemistry, Istanbul University, Istanul, Turkey

Purpose/Objective: To determine whether high sensitive C-reactive protein (hsCRP) levels differ according to glucose tolerance status.
Materials and methods: Data derived from recently completed population-based survey of diabetes, obesity, hypertension and endocrine disease epidemiology in Turkish adult population (n = 26 499), TURDEP-II.
Results: In female hsCRP was significantly higher than in male (mean ± SEM 3.95 ± 0.05 versus 3.53 ± 0.09 mg/dl, p Univariate analysis of variance corrected for age, gender, urban/rural, region, BMI, waist, sBP, dBP, HDL-c, non-HDL-c, 25(OH)D Vit, PTH, creatinine, TSH and FT4 revealed that hsCRP significantly differ across glucose tolerance status pmellitus (DM) and known DM groups [mean ± SEM (mg/dl)]: 4.13 ± 0.25, P = 0.023; 4.49 ± 0.33, P = 0.006; 5.65 ± 0.35, P.
Conclusions: Based on our study results, mean levels of hsCRP increase from NGT through new DM categories. The fact may confirm that any abnormality of the glucose tolerance (pre-DM and DM) is associated with a low-grade inflammatory process. However, in established DM the inflammatory process may not be as important as in the earlier metabolic derangements.

High sensitive C-Reactive protein (hs-CRP) and its correlation with angiographic severity of coronary artery disease: an Indian cohort study

S. Das,* S. K. Gupta,* P. C. Ray* & G. M. P.†
*Department of Biochemistry, Maulana Azad Medical College, New Delhi, India, †Department of Cardiology, G. B. Pant Hospital, New Delhi, India

Purpose/Objective: The association between high sensitive C-reactive protein (hs-CRP) levels and the severity of coronary artery disease (CAD) is highly debated. There are very few studies assessing the role of hs-CRP levels with increasing severity of CAD. The aim of our study was to study the correlation of hs-CRP levels with angiographic clinical vessel score in an Indian population.
Materials and methods: Hundred patients of angiographically proven CAD were studied of which 50 patients were of stable angina (Group I), 50 patients of acute coronary syndrome (Group II) (including 35 patients of unstable angina and 15 patients of MI) from a tertiary health center, New Delhi and a third group comprising of 50 age and sex matched healthy controls were studied over a period of 1 year. The hs-CRP levels were measured by ELISA technique and angiographic clinical vessel scoring was done for all patients.
Results: The mean age of the patients was 49 ± 8.8 years (84% men, 16% women). THe mean hs-CRP levels for stable angina (Group I) (6.04 ± 2.51 mg/l) and acute coronary syndrome (Group II) (8.11 ± 2.84 mg/l) were significantly higher in CAD patients than in controls (1.54 ± 1.27 mg/l, $P < 0.001$). High hs-CRP levels were correlated with higher vessel scores indicating a more severe CAD ($r = 0.735$, $P < 0.001$).
Conclusions: Significant correlations were found between the hs-CRP levels and the angiographic clinical vessel score. High hs-CRP levels have a correlation with the increasing disease severity in CAD patients.

P1122

Human a1-antitrypsin Blocks Heat Shock Protein 70 (HSP70)-Induced Inflammation in Pancreatic Islets

D. O. Ochayon, M. M. Mizrahi, P. C. Cal, B. B. Baranovski, G. S. Shahaf & E. L. Lewis
Clinical Biochemistry, Ben Gurion University of the Negev, Beer-Sheva, Israel

Purpose/Objective: *Introduction.*

Heat shock protein 70 (HSP70) is an abundant chaperone and an endogenous mediator of cell damage. HSP70 enhances inflammation and promotes antigen presentation and subsequent T cell proliferation via membrane CD91. These activities may take part in islet destruction during autoimmune diabetes and during islet transplant rejection. Indeed, circulating HSP70 has been observed in patients with type-1 diabetes. The anti-inflammatory acute phase protein α1-antitrypsin (AAT) promotes islet survival in a transplantation model and in an autoimmune diabetes model. Its protective mechanism of action in these processes is unknown.

Aim.

Examine whether the protective activity of AAT is related to binding and inactivation of HSP70.
Materials and methods: Peritoneal macrophages, bone marrow derived dendritic cells and pancreatic islets were evaluated for inflammatory responses under stimulation with polymyxin B treated recombinant HSP70 (rHSP70) in the presence or absence of clinical-grade human AAT. Islet function was evaluated by insulin secretion. OT-I spleen cells were incubated with OVA peptide and HSP70 in the presence or absence of AAT. The effect of AAT on IL-1β/IFNγ-induced surface levels of CD91 was evaluated. Binding between HSP70 to AAT was determined by direct ELISA.
Results: In all tested cell cultures, AAT diminished rHSP70-induced inflammatory responses. In HSP70-stimulated islets, IL-1β release was reduced 2.43 ± 2.01-fold, IFNγ 1.73 ± 1.06-fold and IL-6 1.27 ± 1.02-fold. AAT restored rHSP70-mediated disrupted islet insulin secretion. OVA/HSP70 introduced to OT-I spleen cells elevated the number of $CD3^+$ $CD8^+$ T-cells 2.28-fold, compared to cells incubated with OVA alone, and 2.79-fold compared to OT-I spleen cells incubated with HSP70 plus AAT. Under inflammatory conditions, surface CD91 levels were reduced in AAT-treated peritoneal macrophages 2.05 ± 0.33-fold compared to untreated macrophages. Finally, we demonstrate that rHSP70 directly binds to human AAT in a concentration-dependent manner.
Conclusions: Our findings suggest that AAT is a natural regulator of inflammatory responses mediated by HSP70, and a possible target during clinical AAT treatment.

Interleukin-1 and leptin synergistically enhance matrix metalloproteinase expression in human gingival fibroblasts

R. C. Williams,* A. D. Rowan,† P. M. Preshaw* & J. J. Taylor*
Centre for Oral Health Research, Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, UK, †Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, UK

Purpose/Objective: The adipokine leptin is elevated in obesity and type 2 diabetes, conditions which are associated with increased susceptibility to chronic inflammatory diseases such as periodontitis. Loss of tissue integrity in inflammatory diseases is caused by extracellular matrix (ECM) degradation by proteases, such as the matrix metalloproteinases (MMPs). Gingival fibroblasts are critical in regulating tissue homeostasis in the periodontium and synthesise MMPs in response to cytokines but the effect of leptin on these cells is unknown. Our aim was to investigate the effect of leptin in regulating MMP expression in primary human gingival fibroblasts (HGFs).
Materials and methods: HGFs were isolated from gingival tissue obtained during canine exposure surgery. HGFs (between passage 5–9) were stimulated under serum-free conditions with leptin (10 μg/ml), interleukin (IL)-1α (0.05 ng/ml) and oncostatin M (OSM) (5 ng/ml) for 24 h. MMP mRNA expression was assessed by real-time and conventional RT-PCR. HGF proliferation was determined using a MTS-based assay.
Results: Leptin significantly increased the expression of the collagenase MMP-1 in a dose-dependent manner, but did not affect the expression of the gelatinase MMP-2, compared to unstimulated HGFs. MMP-3, a stromelysin known to activate MMP-1, was expressed in both leptin-stimulated and unstimulated HGFs. Interestingly, leptin+IL-1 synergistically increased both MMP-1 and MMP-3 expression in HGF cultures above that observed after IL-1 or leptin stimulation alone. Leptin+IL-1 had no effect on MMP-2 expression. It is unlikely that the synergistic upregulation of MMP expression was due to increased HGF proliferation as leptin+IL-1 stimulation did not increase HGF proliferation above that of cells stimulated with leptin alone. Leptin+OSM did not synergistically upregulate MMP-1, MMP-2 or MMP-3 expression in HGFs.
Conclusions: We demonstrate that HGFs respond to leptin by upregulating MMP-1 expression. The synergy demonstrated between leptin and IL-1 highlights the importance of combinations of cytokines in regulating MMP expression. This pathway may be of mechanistic relevance to inflammatory tissue damage as occurs in periodontitis, and underpin the cross-susceptibility between inflammatory diseases associated with obesity.

Investigation of possible relations of SDF-1 and CXCR-4 polymorphisms and CD55 and CD59 markers with etiopathogenesis and prognosis in Type 2 diabetes

B. Aydin,* E. Coskunpinar,† S. Gazioglu,* B. Agachan,† G. Deniz,* M. T. Yilmaz‡ & A. O. Gurol*
*Immunology, Institute of Experimental Medicine (Detae), Istanbul, Turkey, †Molecular Medicine, Institute of Experimental Medicine (Detae), Istanbul, Turkey, ‡Internal Medicine, Istanbul Faculty of Medicine, Istanbul, Turkey

Purpose/Objective: Diabetes is a metabolic hyperglycemic disease resulting from impaired insulin production, secretion or insulin resistance. Complement regulators and chemokines are pivotal in pathogenesis. In the context of complications related to T2DM, CD55, CD59 expressions, and SDF-1, CXCR-4 polymorphisms were investigated.
Materials and methods: Seventy-five patients with T2DM and 73 healthy subjects were enrolled in the study. CD55 and CD59 expressions were evaluated with flow cytometry. DNA was isolated from heperinized periferic blood samples. Real-time PCR assay was carried out using LightSnip (rs17881575 Roche-Germany) for SDF-1 and LightSnip (rs2680880 Roche-Germany) for CXCR-4.
Results: CD55 and CD59 expressions in patients with T2DM nephropathy, retinopathy and cardiovascular disease were significantly lower than healthy subjects. SDF-1 genotype and allele distributions between groups were not different. CXCR-4 genotype distribution wasn't different between groups, while a low significance was observed in allel distributions. CXCR-4 T allele was increased in patients, with 1.6-fold risk in terms of disease. Although SDF-1 genotypes in nephropathics did not show any difference, a significant difference was detected for CXCR-4 genotypes. CXCR-4 A allele carriers had decreased nephropathy, while 2-fold high nephropathy frequency was observed in the carriers of CXCR-4 T allele. The nephropathy risk increases 10-fold in CXCR-4 TT genotype carriers. A significant difference was observed in SDF-1 genotypes associated with retinopathy presence. Our results show that all SDF-1 CC genotype carriers have retinopathy, and CC genotype is effective in retinopathy development, however no significance was found for CXCR-4 genotypes. For the presence of cardiovascular disease, a significant difference was observed for SDF-1 genotypes. Increased cardiovascular risk of 5- and 1.9-fold in SDF-1 T and CXCR-4 T allele carriers respectively was observed.
Conclusions: This is the first study investigating together CD55 and CD59 expressions, and SDF-1 and CXCR-4 polymorphisms in T2DM. In conclusion we suggest that CD55 and CD59 have a predictive importance in the process of the disease, and the polymorphism of CXCR-4 gene promoter site (rs2680880) plays a role in the susceptibility to T2DM. Further studies with an increased number of subjects are needed in this field.

P1125

Low frequency of GITR+ cells in *ex vivo* and *in vitro* expanded Tregs from type-1 diabetic patients

C. Xufré,* M. Costa,* C. Roura-Mir,* E. Codina-Busqueta,* L. Usero,* E. Pizarro,† G. Obiols,‡ D. Jaraquemada* & M. Martí*
*Institut de Biotecnologia i Biomedicina, Biología Celular Fisiología e Inmunología, Barcelona, Spain, †Hospital de Mataró, Servei d'Endocrinologia, Mataró, Spain, ‡Hospital de la Vall Hebron, Servei de Nutrició i Endocrinologia, Barcelona, Spain

Purpose/Objective: Reported alterations in regulatory T cells (T_{regs}) in patients with several autoimmune disorders led us to a revision of the phenotypical features of type-1 diabetic patients' peripheral $CD4^+$ $CD25^{hi}$ T_{regs} compared to controls.
Materials and methods: A fine cytometric analysis was designed to phenotypically characterise T_{regs} from type-1 diabetic (T1D) patients and controls using a staining panel including FOXP3, CTLA-4, GITR and CD127. PBMCs and sorted T_{regs} were cultured with different stimulus: media alone, soluble OKT3 and anti-CD3/anti-CD28 coated beads. Suppression assays of *in vitro* expanded T_{reg} cells were performed.
Results: The frequency of peripheral T_{reg} cells was similar between T1D patients and controls. However, the yield of sorted T_{regs} was significantly lower in patients than in controls ($P < 0.003$). When comparing T_{reg} phenotype between samples, the only difference concerned GITR. A significant decrease of $GITR^+$ cells within the T_{reg} population ($P < 0.0009$) and to a lesser extent in effector ($P < 0.02$) populations, was observed for T1D compared to controls. Since GITR is involved in costimulation, its expression was analyzed in different conditions of T cell activation. Differences were only observed for T1D T_{regs} versus controls when faced to suboptimal stimulation i.e, soluble anti-CD3 ($P < 0.05$) or medium alone ($P < 0.05$), but not in the presence of anti-CD3/anti-CD28 coated beads. Despite this reduced expression, expanded T1D T_{regs} -mediated suppression was as efficient as that mediated by their control counterparts.
Conclusions: Our results suggested that GITR is a T_{reg}-marker that would be primarily involved in T_{reg} maintenance rather than in its suppressor function.

P1126

Mice deficient for the autoimmune regulator, Aire, display altered T cell responses against 21-hydroxylase, the major autoantigen in autoimmune Addison's disease

E. Bratland, A. Hellesen & E. S. Husebye
Institute of Medicine, University of Bergen, Bergen, Norway

Purpose/Objective: The autoimmune regulator, Aire, is a transcriptional regulator playing a critical role in central tolerance by promoting the display of tissue specific self-antigens. In humans mutations in the gene encoding Aire result in the unique disorder autoimmune polyendocrine syndrome type 1 (APS-1). One of the hallmarks of APS-1 is autoimmune Addison's disease (primary adrenocortical failure) with corresponding immune responses against 21-hydroxylase (21OH), an enzyme crucial for the synthesis of steroid hormones. Mice deficient for Aire also develop spontaneous autoimmunity in several organs, but adrenal autoimmunity or anti-21OH immune responses have not yet been described. We therefore wanted to investigate the influence of Aire on immune responses in mice immunized with 21OH protein.
Materials and methods: C57Bl6 mice deficient for Aire and littermate controls were immunized with 21-hydroxylase (21OH) on day 0 and boosted on day 7. All mice were sacrificed on day 14, and spleens, lymph nodes, adrenals and whole blood were collected. CD4+ and CD8+ T cells were stimulated *in vitro* with recombinant 21OH and a panel of 21OH-derived peptides. Cell culture supernatants were assessed for interferon-γ content by ELISA. T cell mediated cytotoxicity were determined using peptide pulsed or 21OH-transfected EL4 cells as targets.
Results: Broad T cell responses against multiple epitopes of 21OH could be induced in C57Bl6 mice, regardless on the presence or absence of Aire. However, in the absence of Aire, T cell responses were enhanced against certain epitopes. Furthermore, some epitopes were uniquely targeted in Aire deficient mice.
Conclusions: Our findings suggest that T cell responses against 21OH can be readily induced in C57Bl6 mice, and that Aire may modulate these T cell responses.

P1128

Obesity-associated autoantibody production requires AIM for retaining the immune complex on follicular dendritic cells

S. Arai & T. Miyazaki

Lab of Molecular Biomedicine for Pathogenesis, Center for Disiease Biology and Integrative medicine, Faculty of Medicine, The University of Tokyo, Tokyo, Japan

Purpose/Objective: Recent evidence has suggested a significant correlation between obesity and autoantibody production, although its mechanism remains unknown. The aim of this study is to address a functional involvement of the apoptosis inhibitor of macrophage (AIM) in this autoimmune process. AIM is a secreted protein produced by macrophages and circulates in blood at around 10 μg/ml in both human and mouse. Interestingly, AIM is associated with pentamers of natural IgM in blood. Natural IgM is polyreactive, recognizing self-antigens, and thus is believed to be associated with autoimmunity. In addition, AIM blood levels increase with progression of obesity in mice when fed with a high-fat diet (HFD). All these observations strongly suggest that AIM/IgM complex might be involved in the development of obesity-associated autoimmunity.

Materials and methods: Following experiments were performed: (1) serum IgM and IgG levels were assessed in $AIM^{+/+}$, $AIM^{-/-}$ and $TLR4^{-/-}$ mice during the progression of obesity, (2) we analyzed autoantibodies in obese $AIM^{+/+}$ and $AIM^{-/-}$ mice using autoantibody array, (3) influence of AIM to the binding of IgM to Fca/mR, an IgM-specific Fc receptor expressed in the splenic follicular dendritic cells (FDCs), was tested. In addition, effect of AIM on the holding of IgM-immune complex (IgM-IC) on the FDCs was analyzed.

Results: In mice fed a HFD, splenic B cells were activated through stimulation of TLR4. This response increased natural IgM production, followed by expansion of IgG autoantibodies. AIM associated with IgM, and inhibited its binding to the Fca/mR such an effect protected IgM-IC from internalization mediated by Fca/mR, and thus retained the ICs on FDCs. This supported IgM-dependent antigen-presentation to B cells leading to plasma cell development. In $AIM^{-/-}$ mice, although elevation of IgM in response to HFD was comparable to $AIM^{+/+}$ mice, the increase of IgG autoantibodies was abrogated.

Conclusions: Our results show that association of AIM with IgM interferes with the internalization of IgM-ICs via Fca/mR, resulting in prolonged retention of the ICs on the surface of FDCs. This contributes to the efficient presentation of autoantigens to germinal center B cells, leading to development of IgG autoantibody producing plasma cells. Thus, suppression of AIM may have therapeutic potential for preventing obesity-associated autoimmune diseases.

Perivascular adipocytes and signaling through toll-like receptors: role in the pathophysiology of atherosclerosis

C. Benaiges,* X. Garcia-Moll,† E. Mateus,* C. Muñoz,‡ E. Cantó,* E. Pérez,* R. Leta,† E. Moga,* S. Vidal* & C. Juarez*

**Immunology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain,* †*Cardiology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain,* ‡*Cardiac Surgery, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*

Purpose/Objective: Perivascular adipose tissue has emerged as a critical regulator of vascular function implicated in the pathophysiology of atherosclerosis. Arteries are surrounded by a significant amount of perivascular adipose tissue that is an active endocrine and paracrine source of inflammatory cytokines and adipokines. Moreover, adipocytes express toll-like receptors (TLRs) to respond to lipids and other self and nonself molecules activating proinflammatory pathways. We analyzed TLR/JAK-STAT transduction pathways in adipose tissue from patients with atherosclerosis to unravel the mechanisms implicated in the pathophysiology of atherosclerosis.

Materials and methods: Perivascular and subcutaneous adipose tissues were obtained from control and atherosclerosis patients. Explants of adipose tissue were cultured in presence of TLR ligands and Affymetrix Expression Arrays were performed to analyze changes in gene expression. Western blot was carried out to analyze expression and activation levels of STATs. Immunohistochemistry was used to identify cell types and STATs' activation in adipose tissue. Secretion of adipokines (Adiponectin, Resistin and Leptin) and cytokines (IL-6, IL-10, TNF and MCP-1) in supernatants were quantified by ELISA.

Results: Perivascular adipose tissue from atherosclerosis patients showed a higher expression of genes implicated in immune processes and lower expression of genes implicated in metabolism. Accordingly, perivascular adipose tissue from atherosclerosis patients showed B and T lymphocytes infiltrates.

TLR stimulation of adipose tissue upregulated the expression and activation levels of STATs. While STAT3 was activated at the basal level, STAT1 was activated in tissues previously stimulated with TLR ligands.

Cytokine secretion, especially IL-6, increased in supernatants from explants stimulated with TLR ligands. No significant changes in adipokine secretion were observed after TLR stimulation.

Conclusions: We identified alterations in the TLR/JAK-STAT signaling pathways in adipose tissue that would help to explain the deleterious effects of lipids and other TLR ligands in the pathophysiology of atherosclerosis. The results will be very useful to understand the role played by adipose tissue in atherosclerosis and to design therapeutic approaches to control this inflammatory process.

Proprotein convertase FURIN is overexpressed in human atherosclerotic plaque leukocytes and associates with vascular stenosis

H. Turpeinen,* E. Raitoharju,† A. Oksanen,* N. Oksala,‡ M. Levula,† L. P. Lyytikäinen,† M. Kähönen,§ M. Pelto-Huikko,¶ T. Lehtimäki† & M. Pesu*

**Institute of Biomedical Technology, University of Tampere, Tampere, Finland,* †*Department of Clinical Chemistry, University of Tampere, Tampere, Finland,* ‡*Division of Vascular Surgery, Department of Surgery, Tampere University Hospital, Tampere, Finland,* §*Department of Clinical Physiology, Tampere University Hospital, University of Tampere, Tampere, Finland,* ¶*Department for Developmental Biology, University of Tampere, Tampere, Finland*

Purpose/Objective: Atherosclerosis is a chronic, multifactorial process, where both environmental and genetic factors have critical roles. Proprotein convertase (PCSKs) proteases cleave and convert immature target proteins into a biologically active form. Many PCSK target proteins control various aspects of atherosclerosis thus making also PCSKs as key determinants in atherogenesis. Previously, 4 PCSKs (PCSK5, PCSK9, FURIN, MBTPS1) have been linked to regulation of cholesterol metabolism and plaque inflammation in experimental models.

Materials and methods: We analyzed the expression of PCSK genes in human atherosclerotic plaques and pinpointed the cell types involved. Immunohistochemistry, microarray and Q-PCR were used. To further dissect the role of FURIN in atherosclerosis we genotyped 7 haplotype tagging SNPs (htSNPs) in the FURIN gene region in three independent collections of atherosclerosis patients and controls. We also addressed whether the FURIN expression in the artery wall is genetically regulated by analyzing more than 500 000 SNPs along the genome and reciprocally how the FURIN htSNPs regulate the expression of all the other genes in the artery wall.

Results: FURIN, but not other PCSK genes, was shown to be universally statistically significantly over-expressed in the plaques of different arterial beds. FURIN dysregulation concentrates in the inflammatory plaque cells, such as CD3+ and CD20+ lymphocytes

and CD68+ macrophages. FURIN expression analysis in peripheral blood cells revealed that FURIN was induced in TCR activated CD4+ T cells, as well as upon TLR4 mediated activation of CD14+ myeloid cells.

Analyzing the htSNPs we found that the FURIN SNP rs4932370 associates with the severity of atherosclerosis. SNP genotype − expression correlation analyses revealed that the expression of the ITGBP3 gene is regulated by the FURIN SNP rs12903530. However, after correcting for multiple comparisons no SNPs were found to associate statistically significantly with the FURIN expression in atherosclerotic plaques.

Conclusions: Taken this all together makes FURIN as one of the most interesting candidate genes important in regulation of atherogenesis and the plaque inflammation. However, the FURIN expression is not directly regulated by the polymorphisms and further investigations are needed to decode the factors that contribute to the FURIN regulation in the human atherosclerotic plaques

P1131

Resistin is a risk factor for myocardial infarction and acute coronary syndrome in the general population

A. Cabrera,* D. Almeida,† J. J. Alemán,‡ A. González,‡ B. Brito,‡ S. Domínguez‡ & M. C. Rodríguez‡

**Hospital Universitario NS Candelaria, Universidad de La Laguna, Unidad de investigación, Santa Cruz de Tenerife, Spain, †Hospital Universitario NS Candelaria, Unidad de Inmunología, Santa Cruz de Tenerife, Spain, ‡Hospital Universitario NS Candelaria, Unidad de investigación, Santa Cruz de Tenerife, Spain*

Purpose/Objective: In mice, resistin is an adipokine that plays a role in insulin resistance (IR). On the other hand human resistin is a cytokine whose main source are macrophages and is not relevant in the RI, but is related to atherosclerosis. The few prospective studies have been conducted in patients with acute coronary syndrome (ACS) and resistin has been associated with mortality. It has not been prospectively studied whether resistin modifies the risk of myocardial infarction (AMI) in the general population; that was our goal.

Materials and methods: We measured serum resistin in which so far is the largest general population sample ($n = 6630$). We followed this cohort for 3.5 years (cohort study 'CDC de Canarias'), recording the incident cases of AMI and ACS and calculated the relative risk (RR) of those who occupied the top quintile of resistin (Q5) compared to the rest of the population. We adjusted RR for age, sex and tobacco in Cox models.

Results: Resistin showed higher values in women (5.9 ± 0.5 versus 5.5 ± 0.5 ng/ml; $P < 0.001$). On average Q5 was younger (41 versus 43 years, $P < 0.001$) and had lower prevalence of obesity (26% versus 29%; $P = 0.006$), diabetes (8% versus 11%; $P = 0.013$), hypertension (29% versus 36%; $P < 0.001$) and LDL-cholesterol >160 mg/dl (16% versus 19%; $P = 0.018$), but showed higher smoking prevalence (34% versus 24%; $P < 0.001$). Q5 showed no differences in RI (HOMA2: 0.5 versus 0.51; $P = 0.502$) but had a higher incidence of MI [RR = 2.1 (1.1−3.9); $P = 0.019$] and ACS [RR = 1.7 (1.0−2.7); $P = 0.044$]. After multivariate adjustment, Q5 showed higher incidence of MI [RR = 2.2 (1.2−4.1); $P = 0.012$] and ACS [RR = 1.8 (1.1−2.9); $P = 0.027$].

Conclusions: Elevated resistin acts as a risk factor for AMI and ACS in general population even though Q5 individuals are younger and have lower frequency of known cardiovascular risk factors.

Serum concentrations and mRNA expression of chemokine CCL17 in patients with type 2 diabetes mellitus and obesity: the influence of caloric restriction and sleeve gastrectomy

M. Mraz,* Z. Lacinova,* P. Kavalkova,* J. Drapalova,* M. Kindlova,* D. Haluzikova,* M. Urbanova,* M. Kasalicky,† S. Svacina* & M. Haluzik*

**3rd Department of Medicine, General University Hospital, 1st School of Medicine Charles University, Prague, Czech Republic, †Department of Surgery, Central Military Hospital, Prague, Czech Republic*

Purpose/Objective: CCL17 (thymus activation-regulated chemokine TARC) is a CC chemokine with chemotactic effects on T_h2 lymphocytes, which are involved in the switch from proinflammatory M1 to antiinflammatory M2 macrophage phenotype in adipose tissue. The aim of our study was to assess the influence of short-term caloric restriction and laparoscopic sleeve gastrectomy (LSG) on serum concentrations and mRNA expression of CCL17 in subcutaneous adipose tissue (SCAT) of patients with obesity and type 2 diabetes mellitus (T2DM).

Materials and methods: Twelve obese females with T2DM undergoing 2 weeks of very-low-calorie diet (VLCD energy content 2500 kJ/day) and 17 non-diabetic women with 3rd grade obesity (BMI > 40 kg/m^2) scheduled for LSG were included into this prospective study. Serum concentrations and mRNA expression of CCL17 together with other investigated parameters were assessed at the beginning and at the end of VLCD and before and 6, 12 and 24 months after LSG.

Results: Both study procedures markedly reduced body weight and improved metabolic parameters including glucose control, insulin resistance and systemic low-grade inflammation. Two weeks of VLCD lead in our obese diabetic patients to a significant increase in serum levels of CCL17 ($P < 0.001$) accompanied by a 7-fold elevation of its mRNA expression in subcutaneous adipose tissue. On the contrary, extremely obese non-diabetic women showed a 30% decrease of systemic CCL17 concentrations at 24 months after LSG, while no significant change could be seen at months 6 and 12. mRNA expression of CCL17 in SCAT exerted a continuous, albeit non-significant, downward trend throughout the whole study period.

Conclusions: Our pilot data suggest the existence of different immunological mechanisms participating in improved metabolic state after short-term and long-term interventions in patients with T2DM and obesity. A more precise definition of the role of CCL17 in these processes might offer novel insights into the mutual link between immunity, inflammation and the pathogenesis of obesity, type 2 diabetes mellitus and their complications.

Ab-proteases and their potential applications in MS diagnostics and treatment

M. Bocharova,* M. Levitan,† D. Kostyushev,* S. Krynsky* & S. Suchkov*
*Pathology, I. M.Sechenov The First Moscow State Medical University, Moscow, Russia, †Neurology, Astrakhan State Medical University, Astrakhan, Russia

Purpose/Objective: Here, we aim at elucidating the role of autoantibodies with proteolytic activity (*Ab-proteases*) in MS pathogenesis and discuss their possible applications in MS diagnostics and treatment.
Materials and methods: A comparative mass-spectrometric and kinetic analysis of the activity of Ab-proteases in serum samples from MS patients, their relatives and healthy donor's war performed.
Results: Ab-mediated proteolytic activity showed a marked difference between MS patients and healthy controls and a strong correlation with EDSS scores and thus with different degrees of disability in MS patients.

Besides, 12–18% of the patients' relatives were also found seropositive for MBP-specific Ab-proteases, but those endowed with activity 8–15 times lower (yet significantly higher than that of individuals seropositive for canonical anti-MBP autoAbs). In course of 3–5 years of observation,7 of 12 relatives suspicious for pre-MS showed a gradual increase in the activity of Ab-proteases, and after it reached mid-level, primary clinical and MRI-manifestations could be identified in those relatives. Another significant feature described for Ab-proteases is their sequence specificity. Anti-MBP Ab-proteases that are able to rec-ognize 48–70 and 85–170 amino acid sequences within the MBP molecule are predominantly more typical of MS patients, but not of patients with neurodegenerative diseases other than MS, while Ab-proteases for 43–68 and 146–170 amino acid sequences were found to be occurring only in MS patients. The proteolytic activity of anti-MBP autoantibodies reached its peak at 82–98 amino acid sequence, which had previously been described as having encephalitogenic and immunodominant properties. The experimental *in vitro* application of 82–98 fragment itself (or its mutant form Copaxone), proved able to inhibit MBP-specific at-mediated catalysis.
Conclusions: Ab-proteases appear to be prospective both as potential MS biomarkers and as therapeautic tools. e.g. by changing the sequence specificity of the Ab-mediated proteolysis of the myelin sheath one may reach a reduction in the density of points of the proteolytic effects within the sheath and decrease lesion load, thus minimizing the proteolytic susceptibility of myelin-associated proteins and lowering scales of demyelination. The possibility of designing abzymes for the development of principally new catalysts with no natural counterparts is of great interest too.

P1135
Absence of IGF1R from oligodendrocytes ameliorates EAE

T. Buch,* G. Locatelli,† O. Prazeres da Costa,‡ B. Ingold,§ L. Koch,¶ J. Brüning¶ & B. Becher†
*TU München, Institute for Medical Microbiology Immunology and Hygiene, München, Germany, †Institute of Experimental Immunology, University of Zurich, Zürich, Switzerland, ‡TU München, Institute for Medical Microbiology Immunology and Hygiene, Munich, Germany, §Charité, Universitätsmedizin Berlin, Institute of Pathology, Berlin, Germany, ¶Institute for Genetics, University of Cologne, Cologne, Germany

Purpose/Objective: Signaling of Insulin-like Growth Factor 1 (IGF-1) through the insulin-like growth factor receptor 1 (IGF1R) mediates anti-apoptotic mechanisms in several cell types and regulates differentiation and myelination of oligodendrocyte (ODC) precursor cells (OPCs) during development and following injury. Interestingly, IGF-1 expression is increased in the CNS parenchyma during cuprizone intoxication and surrounding sclerotic lesions in Multiple Sclerosis and in its inflammatory animal model, experimental autoimmune encephalomyelitis (EAE). However, the role of IGF1R signaling in OPCs and ODCs in the context of neuroinflammation remains unclear as published studies show contradictory Results: .
Materials and methods: We used oligodendrocyte-specific deletion of IGF1R to investigate the role of IGF-1 signalling for disease course and recovery in the oligodendrocyte-ablating paradigms EAE and cuprizone intoxication.
Results: The use of a late-acting myelin-specific Cre strain (MOGi-cre) resulted in efficient ablation of the IGF1R gene without any clinical and histological abnormalities developing in the respective animals. We observed, however, upon cuprizone-mediated oligodendrocyte death impaired remyelination. EAE was, surprisingly, ameliorated. We found that microglia was less activated as shown by CD44 and MHC class II surface expression analysis.
Conclusions: Taken together we show that specific deletion of IGF1R from mature oligodendrocytes increases oligodendrocyte susceptibility to death. Yet in EAE absence of IGF1R from oligodendrocytes results in significant amelioration of disease.

P1138
Chronic gastro-intestinal worm infection enhances prion-mediated CNS-pathology and disease incubation time

D. Donaldson*, B. M. Bradford,* K. J. Else† & N. A. Mabbott*
*Neurobiology, The Roslin Institute, Edinburgh, UK, †Faculty of Life Sciences, University of Manchester, Manchester, UK

Purpose/Objective: Prion (transmissible spongiform encephalopathy) infections are neurodegenerative diseases that affect both humans and animals. Factors which enhance neurodegeneration may be important determinates of the onset of clinical symptoms and disease progression. Pathogen infection is a potential risk factor in the development of other neurodegenerative diseases such as Alzheimer's. Previous studies have shown that the gastro-intestinal worm *Trichuris muris*, which is restricted to the gut lumen, is capable of adversely altering CNS pathology in murine model of stroke through the induction of systemic immune responses. Therefore, the aim of this study was to assess if *T. muris* infection altered CNS pathology and clinical incubation time of ME7 prion disease.
Materials and methods: Groups of mice were infected with ME7 scrapie prions intra-cerebrally (i.c.). At various time-points following ME7 scrapie infection, mice were co-infected with either an acute T_H2-inducing or chronic T_H1-inducing dose of *T. muris* by oral gavage. Mice were culled at the clinical endpoint, after which brains were collected and pathology assessed.
Results: After the onset of TSE pathology, chronic T_H1-inducing *T. muris* infection significantly reduced the time until onset of clinical symptoms and thus the incubation of time of the i.c. scrapie disease. Chronic T_H1-inducing *T. muris* infection prior to the development of TSE pathology enhanced vacuolation in the thalamus and septum but did not alter disease incubation. Infection with an acute T_H2-inducing dose of *T. muris* did not alter either the incubation time or pathology.
Conclusions: Co-infection with T_H1-inducing and not T_H2-inducing doses of *T. muris* is capable of enhancing neurodegeneration in ME7 scrapie-infected mice and accelerating the onset of clinical signs. Determining the basis for this enhancement may help understand how pathogenic infections alter the progression of neurodegenerative diseases and point to novel treatments.

Donor dependent responsiveness dictates effect of CB2-receptor drugs on human leukocyte migration in response to the chemokine SDF-1

E. S. Graham,* E. Burns,* A. Lim,* K. Moodley,* M. Glass* & C. E. Angel†
*Centre for Brain Research, University of Auckland, Auckland, New Zealand, †School of Biological Sciences, University of Auckland, Auckland, New Zealand

Purpose/Objective: The aim of this study is to better understand the function of the cannabinoid type 2 receptor (CB2) expressed by certain human immune cells circulating in blood. Various rodent experimental data suggests that CB2 drugs (CB2 receptor selective agonists) have anti-inflammatory properties in models of stroke and multiple sclerosis. The CB2 drugs appear to improve the neurological deficits, by suppressing the detrimental neuroinflammation in these debilitating diseases (often fatal). A proposed mechanism of action is blockade of leukocyte infiltration into the damage brain.
Materials and methods: We assessed whether a variety of cannabinoid ligands had any cytotoxic properties towards human peripheral blood mononuclear cells (PBMC) from blood of healthy volunteers. In addition, we assessed whether cannabinoid ligands had any pro-chemotactic activity as previously suggested by other authors. Furthermore, we have assessed the ability of selective CB2 agonists to abrogate human leukocyte chemotaxis towards well defined pro-inflammatory chemokines, such as SDF-1. Migration assays were performed using 96-well plate HTS Transwell assay coupled with ATPlite measurement of migrated cells.
Results: The cannabinoid drugs we tested were not cytotoxic towards human leukocytes ($n = 6$ donors). Nor did we observe any basal chemotactic or chemokinetic activity of the cannabinoid drugs ($n = 4$ donors). However, several CB2 agonists, (namely HU308 and JWH015), significantly suppressed the chemotactic responses of human leukocytes *from some donors* towards SDF-1 ($n = 6$). Interestingly, this response was donor-dependent as the CB2 agonists had no effect at all or potentiated the SDF-1 mediated migratory response ($n = 3$).
Conclusions: This donor heterogeneity is clinically very relevant for the application of these drugs in human for neurological diseases or other inflammatory conditions where CB2 receptors are a potential target. The variability clealry demands more detailed studies to understand the donor variability and target cells.

P1141

Elevated IL-10 in Dark Agouti rats suffering from experimental autoimmune encephalomyelitis

J. Blazevski,* F. Petkovic,* M. Momcilovic,* D. Miljkovic* & M. Mostarica Stojkovic†
*Department of Immunology, Institute for Biological Research 'Sini a Stankovi', University of Belgrade Serbia, Belgrade, Serbia, †Department of Immunology, School of Immunology, Institute of Microbiology and Immunology, University of Belgrade Serbia, Belgrade, Serbia

Purpose/Objective: Experimental autoimmune encephalomyelitis (EAE) is an animal model of neuroinflamatory and demyelinating disease multiple sclerosis. EAE in Dark Agouti (DA) rats is characterized by strong inflammation with intense infiltration of immune cells into the central nervous system (CNS) leading to neurological impairments. On the contrary, EAE in Albino Oxford (AO) rats is mild, often asymptomatic, while infiltration of immune cells into spinal cord (SC) is limited, yet present. Cytokines produced by immune cells in lymphoid tissues and within the CNS largely contribute to EAE pathogenesis. So, objective of this work was comparison of various cytokine gene expressions in SC of DA and AO rats.
Materials and methods: Rats were immunized with myelin basic protein (MBP) or SC homogenate and complete Freund's adjuvant. SC were isolated from rats at different stages of the disease, and homogenates and SC immune cells (SCIC) were assessed for cytokine gene expression by real-time RT-PCR and protein production by ELISA assay. Cells were isolated from lymph nodes draining the injection site (DLNC) of the animals at the induction phase of EAE and from cervical lymph nodes (CLNC) of unimmunized rats. Also, $CD4^+$ cells were obtained from DLNC by magnetic beads separation.
Results: We found higher expression of pro-inflammatory cytokines IL-17 and IFN-gamma, but also of anti-inflammatory IL-10 at the peak of EAE in SC homogenates and SCIC in DA rats comparing to AO rats. On the contrary, lower expression of anti-inflammatory TGF-beta was detected in DA rats. IL-4 gene expression was extremely low in both strains. Increased gene expression of IL-10 was accompanied with greater IL-10 production in SCIC. Higher IL-10 expression and generation were also recorded in DLNC and $CD4^+$ DLNC, but not in mitogen-stimulated CLNC of DA rats in comparison to AO rats.
Conclusions: Although IL-10 is an anti-inflammatory cytokine with a prominent role in immunoregulation and its role in the course of EAE is thought to be protective, our results showing its higher expression and production in DA rats at the peak of disease imply that IL-10 might not have such a unilateral role in EAE pathogenesis.

P1142

Expression of IL-22 in the central nervous system during development of experimental autoimmune encephalomyelitis (EAE)

A. Noofeli, M. Barbour, D. Alan, O. Millington & H. Jiang
Institute of Pharmacy and Biomedical Sciences, University of Strathclyde, Glasgow, UK

Purpose/Objective: Interleukin (IL)-22 is a member of the IL-10 family, which are important regulators of the inflammatory response. Interestingly, IL-22 is also produced by Th17 cells, which play a key immunopathogenic role in many autoimmune diseases. However, the function of IL-22 in the development of central nervous system (CNS) inflammation is less clear. IL-22 deficient mice are fully susceptible to the development of experimental autoimmune encephalomyelitis (EAE), while IL-22 receptor (IL-22R) is expressed on blood-brain barrier (BBB) endothelial cells and IL-22 disrupts BBB tight junctions *in vitro* and *in vivo*. Therefore, the aim of this study is to examine the expression of IL-22 in the CNS tissues and to investigate whether the expression level correlates with the development of EAE.
Materials and methods: EAE was induced by immunising mice with MOG_{35-55} peptide emulsified in Complete Freunds Adjuvant (CFA), together with intraperitoneal injection of pertussis toxin (PTX). Naive mice or mice immunised with PBS in CFA together with PTX were used as controls. EAE clinical score and mouse weight were examined and recorded daily. At day 9, 17 and 28 post-immunisation, mice were sacrificed and spleen and spinal cord tissues harvested. Single cell suspension of spleen cells were cultured with or without MOG_{35-55} and supernatant were collected for cytokine detection using ELISA. Spinal cord tissues were visualised by histological and immunohistochemical staining.
Results: Our data demonstrate that MOG_{35-55} immunised mice developed EAE around day 9 and reached peak at day 15 while PBS immunised mice remained unaffected. ELISA of the spleen cell cultures show that cells from EAE mice produced more antigen-specific IL-17, IL-22 and IFN-γ at day 9 and day 17. Furthermore, immunohistological staining data show that whilst IL-22 was expressed by naïve/PBS spinal cord tissues, expression was highly up-regulated in the spinal cord of EAE mice.
Conclusions: Our data therefore suggest that IL-22 may play a pathogenic role in autoimmune disease in the CNS, possibly through divergent roles in both the peripheral immune and CNS systems.

P1143

FoxP3+ T-regulatory cells are reduced in peripheral blood in ischemic stroke patients

J. Ruhnau,* M. Heinrich,* C. Kessler,* B. M. Bröker,† A. Dressel* & A. Vogelgesang†

*Neurology, University of Greifswald, Greifswald, Germany, †Immunology, University of Greifswald, Greifswald, Germany

Purpose/Objective: Stroke is a leading cause of disability and death. Recently it became evident that cerebral ischemia leads to a defect of the innate and the adaptive immune response which is associated with an increased risk of secondary infections. To date, only scarce information is available on the underlying immunopathology. T-regulatory cells (Treg) are an important inhibitor of immune responses. In experimental stroke conflicting data have been reported regarding the survivial and importance of Treg. This study aimed to quantify and phenotype Treg in the peripheral blood of stroke patients and to assess their function.

Materials and methods: Stroke patients ($n = 38$) and age matched non-stroke controls ($n = 15$) were recruited. Blood samples of patients were obtained on stroke unit admission and on days 1, 3, 5 and 7 thereafter. Treg were phenotyped by staining $CD4^+$ $CD49d^-$ $FoxP3^+$ cells using FACS analysis. Additionally we determined CD39 and CD45RA expression to identify active and naïve Treg.

In a functional assay the suppressive capacity of $CD4^+$ $CD25^+$ $CD127^{dim/-}$ Treg on T-effector (Teff) was evaluated by measuring the expression of CD69 and CD154 on anti-CD3/anti-CD28 stimulated Teff.

Results: In stroke patients the percentage of $CD4^+$ T-cells expressing Treg markers was reduced on day (d) 0 ($P < 0.01$), d1 ($P < 0.01$), d3 ($P < 0.05$), and d5 ($P < 0.01$) compared to healthy controls. This effect was also seen in $CD39^+$ Treg. Functional testing revealed an impaired inhibition of CD154 expression ($P < 0.01$) in stroke derived samples but no difference in CD69 expression.

Conclusions: Our data show that in peripheral blood of stroke patients $CD4^+$ T-cells contain less Treg than in controls. In addition, in stroke patients the suppressive efficacy of Treg appears partly impaired. This could either be due to impaired Treg function or due to altered Teff function. We conclude that stroke induced immune suppression is unlikely to be caused by a selective survival and extensive suppressive activity of Treg. Since we have only access to peripheral blood, we cannot exclude that Treg have migrated to other compartments.

P1144

High levels of free kappa light chains incerebrospinal fluid predict conversion to multiple sclerosis

M. Espiño,* L. Costa-Frossard,† A. Muriel,‡ J. C. Alvarez-Cermeño† & L. M. Villar†

*Immunology, Hospital Ramon y Cajal, Madrid, Spain, †Neurology, Hospital Ramon y Cajal, Madrid, Spain, ‡Biostatistics, Hospital Ramon y Cajal, Madrid, Spain

Purpose/Objective: A clinically isolated syndrome (CIS) may be the initial presentation of multiple sclerosis (MS). However, some CIS never develop MS. The identification of patients at risk of MS conversion is crucial as early treatment may improve their outcome. Free kappa chains (FKC) are increased in cerebrospinal fluid (CSF) of MS patients. We studied the accuracy of CSF FKC level measurement, using a new nephelometric test, to predict conversion of CIS patients to MS.

Materials and methods: We quantified this protein in CSF from 25 patients with non-inflammatory neurological diseases (NIND) and 78 consecutive CIS patients. We assessed whether high CSF FKC levels associate with CIS conversion to clinically definite MS, defined as the onset of new relapses during follow-up.

Results: A cut-off value of 0.53 mg/l (mean+2SD of NIND group CSF FKC values) was calculated. CIS patients with CSF FKC above this value showed earlier conversion to MS in univariate and multivariate Cox analysis (HR = 6.41; 95% CI = 1.88−21.78, $P = 0.003$).

Conclusions: High CSF FKC levels accurately predict CIS patient conversion to MS.

P1146

High serum LPS values associate with lower disability in multiple sclerosis

R. Alenda-Asensi,* I. Toboso,* L. Costa-Frossard,† E. Rodriguez-Martin,* M. Espiño,* J. C. Alvarez-Cermeño† & L. M. Villar*

*Inmunology, MS unit, Hospital Universitario Ramon y Cajal, Madrid, Spain, †Neurology, MS unit, Hospital Universitario Ramon y Cajal, Madrid, Spain

Purpose/Objective: High LPS values may induce endotoxin tolerance in monocytes, which is characterized by a decreased production of cytokines in response to proinflammatory stimuli. We aimed to explore this phenomenon in multiple sclerosis (MS) and to investigate if increased LPS values associate with any clinical or immunological variables in the disease.

Materials and methods: The study included 55 with MS patients and for comparison, 11 patientswhith other inflammatory neurological diseases (OIND), 13 patients with non inflammatory neurological diseases (NIND) and 10 healthy individuals (HC). No differences were found in age or gender between the four groups. We also monitored in MS group disease duration, time to a relapse and disability measured by the EDSS score. Serum samples were stored at −80°C until assayed. LPS was measured under sterile conditions by the endopoint chromogenic Limulus Amebocyte Lysate test (Lonza). Serum levels of activin A were measured by ELISA (R&D). Peripheral blood T and B cell subsets were studiedby by flow cytometry on a FACS-Canto II instrument. Immunoglobulin and albumin indexes were assessed by nephelometry on a Beckmann nephelometer.

Results: We did not find differences in the LPS levels between MS patients and the other patient groups. We classified MS patients in two groups according to serum LPS values and did not find differences between both groups in the percentages of Tor B cell subsets, immunoglobulin indexes or in activin A concentration. However, we found a striking difference in patient disability. Those with high LPS values showed a significantly lower EDSS score ($P = 0.004$).

Conclusions: This data suggest that endotoxin-tolerance induced by high LPS serum values may contribute to regulate the abnormal inflammatory response taking place in MS and ameliorate disease course.

P1147

IL-33 protects mice from experimental autoimmune uveoretinitis

D. Allan,* H. Xu,† C. Pei,* M. Chen,† W. Niedbala,‡ S. Y. Fukada,‡ A. G. Besnard,‡ J. C. Alves-Filho,‡ J. V. Forrester,§ F. Y. Liew‡ & H. R. Jiang*

*Strathclyde Institute of Pharmacy and Biomedical Sciences, University of Strathclyde, Glasgow, UK, †Centre for Vision and Vascular Science, Queen's University Belfast, Belfast, UK, ‡Institute of Infection Immunity and Inflammation, University of Glasgow, Glasgow, UK, §Ophthalmology Department, University of Aberdeen, Glasgow, UK

Purpose/Objective: IL-33 is a recently discovered IL-1 cytokine family member. Previously, we have reported that IL-33 is an important modulator of the immune system and is associated with several immune-mediated disorders. The aim of this study is to evaluate the role of IL-33 cytokine in the development of experimental autoimmune uveoretinitis (EAU).

Materials and methods: The expression of IL-33 and its receptor ST2 on retinal pigment epithelial (RPE) cell line was examined by immunohistochemical staining. Next the severity of IRBP peptide induced-EAU was assessed in C57BL/6 mice treated with recombinant IL-33 or PBS. Cytokine secretion and production by the draining lymph nodes (DLNs) or spleen cells were measured at day 26 after immunization.
Results: We demonstrate that RPE cells expressed high levels of both IL-33 and ST2. Administration of IL-33 cytokine to EAU mice led to reduced disease severity. In line with the reduced inflammation in the retina of IL-33 treated mice, the percentage of IFN-γ+ or IL-17+ cells in the DLNs and spleen was markedly lower, while IL-5+ or IL-4+ cell percentage was increased. Furthermore, antigen specific production of IFN-γ, IL-17 and IL-6 by the DLN cells from IL-33 treated mice was also significantly reduced.
Conclusions: Our results suggest that IL-33 may play a protective role in the development of EAU possibly via its known role in promoting the function of alternatively activated macrophages.

P1148

Is Parkinson's disease the result of autoimmunity arising from Influenza A infection of the brain?

K. Bryson,* Y. Ligertwood,* M. Quigg-Nicol,* R. Mellanby,* D. Brown,* S. Anderton† & A. Nash*
**The Roslin Institute and R(D) SVS, University of Edinburgh, Edinburgh, UK, †The Queen's Medical Research Institute, University of Edinburgh, Edinburgh, UK*

Purpose/Objective: The mechanism of dopaminergic neuronal cell death remains a mystery in Parkinson's disease. Compelling epidemiological evidence links Parkinson's disease with Influenza A infection, with 5 million people developing the Parkinson's associated disease Encephalitis lethargica following the 1918 influenza pandemic. However, as Influenza induces an acute infection, where as Parkinson's disease is a chronic condition, and in the majority of cases the virus is absent from the lesion, this suggests that the virus has an indirect mode of action. An autoimmune reaction may thus be the effector mechanism linking the infection to neurological disease. Using a murine model we set out to investigate the relationship between influenza A and Parkinson's disease, and in particular, investigate the hypothesis that autoimmunity arising from infection results in dopaminergic neuronal death in the substantia nigra.
Materials and methods: A murine model was established with intranasal delivery of the neurotropic H1N1 A/WSN/33 Influenza strain. Following infection, brains were harvested and examined for the presence of the virus, T cell infiltrate and dopaminergic neuronal loss by immunohistochemistry and flow cytometry. Murine behaviour was also examined for Parkinsonian symptoms. A potential autoantigen, alpha synuclein; a protein central to the pathology in Parkinson's disease, was also examined. Mice were primed against alpha synuclein in CFA and T cell behaviour examined.
Results: Preliminary data using our murine model has shown that the Influenza virus was detected in the midbrain as late as 21 days post infection. T cell subsets were also detected in the brain following infection. In addition to this, we were able to generate alpha synuclein reactive T cells, and these cells were able to traffic to the brain.
Conclusions: Identifying autoimmune mediated dopaminergic neuronal loss would radically change therapeutic approaches and may thus provide new targets to prevent the disease or preserve the quality of life of the patients. We thus need to further examine the aberrant immune response in Parkinson's disease.

P1149

Is there a functional role for KCNMA1 in the multiple sclerosis?

A. Vanheel, B. Brône, R. Daniels, P. Stinissen, J. P. Noben & N. Hellings
Biomedical Research Institute, Hasselt University, Diepenbeek, Belgium

Purpose/Objective: A more detailed insight into disease mechanisms of multiple sclerosis (MS) is crucial for the development of new and more effective therapies. MS is a chronic inflammatory autoimmune disease of the central nervous system. The aim of this study is to identify novel disease associated proteins that are functionally involved in the MS brain pathology.
Materials and methods: In a previous proteomics study, brainstem proteins were obtained from Lewis rats with MBP induced acute experimental autoimmune encephalomyelitis (EAE), a well characterized disease model of MS. Samples were collected at different time points: just before onset of symptoms, at the top of the disease and following recovery. To analyze changes in the brainstem proteome during the disease course, a quantitative proteomics study was performed using two-dimensional difference in-gel electrophoresis (2D-DIGE) followed by mass spectrometry.
Results: We identified 75 proteins with a significant abundance difference between the different disease stages. Regulated proteins were mapped to existing biological networks by Ingenuity Pathway Analysis (IPA). Post-synaptic density protein 95 (DLG4), a key player in neuronal signalling and calcium-activated potassium channel alpha 1 (KCNMA1), involved in neurotransmitter release, are 2 putative regulators connecting 64% of the proteins identified. The involvement of KCNMA1 in macrophage functionality was studied *in vitro* by using a specific functional blocker for KCNMA1, paxillin. We show that blocking of KCNMA1 altered myelin phagocytosis and proinflammatory cytokine release, disease mechanisms which are highly involved in EAE and MS pathology. We are currently investigating possible influences of this blocker on functionality of other disease relevant cells and processes using *in vitro* and *in vivo* models.
Conclusions: This study will elucidate to what extent modulation via this ion channel affects disease processes in the context of EAE/MS.

P1150

Mast cells protect from post-traumatic spinal cord inflammation in mice by degrading inflammation-associated cytokines via mouse mast cell protease 4

S. Hendrix,* S. Nelissen,* E. Lemmens,* T. Vangansewinkel,* P. Vidal Vera,* L. Willems,* F. Boato,* D. Dooley,* G. Pejler,† M. Maurer‡ & M. Metz‡
**Morphology, BIOMED Institute Hasselt University, Diepenbeek, Belgium, †Swedish University of Agricultural Sciences, Anatomy, Uppsala, Sweden, ‡Dermatology and Allergy, Charité- Universitätsmedizin, Berlin, Germany*

Purpose/Objective: It becomes increasingly clear that mast cells (MCs) are not only key players in allergic diseases (e.g. asthma), but seem to play a complex role in neuroinflammatory diseases such as multiple sclerosis and stroke. However, their role during and after mechanical CNS trauma is not clear. In the present study, we have investigated the effects of MC-deficiency on the histological and clinical outcome after spinal cord injury (SCI) in mice.
Materials and methods: MC-deficient W-sash c-kit mutant knockout mice ($kit^{W\text{-}sh/W\text{-}sh}$), mMCP-4 deficient ($mMCP4^{-/-}$) mice and control mice underwent spinal cord hemisection at thoracic level T8 resulting in a complete transection of the dorsomedial and ventral corticospinal tract. Functional recovery in SCI mice was tested with the Basso Mouse Scale. Spinal cord sections were analyzed by immunofluorescence. RT-PCR and Western blotting were used to analyze cytokine/chemokine mRNA and protein levels. In degradation assays murine recombinant

IL-1β, IL-4, IL-6, IL-10, IL-13, TNF-α and MCP-1 were incubated with supernatant from BMCMC derived from either C57BL/6 or from mMCP4$^{-/-}$ mice. Cleaved fragments were identified using tris-tricine SDS-PAGE and analyzed by intensity analysis.
Results: We show that MC-deficient *kit*$^{W\text{-}sh/W\text{-}sh}$ mice display significantly increased astrogliosis and T cell infiltration as well as significantly reduced clinical outcome after SCI compared to wildtype mice. In addition, MC-deficient mice show significantly increased levels of MCP-1, TNF-α, IL-10 and IL-13 protein levels in the spinal cord after SCI. Mice deficient in mMCP-4, a MC-specific chymase, also showed increased MCP-1, IL-6 and IL-13 protein levels in spinal cord samples and a decreased functional outcome after SCI. A degradation assay using supernatant from MCs derived from either mMCP4$^{-/-}$ or wildtype mice revealed that mMCP-4 cleaves MCP-1, IL-6 and IL-13, suggesting a protective role for MC proteases in neuroinflammation. These data indicate that MCs may be protective after SCI and that they may reduce CNS inflammation by degrading inflammation-associated cytokines via the mast cell-specific chymase mMCP-4.
Conclusions: In summary, our results suggest a new and complex mechanism how MCs and their proteases may protect the CNS from exacerbated and/or chronic inflammation after damage.

P1151
Peripheral blood CD16+56$^-$ cells may contribute to the early diagnosis of multiple sclerosis

E. Rodriguez-Martin,* E. Roldan,* L. Costa-Frossard,† M. Espiño,* R. Alenda-Asensi,* J. C. Alvarez-Cermeño† & L. M. Villar*
**Servicio de Inmunologia MS Unit, Hospital Universitario Ramon y Cajal, Madrid, Spain, †Servicio de Neurologia MS Unit, Hospital Universitario Ramon y Cajal, Madrid, Spain*

Purpose/Objective: Alterations in peripheral blood natural killer (NK) cell subset numbers and functions have been linked to multiple sclerosis (MS). NK cells are classified in two major subsets, CD56 dim and CD56 bright, which differ in their functional and homing properties. In early HIV infection, a CD16+ CD56$^-$ NK cells subset are expanded are correlated with a higher plasma viral load set point, suggesting its utility as a predictive marker for disease progression. The aim of this study was to investigate this recently described NK subset in MS and in patients with other neurological diseases.
Materials and methods: We studied 63 patients with relapsing remitting MS, 16 with other inflammatory neurological diseases of the central nervous system (OIND) and 17 patients with non-inflammatory neurological diseases (NIND). Peripheral blood cells were labelled with conjugated monoclonal antibodies and analyzed on a standard FACSCanto-II cytometer (BD). Results were analyzed with the Mann Whitney U-test for comparison between groups.
Results: NK bright and the NK dim cells subsets did not change in MS patients when compared to the other groups. In addition, we did not find differences in CD56$^+$ CD3$^-$ or CD56+ CD3+ NK cells subsets between the three groups of patients. However, CD16$^+$ CD56$^-$ cells were clearly increased in OIND patients when compared to MS ($P = 0.01$) and NIND ($P = 0.0084$) patients.
Conclusions: These results may be of clinical relevance in the early differential diagnosis of MS.

P1152
Protein profiling of the cerebrospinal fluid in diagnostics, prognosis and treatment management of multiple sclerosis

S. Krynskiy,* M. Bocharova,† D. Gnatenko,* M. Levitan‡ & S. Suchkov§
**Department of Pathology, I.M.Sechenov The First Moscow State Medical University, Moscow, Russia, †Department of Neurological Diseases, I.M.Sechenov The First Moscow State Medical University, Moscow, Russia, ‡Department of Neurological Diseases, Astrakhan State Medical Academy, Astrakhan, Russia, §Department of Pathology, I. M. Sechenov The First Moscow State Medical University, Moscow, Russia*

Purpose/Objective: When dealing with diseases of the central nervous system (CNS), the cerebrospinal fluid (CSF) seems to be the most appropriate body fluid for early and accurate diagnosing. Specifity of any changes found in the protein profile of the CSF is higher, and there is higher possibility for detection of low-abundance proteins. With the CSF it is also possible to skip separation by means of electrophoresis, chromatography etc.
Materials and methods: To access possible diagnostic and prognostic criteria for MS, protein profiling of the CSF was used, using patients with inflammatory and non-inflammatory diseases of the CNS as controls. Protein profiling of the CSF was performed by means of MALDI-TOF mass-spectrometry.
Results: Biomarkers of multiple sclerosis (MS) are devided into 2 groups: markers of immune inflammation and markers of neurodegenerative processes.

Markers of immune inflammation include oligoclonal IgG bands, light Ig chains, chromogranin A, clusrerin, CC3.

Markers specific to autoimmune processes taking place in MS areautoantibodies to myelin basic protein (anti-MBP) and to myelin olygodendrocyte protein (anti-MOG). Antiganglioside antibodies (anti-GM) are more of prognostic value, as there is a correlation between anti-GM antibody type and clinical type of the disease (primary progressive, back-and-remitting, and secondary progressive). Markers of neurodegenereation are components of structures altered during the clinical attack of MS. The best studied marker is the main target of autoimmune reactions in MS myelin basic protein (MBP). High levels of MBP have been shown to correlate with upcoming relapses of MS, as well as with the disease attaining the progressive clinical type. Another prognostic marker is acidic calcium-binding protein a component of axons damaged during the course of the disease. Another important task is predicting transformation of clinically isolated syndrome (CIS) into manifest MS. Some protein markers that have shown diagnostic value are *14-3-3 protein and chemokin CXCL13.*.
Conclusions: Proteomics of liquor gives a possibility of diagnosing the disease and planning the protocols of treatment conveniently and fast, without excessive time and resource consumation. Hovewer, there is a number of methodological problems. One of these is the fact that it is impossible to form control groups of healthy individuals. Another reason is lack of standarts for sample collecting and storing, and lack of international bases including protein profiles of the CSF. Overcoming this obstacle is obligatory for further progress in this field of predictive medicine.

P1153
Regulation of class II MHC antigen expression in microglial cells

M. Kalognomou & I. Athanassakis
Biology Department, University of Crete, Heraklion, Greece

Purpose/Objective: Deregulation of microglial activation mechanisms plays a critical role in the development of neurodegenerative conditions like ageing, Alzheimer's disease, Parkinson's disease, Huntington's disease and schizophrenia. Studies have shown that the

neurodegenerative role of microglia has been highly correlated with the expression of MHC-II molecules. The aim of the present study was to define the membrane and intracellular expression of H-2A as well as the intracellular expression of H-2M, H-2O and CD74 in different activation states of microglial cells, using the BV-2 cell line.
Materials and methods: Flow cytometry and confocal microscopy analysis were used to define the expression of H2-A, -O, and -M molecules in BV-2 cells. Isolated mRNAs were submitted to RT-PCR experiments using *CD74* specific primers. LPS, IFN-γ and IL-4 were used to explore microglial activation mechanisms. Secretion of H2-A molecules in different activation states was evaluated by ELISA experiments.
Results: BV-2 cells expressed all necessary components for post-translational regulation of MHC class II molecules and their transport to the cell surface. Regarding microglial activation mechanisms, LPS did not affect MHC-II expression but induced TNF-a secretion while promoting the cytophagic properties of microglia. The proinflammatory cytokine IFN-γ reduced of MHC-II expression but increased secretion of H2-A molecules as tested by ELISA experiments. IL-4 activation reduced membrane and intracellular H2-A while inducing H2-O expression.
Conclusions: Stimulation of BV-2 cells with LPS, IFN-γ and IL-4 demonstrated that different activation stimuli could lead to different activation pathways of microglial cells promoting a variety of events ranging from neuroprotection to neurodegeneration. Studying the regulatory pathways of microglial MHC II expression could delineate mechanisms of stimulation versus suppression, surface expression versus secretion of MHC-II molecules during pathological conditions in neurodegenerative diseases and dictate new strategies of therapeutic approaches.

P1154
The acute-phase protein Hemopexin regulates Th17 cells and experimental allergic encephalomyelitis development

S. Rolla,* G. Ingoglia,† V. Bardina,* L. Silengo,† F. Altruda,† F. Novelli* & E. Tolosano†
**Department of Medicine and Experimental Oncology, University of Turin, Torino, Italy, †Molecular Biotechnology Center, University of Turin, Torino, Italy*

Purpose/Objective: Hemopexin (Hx) is an acute phase protein synthesized by hepatocytes in response to the pro-inflammatory cytokines IL-6, IL-1β and TNF-α. Hx is the plasma protein with the highest binding affinity to heme and controls heme-iron availability in peripheral cells and also in T lymphocytes, where it modulates their responsiveness to IFNγ. Recent data have questioned about an anti-inflammatory role of Hx, a role that seems heme-binding independent. The aim of this study was to investigate the role of Hx in the development of a T-cell mediated autoimmune response.
Materials and methods: Experimental autoimmune encephalomyelitis (EAE), the animal model of MS, was induced in WT and Hx knockout ($Hx^{-/-}$) mice. The development of the disease, the levels of Hx, the activation of Th1 and Th17cells and the production of inflammatory cytokines by macrophages were evaluated.
Results: During EAE Hx level increased and remained high. $Hx^{-/-}$ mice developed a clinically earlier and more severe and pathologically exacerbated expression of EAE compared to WT controls. $Hx^{-/-}$ mice displayed a higher amount of CD4+ infiltrating T cells and a more severe demyelization in the CNS compared to WT. The severe EAE developed by $Hx^{-/-}$ mice could be ascribed to the higher amount of Th17 cells infiltrating the CNS and circulating in the periphery of $Hx^{-/-}$ mice compared to WT mice. *In vitro*, T cells from $Hx^{-/-}$ mice polarized more efficiently towards IL-17 producing cells compared to WT lymphocytes. Moreover, the lack of Hx was associated with enhanced production of inflammatory cytokines in the antigen presenting cells, in particular IL-6 and IL-23, the major Th17 differentiating factors.
Conclusions: Over all our observations indicate that Hx could influence the generation of Th17 response during EAE and account for the anti-inflammatory role of Hx in T cell-mediated autoimmune disease.

P1155
The different role of NKT and NK cells functional activity in demyelinating polyneuropathies

R. Sepiashvili,* I. Balmasova,† O. Timchenko‡ & N. Yushchuk‡
**Immunology, National Institute of Allergology and Clinical Immunology, Tskhaltubo, Georgia, †Immunology, Peoples' Friendship University of Russia, Moscow, Russia, ‡Laboratory of Pathogenesis and Treatment Methods of Infectious Diseases, Moscow State University of Medicine and Dentistry, Moscow, Russia*

Purpose/Objective: Acquired autoimmune demyelinating polyneuropathies include Guillain-Barr' Syndrome (GBS) and Chronic Inflammatory Demyelinating Polyneuropathy (CIDP), which differ in the etiology (GBS usually develops as a complication of infectious processes, immunopathogenesis, course duration, methods of treatment and therefore call for differential diagnosis.
Materials and methods: Were observed 68 patients with demyelinating polyneuropathiesby flow cytometry who were divided into two groups: 42 GBS patients and 26 with CIDP. Expression of cell-surface markers such as CD3+/CD56+/CD4+, CD3+/CD56+/CD8+, CD3+/CD56+/DN, CD3−/CD16-/CD56+, CD16+/CD56+/CD158a, h+, CD16+/CD56+/CD94+, CD16+/CD56+/NKG2D+, CD16+/CD56+/NKp46+ were assessed by multiparametric FACS.
Results: It was found that in GBS unlike in the CIDP the fall of NKT number was not present but reliably reduced the NK cell number. In all patients D4+ NKT increased 10 and more times, subpopulation CD8+ NKT significantly decreased. The changes in NK cell in GBS patients were accompanied by a decline in their expression of KIR (D158a, h), NKG2D, NKp46. The fall of natural cytotoxicity of receptor content (NKp46) in 1.8-fold on NK membrane is observed only in GBS while negative shift in receptor expression of antibody dependent cytotoxicity is observed in all manifestations ofdemyelinating polyneuropathies.
Conclusions: It is expected that the observed immunopathogenetic features with NKT and NK cells participation can help in differentiation of GBS from CIDP.

P1156
The pro-inflammatory cytokines IL-1ß and TNFa both have deleterious effects on human astrocytes

E. S. Graham,* J. Costa,* K. Moodley* & C. E. Angel†
**Centre for Brain Research, University of Auckland, Auckland, New Zealand, †School of Biological Sciences, University of Auckland, Auckland, New Zealand*

Purpose/Objective: Astrocytes play important roles within the human central nervous system through trophic support of neurons and are inextricably involved in the brain's immune status. Astrocytes are part of the blood-brain barrier vasculature, which maintains cellular and soluble traffic into this immune specialised tissue. Any event (immune response, infections, and drug treatments) that is detrimental to astrocyte survival or function will have a negative effect neurologically. Our aim was to investigate acute and long-term influence of neuro-inflammatory events on astrocyte survival and fate.
Materials and methods: We used xCELLigence technology to track astrocyte responses to various inflammatory mediators, in conjunction

with classical assays including cell counts and caspase-3 expression as markers of cell loss/death.xCELLigence is a real-time biosensor technology, which directly measures the level of adhesion of living cells. Theoretically, any treatment that significantly or acutely affects adhesion, (e.g. changes cell morphology, cell proliferation or cell death), can be investigated using xCELLigence, with appropriate validation of the responses. Specific cellular responses produce signature changes in growth curve dynamics and we reveal and explain several of these. All responses were verified and corroborated using conventional assays.

Results: We show that the pro-inflammatory cytokines IL-1β and TNFα are both cytotoxic towards astrocytes. IL-1β is more potent than TNFα, with cytotoxic effects induced in the high fempto-molar range (>250 fM), whereas TNFα induced astrocyte death occurred in the pico-molar range (>250 pM). xCELLigence technology elegantly revealed the differential responsiveness of astrocytes to IL-1β and TNFα, and other cytokines including IFNγ, CXCL8 and IP10, which had no influence on astrocyte viability but have important roles in neuroinflammation.

Conclusions: Certain pro-inflammatory environments clearly have a detrimental effect on these very important brain immune cells. These findings have important implications for understanding the adverse events occurring during neuroinflammation that exacerbate or perpetuate the primary insult. Similar events may occur in brain diseases such as stroke or MS, where vascular inflammation and damage are hallmarks of the disease.

P1157

The role of iron in inflammatory demyelinating diseases: development of experimental *in vitro* and *in vivo* models

C. Schuh, S. Hametner, M. Bradl & H. Lassmann
Neuroimmunology, Center for Brain Research, Vienna, Austria

Purpose/Objective: Inflammatory processes play a key role in various neurodegenerative diseases such as Multiple Sclerosis (MS), Alzheimer's Disease and Parkinson's Disease. Increasing evidence suggests that iron accumulation in the brain might contribute to neurodegeneration. Iron is a potential source of free radicals as it can catalyze the production of hydroxyl radicals under oxidative conditions. This can lead to amplification of tissue injury caused by oxidative damage. In preliminary experiments we found evidence that the presence of iron exacerbates H2O2 induced cell death in glial cells *in vitro*.

Materials and methods: We thus characterized iron storage within the central nervous system (CNS) of animal models of different neurodegenerative diseases. We examined animals with acute inflammation mediated by CD8 or CD4 positive T cells and animals suffering from T cell and antibody mediated chronic inflammation due to active immunization. Further, we studied LPS induced lesions which represent CNS disease caused by the innate immune system. Similarly, we characterized oxidative damage in the different models for inflammation.

Results: We did not find evidence for the presence of oxidized phospholipids or oxidized DNA in the experimental lesions, which is in contrast to our results of MS lesions. None of these models showed iron accumulation in glial cells comparable to what is seen in MS tissue. However, some iron positive microglia and perivascular macrophages were observed in acute and chronic models. As iron accumulates progressively with aging, we analyzed iron storage in aged rats. We observed that iron is stored in oligodendrocytes and myelin in certain areas of the brain such as the deep cerebellar nuclei and the basal ganglia. To address the question, if iron could influence CNS inflammation, we compared acute young and old animals. We found a similar disease course in both groups whereas in the pathological analysis we detected higher levels of inflammatory infiltrates in young animals. In contrast, we found a higher degree of neurodegeneration in the spinal cords of old animals. Nevertheless, we did not find any evidence for iron deposition in glial cells.

Conclusions: These observations necessitate the search for additional animal models mimicking the human situation more closely with respect to age dependent iron accumulation and neurodegeneration.

P1158

The Vagus nerve, importance in immunodepression following stroke

L. Akyüz,* C. Dames,* O. Engel,† K. Winek,† H. D. Volk,‡ A. Meisel† & C. Meisel‡
**Institute for Medical Immunologie, Charité Universitätsmedizin Berlin, Berlin, Germany, †Department of Experimental Neurology, Charité Universitätsmedizin Berlin, Berlin, Germany, ‡Institute of Medical Immunology, Charité Universitätsmedizin Berlin, Berlin, Germany*

Purpose/Objective: Impaired immune function due to overactivation of neuro-humoral stress pathways, in particular of the sympathetic nervous system, has been proposed as risk factor for the high incidence of pneumonia after stroke. However, changes in pulmonary immunity and the role of the parasympathetic vagus nerve (VN) in stroke-induced suppression of immune responses are poorly understood so far. We hypothesize that after stroke pulmonary macrophage function is impaired due to release of acetylcholine by the VN resulting in reduced lung anti-bacterial responses. This anti-inflammatory effect mediated by the VN is dependent on alpha7 nicotinic acetylcholine receptor (α7nAChR).

Materials and methods: To investigate the role of the VA in stroke-associated pneumonia we analyzed effects of vagotomy (Vtx) on cellular immune responses to bacterial pneumonia in an experimental model of cerebral ischemia (MCAo) in WT C57/BL6 mice. In addition, α7nAChR$^{-/-}$ mice and littermate controls were used to address the role of the α7nAChR in stroke-induced immunosuppression. To determine the role of the α7nAChR expression on pulmonary immune versus parenchymal lung cells we used bone marrow chimeras reconstituted with α7nAChR$^{-/-}$ and WT cells. The immune responses in lung and spleen were analyzed by flow cytometry, by multiplex cytokine analysis of BAL fluid and *ex vivo* TLR-ligand induced cytokine secretion, and assessment of macrophage phagocytic activity.

Results: Inhibition of VN activity by Vtx significantly ameliorated spontaneous bacterial infections after stroke in wt mice. Release of pro-inflammatory cytokines such as TNF-a by alveolar macrophages upon *ex vivo* stimulation with TLR-ligands was significantly increased in Vtx mice. Interestingly, our mixed bone marrow chimera experiments indicate that α7nAChR expression on lung parenchymal cells is also important for impaired pulmonary anti-bacterial responses mediated by increased VN activity after stroke.

Conclusions: We could show that the VN and the a7AchR play a crucial role in suppression of lung immunity after stroke. Inhibition of parasympathetic activity by Vtx or a7AchR deficiency reduces susceptibility to bacterial lung infection after acute CNS damage. Expression of a7AchR on both lung macrophages and parenchymal cells seem to be important to the immunosuppressive effect of increased VN activity after stroke.

P1160

A role for plasmacytoid dendritic cells in promoting Th2 immunity against helminths

R. J. Lundie,* L. M. Webb,† P. C. Cook,† A. T. Phythian-Adams,† L. H. Jones,† L. Boon‡ & A. S. MacDonald†
*Centre for Immunology, Burnet Institute, Melbourne, Australia, †Institute of Immunology and Infection Research, University of Edinburgh, Edinburgh, UK, ‡Department of Cell Biology, Bioceros B.V., Utrecht, Netherlands

Purpose/Objective: Plasmacytoid dendritic cells (pDC) are a distinct subset of dendritic cells that are found in the blood as well as in peripheral lymphoid tissues. While pDC are best known for their role in antiviral immunity (and their potent ability to produce type I interferons), they also appear to be involved in regulation of Th2 responses in allergy. However, it is not known how pDC respond to Th2-associated pathogens such as the parasitic helminth *Schistosoma mansoni*, and whether they play an immunogenic or tolerogenic role in Th2 infection settings.
Materials and methods: In this study, we have characterized the response of pDC in the liver effector site during *S. mansoni* infection, both in terms of their phenotypic activation and their ability to present antigen to naïve and effector/memory $CD4^+$ T cells. The mAb 120G8 was also used to determine the impact of pDC depletion on the development of Th2 immunity *in vivo*.
Results: Our results demonstrate that liver pDC recognise and respond to *S. mansoni* antigens by up-regulating surface expression of MHC class II and co-stimulatory molecules. Liver pDC also acquire the capacity to support the proliferation of antigen-experienced IL-4/IL-13 producing $CD4^+$ T cells during infection. Furthermore, in the absence of pDC, *S. mansoni*-specific $CD4^+$ T cell production of IL-4 and IL-13 was impaired in the liver.
Conclusions: Together our data provide strong evidence that liver pDC promote Th2 immunity against *S. mansoni* parasites.

P1161

A SAG2A protein-based algorithm to analyze the production of IgG1 and IgG3 subclasses in sequential serum samples from patients with acute toxoplasmosis

J. Mineo,* S. S. Silva,* D. A. Silva,* L. D. Vaz,* C. P. Pirovani,† G. B. Barros,‡ E. M. Lemos,§ R. Dietze§ & J. P. Cunha-Junior¶
*Immunology Microbiology and Parasitology, Institute for Biomedical Sciences, Uberlandia, Brazil, †Institute of Biotecnology, Universidade Estadual de Santa Cruz, Ilhéus, Brazil, ‡Faculdade de Medicina, Universidade Federal do Espírito Santo, Vitória, Brazil, §Núcleo de Doenças Infecciosas, Universidade Federal do Espírito Santo, Vitória, Brazil, ¶Immunology Microbiology and Parasitology, Institute for Biomedical Sciences, Universidade Federal de Uberlândia, Uberlandia, Brazil

Purpose/Objective: The major aim of the present study was to evaluate the kinetics of the humoral immune response to the recombinant SAG2A antigen in comparison with *T. gondii* soluble antigen (STAg) through the detection of specific IgG, IgG1 and IgG3 antibodies in serum samples of patients with toxoplasmosis in different time points of infection. Also, we investigated the association of these serological markers based on SAG2A reactivity as potential tools to distinguish early acute from convalescent phase of toxoplasmosis.
Materials and methods: It was carried out a prospective longitudinal study that evaluated a total of 130 serum samples obtained from 19 patients with acute toxoplasmosis after different time points of illness onset. The patients enrolled in the study were attended at the Infectious Disease Center of the Federal University of Espirito Santo, Vitoria, ES, Brazil, after an initial screening by physicians of the region. Serological evidence of recent infection was characterized by the presence of IgM and/or IgG antibodies to *T. gondii* in conventional serological assays using a commercial kit (ELFA, VIDAS® Toxo IgM and IgG II, Biom−rieux SA, Lyon, France). Exclusion criteria were pregnancy and/or human immunodeficiency virus (HIV)-positive patients. Indirect ELISAs for the detection of IgG antibodies and their subclasses (IgG1, IgG2, IgG3, and IgG4) to SAG2A and STAg were also performed.
Results: The follow up of IgM and IgA levels to STAg showed a gradual decrease, with the majority of patients (88%) seropositive for IgM up to 12 months of infection, whereas IgA seropositivity was relatively low (78%) compared to IgM (100%) in the first 3 months of infection. The follow up of IgG and IgG1 antibodies showed a similar increasing profile for both SAG2A and STAg, with slightly higher seropositivity for STAg. The kinetics of IgG3 to STAg was similar to that of IgG1, contrasting with the kinetics of IgG3 to SAG2A that showed high levels up to 6 months of infection, with continuous decreasing over the time. Higher IgG3 seropositivity to SAG2A than STAg was also observed in the initial phases of infection. A higher IgG3/IgG1 ratio for SAG2A than STAg was detected in the first 3 months of infection, with decreasing profile over the time.
Conclusions: Altogether, our results demonstrate a differential kinetics of IgG3 antibodies to SAG2A and STAg in patients with toxoplasmosis up to 12 months of infection. Also, the IgG3/IgG1 ratio to SAG2A in association with classical serological markers of acute phase could constitute valuable tools to distinguish early acute from convalescent phases of Toxoplasma gondii infection.

P1162

Activation of PPAR-alpha decreases *in vitro* nitric oxide production and increases mice susceptibility to *Toxoplasma gondii* infection

G. Bonfá,* L. Benevides,* M. T. C. Fonseca,* F. R. Guimarães,† D. M. Fonseca,* N. M. Silva,‡ J. S. Silva* & C. R. B. Cardoso†
*Bioquímica e Imunologia, Faculdade de Medicina de Ribeirão Preto, Universidade de São Paulo − FMRP/USP, Ribeirão Preto, SP, Brazil, †Análises Clínicas Bromatológicas e Toxicológicas, Faculdade Ciências Farmacêuticas de Ribeirão Preto, Universidade de São Paulo − FCFRP/USP, Ribeirão Preto, SP, Brazil, ‡Instituto de Ciências Biomédicas, Universidade de Uberlândia − UFU, Uberlândia, MG, Brazil

Purpose/Objective: Peroxisome proliferator-activated receptors (PPARs) are a family of nuclear receptors, consisting of three known isoforms (α, β and γ), of which PPARα is the most studied. PPARs function as lipid sensors, regulating metabolism and immune response by acting in the inhibition of pro-inflammatory cytokines. *Toxoplasma gondii* infection induces a robust Th1 inflammatory response with excessive nitric oxide (NO) production. The role of PPARs in the gut inflammation caused by *T. gondii* in different susceptible mice lineages is still unclear and the aim of this work was to evaluate the expression and activation of PPAR-α and its role in the susceptibility to *T. gondii* infection.
Materials and methods: C57BL/6 mice were orally infected with cysts of *T. gondii*, ME-49 strain. The transcripts of PPAR-α were evaluated at 0, 4, 6 and 8 days post-infection (p.i.) by real time PCR (qPCR) of ileum and liver on mice inoculated with 40 cysts. One group of animals infected with five cysts was treated with PPAR-α agonist (Gemfibrozil) for mortality evaluation. NO production was assessed in the supernatant of splenocytes cultured for 48 and 72 h after *T. gondii* infection and agonist treatment *in vitro*.
Results: PPAR-α expression was downregulated in ileum and liver at day 8 p.i. when compared to the previous periods evaluated. Interestingly, when mice were treated with PPARα agonist at 10 mg/

kg/day during 7 days p.i. there was an increase on mortality. *In vitro* infection and agonist treatment showed that PPAR-α activation reduced NO production of C57BL/6 mice infected spleen cells.
Conclusions: These data indicate that PPAR-α is modulated by *T. gondii* infection with equals patterns of expression in ileum and liver in susceptible mice. Moreover, activation of PPAR-α induces an increase of mortality and susceptibility to infection besides a reduction in NO production caused by *T. gondii*. These results lead to a better understanding of the susceptibility to this infection and provide basis for future approaches aimed at controlling exacerbated gut inflammation.

P1163
Apoptosis as mechanism of supression of regulatory T cells in Chagas disease

M. P. S. Damasio,* M. O. C. Rocha,† K. S. Ferreira,* V. A. A. Valente,* G. R. Sousa,‡ R. C. G. Fares,§ R. Correa-Oliveira§ & J. A. S. Gomes*
**Morphology, Federal University of Minas Gerais, Belo Horizonte, Brazil, †Clinical Medicine, Federal University of Minas Gerais, Belo Horizonte, Brazil, ‡Tropical Medicine and Infectology, Federal University of Minas Gerais, Belo Horizonte, Brazil, §Cellular and Molecular Immunology Laboratory, Rene Rachou Research Center, Belo Horizonte, Brazil*

Purpose/Objective: The Chagas disease is the fourth most important tropical disease, which affects approximately 15 million people in Latin America. The mechanisms involved in the development of the severe forms of this illness are not well known yet. Recently, it has been observed an important protective role of regulatory Tcells in this disease, although its mechanism remains unclear. Thus, the aims of this study is to evaluate apoptosis as possible mechanism used by regulatory Tcells ($CD4^+$ $CD25^+Foxp3^+$) and characterize the profile cytokines in Chagas disease.
Materials and methods: To this end, the peripheral blood of 11 patients were collected and the analyzed by flow cytometry. The patients were grouped in the indeterminate (IND) and cardiac (CARD) clinical forms of Chagas disease. To evaluate the apoptotic profile, it was used monoclonal antibodies reactive to PD1, PD1L, CD39, CD95, CD95L, CTLA-4, GITR, CD107 and granzyme B conjugated with PERCP, APC, PE and FITC fluorochromes. The profile of cytokines was also evaluated through the staining of IL-1β, IL-17, TGF-β and IL-10 conjugated with PE fluorochrome.
Results: The results show no significative difference in the expression of CD95, CD95L, CTLA-4, GITR and granzyme B after comparison between patients of the different groups in the presence or absence of stimulus. However, it may be observed a higher expression of PD1 after stimulus in the IND group ($P = 1.000$) and CARD group ($P = 1.000$). In addition to a reduction in the expression of CD39 after stimulus in the IND group ($P = 0.312$) and CARD group ($P = 0.437$). CARD patients present higher expression of PD-1L ($P = 0.0173$) than IND patients in the absence of stimulus. Moreover, the regulatory Tcells of CARD patients present higher expression of CD107 after comparison with and without stimulus ($P = 0.0313$). No significative difference was observed in the expression of IL-1β and IL-10. However, it may be observed a reduction in the expression of IL-17 after stimulus in both groups IND ($P = 0.2087$) and CARD ($P = 0.3125$). Furthermore, IND patients present higher production of TGF-β by regulatory Tcells, If compared to CARD patients ($P = 0.1576$) in the absence of stimulus.
Conclusions: In conclusion, many mechanisms are involved in the apoptosis caused during the infection by *T. cruzi* and the presence of severe forms may be related to the fratricide of regulatory Tcells or the apoptosis of effector cells.

P1164
ArtinM, a D-mannose-binding lectin extracted from *Artocarpus integrifolia*, plays a potent adjuvant role in immunization process against *Neospora caninum*

J. Mineo,* M. R. Cardoso,* C. M. Mota,* D. P. Ribeiro,* F. M. Santiago,* E. C. Araújo,* N. M. Silva,* T. W. Mineo,* M. C. Roque-Barreira† & D. A. Silva*
**Immunology Microbiology and Parasitology, Institute for Biomedical Sciences, Universidade Federal de Uberlândia, Uberlandia, Brazil, †Cellular and Molecular Biology and Pathogenic Bioagents, Faculdade de Medicina de Ribeirão Preto, Universidade de São Paulo, Ribeirão Preto, Brazil*

Purpose/Objective: *Neospora caninum* is a coccidian parasite, closely related to *Toxoplasma gondii*, with wide host range and worldwide distribution, causing neuromuscular disease in dogs and abortion or reproductive disorders in cattle. Neosporosis seriously impacts the dairy and beef industries leading to substantial economic losses. Cattle acquire the infection by horizontal transmission, through ingestion of food and drinking water contaminated with oocysts eliminated in faeces from canine definitive hosts; or more often, by transplacental vertical transmission, endogenous or exogenous, from an infected dam to her offspring during pregnancy. Vaccination is an important approach to control neosporosis, however, so far there is no effective vaccine to control this parasitic disease. ArtinM and Jacalin (JAC) are lectins from the jackfruit (*Artocarpus integrifolia*) that have important role in modulation of immune responses to pathogens.

The major aim of the presente study was to evaluate the adjuvant effect of ArtinM and JAC in immunization of mice against neosporosis.
Materials and methods: Six C57BL/6 mouse groups were subcutaneously immunized three times at 2-week intervals with Neospora lysate antigen (NLA) associated with lectins (NLA+ArtinM and NLA+JAC), NLA, ArtinM and JAC alone, and PBS (infection control). Animals were challenged with lethal dose of Nc-1 isolate and evaluated for morbidity, mortality, specific antibody response, cytokine production by spleen cells, brain parasite burden and inflammation.
Results: Our results demonstrated that ArtinM was able to increase NLA immunogenicity, inducing the highest levels of specific total IgG and IgG2a/IgG1 ratio, ex vivo Th1 cytokine production, increased survival, the lowest brain parasite burden, along with the highest inflammation scores. In contrast, NLA+JAC immunized group showed intermediate survival, the highest brain parasite burden and the lowest inflammation scores.
Conclusions: In conclusion, ArtinM presents stronger immunostimulatory and adjuvant effect than Jacalin in immunization of mice against neosporosis, by inducing a protective Th1-biased pro-inflammatory immune response and higher protection after parasite challenge.

Divison of Malaria & Parasitic Disease, Korea National Institute of Health, Cheonwon-gun, Korea

Purpose/Objective: Serological diagnosis of clonorchiasis with crude antigens of *C. sinensis* is hampered by the cross reactivity with other trematode. Therefore identification and the use of highly sensitive and specific antigens are essential for the improvement and standardization of the serological diagnosis of clonorchiasis. In this study, we have studied to find strong antigen of *C. sinensis* via B cell epitope screening.

Materials and methods: We selected 22 peptides on 52 antigenic proteins which were reported and identification in *C. sinensis* utilizing five epitope prediction tools (BepiPred, BCPred, FBCPred, AAPPred and Antigenic). These peptides ranged between 13 and 29 amino acids were chemically synthesized and conjugated with biotin respectively. The peptides were spotted onto microarrays and screening the reactivity against sera from clonorchiasis patients. Seropositive human serum samples ($n = 50$) were collected from egg positive cases and seronegative human serum samples ($n = 20$) were volunteer healthy human.

Results: From a total of 22 peptides contained in the microarray, nine peptides showed the antigenic reactivity against pooled sera from clonorchiasis patients. The positive peptides that reacted above the cut-off determined from volunteer healthy human. The highest of antigenic peptides were ProR1 and Cys7 derived from Proline rich protein and Cysteine proteinase, respectively. When the antigenicity of both peptides was analyzed with individual serum of clonorchiasis patients, the sensitivity showed different pattern.

Conclusions: In the current study, we have identified two antigenic peptides for effective serological diagnosis could useful for diagnostic development. Our study provides the proof that the bioinformatic prediction and peptide microarray analysis are valuable tools for the discovery of *C. sinensis*-derived epitopes as serodiagnostic antigens with sufficient sensitivity and specificity.

B-1 cells increase susceptibility to murine visceral leishmaniasis

V. Xavier,* B. C. Vivanco,† W. F. K. M. Gonzaga,* C. L. Barbieri,† J. D. Lopes† & P. Xander*
**Ciências Biológicas, Universidade Federal de São Paulo campus Diadema, São Paulo, Brazil, †Microbiologia Imunologia e Parasitologia, Universidade Federal de São Paulo, São Paulo, Brazil*

Purpose/Objective: Leishmaniasis belongs to a group of diseases caused by protozoan parasites from *Leishmania* genus. The immune response to leishmaniasis is complex and the result of infection depends both on the genetic composition of different species of *Leishmania* and the host immunity. Clinical and experimental evidences suggest that activation of B cells leads to exacerbation of visceral leishmaniasis and contributes to susceptibility of cutaneous leishmaniasis. B-1 cells are a subtype of B lymphocytes whose role in the physiology of the immune system as well as in the pathogenesis of various diseases is still poorly understood. These cells produce large amounts of IL-10 cytokine which plays a key role in immunosuppression in several diseases such as leishmaniasis. In this study we investigated the role of B-1 cells in the pathogenesis of visceral leishmaniasis.

Materials and methods: Experiments were performed with BALB/c, BALB/*Xid* or BALB/*Xid* mice that receive adoptively peritoneal B-1 lymphocytes. These groups were infected or uninfected with *L. (L.) chagasi*.

Results: Our results showed that BALB/*Xid* mice, a mouse strain deprived of B-1 cells, infected for 45 days with *L. (L.) chagasi* had a significant reduction in parasite load in the spleen ($0.63 \times 10^7 \pm 0.4$ parasites/mg tissue) when compared to control animals BALB/c ($1.87 \times 10^7 \pm 0.6$ parasites/mg of tissue) or BALB/*Xid* that received adoptive transfer of B-1 cells ($1.44 \times 10^7 \pm 0.5$ parasites/mg tissue). These data were also confirmed by qPCR. Flow cytometry analysis demonstrated changes in peritoneal B-1 cell population. Infected BALB/c mice showed a significant increase in the percentage of peritoneal B-1 cells (70.0% ± 1.50) compared to control (63.3% ± 1.88). On the other hand, BALB/*Xid* that received adoptive transfer of B-1 cells and were infected with *L. (L.) chagasi* showed a significant decrease in the percentage of peritoneal B-1 cells (6.14 ± 3.01%) when compared to uninfected group (25.48 ± 7.60%). The IL-10 production was evaluated in supernatants from spleen homogenates of uninfected and infected mice. No differences were detected between BALB/c uninfected and infected group. However, BALB/*Xid* that received adoptive transfer of B-1 cells and were infected with parasite had higher levels of IL-10 when compared with unifected mice.

Conclusions: Our results suggest a possible role of B-1 cells in susceptibility to *L. (L.) chagasi*.

P1167
CD8+ T cell epitopes: a new source for vaccination against cutaneous *Leishmania major* infections

K. Schwonberg,* S. Brosch,* G. van Zandbergen,† B. Grewe,* M. N. Harndahl,‡ S. Buus,‡ H. Schild,§ S. Tenzer§ & E. von Stebut*
**Dermatology, University Medical Center of the Johannes Gutenberg, University of Mainz, Mainz, Germany, †Divsion of Immunology, Paul-Ehrlich-Institut, Langen, Germany, ‡Panum Institute 18.3, University of Copenhagen, Copenhagen, Denmark, §Institute of Immunology, University Medical Center of the Johannes Gutenberg, University of Mainz, Mainz, Germany*

Purpose/Objective: Infections with the parasite *Leishmania* (L.) *major* are caused by the bite of a sandfly. Healing is eventually based on IFNg secretion by $CD8^+$ and $CD4^+$ T cells. However, it is still unclear, which peptides finally promote protection and long-lasting immunity against infections with *L. major*. Up to date, no vaccine against this human pathogen exists. Thus, we are highly interested in identifying peptides that mediate healing of *L. major* infections.

Materials and methods: The most abundant proteins of both life-forms were identified by mass spectrometry. Subsequently, from these proteins, epitopes were predicted using the computer-based algorithm SYFPEITHI. 300 K^b/D^b peptides were chosen based on their predicted immunoreactivity. Additionally, all peptides were analysed for their binding-affinity towards MHC class-I molecules. A correlation between the predicted and meassured binding affinity of the peptides towards MHC class-I molecules was observed. Further, all 300 peptides were tested in *in vitro* assays. To this aim, peptide-loaded dendritic cells of C57BL/6 mice were cocultured with primed $CD8^+$ T cells for 48 h.

Results: Supernatants were analysed for their IFN-g, IL-4 and IL-10 content. Interestingly, we identified ~20 peptides with induction of high amounts of IFN-g and low levels of IL-4 and IL-10. Based on their cytokine profile, we randomly chose 16 peptides for further *in vivo* experiments. Here, C57BL/6 mice were immunized either in a prime/boost (P/B) (10 μg peptide twice) or a prime/boost/boost (P/B/B) (20 μg/2 × 10 μg peptide) approach in one ear. Three weeks later, mice were infected with 1×10^3 metacyclic promastigotes in the alternate ear. Lesions volumes were assessed weekly. Surprisingly, five peptides partially protected mice against challenge using the P/B approach compared to PBS-control mice. This effect even increased, when mice were immunized in the P/B/B approach.

Conclusions: In summary, identifying peptides which protect mice against challenge with *L. major* would finally lead to a long desired vaccine against this human pathogen. Further, tetramer development with *L. major* specific peptides would aid the understanding of T cell priming during parasitic infection.

Characterization of the virulence of *Leishmania infantum* isolates from human patients

J. Cunha,* E. Carrillo,† C. Sanchez,† J. Tavares,* J. Moreno† & A. Cordeiro-da-Silva*

**Parasite Disease Group, Institute for Molecular and Cell Biology, Porto, Portugal, †WHO Collaborating Center for Leishmaniasis National Center of Microbiology, Institute of Health Carlos III, Madrid, Spain*

Purpose/Objective: Leishmaniasis is a group of diseases with a variety of clinical manifestations. The severity of the disease is highly dependent on the immunological status and genetics of the host. The virulence of the species/strain also plays an important role in the progression of the infection. In this study we have characterized some strains of *L. infantum* in terms of *in vitro* cultivation and differentiation through the life cycle of promastigotes and compared their virulence and infectivity *in vivo*.

Materials and methods: *L. infantum* strains used in this study were isolated from 2 HIV/*Leishmania*-coinfected patients and 1 immunocompetent patient with cutaneous disease. We defined the best culture conditions to grow the parasites, having tested five well-established culture media that differ in their complexity and nutrients availability. Growth curves, viability analysis, cell cycle progression and metacyclogenesis-specific Meta-1, SHERP and Histone H4 relative expression were evaluated. In adition, *Leishmania* infections in bone marrow-derived macrophages were executed and final assays of virulence were performed in Balb/c mice.

Results: From the culture media tested, NNN medium demonstrated to maintain viability and to generate stationary promastigotes, allowing the differentiation into metacyclic forms for all strains. *In vitro* infections showed one of the tested strains to be more infective and resistant to the hostile intracellular environment of the macrophages. We have confirmed this result with Balb/c mice infections, where this differential virulence was maintained in acute and chronic infections. In addition, other assays were carried out using mice previously infected with each strain and challenged with the most virulent strain. Mice infected with least virulent strains showed high parasite loads in spleen, liver and bone marrow; however animals inoculated and reinfected with the most virulent strain induced lower parasite loads and a protective response.

Conclusions: In conclusion, this work has shown an efficient approach to characterize the virulence of *Leishmania infantum* strains and to study some of the underlying mechanisms that makes a host to be capable of control *Leishmania* infection.

Acknowledgements: We thank Dr Maria da Luz Duarte from S'o Marcos Hospital, Braga, Portugal, for kindly provide us with the virulent strain of *L. infantum*.

Chronic infection drives co-expression of the inhibitory receptor CD200R, and its ligand CD200, in mouse and human T cells

S. Caserta, N. Nausch, A. Sawtell, R. Drummond, A. Phythian-Adams, A. S. MacDonald, F. Mutapi & R. Zamoyska

Institute of Immunology and Infection Research, University of Edinburgh, Edinburgh, UK

Purpose/Objective: Certain parasites evade the immune response and establish chronic infections that may persist for years. Under these conditions, upregulation of surface receptors with inhibitory properties regulate immune cellular activation and associated pathology. The negative regulator, CD200 receptor, and its ligand, CD200, regulate macrophage activation and reduce pathology in viral infections. Little is known about the modulation of CD200:CD200R in T cells and during chronic helminth infection.

Materials and methods: T cells were either transiently or chronically stimulated with anti-CD3/CD28 and peptide, *in vitro*, or recovered from different organs (liver, spleen and mesenteric lymph nodes) of chronically infected mice with the trematode, *Schistosoma mansoni* (80 Cercariae, 8 weeks post-infection). T cell expression of CD200: CD200R was investigated alongside expression of activation markers (CD44, CD25 and CD69) and secretion of cytokines (IL-2, TNFa, IFNg and IL-4) following 5 h-re-stimulation with PdbU and Ionomycin by flow cytometry. Additionally, expression of CD200R in T cells in PBMC from individuals endemically exposed to Schistosoma heamatobium was correlated to cytokine secretion and parasite egg counts in the urine.

Results: T cells co-express CD200 and CD200R after TCR stimulation. Sustained expression of CD200R required chronic rather than transient TCR stimulation and coincided with loss of multifunctional potential (IL-2 and TNFa) and terminal effector differentiation in T cells. Terminally differentiated CD4 T cells increased expression of CD200R in response to chronic helminth infection, with *Schistosoma mansoni,* particularly in organs of pathogen persistence, where Th-2 effectors accumulate in infection. Similarly, in humans infected with *Schistosoma haematobium*, we detected an association between IL-4 production and CD200R expression on T effector cells that correlated effectively with egg burden and, thus infection intensity.

Conclusions: CD200:CD200R in T cell responses to helminths has diagnostic and prognostic relevance as a marker of infection for chronic schistosomiasis in mouse and man. CD200R efficiently marks terminally differentiated effectors. We suggest that interfering with CD200:CD200R may recover functional properties of Th2 effectors.

Evaluation of IL-17 expression in human Chagas disease

G. R. Sousa,* R. Correa-Oliveira,† M. C. P. Nunes,‡ R. C. G. Fares,† A. T. Chaves,† M. P. S. Damasio,§ K. S. Ferreira,§ V. A. A. Valente,§ J. A. S. Gomes§ & M. O. C. Rocha‡

**Tropical Medicine and Infectology, Federal University of Minas Gerais, Belo Horizonte, Brazil, †Molecular and Cellular Immunology Laboratory, Rene Rachou Research Center, Belo Horizonte, Brazil, ‡Clinical Medicine, Federal University of Minas Gerais, Belo Horizonte, Brazil, §Morphology, Federal University of Minas Gerais, Belo Horizonte, Brazil*

Purpose/Objective: This study was designed to investigate whether the expression of IL-17 is associated with the no apparent heart disease or cardiomyopathy clinical forms of Chagas disease.

Materials and methods: It was employedacross-sectionaldesigninvolvingpatientsfromendemicareaswithin MinasGerais, Brazil, underthe medicalcareofone of us (MOCR). Positive serology for Chagas disease was determined by two or more different tests. The patients infected with *T. cruzi* were grouped as no apparent heart disease (NAHD) and cardiomyopathy (CARD) patients ranging in age from 18 to 65 years old. The NAHD group included 82 individuals, with no significant alterations in electrocardiography, chest X-ray and echocardiogram. All 94 CARD patients presented with dilated cardiomyopathy, characterized by the echocardiographic finding of a dilated left ventricle with impaired ventricular systolic function. A total of 24 Normal healthy individuals, ranging in age from 29 to 55 years old, from a non-endemic area for Chagas disease and showing negative serological tests for the infection were included as a control group (NI). A cytometric bead array (CBA) immunoassay kit (BD Biosciences, USA) was used for the analysis of plasmatic cytokines, including IL-17. A second fluorescently labeled PE-anti-cytokine antibody was added and the concentration of the individual cytokines was indicated by their Mean Fluorescence Intensity (MFI). Data were acquired in a FACScalibur flow cytometer (Becton Dickinson-BD) and the analyses were performed using BD CBA software.

Results: It was compared the three groups with relation to the expression of IL-17. The Kruskal-Wallis test was used with the significance of 5%. The hypothesis of equality between the groups was rejected. The comparison was performed between groups of two. It was used the Wilcoxon test with Bonferroni correction (significance level = 0.05/3 = 0.0167). It was observed difference between the groups CARD and NAHD (P-value < 0.001) and between NI and NAHD (P-value = 0.008). There was not significative difference between the groups CARD and NI (P-value = 0.376). The expression of IL-17 was higher in patients of the NAHD group, If compared with patients in the other groups, median of 11.81 (5.79−22.86) versus 5.38 (3.87−10.55) of CARD group and 5.715 (4.25−11.31) of the NI group.
Conclusions: Therefore, IL-17 expression seems to be associated with a protective cardiac function in human Chagas disease.

P1171

Evaluation of serum cytokine concentrations of patients in different clinical stages of Chagas' disease

M. C. Chambela,* P. E. A. A. do Brasil,* S. S. Xavier,* A. M. Hasslocher-Moreno,* R. M. Saraiva,* L. H. C. Sangenis,* A. S. Souza,* J. de Meis,† L. DeCastro* & G. M. Sperandio da Silva*
**Institute of Clinical Research Evandro Chagas, Oswaldo Cruz Foundation, Rio de Janeiro, Brazil, †Oswaldo Cruz Institute, Oswaldo Cruz Foundation, Rio de Janeiro, Brazil*

Purpose/Objective: The aim of this study was to evaluate serum concentrations of cytokines IL-4, IL-10, IL-12, TNF-α and IFN-γ in patients in different clinical forms of Chagas' disease.
Materials and methods: We conducted a case-control study of 115 individuals. Infected individuals were divided into four stages as the Brazilian consensus of Chagas' disease: indeterminate patients or without apparent heart disease (normal electrocardiogram and echocardiogram) cardiac patients on the stage A (electrocardiogram changes and normal echocardiogram), cardiac patients on the stage C [electrocardiogram and echocardiogram altered with compensable congestive heart failure (CHF)] and cardiac patients on the stage D (electrocardiogram and echocardiogram changed with refractory CHF). Also were included uninfected individuals with *T. cruzi*. We included 30 indeterminate patients, 31 cardiac patients on the stage A, 14 cardiac patients on the stage C, 11 cardiac patients on the stage D and 29 uninfected individuals.
Results: Among the pro-inflammatory cytokines, IFN-γ showed higher serum levels in relation to IL-12 and TNF-α. The cardiac patients on the stage A had higher concentrations of TNF-α, however, there was a significant decrease in the concentrations of this cytokine in the same time that we observed the later stages of the chronic Chagas cardiomyopathy (CCC). Both indeterminate and cardiac patients showed high levels of TFN-α and IFN-γ and low levels of IL-4 and IL-10, demonstrating a dominant Th1 profile with an imbalanced immune response.
Conclusions: This study demonstrated a direct proportionality in concentrations of pro-inflammatory and anti-inflammatory cytokines with respect to the left ventricular ejection fraction in all groups of patients, suggesting that this correlation could be used as a marker of progression to CCC.

P1172

IgG and IgM anti-toxoplasma gondii antibodies class in high risk pregnant women in Brazil

C. C. B. de Mattos,* F. Nakashima,* M. B. Vono,* T. Pandossio,* A. C. F. Rodrigues,* S. Uezato,* L. C. J. F. Spegiorin,† A. H. Oliani,† D. C. M. Vaz Oliani† & L. C. de Mattos*
**Immunogenetics Laboratory, Department of Molecular Biology, Faculdade de Medicina de São José do Rio Preto − FAMERP, São José do Rio Preto, SP, Brazil, †Gynecology and Obstetrics Department Faculdade de Medicina de São José do Rio Preto − FAMERP and Hospital de Base − FUNFARME, Faculdade de Medicina de São José do Rio Preto − FAMERP, São José do Rio Preto, SP, Brazil*

Purpose/Objective: Toxoplasmosis is a zoonosis caused by *Toxoplasma gondii*, an apicomplexa obligate intracellular protozoan parasite, which infects different species including humans. Fetuses can be infected by transplacental transmission, a condition that may cause significant sequelae in babies. The knowledge of the antigenic profile of IgM and IgG anti-*T. gondii* antibodies during the gestational period gives clinical support towards preventing the fetal infection by this parasite. This study aimed to verify the serological profile of the pregnant women from S'o Jos* do Rio Preto, S'o Paulo State, Brazil, which received medical attention in a public health service from a tertiary school hospital.
Materials and methods: The medical records of 793 pregnant women, attended in the High Risk Antenatal Care and Fetal Medicine, Gynecology and Obstetrics Outpatient Clinic of the Hospital de Base in S'o Jos* do Rio Preto, S'o Paulo State, Brazil, between 2001 and 2004, were analyzed. The serology tests performed to determine specific IgG and IgM anti-*T. gondii* antibodies were based in a commercial immunoenzymatic assay kit (ETI − TOXOK * IgG, ETI − TOXOK * IgM DiaSorin, Italy).
Results: From the overall data, 503 (63.4%) were reagent and 290 (26.6%), non reagent. Among the reagent pregnant women, 32 (4.0%) presented a serology profile with both anti-*T. gondii* antibodies IgG and IgM positive and 471 (59.4%), with anti-*T. gondii* antibodiesIgG positive and IgM negative. The profile of anti-*T. gondii* antibodies IgG negative and IgM positive was not found.
Conclusions: The prevalence of *T. gondii* infection is high in the region where this study was carried out and the majority of the pregnant women with positive serology tests are not under risk of gestational transmission of this parasite. However, considering that 4.0% of the pregnant women are under risk of gestational transmission, these results attract the attention for the necessity to implement a protocol for serological and molecular screening of mother and newborn babies, to contribute with the clinical guidance and to prevent babies sequelae.

P1173

IL-10 secreting, type 1 regulatory T cells and naturally occurring regulatory T cells differently modulate IgG secretion by B cells in human hypo-responsive onchocerciasis

T. Adjobimey,* C. von Horn,* J. Satoguina,* J. Oldenburg,† L. E. Layland* & A. Hoerauf*
**Parasitology, Institute for Medical Microbiology Immunology and Parasitology (IMMIP), Bonn, Germany, †Hematology, Institute of Experimental Hematology and Transfusion Medicine, Bonn, Germany*

Purpose/Objective: Onchocerciasis or river blindness is the second leading infectious cause of blindness after trachoma. The disease is caused by infections with the filarial nematode *Onchocerca volvulus* and usually present two distinct pathological forms: the hyper-reactive or Sowda form and the hypo-reactive or generalized form. The hypo-reactive form is characterized by anergy and tolerance to the parasite,

whereas the Sowda form is associated with strong local immune reactions leading to immunopathology. The cellular and molecular patterns associated with this polarization of the disease are still not fully clarified. The present study has focused on the capacity of Tr1 and Foxp3 expressing regulatory T cells Tregs isolated according to their expression of CD25 alone, CD25 and CD127, and CD25 and CD49d, to modulate B cells antibody secretion in the presence or absence of additional B cell activating signals.

Materials and methods: The different cell subsets were isolated from filarial-infected individuals or healthy blood spenders, using magnetic cell isolation. Purity and cell phenotype were assessed by FACS analysis. Cytokines and antibody secretion were analyzed by ELISA and cytometric bead array.

Results: We could show that, the secretion of the non-cytolytic immunoglobulin IgG4 constitutes a humoral signature, associated with hyporesponsiveness and tolerance in human onchocerciasis. Using a sequential depletion-reconstitution strategy on peripheral blood mononuclear cells from patients with the generalized form of onchocerciasis, we could also demonstrate that, both Tr1 and Treg cells are involved in this IgG4 secretion. However, direct co-cultures of Tr1 and Tregs with autologous B cells reveal significant differences in the modulation of B cells antibody secretion by the two regulatory T cell types. While Tr1 are capable of activating B cells and preferentially induce IgG4 secretion, purified Foxp3 expressing $CD4^+$ $CD25^+$ regulatory T cells only weakly induced IgG4 secretion. Remarkable differences were also observable depending on the methods used for Treg purification. While $CD4^+$ $CD25^+$ Tregs slightly induced IgG4 secretion, $CD4^+CD25^+CD127$dim and $CD4^+CD25^+CD49d^-$ Tregs inhibited B cells activation and antibody secretion by reducing B cell proliferation, survival and maturation into plasma cells.

Conclusions: These findings confirm the implication of both IL-10 secreting regulatory T cells and $CD25^+$ Tregs in IgG4 induction during generalized onchocerciasis. Our results also suggest a direct role for Tr1 cells in IgG4 secretion by B cells, whereas $Foxp3^+$ Tregs inhibit IgG secretion and only indirectly promote IgG4 secretion.

P1174

IL-7 reverses T cell hypo-responsiveness in chronic schistosomiasis

S. Caserta, R. J. Lundie, A. Phythian-Adams, A. S. MacDonald & R. Zamoyska

Institute of Immunology and Infection Research, University of Edinburgh, Edinburgh, UK

Purpose/Objective: Schistosomiasis is a major cause of morbidity worldwide. Infected individuals are susceptible to re-infection and lack effective T cell memory. The T cell response against schistosomes is a combination of activation, hypo-responsiveness/anergy and strong immunoregulation. IL-7 plays non-redundant roles in both B and T cell biology, crucially regulating thymopoiesis, naïve T cell survival/homeostasis, generation/maintenance of memory T cells, transition from effector to memory, and tumor-associated T cell exhaustion. We thus investigated whether IL-7 reverses T cell hypo-responsiveness in chronic schistosomiasis.

Materials and methods: T cells were recovered from different organs (liver, spleen, mesenteric and subcutaneous lymph nodes) of naïve and chronically infected mice with increasing dose of *Schistosoma mansoni* cercariae (8 weeks post-infection) and cultured with IL-7. Applications of IL-7 were tested during schistosomiais (7–8 weeks). T cell activation, polarization, exhaustion and hypo-responsiveness were evaluated by surface marker expression and secretion of cytokines (IL-2, TNFα, IFNγ, IL-5 and IL-4) following 5 h-re-stimulation with PdbU and Ionomycin by flow cytometry or in ELISA assays, upon SEA and anti-CD3-restimulation.

Results: In chronic schistosomiasis, depending on pathogen burden, T cells are widely activated leading to thymic atrophy accompanied by severe reduction in T cell numbers in lymphoid organs distal from the site of persistent infection. Activated cells localizing in the site of antigen persistence differentiate into effector/effector memory cells, with a reduction in less differentiated central memory CD4 T cells. These effector T cells show typical aspects of exhaustion (PD-1, CD200R), apoptosis (low Bcl-2) and hypo-responsiveness, while maintaining IL-7Rα expression. Application of IL-7 led to an increase in effector T cell cytokine responsiveness to schistosome antigens.

Conclusions: Chronic schistosomiasis leads to T cell polarization and exhaustion in the sites of parasite antigen persistence. We suggest that IL-7 may be useful to recover functional properties of Th2 effector cells and may be involved in regulating immunopathology.

Acute and chronic immune response in *Leishmania infantum*-infected Rhesus macaques. A novel model for visceral leishmaniasis

V. Rodrigues,[1] M. Laforge,[1] A. Cordeiro-da-Silva,[2] R. Silvestre[2] & J. Estaquier[1]

[1]UFR Biomédicale, CNRS FRE 3235 – R.T.M.G., Paris, France, [2]Intituto de Biologia Molecular e Celular, Parasite Disease Group, Porto, Portugal

Purpose/Objective: Visceral leishmaniasis (VL) is a chronic infectious disease caused by the protozoan *Leishmania infantum* or *L. donovani*. Rodent models have been widely used to dissect the immune response developed during VL. However, significant variations between these and human disease claim a shift towards new models capable of accurately mimicking human VL. We developed a non-human primate model for VL in Rhesus monkeys (RM) to dissect parasite dynamics and counteractive immune responses developed during acute and chronic infection.

Materials and methods: RMs of Chinese origin were intravenously inoculated with *L. infantum* (2×107 parasites/kg of body weight). Infected animals were subdivided in three groups that were sacrificed at day 11 post-infection (p.i.) (group 1), day 28 p.i. (group 2) and day 250 p.i. (group 3) for internal organ removal and analysis. Additionally, blood was sampled from remaining alive animals at days 7, 14, 21, 60 and 180 p.i.

Results: Quantification of parasite loads revealed the presence of parasites in the spleen, blood, liver and bone marrow early after infection. Parasite dissemination to lymph nodes (LN) was observed at the chronic phase concomitant with an increase in parasite loads in the blood and visceral organs. Early infection was characterized by splenic CD4 and CD8 T cell differentiation towards effector-memory phenotypes accompanied by increased sensibility to FasL-mediated cell death. Increased transcript levels of splenic IL-21 and IFN-γ were noticed at the acute phase. We demonstrated by intracellular cytokine staining the transient expansion of IL-21+ expressing CD4+ T cells associated with the production of specific IgM and IgG antibodies towards L infantum antigens. Consistent with the absence of parasite detection in peripheral LNs during acute phase, CD4 T cell differentiation to effector cells was modest without significant modifications on the cytokine microenvironment. In clear contrast, at the chronic phase, we observed decreased transcript levels of IFNγ and TNFα and increased IL-10 in both spleen and LNs.

Conclusions: Collectively, our findings point out the existence of a complex response to *L. infantum* infection in RMs with an early reaction of the host to infection, that includes expansion of IL21+ CD4 T cells, severely restricting parasite survival and an ability of the pathogen to colonize additional organs such as the LNs at chronic stages.

P1176

In *Leishmania major* infections the presence of leukocytes on C57BL/6 or BALB/c background is sufficient to induce a C57BL/6 or BALB/c phenotype, whereas stromal cells are not

M. R. Fischer,* B. Lorenz,* K. Griewank† & E. von Stebut*
*Department of Dermatology, University Medical Centre Johannes Gutenberg University, Mainz, Germany, †Department of Dermatology, University Clinic Essen, Essen, Germany

Purpose/Objective: Susceptibility to *Leishmania major* in BALB/c mice the result of predominant Th2 development, whereas C57BL/6 mice show a protective Th1 response. Previously, we reported that this is * in part − a result of differences in DC cytokine production, e.g. IL-1α/β and IL-12p80 homodimer. Others demonstrated the importance of cytokine production by stromal cells, e.g. keratinocytes. Applying a bone marrow chimera model we aimed to determine the key cell population(s) responsible for this strain-dependent dichotomy.
Materials and methods: Irradiated mice were injected with 5×10^6 bone marrow (BM) cells. Six to 10 weeks later, hematopoietic engraftment was analyzed by flow cytometry of blood samples. Reconstituted mice were infected with 2×10^5 *L. major* promastigotes intradermally into both ears and lesion development was measured weekly.
Results: To investigate this we used BALB/cxC57BL/6 F1 mice reconstituted with either BALB/c or C57BL/6 BM. Interestingly, the course of disease in infected mice reflected the origin of the BM: Mice reconstituted with BALB/c BM showed rapid disease progression, whereas mice reconstituted with C57BL/6 BM developed self-healing lesions. To further narrow down the key cell population(s) causing this effect, we applied a mixed bone marrow chimera model with mice differing only in T and B cells being either of BALB/c or C57BL/6 origin. Everything else, including the hematopoietic compartment, was uniformly BALB/cRag1$^{-/-}$ × C57BL/6Rag1$^{-/-}$ F1. These mice exhibit a disease phenotype according to the lymphocyte origin. Preliminary data shows that this holds also true in mice with C57BL/6 lymphocytes and the rest of the hematopoietic cells being of BALB/cRag1$^{-/-}$ origin (and *vice versa*).
Conclusions: These experiments showed clearly, that the presence of BALB/c-derived lymphocytes is not protective, while the presence of C57BL/6 lymphocytes is sufficient for protection. To further investigate the relevance of the genetic background of individual cell populations in this important disease, we have reconstituted mice leading to the concomitant presence of C57BL/6 T and BALB/c B cells and *vice versa*. Overall, the method of mixed bone marrow chimeras offers various opportunities to test the effects of individual cell populations in *L. major* infections as well as several other diseases.

P1178

Induction of IL-10-producing CD1dhighCD5$^+$ regulatory B cells following *Babesia* microti-infection

Y. I. Jeong, S. H. Hong, S. H. Cho, W. J. Lee & S. E. Lee
KNIH, maralia & parasitic Disease, Cheonwon-gun, Korea

Purpose/Objective: Understanding the induction of immune regulatory cells upon helminth infection is important for understanding the control of autoimmunity and allergic inflammation in helminth infection. *Babesia microti*, an intraerythrocytic protozoan of the genus *Babesia*, is a major cause of the emerging human disease babesiosis, an asymptomatic malaria-like disease. We examined the influence of acute infection by *B. microti* on the development of regulatory B cells together with regulatory T cells.
Materials and methods: To establish a well-defined animal model for *B. microti* infection, we monitored Babesiosis during the acute phase of infection. To confirm successful infection, spleens were weighed and parasitemia was calculated. Next, to determine whether *B. microti* infection selectively induces Bregs, we analyzed the expression of cell surface markers on various splenic B cell subpopulations in uninfected and infected mice. Flow cytometry was performed to examine the frequency of IL-10-secreting CD1d^{high}CD5$^+$ B cells and CD4$^+$ CD25$^+$ FoxP3$^+$ Tregs in the spleen of *B. microti*-infected mice.
Results: *B. microti* infection induced interleukin-10-producing CD1d^{high}CD5$^+$ regulatory B cells. Moreover, the CD4$^+$ CD25$^+$FoxP3$^+$ T cell frequency was increased significantly during the course of *B. microti* infection. After infection with *B. microti*, a high level of IL-10 was detected in the serum throughout the experiment.
Conclusions: This study is the first demonstration of the expansion of immune regulatory cells such as regulatory B cells following infection by an intraerythrocytic protozoan parasite. These data suggest that *B. microti* infection in mice provides an excellent model for studying Breg-mediated immune responses, as well as indirectly elucidating the mechanism by which helminth infection regulates autoimmunity and allergic inflammation.

P1179

Insight in the intestinal immune response during a Giardia muris infection in BALB/c mice

L. Dreesen, E. Claerebout & P. Geldhof
Laboratory of Parasitology, Ghent University, Merelbeke, Belgium

Purpose/Objective: The protozoan parasite *Giardia duodenalis* is one of the most commonly found intestinal pathogens in humans and animals. Previous work on *Giardia* infected calves revealed an upregulated expression of the peroxisome proliferator-activated receptors (PPAR) in infected animals. The upregulation of these transcription factors and their anti-inflammatory capabilities could possibly explain the chronic nature of a *Giardia* infection. The aim of this study was to further unravel the role of these transcription factors in the host response using a *Giardia muris* − mice infection model.
Materials and methods: In a first trial, the intestinal immune response in BALB/c mice was investigated 1, 2 and 3 weeks after an infection with *G. muris*. Cyst secretion in the faeces was counted daily and intestinal gene expression levels for a panel of cytokines and PPARs were examined using qRT-PCR. In a second trial, the effect of a PPARα agonist (fenofibrate) on the intestinal immune response during a *Giardia* infection was analysed and compared to infected control mice and mice just receiving the agonist. Identical as in experiment 1, cyst secretion was monitored daily and changes in gene expression levels were measured by qRT-PCR.
Results: Analysis of the cytokine response in trial 1 showed a major upregulation of IL17A from 1 week p.i. onwards. The highest upregulation was observed at week 3, coinciding with a drop in cyst secretion. In contrast to the situation in calves, no transcriptional changes were observed for the PPARs. Identical as in trial 1, IL17 expression was also significantly upregulated in all the infected animals of trial 2, with the highest levels found in the infected animals treated with the fenofibrate. Analysis of the PPARs showed that, in contrast to trial 1, a modest upregulation of PPARα expression was observed in the *Giardia* infected control mice. Although this upregulation was not further induced by the fenofibrate treatment, animals receiving the fenofibrate shedded significantly less cysts compared to control animals during the first 3 weeks of an infection.
Conclusions: The outcome of this study suggests that IL17 plays an important role in the protective immune reponse against *G. muris* in mice. The role of PPARα in the immune response is still unclear and needs further research.

P1180

Investigation into the metabolic profile and transcriptional regulation of alternatively activated macrophages during helminth infection

G. Thomas,* D. Ruckerl,* B. Maskrey,† P. Whitfield,† M. Blaxter‡ & J. Allen*
*Institute of Immunology and Infection Research, University of Edinburgh, Edinburgh, UK, †Lipidomics Research Facility, University of the Highlands and Islands, Inverness, UK, ‡Institute of Evolutionary Biology, University of Edinburgh, Edinburgh, UK

Purpose/Objective: Chronic inflammation is the hallmark of many diseases, in particular those associated with the metabolic syndrome. A growing body of evidence links alterations in cellular metabolism with inflammation, in particular classical macrophage activation with glycolysis. *In vitro* studies have defined a role for mitochondrial lipid metabolism, and the transcription factor PPARγ, in maintaining anti-inflammatory alternatively activated macrophages (AAMΦ). Using the helminth infection model *Brugia malayi*, a potent inducer of AAMΦ, we sought to investigate the role of lipid metabolism in AAMΦ *in vivo*.
Materials and methods: We obtained MΦ from wild type or IL4R$\alpha^{-/-}$ mice 21 days after *B. malayi* (NeMΦ) infection, or 3 days post thioglycollate injection (ThioMΦ). MΦ were FACS purified and RNA-Seq was performed. After gene expression quantification and differential expression analysis, coordinately regulated metabolic pathways were identified using GSEA. Transcription start sites were identified using a novel method, and over-represented transcription factor binding sites (TFBSs) were assessed using Clover. Mass spectroscopy was used to identify MΦ-derived eicosanoids elicited in the same manner as for the RNA-Seq experiment.
Results: NeMΦ up-regulated mitochondrial gene expression *in vivo*. Surprisingly NeMΦ expressed very low levels of PPARγ, but did express PPARδ. Analysis of *cis*-regulatory features in AAMΦ promoters revealed an over-represented PPAR response element. Finally, lipidomic profiling of macrophage-derived eicosanoids showed that AAMΦ abundantly produce the PPARδ ligand prostacyclin (PGI2).
Conclusions: We show that NeMΦ demonstrate enhanced mitochondrial metabolism, in particular the TCA cycle. Furthermore, the over-represented PPAR motif in AAMΦ promoters provides evidence for PPAR-dependent gene expression *in vivo*. Although PPARγ expression levels are low in NeMΦ, we show that NeMΦ abundantly produce the PPARδ ligand PGI2 providing a mechanism for PPAR-dependent transcriptional regulation in NeMΦ *in vivo*.

LL37 specific killing of *Leishmania* parasites inside human macrophages

E. Bank,* P. Crauwels,* N. Reiling,† & G. van Zandbergen*
*Paul-Ehrlich-Institut, Immunology, Langen, Germany, †Forschungszentrum Borstel, Laborgruppe Mikrobielle Grenzflächenbiologie, Borstel, Germany

Purpose/Objective: Leishmaniasis is induced by promastigote parasites. Inside macrophages (MF) parasites change into multiplying amastigotes, propagating disease. There are different phenotypes of human MF, such as inflammatory type I (MF I) and anti-inflammatory type II (MF II) and it is not yet clear which phenotype of MF is involved in parasite propagation or killing. In a murine model for *Leishmania* infection it was demonstrated that parasites can be killed in an iNOS dependent manner.
Materials and methods: For human MF it is unclear which anti-parasitic mechanisms are used to control *Leishmania*. In this study we search for MF phenotype specific control mechanisms of both *Leishmania major* (*L. major*) promastigotes and amastigotes.
Results: We found that MF II are more susceptible to infection as compared to MF I. Characterizing both phenotypes in more detail revealed the antimicrobial peptide LL37 is up-regulated in MF I as compared to MF II. LL37 is shown to be involved in the innate host defence against various pathogens. Consistent with this we found that recombinant human LL37 can kill *L. major* parasites, extracellularly. To demonstrate its intracellular activity against *Leishmania*, we established a siRNA knockdown for LL37 in primary human MF. Subsequently, we found that a LL37 knockdown in MF I resulted in a significant higher promastigote survival, as compared to control MF I.
Conclusions: In conclusion, we demonstrate that LL37 is able to specifically kill *L. major* promastigotes, not amastigotes, in human MF I. Interestingly, the lack of anti-leishmania LL37 activity in MF II suggests them to be more suitable host cells.

Lymphoid organs behavior and dinamic of lymphocyte populations in *Trypanosoma cruzi* infected mice by oral or intraperitoneal route

J. Barreto de Albuquerque,* D. A. Farias-de-Oliveira,* J. Juberg,* V. Cunha,* C. E. Carvalho-Pinto,† D. Silva-dos-Santos,* L. R. Berbert,* W. Savino,* & J. de Meis*
*FIOCRUZ, Oswaldo Cruz Institute, Rio de Janeiro, Brazil, †Fluminense Federal University, Immunobiology, Niterói, Brazil

Purpose/Objective: To analyze subcutaneous lymph nodes, mesenteric lymph nodes, spleen and Peyer patches behavior, dynamic of lymphocyte populations and cytokine production in experimental Chagas' disease infected by oral/intragastric (IG) or intraperitoneal (IP) route.
Materials and methods: BALB/c mice were infected with 5×10^4 *Trypanosoma cruzi* trypomastigotes IP or IG and parasitemia was followed. After 9, 12, 16, 27 days, subcutaneous (SCLN) and mesenteric lymph nodes (MLN), spleen (Sp) and Peyer patches (PP) were harvested for cell counting and flow cytometry. Blood samples were collected for cytokine detection in 3, 9 and 12 days post-infection (dpi). Hearts were harvested at 15 dpi and histological analysis performed.
Results: IG infected mice presented lower parasitemia and mortality than IP infected mice. Parasites appeared within the blood after 3 days in IP mice and 9 dpi, in IG mice. In IP infection, 95% of mice died before 18 dpi, while in IG group, 90% were still alive 27 dpi.SCLN and Sp showed increased number of cells in both groups; however, hypertrophy of these tissues as well as T and $CD19^+$ cells expansion was less evident IG mice than IP. In mucosal-associated lymphoid tissues, such as PP, IP infection promoted atrophy after 12 dpi, due to decrease in $CD19^+$ and $CD4^+$ cells. In IG, PP cell number and T and $CD19^+$ cell depletion occurred in later stages of infection. MLN atrophy was only observed in IG group after 16 dpi, due to depletion of $CD19^+$ cells. Serum analysis of IP infected mice showed a Th1 bias, with increased production IFN-γ and TNF-α compared to IG and controls. Interestingly, IG group seems to be Th2 biased, with higher IL4 production than IP. Heart histological sections stained with Hematoxilin and Eosin showed alterations in 15 dpi (parasite nests, inflammatory infiltrate and tissue damage) were similar in both groups, even with the lower number of circulating parasites in IG mice.
Conclusions: Our results indicate that the route of *T. cruzi* infection is a key factor to stimulate the immune response against the parasite in the host.

P1184

Motor behavior dysfunction, neuronal death and glial activation in IL-12p40KO mice that were infected with *Trypanosoma cruzi*

J. Alvarez Mosig,* A. L. Bombeiro,* L. A. Gonçalves,† C. R. F. Marinho,‡ C. Penha-Gonçalves,† M. R. D'Império Lima,* & G. Chadi§

*Instituto de Ciências Biomédicas University of São Paulo, Immunology, São Paulo, Brazil, †Instituto Gulbenkian de Ciência, Immunology, Oeiras, Portugal, ‡Instituto de Ciências Biomédicas University of São Paulo, Parasitology, São Paulo, Brazil, §Neuroregeneration Center FMUSP, Neurology, São Paulo, Brazil

Purpose/Objective: Neurological disorders have been described in children and in immunosuppressed hosts with Chagas' disease, a Latin America protozoosis caused by *Trypanosoma cruzi*. Recently we showed that IL-12p40KO mice that were infected by *T. cruzi*, but not infected wild-type (WT) mice, develop a progressive paralysis that culminates in death.

Objective: To analyze the elements involved in the neurodegenerative process presented by *T. cruzi*-infected IL-12p40KO (KO) mice.

Materials and methods: KO and WT mice were infected by *T. cruzi* Sylvio X10/4 and submitted to behavioral analyses. Spinal cords (SCs) of both groups were analyzed every week by RT-PCR to estimate the kinetics of parasitism and immune transcripts, or analyzed by immunohistochemistry when KO mice presented complete paralysis to quantify neurons, astrocytes, macrophages/microglias, *T. cruzi* and other parameters.

Results: Eye-seen and computerized behavior evaluation revealed that KO mice developed a progressive paralysis, from the tail to the forelimbs (p *T. cruzi* amastigotes, most of them inside macrophages/microglias. No lesions were observed in WT SCs. Compared to WT, KO SCs showed increased immunoreactive area for nitrotyrosine (239%, p *T. cruzi* 18S rRNA transcripts revealed the parasite was controlled in WT SC but kept increasing in KO SC (p *T. cruzi* transcripts were significantly lower in WT SCs.

Conclusions: IL-12 and IL-23 efficiently act constraining *T. cruzi* parasitism in the CNS, occurring exacerbated inflammation and neurodegeneration in their absence.

P1185

Mucosal barrier attenuates exaggerated inflammatory responses to toxoplasma but does not restrict pathogen dissemination to the brain

N. Kobets,* E. Domonova,† D. Goncharov,* M. Mezentseva,‡ O. Silveistrova,† E. Gubareva,* I. Shapoval,‡ & E. Ievleva*

*Gamaleya Research Institute for Epidemiology and Microbiology, Lab of Protozoan Infection, Moscow, Russia, †Central Institute for Epidemiology, Lab. of Molecular Diagnostics, Moscow, Russia, ‡Gamaleya Research Institute for Epidemiology and Microbiology, Lab of Latent Infections, Moscow, Russia

Purpose/Objective: Toxoplasma enters the host mostly through the oral route, overcomes local and systemic host resistance and passes mucosal and blood-brain barriers in order to reside in brain. As the mechanisms restricting pathogen entrance to the brain are not clearly understood the aim of this study was to compare the dissemination of toxoplasma in intraperitoneally (ip) and orally infected mice and local immune responses that accompany systemic and mucosal route of infection.

Materials and methods: A/Snell mice were infected with 10^5 tachyzoites of *T. gondii* RH strain either ip or per os (intraduodenally). The levels of *T. gondii* DNA were assessed in blood, spleen, liver, lungs, heart, brain, eyes, lamina propria and Payer's patches at different time points post infection (PI) by RT-PCR. The recruitment of neutrophils, macrophages, dendritic cells, B cells and T cells to the peritoneum was studied by flow cytometry and the levels of cytokines (IFN-g, TNF-a, IL-2, IL-4, IL-6, IL-18) in spleen were assessed by PCR and flow cytometry.

Results: We found that the levels of toxoplasma DNA in orally infected mice were lower in the majority of the organs under the study (for example, spleen or liver) compared to ip infected mice. However they were higher in the brain and Payer's patches of orally infected mice. Earlier and more pronounced recruitment of inflammatory cells such as neutrophils, dendritic cells and macrophages to the peritoneum was observed in ip infected mice, while higher amounts of B cells (both $CD5^-$ and $CD5^+$) were found in orally infected mice starting from day 5 PI. Higher levels of inflammatory cytokines such as IL-1b, TNF-a and IL-18 were found in ip infected mice compared to per os infection.

Conclusions: Our results suggest that systemic toxoplasma infection directs the immune response towards better control of toxoplasma dissemination to the brain. Precise mechanisms of this control are currently under investigation.

P1186

NKT cell expansion in absence of B cells may be related to an increased regulatory NKT cell function during *Trypanosoma cruzi* infection

F. Cardillo,* J. Nihei,† & J. Mengel‡

*FIOCRUZ, Gonçalo Moniz Research Center ZIP 40.296-710., Salvador-Bahia, Brazil, †Universidade Federal do Recôncavo-UFRB, Centro de Ciências da Saúde-CCS ZIP 44.570-000, Cajueiro Santo Antônio de Jesus-Bahia, Brazil, ‡FIOCRUZ and Faculty of Medicine of Petrópolis FMP-FASE (ZIP 25.680-120), Oswaldo Cruz Institute ZIP 21.040-360, Rio de Janeiro-RJ, Brazil

Purpose/Objective: Chagas disease is a tropical disease caused by the protozoan parasite *Trypanosoma cruzi* (*T. cruzi*). We have previously demonstrated that Natural Killer (NK) cells were related to resistance to *T. cruzi* infection in C57Bl/6 mice. Depletion of total $NK1.1^+$ cells in C57Bl/6 infected mice resulted in diminished convertion of recently activated peripheral T cells in effector/memory lymphocytes, thus resulting in T cell hyperactivation without maturation to effector functions. Additionally, we have studied the role of B cells in the activation/differentiation of peripheral T cells during *T. cruzi* infection. We have found that muMT knockout (KO) mice were more susceptible to *T. cruzi* infection and had fewer central and effector memory T cells when compared with wild type mice. Taken together, these results might suggest a relationship between B cells and $NK1.1^+$ cells. The present study was designed to evaluate NKT cell-numbers in both muMT and WT infected mice.

Materials and methods: Mice were kept in microisolators and were manipulated according to institutional ethical guidelines. Spleen cells were isolated from C57Bl/6 and C57Bl/6 muMT KO mice (1–2 months old). B cells were obtained by magnetic separation and were adoptively transferred to muMT C57Bl/6. After infection with Tulahuen strain of *T. cruzi*, flow cytometry analysis of the spleens from muMT or from B-cell-sufficient C57Bl/6 mice were performed. Fluorochrome-conjugated anti-alpha beta and anti-NK1.1 monoclonal antibodies were used.

Results: During the acute phase of infection, NKT cells were decreased in B cell-transferred muMT, when compared to control muMT infected mice, suggesting that B cells may down-regulate NKT-cell numbers during the infection. As a result, decreased of effector/memory T cells and increased NKT cell number may be related to diminished capacity to mobilize inflammatory cells to infected tissues, resulting in the increase in parasite load.

Conclusions: NKT cell expansion in absence of B cells might be related to an increased negative regulatory NKT cell function latter on early chronic infection, helping to inhibit the generation of effector/memory T cells.

P1187

Nucleosides from phlebotomus papatasi salivary gland exacerbate leishmaniasis by generating tolerogenic dendritic cells-dependent treg

V. Carregaro,* D. Lima-Júnior,* D. Costa,* C. Oliveira,† C. Milanezi,‡ J. Valenzuela,§ J. M. Ribeiro,§ F. Cunha,¶ & J. Silva*
**Faculdade de Medicina de Ribeirão Preto — University of São Paulo, Biochemistry and Immunology, Ribeirão Preto, Brazil, †Institute of Biological and Natural Sciences Federal University of Triangulo Mineiro, Patology, Uberaba, Brazil, ‡Faculdade de Medicina de Ribeirão Preto-University of São Paulo, Biochemistry and immunology, Ribeirão Preto, Brazil, §NIAID/NIH, Section of Vector Biology and Vector Molecular Biology Unit Laboratory of Malaria and Vector Research, Bethesda, MD, USA, ¶Faculdade de Medicina de Ribeirão Preto — University of São Paulo, Biochemistry and Immunology Pharmacology, Ribeirão Preto, Brazil*

Purpose/Objective: Phlebotomines saliva plays a crucial role in the establishment of *Leishmania* infection. Among several potent pharmacologic substances, we recently purified and identified adenosine-(ADO) and adenosine-monophosphate-(AMP) as saliva's active pharmacologic compounds presents on *P. papatasii* that inhibits dendritic cells-(DC) functions through PGE_2/IL-10-dependent mechanism. *AIM:* We evaluate whether ADO and 5′AMP are compounds present into *Phlebotomus papatasii* saliva responsible for leishmania establishment into vertebrate host and such immunomodulatory mechanism.
Materials and methods: C57BL/6WT or C57BL/6IL-$10^{-/-}$ mice were coinoculated with *L. amazonensis* promastigotes forms (1×10^5parasites/ear-i.d. route) in the presence of ADO+AMP or vehicle (PBS). The ear lesion size, parasites burden, cytokines production and inflammatory infiltrated were analyzed at 12nd week post infection.
Results: ADO+AMP mimicked the exacerbative effect of saliva in leishmaniasis, increasing parasites numbers and ear lesion. Enzymatic catabolism of salivary nucleosides reversed the SGE-induced immunosuppressive effect. Such effect was associated with pro-inflammatory cytokines reduction (IFN-γ, TNF-α) and IL-10 enhancement. Moreover, ADO+AMP failed to enhance ear lesion and parasite burden in IL-$10^{-/-}$ infected mice. Interestingly, nucleosides increased Tregs makers (GITR; CTLA-4; CD39; CD73 expression) on $CD4^+$ $CD25^-$ population, suggesting the induction of Tregs on T effector cells. Treg induction was associated with nucleosides-induced tolerogenic dendritic cells (tDC) expressing higher levels of COX_2 and IL-10. Furthermore, nucleosides-induced tDC displayed a semi-mature phenotype and produced lower levels of proinflammatory cytokines *in vitro* and *in vivo*.
Conclusions: We demonstrated that ADO and 5′AMP are constituents present in *P. papatasi* saliva that exacerbated leishmania infection. The exacerbative effect is associated with Tregs enrichment generated by nucleosides-induced tDC in the inflammatory foci.

P1188

Pharmaceutical sodium chlorite (DAC-N-055) acts as anti-parasitic and immunomodulating compound in the defense against *Leishmania* parasites

P. Wentker,* K. W. Stahl,† H. C. Stahl,‡ C. Bogdan* & U. Schleicher*
**Institute of Clinical Microbiology Immunology and Hygiene, Universitätsklinikum Erlangen, Erlangen, Germany, †Waisenmedizin Freiburg e. V., Freiburg, Germany, ‡Institute of Public Health, Universitätsklinikum Heidelberg, Heidelberg, Germany*

Purpose/Objective: Cutaneous leishmaniasis, caused by *Leishmania* parasites, is characterized by chronic, frequently ulcerating and slowly healing skin lesions. An efficient local therapy is not available. The widespread use of intralesional injection of antimony is limited by emerging resistant parasites and high costs. In clinical trials we obtained evidence that local application of pharmaceutical sodium chlorite (DAC-N-055) after removal of necrotic tissue accelerated the wound healing. Based on these observations we investigated possible anti-parasitic, immunomodulating and wound healing effects of DAC-N-055.
Materials and methods: Anti-parasitic effects of DAC-N-055 on extra- and intracellular *Leishmania* were evaluated by microscopic and photometric analyses. The influence of DAC-N-055 on several mouse and human immune cells involved in skin wound healing [bone marrow-derived macrophages (BMM) and dendritic cells (BMDC), monocytes, fibroblasts, endothelial cells, keratinocytes, peripheral blood mononuclear cells (PBMC)] and their effector responses were investigated by mRNA (real-time PCR) and protein expression analyses (ELISA, Western blot, proteome array) as well as by an *in vitro* wound healing scratch assay.
Results: *In vitro* DAC-N-055 exerted a cytotoxic effect on extracellular *Leishmania* promastigotes, but did not influence intracellular *Leishmania* amastigotes in BMM. In IFN-gamma-stimulated BMM the expression of iNOS, production of leishmanicidal NO and release of TNF and IL-6 were enhanced by DAC-N-055. In BMDC and in BMM production of IFN-alpha/beta, which is required for the early iNOS expression in murine *L. major* infections, was increased by DAC-N-055 upon stimulation with *Leishmania*, IFN-gamma or LPS. DAC-N-055 also augmented the expression of TNF and IL-6 in human MonoMac6 monocytes and HaCaT keratinocytes. Moreover, it modulated the expression of several chemokines and cytokines in human PBMC. Unexpectedly, DAC-N-055 did not show effects on the proliferation and/or migration of fibroblasts, endothelial cells and keratinocytes in wound healing scratch assays.
Conclusions: Together, our data indicate that DAC-N-055 is a leishmanicidal and immunomodulating compound, which *in vitro* influences the production of several effector molecules and cytokines that are protective in leishmaniasis and involved in wound healing.

P1189

Proportions of CD_4^+ but not $CD8^+$ memory T cells are altered in older individuals chronically infected with Schistosoma haematobium

N. Nausch,* C. D. Bourke,† L. J. Appleby,* N. Rujeni,* O. Lantz,‡ F. Trottein,§ T. Mduluza,¶ N. Midzi & F. Mutapi***
**Institute of Immunology & Infection Research, University of Edinburgh, Edinburgh, UK, †Biology Department, University of York, York, UK, ‡Laboratoire d'Immunologie et Unité Inserm 932, Institut Curie, Paris, France, §Center for Infection and Immunity of Lille INSERM U 1019, Institut Pasteur de Lille Univ Lille Nord de France, Lille, France, ¶Biochemistry, Harare, University of Zimbabwe, Zimbabwe, **Schistosomiasis, National Institute of Health Research, Harare, Zimbabwe*

Purpose/Objective: There are indications that the efficacy of vaccines can be reduced in helminth infected individuals but so far there are no

studies on how helminths may mediate this effect in human or experimental studies. The efficacy of vaccines relies on the effective generation and maintenance of $CD4^+$ and $CD8^+$ T cell memory immune responses. Therefore the aim of this study was to characterise human $CD4^+$ and $CD8^+$ memory T cell accumulation in people exposed to *Schistosoma haematobium* infection and relate this to host infection status and schistosome-specific immune responses before and after anti-helminthic treatment.

Materials and methods: Proportions of $CD4^+$ and $CD8^+$ memory T cells were analysed in a cohort of 105 participants who are lifelong residents in an area endemic for *Schistosoma haematobium*. Fifty-one participants were analysed following treatment with an anti-helminthic drug. In addition schistosome-specific effector antibody responses and the overall function of $CD4^+$ effector/memory cells were determined.

Results: Our results show that helminth infection is associated with alteration of $CD4^+$ memory T cell proportions. This alteration was not observed in $CD8^+$ memory T cells. The changes in $CD4^+$ memory T cells are associated with an impaired T_H1 response and changes in activation markers. Treatment with an anti-helminthic drug leads to alterations of the $CD4^+$ memory T cell pool. Furthermore, reduced $CD4^+$ memory T cell proportions were associated with lower schistosome-specific effector antibody responses.

Conclusions: In summary, individuals infected with *S. haematobium* who did not to develop protective immunity with accumulative exposure show alteration in the overall CD4 T cell memory. These findings have implications for the development of the natural or the vaccine induced immune response against schistosome-specific as well as against unrelated pathogens.

P1190

The effect of vaccination with recombinant *L. donovani* and *L. mexicana* gamma glutamyl cysteine synthetase by different routes of administration on host immune responses

B. Doro, M. Wiese, A. B. Mullen & K. C. Carter
Immunology, University of Strathclyde, Glasgow, UK

Purpose/Objective: Human leishmaniasis is a spectrum of diseases caused by protozoan parasites of the genus *Leishmania*. Drugs existing for the treatment of leishmaniasis have been unsatisfactory. Ideally a vaccine could prevent infection and would be a feasible control method as infected individuals are resistant to clinical re-infection. In this study the ability of recombinant *L. donovani* and *L. mexicana* gamma glutamyl cysteine synthetase (γGCS) to induce a protective immune response in BALB/c mice was determined.

Materials and methods: Animals were immunised by different routes with the recombinant proteins and the effect of vaccination on production of parasite-specific IgG1 and IgG2a was determined using an ELISA assay. In addition the effect of immunisation on cytokine production by *in vitro* stimulated splenocytes from immunised mice was determined.

Results: Immunization with γGCS inducing significantly higher titers ($P < 0.05$) comparing to control group.

Conclusions: Vaccination induced significant Th1 and Th2 immune responses after single dose treatment.

P1191

The expression of B blood group carbohydrate under control of FUT2 gene (19q13.3) increases the risk for digestive Chagas disease

L. de Mattos,* C. R. Bernardo,* A. P. Oliveira,* A. V. S. Camargo,* C. C. Brandão de Mattos,* C. E. Cavasini,† L. S. Ronchi,‡ J. G. Netinho,‡ R. B. Bestetti,‡ O. Ricci Jr‡ & A. A. Borim‡
**Molecular Biology, Faculdade de Medicina de Sao Jose do Rio Preto, Sao Jose do Rio Preto, Brazil, †Dermatology and Infectious Diseases, Faculdade de Medicina de Sao Jose do Rio Preto, Sao Jose do Rio Preto, Brazil, ‡Faculdade de Medicina de Sao Jose do Rio Preto, Hospital de Base — FUNFARME, Sao Jose do Rio Preto, Brazil*

Purpose/Objective: The infection by *Trypanosoma cruzi* can result in distinct clinical manifestations of Chagas Disease (CD) including heart (cardiomyopathy) and gastro-intestinal disease (megaesophagus and megacolon). Different factors contribute for this disease but there are no genetic markers indicating what form of the disease will occur. Previous reports evaluated the ABO blood group carbohydrates in relation to CD but they did not explore the influence of *FUT2* gene which controls the expression of these carbohydrates in the gastro-intestinal tract. This study aimed to verify the combined effect of the *FUT2* gene and the ABO blood group carbohydrates in heart and gastro-intestinal CD.

Materials and methods: Two hundred and forty patients were enrolled (cardiomyopathy: $n = 120$; gastro-intestinal: $n = 120$). The *FUT2* genotyping and the ABO blood group carbohydrates were identified by PCR-RFLP and hemagglutination methods, respectively. The qui-square test, the exact Fisher's test, and the Odds Ratio were used to compare the proportions.

Results: The differences between heart and gastro-intestinal CD were not statistically significant in relation to the FUT2 gene (χ^2: 1.141; DF: 1; $P = 0.2854$) and the ABO blood group carbohydrates (χ^2: 1.855; DF: 3; $P = 0.6031$) when analysed in isolation. However, when these two markers were analysed in combination, the differences were statistically significant for gastro-intestinal CD (χ^2: 9.961; DF: 3; $P = 0.0189$) and associated with the expression B (B and AB phenotypes) carbohydrates (OR: 10.969; CI 95%: 1.415−85.022; $P = 0.0114$).

Conclusions: The role of the *FUT2* gene and the ABO blood group carbohydrates in CD remains unclear and there are no evidences that these carbohydrates act as receptors for *T. cruzi*. Since the ABO carbohydrates expressed in the gastro-intestinal tract under control of the *FUT2* gene are structurally distinct from those expressed in the heart tissues, maybe these differences increase the risk for CD in the gastro-intestinal tract, especially among those carrying the B carbohydrate. In conclusion the expression of B carbohydrate from ABO blood group system in the gastro-intestinal tract is associated with this form of CD.

P1192

The role of mast cells in protection against *Leishmania donovani* infection

K. Carter,* K. Ross,* F. Tacchini-Cottier† & C. Lawrence*
**Strathclyde Institute of Pharmacy and Biomedical Sciences, University of Strathclyde, Glasgow, UK, †Department of Biochemistry, University of Lausanne, Lausanne, Switzerland*

Purpose/Objective: Visceral leishmaniasis is a major health concern in many parts of the world and designing suitable interventions to control the disease relies on understanding the role of host immunity in controlling susceptibility/resistance to infection.

Materials and methods: The role of mast cells in *Leishmania donovani* infection was determined by comparing the outcome infection in *Kit (Wsh)* mast cell *deficient* mice and their wild-type counterparts.

Specific antibody responses and cytokine production by *in vitro* stimulated splenocytes from infected mice were assessed. The role of mast cells in neutrophil recruitment was determined by monitoring their levels during infection, studying the effect of depletion on the outcome of infection, and determining myeloperoxidase levels in tissues of WT and *Wsh* infected mice.

Results: Mast cell deficient mice had significantly lower liver and splenic parasite burdens compared to wild-type mice and this reduction was associated with significant inflammation in the spleen, based on spleen weight.

Conclusions: Results of studies showed that mast cells have an important role in controlling the outcome of infection and that neutrophils are involved in protection in both mouse strains.

P1193

Two unique IL-10 producing B cell subsets contribute to the host cytokine balance during Trypanosoma brucei infections

F. Kauffmann, V. Bockstal, J. Cnops, C. Haynes, C. De Trez & S. Magez

VIB Structural Biology, Vrije Universiteit Brussel (VUB), Brussels, Belgium

Purpose/Objective: IL-10 producing B cells have been described as a new regulatory cell type important not only in balancing auto-immune diseases, but also in the establishment of tolerance during parasitic infections. Infection with *Trypanosoma brucei* elicits a strong pro-inflammatory response and although it has been established that the anti-inflammatory cytokine IL-10 is crucial to prevent death of the host from hyper-inflammation, the cellular source of IL-10 has not been clarified so far.

Materials and methods: Blood serum cytokine levels and cytokine production by total spleen and liver cells was measured by ELISA. The production of IL-10 by individual cells was assessed through intracellular flowcytometric staining for IL-10 and the use of GFP IL-10 transcriptional reporter mice.

Results: After control of the first parasitemia wave there is a peak of IL-10 production in the spleen. The majority of the IL-10 producing cells has a B cell phenotype and can be divided into a $B220^{int}CD19^{hi}TIM\text{-}1^{+}$ $CD23^{int}CD11b^{+}$ $CD5^{low}$and a $B220^{low}CD19^{int}$ $TIM\text{-}1^{-}$ $CD23^{-}$ $CD11b^{low}CD5^{-}$ B cell population. Both cells populations are IgM^{+} $CD21^{low}LY6C^{+}BST2^{+}$ $CD11c^{low}IgD^{low}CD1d^{-}$ $AA4.1^{-}$ $CD138^{-}$. Two IL-10 producing B cell populations, a $B220^{lo}CD19^{int}$ and a $B220^{int}CD19^{hi}$ can be found in the liver as well, exhibiting a similar phenotype as the splenic populations.

Conclusions: Using both intracellular staining for IL-10 and GFP IL-10 transcriptional reporter mice, our results suggest that two distinct regulatory B cell subsets with 'DC-like' features are the major producers of IL-10 in the spleen during *Trypanosoma brucei* infection and may be involved in activating regulatory immune responses.

P1194

Unravelling the events leading to inflammation-induced trypanosomiasis-associated acute anemia

J. Cnops, V. Bockstal, C. Haynes, C. De Trez & S. Magez

Cellular and Molecular Immunology, Vrije Universiteit Brussel (VUB), Brussels, Belgium

Purpose/Objective: African trypanosomes are extracellular parasites that cause infections in human and livestock in sub-Saharan Africa. The common hallmark of *T. brucei* infections is hyper-inflammation due to an ill-controlled immune reaction. During the acute phase of experimental murine trypanosomiasis, there is a 50% reduction in red blood cell counts. It has previously been shown that during several microbial infections in mice, acute anemia is caused by erythrophagocytosis, and IFNγ is the critical driver in this immunopathology. Our purpose is to unravel the mechanism(s) implicated in the acute inflammation-associated anemia observed following control of the first parasitemia peak.

Materials and methods: 8-week-old female C57Bl/6 mice were infected by intraperitoneal injection of 5000 *T. b. brucei* AnTat1.1E clone parasites. Parasitemia and red blood cell counts were performed at 2-day intervals using a hematocytometer. Lymphocyte cell populations were analyzed by flowcytometry.

Results: We previously observed that serum IFNg levels are highest during the first days post infection. Here, we report that $IFN\gamma^{-/-}$ mice display reduced acute anemia. Moreover, this reduced pathology is also observed in beta-2-microglobulin (β_2m) deficient mice but not in transporter associated with antigen processing 1 (TAP1) deficient mice, suggesting that the cell population which plays a major role in the induction of acute anemia is independent of TAP transport for surface expression of the relevant MHC I molecule. Future analysis of anemia profiles of $K^{b}D^{b\text{-}/\text{-}}$ mice will determine whether the cell population is dependent on MHC Ia or MHC Ib.

Flow cytometric analysis during the first days post infection reveals that at day 4 (right before the appearance of the anemic phenotype) there is a significant increase in the number and percentage of NKT cells, $CD8^{+}$ T cells and $NK1.1^{+}$ $CD8^{+}$ cells in the liver and blood of wild type C57Bl/6 mice.

Conclusions: Further flow cytometric experiments will determine the presence or absence of these cell populations in $TAP1^{-/-}$ versus $b_2m^{-/-}$ mice. In addition, it will be investigated which cell population is the major IFNg producer during the first days post infection.

Together, these data will help to identify the cell population(s) responsible for the acute anemia during the initial phase of *T. brucei* infection.

P1195

Vitamin E as an adjuvant in an Taenia crassiceps mouse immunization

E. De Gaspari

Immunology, Adolfo Lutz, São Paulo, Brazil

Purpose/Objective: In this study we evaluates the efficacy of vitamin E as an adjuvant, using *Taenia crassiceps* antigens against murine cysticercosis. The efficacy of vitamin E was compared with three well known experimental adjuvants (complete Freund's adjuvant, aluminum salts, and saponin), and assessed with respect to the humoral immune response elicited and the reduction in parasite load. Vitamin E is a well-known anti-oxidant and has been shown to exert immunostimulatory activity by dietary supplementation . The beneficial use of α-tocopherol formulated in an oil emulsion as an adjuvant has been utilized for the development of various veterinary vaccines .

Materials and methods: Groups of 5 BALB/c mice were immunized intramuscularly, subcutaneously, or intraperitoneally with different doses (10 μg/mouse) of *T. crassiceps* antigens emulsified in mineral oil emulsions that was prepared as previously described (Valdez *et al.*1994). Saponin (Sigma) was prepared at a concentration of 50 μg/mouse as reported previously (McColm *et al.*1982). Aluminum salts and vitamin E were prepared as described by Ito *et al.*, 2009 and Tengerdy and Lacerda.1991, respectively. The solution containing vitamin E and VF-Tcra was emulsified using (Ultrasonic Devices for Liquid Processing, 2 kw). Thirty days later, the mice were given a booster with the same immunizing dose of the same peptide in the same adjuvant as had been done before. Animals were bled from the retro-orbital plexus at 60 days after immunization. The sera were pooled and kept frozen in aliquots at -20°C.

Results: Anti-VF-Tcra IgG antibodies that were produced were detected by ELISA on day 60 in all groups independently of the immunization method and of the type of adjuvant used. The compartive study of the different adjuvants showed that vitamin E produced the high titre of antibodies and was a good adjuvant $P \leq 0.05$. SDS*PAGE shows the pattern of VF-Tcra and VF-tso. VF-tso pathogens presented various peptides of 8−158 kDa, and the VF-Tcra pathogen was rich in <20 kDa polypeptides. The protection was induced using VF-Tcra as an immunogen and the igG avidity Index was high with vitamin E as adjuvant.

Conclusions: In the present study, we evaluated the humoral immunity induced by vitamin E and VF-Tcra as a alternative vaccination and adjuvant strategies in a murine model of cysticercosis meanwhile further investigation are required to identifiy others aspects of the immune response.

Poster Session: Primary Immunodeficiency and Rare Diseases

A novel mutation in the WSXWS motif of the common gamma chain interleukin receptor in a patient with severe combined immunodeficiency

R. de la Varga Martínez, F. Mora-López, R. López-Blanco, M. Vilches, E. García-Moreno, J. A. Brieva & A. Sampalo
Hospital Puerta del Mar, Inmunología, Cádiz, Spain

Purpose/Objective: Molecular characterization of a primary immunodeficiency: severe combined immunodeficiencies (SCID) are a heterogeneous group of genetic inherited diseases characterized by a profound impairment of both cellular and humoral immune response. X-linked SCID (X-SCID) is the most frequent type, affecting almost half of the patients. X-SCID is characterized by a total absence or very low numbers of T cells and natural killer (NK) cells. B cells are present, although they are nonfunctional. A 9 month old boy was submitted to hospital for severe recurrent respiratory and gastrointestinal infections from his first month of life, severe malnutrition and failure to thrive. Laboratory studies showed lymphopenia (720 lymphocytes/μl), absence of T and NK lymphocytes, normal number of B cells and panhypogammaglobulinemia. Parents were not consanguineous, two brothers died at 5 and 7 months of age and he had three healthy sisters. An X-linked SCID was suspected. He developed pneumonia, muguet and systemic candidiasis. Adequate treatment and profilaxis against infections were prescribed in order to receive a transplant from one of his three HLA identical sisters.
Materials and methods: More than 200 different mutations have been identified in patients with X-SCID. Primers were designed to amplificate the eight exons of ILRG2 by polymerase chain reaction (PCR). The gene was sequenced by using an automatic sequencer (ABI PRISM), and the sequence was compared with the reference sequence of the gene.
Results: DNA sequencing in the patient revealed a T>G transversion at the nucleotide 713 (c.713T>G) resulting in the substitution of the serine in position 238 by a arginine: p.Ser238Arg.
Conclusions: X-SCID is caused by mutations in the IL2RG gene, coding for the cytokine receptor gammasubunit common to IL-2, IL-4, IL-7, IL-9, IL-15 and IL-21 receptors, known as the common gamma chain (γC). Cytokine receptors of the γC group belong to the class I cytokine receptor family, which includes the receptors of other interleukins and hormones. They are heterodimeric or heterotrimeric transmembrane complexes expressed on the surface of cells that share a highly conserved Trp-Ser-X-Trp-Ser motif (WSXWS motif). This motif is essential in receptor function, acting as a molecular switch involved in receptor activation. The sequence variant found in the patient has not been previously reported, however, we consider it is a pathogenic mutation, as it affects the WSXWS motif.

P1198

Autoantibody specificity from T cell receptor alpha chain deficient mice

A. Maceiras Oliveira, A. Agua-Doce, A. Varela & L. Graca
Instituto de Medicina Molecular, University of Lisbon, Lisbon, Portugal

Purpose/Objective: Mice deficient for the alpha chain of the T cell receptor (TCR $\alpha^{-/-}$ mice) spontaneously develop autoimmunity. Although these mice have a developmental defect of TCR α/β T cells, they are able to develop germinal center reactions (GCR) and produce all immunoglobulin (Ig) classes with help from TCR γ/δ cells and from a small population of TCR α^{-}/β^{+} T cells. Given the fact that GCR and antibody production is impaired in TCR $\beta^{-/-}$ mice, we believe that the small population of T cells with a receptor consisting of a pre-T α and a β chain are essential for GCR.
Materials and methods: In order to determine the age of disease onset, as well as, the specificity of the autoantibodies produced, we have followed TCR $\alpha^{-/-}$ mice for several months to check the presence, by immunofluorescence, of autoantibodies that recognize cellular structures.
Results: We found that, although at 3 months of age autoantibodies are still absent, at 5 months autoantibodies are present in significant amounts in the serum. Moreover, these autoantibodies have preferential specificity to nuclear cell components even though in some individuals anti-cytoplasmatic antibodies are also identified.
Conclusions: We, therefore, conclude that α/β T cell lymphopenia in TCR $\alpha^{-/-}$ mice is sufficient to drive GCR and antibody production, but with a bias towards auto-reactivity.

P1199

CD107a expression-based NK degranulation assays for classification of familial hemophagocytic lymphohistiocytosis (FHL)

L. Vargas Henny,* I. Astigarraga,† U. Zur Stadt,‡ M. Alonso-Martínez,§ P. Francos,* I. Martínez-Río,* S. García-Obregón,† D. G. Viedma§ & J. Gil*
**Hospital General Universitario Gregorio Marañón, Immunology, Madrid, Spain, †Hospital de Cruces, Pediatrics, Bilbao, Spain, ‡Pediatric Hematology and Oncology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, §Hospital General Universitario Gregorio Marañón, Molecular Analysis Central Unit, Madrid, Spain*

Purpose/Objective: HLH is an uncommon, serious disease, lethal whithout treatment, characterized by a fail on the granules dependent cytotoxic activity and therefore on the immune system regulation, manifests as an uncontrolled and fatal systemic inflammatory syndrome. NK cells degranulation assays constitute a recent laboratory tool that allows an early diagnosis of familial hemophagocytic lymphohistiocytosis (FHL). In order to validate this assay, we intended to study differences between healthy individuals (HC), FHL and secondary HLH patients and establish local references values of NK cells' CD107a expression.
Materials and methods: Within December 2011 and April 2012, 20 samples from suspected HLH patients and 24 HC samples were analyzed. NK lymphocytes were incubated in complete medium (resting NK cells) or IL-2 conditioned medium (IL-2/NK cells) and posteriorly co-cultured with K-562 cells. The quantification of the CD107a percentage expression on the NK lymphocytes surface (ΔCD107a%) and mean fluorescence intensity (MFI) were obtained by multi-parametric flow cytometry (BD Biosciences). Descriptive statistics, Mann−Whitney *U*-test and ROC curves analyses were performed.
Results: Genetic diagnosis of FHL was confirmed in 3/4 patients with abnormal degranulation activity through sequencing of *UNC13D*, *STX11*, *STXBP2* and *RAB27A* genes; while nine patients who fulfilled HLH criteria were diagnosed as secondary HLH. HLH diagnosis was dismissed in seven patients.

	HC (n = 24)	FHL (n = 4)	P	Secondary HLH (n = 9)	P
DCD107a% resting NK cells $X \pm$ SD (p5-p95)	32 ± 12 (13–55)	4.7 ± 3.8	0.002	28 ± 19	0.94
DCD107a% IL-2/NK cells $X \pm$ SD (p5-p95)	52 ± 13 (28–72)	18.8 ± 11.7	0.003	43 ± 24	0.49
MFI resting NK cells $X \pm$ SD (p5-p95)	89 ± 38.6 (43–191)	48 ± 14.7	0.015	108.6 ± 45.8	0.15
MFI IL-2/NK cells $X \pm$ SD (p5-p95)	134 ± 71.5 (48–324)	72.8 ± 54.8	0.057	177 ± 66.4	0.057

A resting NK cells DCD107a% cutoff value at 10.9 (p5:13%) was identified for classification of FHL forms.

Conclusions: Normal ΔCD107a% ranges, sensitivity and specificity are similar to those described by other authors. Therefore we confirm and validate the NK lymphocytes degranulation assays as a very useful technique for HLH immunologic diagnosis. Further studies are needed to assess whether higher values of MFI may be helpful for secondary HLH diagnosis.

P1200
Common variable immunodeficiency (CVID) and T immunoregulatory cells

F. Cinetto, A. Parolo, N. Compagno, V. Ferri, M. Gazzola, P. Tartaro, S. Carraro, M. Facco, G. Semenzato & C. Agostini
Department of Medicine, University of Padua, Padova, Italy

Purpose/Objective: CVID is a common immune defect in the adulthood. Besides the infective risk, CVID is characterized by an increased incidence of autoimmune diseases, mainly autoimmune cytopenias. Unbalance in the ratio between T regulatory cells (Treg, decreased) and Th17 cells (increased) has been reported in several autoimmune conditions. These cells represent targets for different immunomodulatory therapy, included intravenous immunoglobulin (IVIg). Both IVIg and subcutaneous immunoglobulin (SCIg) are currently used as Ig replacement therapy in CVID. In this study we decided to investigate the possible immunomodulatory role of SCIg therapy and, specifically, its impact on Treg and Th17 levels.
Materials and methods: Ten CVID patients were subdivided according to EUROclass classification and cytofluorimetric analysis of peripheral blood Treg and Th17 cells levels was performed before and after SCIg administration. As a comparation, 10 healthy volunteers were analyzed for Treg and Th17 cells levels.
Results: No significant correlation was demonstrated between B phenotype and T immunoregulatory cells levels. A significant reduction of Th17 level was observed 48–60 h after SCIG infusion (post versus pre: 1.12 ± 0.87% versus 1.71 ± 0.70%; $P < 0.05$). By contrast, no significant results were obtained comparing Treg levels before and after SCIg. As a result, Treg/Th17 ratio significantly increased after SCIg infusion (pre versus post: 1.60 ± 1.18 versus 2.68 ± 1.65; $P < 0.05$).
Conclusions: In CVID, SCIg seem not to play the only role of replacement therapy, since they significantly modified Treg/Th17 balance in our group of patients. This suggest the possibility of using SCIg as immunomodulatory treatment in different settings.

P1201
Disseminated BCG-infection in patient with autosomal recessive chronic granulematosis disease

L. I. Chernyshova & A. V. Bondarenko
Department of Pediatric Infectious Diseases and Clinical Immunology, National Medical Academy for Post-graduate Education, Kiev, Ukraine

Purpose/Objective: Mycobacterial infection is not common cause of infectious syndrome in children with chronic granulomatosis disease (CGD).
Materials and methods: Observation of case with CGD with generalized BCG infection. Immunologic and genetic examinations were used for diagnosis of CGD.
Results: The child was born from III pregnancy, II delivery on 37th week of gestation with body mass 2750 g. She received BCG vaccination at 4th day of birth. At 3 months the local inflammation with regional lymphadenitis developed which was treated with isoniazid for 3 months. Then bilateral purulent cervical lymphadenitis developed at 6, 9 and 11 months treated with wide spectrum antibiotics. Culture from pus was negative. PCR for *Mycobacterium tuberculosis* complex was negative. Since 1 year old causeless periodic fevers occurred with progressive hepatosplenomegaly, loss of weight, progressive anemia, inflammatory changes in blood for almost 6 months. Bacteriological cultures were negative. Treatment with wide spectrum antibiotics had insufficient effect. Antitubercular treatment with amycacinum, rifampin and izoniazid was started *ex juvantibus* for 6 months and positive effect had been received. Three months after antitubercular treatment was stopped the child had pneumonia which did not give in to traditional treatment during 2 months. Then antitubercular treatment was renewed with positive effect. At the age of 7 during the unexplained fever multiple formations were identified in the liver, biopsy showed caseous mass, histologically confirming the mycobacterial nature of lesions. Immunological findings revealed normal serum CH_{50}, Ig A, IgM, IgG, IgE and lymphocyte subpopulations levels, NBT-test 2–14%, phagocytic activity 4–28%. At the age of five the blood samples were tested at INSERM and autosomal recessive CGD was confirmed ($p22^{phox}$).
Conclusions: Universal BCG vaccination of newborns may cause problems in patients with CGD. Difficulties in diagnostics of BCG infection require administration of anti-tuberculosis drugs in suspicious cases.

P1203
Enhanced formation of giant cells in common variable immunodeficiency

T. H. Scott-Taylor,* K. Whiting† & D. A. Webster‡
**London Metropolitan University, Life Sciences, London, UK, †School of Life Sciences, Kingston University, Kingston, UK, ‡Department of Immunology, University College London, London, UK*

Purpose/Objective: To examine the propensity of peripheral blood monocytes in Common Variable Immunodeficiency to fuse to form multinucleate giant cells in relation to the tendency to form granuloma.
Materials and methods: The fusion index of cells from individuals with Common Variable Immunodeficiency (CVID) and normal controls were compared in a range of cytokines, supernatants and mitogens over a week in culture. Cultured monocytes at different of differentiation were centrifuged onto coverslips and examined under electron and confocal microscopes.
Results: Cell fusion of CVID peripheral blood monocytes was variable but on average was quicker, approximately twofold more frequent and formed giant cells with higher numbers of nuclei in culture medium without cytokines than normal. Addition of IL4, GMCSF, IFNg, TNFa and T cell conditioned media further induced normal and particularly CVID giant cell formation and combinations of cytokines and

monokines acted synergistically in promoting monocyte fusion. Treatment with anti INFg antibody reduced normal giant cell formation particularly, indicating a greater predisposition of peripheral CVID cells to fuse, while a greater tendency of CVID cells to fuse with immunoglobulin conditioned media my indicate the contribution of IVIG treatment in granuloma formation. CVID and normal giant cells expressed similar levels of MHC class II and costimulatory molecules and FC receptors and demonstrated metabolic and phagocytic activity with bacteria, yeast and fluorescent carboxilated beads.

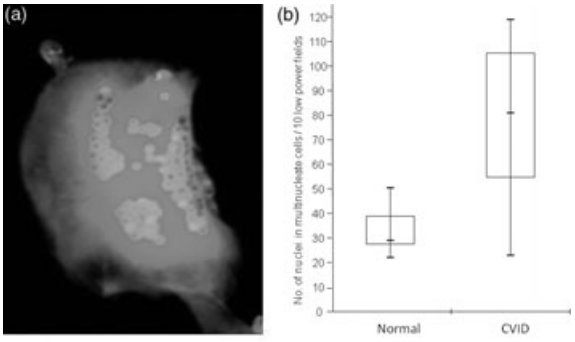

Figure 1: Appearance Of Multinucleate Cells In Culture. CVID mononuclear cells formed large multinucleate cells when cultured in GM CSF and IL4 (A): stained with MHC class II DR FITC and DAPI. (B): PBMC were plated in 6 well plates at a density of 5 x 10^5 cells per ml in GM CSF and IL4 and fused cells examined under a bright field microscope. Data displayed as A: mean (-), 25 to 75% (□) and complete range (⊥) of the fusion index of normal and CVID cells of 8 individuals.

Conclusions: A 2- to 5-fold greater tendency to form giant cells was induced in peripheral CVID monocytes by an extensive range of monokines, inflammatory lymphokines and T cell supernatants. CVID and normal cell giant cells were metabolically active and phenotypically similar.

P1204
Familial multiorgan-autoimmunity syndrome with cytopenia, liver-, and islet cell autoantibodies — a novel inherited immune dysregulation syndrome?

M. Seidel,* W. Schwinger,* H. Lackner,* A. Deutschmann,* G. Gorkiewicz,† M. R. Speicher,‡ K. Boztug§ & E. C. Urban*
**Pediatric Hematology Oncology, Medical University, Graz, Austria, †Institute of Pathology, Medical University, Graz, Austria, ‡Institute of Human Genetics, Medical University, Graz, Austria, §Austrian Academy of Sciences, Research Center for Molecular Medicine, Vienna, Austria*

Purpose/Objective: A now 16-years-old girl from a Kurdish consanguineous family underwent stem cell transplantation (SCT) from her HLA-identical mother for suspected type 3 (non-classic) autoimmune lymphoproliferative syndrome (ALPS) after suffering from chronic immune thrombocytopenia (ITP) starting from her 2nd year of life and recurrent bacterial infections, developing into generalized massive lymphadenopathy and splenomegaly without evidence of EBV infection. Soon after successful SCT lymphoproliferation resolved, but chronic ITP recurred. Both mother and daughter have normal immunoglobulin (Ig) levels and antibodies against viral and vaccine antigens, but were found to be positive for liver/mitochondrial autoantibodies (AMA, M2) without liver/biliary disease or cryptosporidia in stool.

A now 8-years-old sister was diagnosed with autoimmune hemolytic anemia (AIHA) at the age of five years. AIHA resolved under immunosuppression with rituximab, FK506 and MMF; total B cell numbers and Ig levels were normal prior to anti-CD20 therapy. Later, the girl developed a persistent CVID-like syndrome with low B cell numbers (<50−100 μl) and hypogammaglobulinemia, chronic enteropathy with growth arrest, positive tests for Noro-, Adenovirus, HSV, CMV. The girl is Ig-substituted, has hypothyroidism, anti-mitochondria- (AMA, M2), islet-cell, insulin- and glutamate decarboxylase- but no other autoantibodies. Family history including a 3-years-old healthy brother is unremarkable.

Materials and methods: Standard immune phenotypical assays including TCR-Vb-spectratying did not reveal a known type of cellular immunodeficiency. CD4/CD8 double-negative T cells were borderline increased (2−10%), but serologic parameters (VitB12, Apolipoprotein), apoptosis, killing, and lymphocyte proliferation assays were normal, lymph node histology from the older girl was 'compatible' with ALPS, but gene sequence of CD95, CD95L, Caspase-8, and -10 were normal. Bowel histology of the younger patient showed lymphocytic enteritis.

Results: In summary, one sibling shows an iatrogenous CVID-like syndrome and multiple viral infections after anti-CD20-treated AIHA, and the other girl partial remission of atypical ALPS post-HSCT.

Conclusions: In search for an unrecognized immune dysregulation syndrome, the currently ongoing steps of diagnostic work up are homozygosity mapping and exome sequencing.

P1205
Humoral immunity in patients with diGeorge syndrome

A. Sediva,* A. Klocperk,* J. Grecová,* A. Skalicka,* M. Mattanelli,* R. Zachova* & T. Kalina†
**Department of Immunology, 2nd School of Medicine Charles University and University Hospital Motol, Prague, Czech Republic, †Department of Pediatric Hematooncology, 2nd School of Medicine Charles University and University Hospital Motol, Prague, Czech Republic*

Purpose/Objective: Syndrome diGeorge is a complex disorder caused by an embryopathy based on del22q11. Due to hypo/aplasia of a thymus resulting immunodeficiency affects mainly T cells. Recent data, however, show a pathology also in humoral immunity. We have, therefore, investigated B cell compartment and antibody response in a cohort of diGeorge patients.

Materials and methods: Total cohort of 50 patients was available for investigation. Immunoglobulin levels and antibody response against tetanus were measured repeatedly in all subjects, post-vaccination antibodies against Pneumococcus sp. and Hemophilus infl. in subcohorts (33 and 37, respectively). Seventeen patients, age 3 months till 20 years, were available for B cell phenotyping.

Results: Only 14% of patients had all immunoglobulin isotypes in normal range. We have observed higher tendency to increased than decreased values of immunoglobulins (increased IgG 24%, IgA 33%, IgM 5%, decreased IgG 12%, IgA 10%, IgM 17%). Seventy two percent of patients had normal post-vaccination response, all others presented with low values of specific antibodies. All tested patients showed markedly increased population of transitional and naïve B cells (14/17 samples above median) and decreased switched memory B cells (17/17 samples below median). Decrease of switched memory B cell is highly significant and progressive with age.

Conclusions: B cell compartment and antibody response are disturbed in diGeorge patients. Regular investigation of humoral immunity would help in clinical management and vaccination strategy.

P1206

IL-12/23-IFN-gamma axis defects and their effects on human NADPH oxidase system activation – myelomonocytic cell model

W. Cutrim Aragão Filho,* L. Alberto Pedrosa,* J. Antonio Tavares Albuquerque,* O. Cabral Marques,* M. Wall Barbosa-Carvalho,* J. Bustamante,† J. Laurent Casanova† & A. Condino Neto*
*University of Sao Paulo, Institute of Biomedical Sciences, Immunology, São Paulo, Brazil, †Un of Paris René Descartes Necker Medical School, Laboratory of Human Genetics of Infectious Diseases, Paris, France,

Purpose/Objective: To evaluate the NADPH oxidase in myelomonocytic human cells with IL-12/23-IFN-γ axis defects.
Materials and methods: Cell model: wild type U937 cells or treated with control, IFN-γRα (IFNGR1) or IFN-γRβ (IFNGR2) shRNA lentiviral particles for the silencing of IFNGR1 or IFNGR2 gene. The cells were differentiated or not with PMA or IFN-γ+TNF-alpha before the experiments. NADPH oxidase activation was measured by flow cytometric assay using dihydrorhodamine 123 (DHR); CYBB, CYBA, NCF1 and NCF2 gene expression was evaluated by real-time PCR; phagocytic activity was measured by cytometric assay using Paracoccidioidomicose brasiliensis marked particles. We also analysed the flavocytochrome b558 and CD54 (ICAM-1) expression by flow cytometric assay.
Results: U937 shRNA IFNGR1 and U937 shRNA IFNGR2 lineages showed impairment of NADPH oxidase activation measured by DHR assay when stimulated with IFN-γ, PMA or IFN-γ+PMA. There was a decrease on flavocytochrome b558 Median Fluorescence Intensity (MFI) in the IFN-γ-stimulated U937 shRNA IFNGR2 lineage. The CD54 MFI was found diminished mainly in IFN-γ-stimulated U937 shRNA IFNGR1 lineage. The gene expression of the components of NADPH oxidase system evaluated here was decreased in U937 shRNA IFNGR1 and U937 shRNA IFNGR2 lineages, stimulated or not with IFN-γ. The silencing of IFNGR1 or IFNGR2 gene did not influenced the phagocytic capacity of IFNGR1 or IFNGR2 deficient cell lineages.
Conclusions: The activation defect of NADPH oxidase system showed in our myelomonocytic human cell model can contributes to explain the susceptibility to Mycobacteria in Mendelian Susceptibility to Mycobacterial Diseases as well as the reduction of ICAM-1 showed here.

P1207

Immunoglobulin G fraction of APECED sera inhibits type I interferons and Th17-related interleukins

J. Kärner,* A. Meager,† M. Laan,* J. Maslovskaja,* E. Juronen,‡ N. Willcox,§ P. Peterson* & K. Kisand*
*Institute of General and Molecular Pathology, Molecular Pathology Study Group, Tartu, Estonia, †National Institute for Biological Standards and Control, Biotherapeutics, South Mimms, UK, ‡Institute of General and Molecular Pathology, Immunology Group, Tartu, Estonia, §Weatherall Institute of Molecular Medicine University of Oxford, Neurosciences, Oxford, UK

Purpose/Objective: Autoimmune polyendocrinopathy candidiasis ectodermal dystrophy (APECED) is a recessive disorder resulting from mutations in the autoimmune regulator (*AIRE*). In addition to organ-specific autoantibodies, almost all of these patients have serum autoantibodies to several cytokines. Those against type I IFNs are specific and sensitive disease markers. Autoantibodies to Th17-related interleukins are associated with chronic mucocutaneous candidiasis. APECED sera have high neutralizing capacities against the respective cytokine. Although these are assumed to be caused by serum autoantibodies it has not yet been proved directly.
Materials and methods: In this study, cell-based cytokine neutralization tests were performed with purified IgGs and IgAs from APECED patients' and control sera to test serum immunoglobulin neutralization capacity. In addition, luciferase immunoprecipitation systems (LIPS) assays were carried out to specify the dominant IgG subclass(es) in APECED and thymoma patients against these cytokines and to find out the main immunogenic epitopes of IFN-α2a and IL-22.
Results: Neutralization of cytokine function was detectable only with APECED IgG and IgA samples. IFN-ω and IFN-α2a were neutralized by IgG with significantly higher efficiency than by IgA, while IL-22 and IL-17A were neutralized almost exclusively by IgG. Their dominant isotypes proved to be IgG1 and surprisingly IgG4 (but not IgE), thus implicating Th2 or regulatory T-cell responses in their initiation. Patients with thymomas showed striking parallels, possibly implicating epithelial autoimmunization in these AIRE-deficiency states. The epitopes on IL-22 and IFN-α2a appeared to be mainly conformational, but some mapped closer to their C-termini.
Conclusions: In conclusion, the predominance of IgG type anti-cytokine autoantibodies over IgA suggests that autoimmunization against cytokines in APECED is not just secondary to chronic *Candida* infection at mucosal surfaces but intimately related to the disease pathogenesis.

P1209

Somatic mutations in immunodeficiencies: is it a frequent event in '*de novo*' PID?: suggestions from a case report of X-linked Severe Combined Immunodeficiency

M. Juan-Otero,* L. Alsina,† E. González-Roca,* M. T. Giner M. Piquer,† I. Puga,‡ M. A. Martín-Mateos,† I. Badell,§ A. Cerutti,‡ J. Yagüe,* J. I. Arostegui* & A. M. Plaza¶
*Hospital Clínic, Immunology Service, Barcelona, Spain, †Hospital Sant Joan de Déu, Clinical Immunology and Allergy Section, Barcelona, Spain, ‡Institut Municipal d'Investigació Mèdica-Hospital del Mar, B cell biology, Barcelona, Spain, §Hospital Sant Pau, Paediatric Haemato-Oncology Service, Barcelona, Spain, ¶Hospital Sant Joan de Déu, Clinical Immunology and Allergy Section & Unitat funcional d'Immunologia SJD-Clínic, Barcelona, Spain

Purpose/Objective: X-linked Severe Combined Immunodeficiency (X-SCID) is due to deleterious IL2RG mutations, and represents the most frequent type among SCIDs. The healthy mother may carry a mutated chromosome and transmit it to the offspring. Alternatively, a *de novo* occurring mutation in the patient can occur. Rarely in this disease, somatic mutations have been described. To define the pattern of inheritance (*de novo* or maternally inherited) of an already known p.R226C IL2RG mutation in a classical X-SCID patient.
Materials and methods: Sanger-based sequencing of gDNA of the mother and her affected son. Confirmation of the mosaicism by high throughput sequencing (with high coverage level).
Results: By Sanger-based sequencing methods, we detected in patient's mother peripheral blood the nucleotide exchange as a potential somatic mutation, with low-level mosaicism that was confirmed by massive parallel sequencing with high coverage. The vertical transmission of the deleterious IL2RG allele to her male offspring indicated its presence in gonadal tissues. The mutation was absent in maternal patient's grandparents. Altogether, these evidences support that a *de novo*, somatic IL2RG mutation occurred in this carrying mother, most probably early during embryogenesis.
Conclusions: The present report describes a rare and unusual genetic phenomenon, emphasizing the inclusion of X-SCID in the group of genetic diseases in which somatic mutations can play a role in the pathogenesis. Since they can be vertically transmitted, their identification has serious implications in genetic counselling. However, their detection is usually difficult by conventional Sanger-based sequencing methods. Thus, similar studies should benefit of the systematic use of sensitive and quantitative genetic methods.

P1210

Study of a functional c-kit rs6554199 polymorphism and achalasia in a Spanish population

J. L. Santiago,* E. G. de la Concha,* J. Pérez de la Serna,† C. Sevilla,† E. Urcelay* & A. Ruiz de León†

HCSC, Immunology, Madrid, Spain, †HCSC, Gastroenterology, Madrid, Spain

Purpose/Objective: Idiopathic achalasia, a primary motility disorder of the esophagus characterized by failure of the lower esophageal sphincter (LES) and aperistalsis, is mainly caused by loss of the inhibitory effect of the esophageal myenteric plexus and subsequent LES relaxation. The possible etiologies proposed for achalasia include neuronal degeneration, viral infection, genetic predisposition and immune-mediated destruction of the myenteric plexus. The *c-kit* gene encodes a tyrosine kinase receptor expressed among others by interstitial cells of Cajal (ICCs), which together with the enteric nervous system are involved in gastrointestinal motility. In fact, alterations in ICCs distribution have been reported in different intestinal disorders. A functional polymorphism (rs6554199) located in the *c-kit* gene has been reported associated with achalasia in a Turkish cohort. Our aim was to replicate the aforementioned result in a large cohort of Spanish patients and controls.
Materials and methods: A case control study was performed with 282 Spanish white unrelated patients diagnosed of achalasia and 687 healthy controls. All of them were genotyped for the SNP rs6554199 using a TaqMan Assay by Design (Applied Biosystem, Foster City, CA, USA) analyzed in a 7900HT Fast Real-Time PCR System.
Results: No association was found for the *c-kit* rs6554199 polymorphism and achalasia in our study. The frequency of the T allele was similar in patients and controls (47.3% versus 49.4%; OR = 0.92, $P = 0.41$) and no trend for association was detected in genotypes or carriers of T allele. Additionally a gender stratified analysis was performed and again no differences were found.
Conclusions: The finding that the T allele of the *c-kit* rs6554199 polymorphism could be associated with achalasia, as previously reported in a Turkish population could not be replicated in a Spanish cohort. Although ethnic differences might explain these data, the sample size that compromised the statistical power in the Turkish cohort and is higher in our study, led us to conclude that the reported association seems to be a false positive.

P1211

Study of gamma delta T cells in a Tab-Tgd+B+NK+ SCID due to CD3D mutations

B. Garcillán,* M. S. Mazariegos,* P. Fish,† M. Muñoz-Ruiz,* J. Gil,‡ E. López-Granados§ & J. R. Regueiro*

Facultad Medicina Universidad Complutense, Inmunología, Madrid, Spain, †Institute of Pathology, University Hospital Freiburg, Pathology and Pathological Anatomy, Freiburg im Breisgau, Germany, ‡Hospital Gregorio Marañón, Inmunología clínica, Madrid, Spain, §Hospital La Paz, Inmunología clínica, Madrid, Spain

Purpose/Objective: CD3δ deficiency is usually associated to absent T lymphocytes. However, a leaky CD3D mutation leading to half CD3δ protein levels in homozygous SCID patients allowed for normal numbers of peripheral blood $\gamma\delta$ T cells. Our objective was to study the phenotype, function and V region usage of $\gamma\delta$ T cells from two unrelated infants *ex vivo* and *in vitro*.
Materials and methods: Flow cytometry, cell culture and TCRD V01−3 spectratyping.
Results: Despite their normal numbers, $\gamma\delta$ T cells showed a stronger reduction of surface TCR expression levels (5-fold) as compared to $\alpha\beta$ T cells (2-fold) in both patients. Upon CD3 triggering, both TCR isotypes modulated well but signalled poorly. TCRD V usage by $\gamma\delta$ T cells was, however, quite normal as judged by spectratyping and flow cytometry, and was not perturbed by CMV infection, which was ascertained in one of the patients. The CD4- $\gamma\delta$ T cell subset (both DN and CD8+), was normally represented. In contrast, the CD4+ $\gamma\delta$ T cell subset, which is marginal in healthy individuals (<2%), was strongly expanded in both patients (30%), had an activated phenotype and could be grown *in vitro* with feeder cells. Normal CD4+ $\gamma\delta$ T cells are frequent in fetal liver, poorly cytolytic compared to CD4- $\gamma\delta$ T cells, but good MHC class II- and CD4-independent B cell helpers.
Conclusions: The results indicate that low CD3δ strongly impairs $\gamma\delta$ TCR expression but not $\gamma\delta$ T cell selection or diversity, particularly of the rare CD4+ $\gamma\delta$ T cell subset.

P1212

The presence of intermediate phenotype of CD4 T cells in CVID is a result of increased CD70 expression on activated T and B cells

V. Kanderova,* J. Stuchly,* M. Vlkova,† O. Hrusak,* A. Sediva,‡ J. Litzman† & T. Kalina*

2nd Faculty od Medicine, CLIP (Childhood Leukaemia Investigation Prague) DPHO, Charles University, Prague, Czech Republic, †Department of Clinical Immunology and Allergology, Faculty of Medicine and St. Anne's University Hospital, Masaryk University, Brno, Czech Republic, ‡Department of Immunology, Charles University 2nd Faculty od Medicine, Prague, Czech Republic

Purpose/Objective: Common Variable Immunodeficiency (CVID) is characterized by low levels of serum IgG, IgA, and/or IgM and impaired specific antibody response after antigen challenge (Conley Clin Immunol 1999). Investigation of peripheral blood (PB) cellular compartments revealed abnormalities in B and T cells (Vlkova Clin Exp Immunol 2006). Using polychromatic flow cytometry and probability binning computational approach (Kalina Cytometry A 2009) we found accumulation of CD4pos T cells with increased proportion of intermediate (Appay Semin Immunol 2004) CD28posCD27neg cells in CVID patients. We asked if the disappearance of CD27 on CD4pos T cells could be related to prolonged expression of its ligand CD70 on B and T cells or dendritic cells (DCs). Since CD70 is expressed transiently upon activation on B and T cells (Arens Immunity 2001) we analyzed activation status of immune system of CVID patients based on CD69 and changes in cytokine milieu in PB.
Materials and methods: We analysed expression of CD70 and CD69 on PB B cells, T cells and DCs and monitored 11 plasma cytokines of CVID patients ($n = 21$) and healthy age-matched controls ($n = 18$) using 8-color flow cytometry.
Results: Expression of activation marker CD69 was more frequent on B andT cells of CVID patients compared to healthy controls (mean 11.1% versus 1.5% on B cells and 7.6% versus 1.7% on T cells, $P < 0.05$). CD70 was more frequent on naïve CD27neg B cells (8.6% versus 2.6%), less frequent on mature CD27pos B cells (11.8% versus 34.7%) and more frequent on CD3pos T cells (6.8% versus 1.5%) [both CD4pos (8.9% versus 1.6%) and CD8pos (6.3% versus 1.5%)] in CVID patients compared to healthy controls ($P < 0.05$). Neither CD69 nor CD70 were expressed on DCs. Surprisingly, we did not observe elevated expression of cytokines usually connected with immune system activation such as IFNg, IL-2, IL-4, IL-5 or IL-6 in plasma of CVID patients.
Conclusions: Since CVID pathogenesis is clearly heterogeneous, it is difficult to pinpoint the cause versus the effect of the deregulation in T to B cell interaction. Here we show that accumulation of CD4pos T cells with intermediate CD28posCD27neg phenotype could be explained by engagement of CD27 by its ligand CD70 expressed on activated B and T cells. This is not accompanied by changes in inflammatory cytokines levels. Our findings add evidence to the B × T cell interplay defect in CVID patients.

The role of LEKTI deficiency in immunity and skin homeostasis

B. Hagl,* M. Senn,* B. Halm,* A. Jayakumar,† M. H. Schiller,* S. Anover-Sombke,‡ J. S. Orange,§ T. R. Torgerson,‡ H. D. Ochs‡ & E. D. Renner*

**Ludwig Maximilians University, University Children's Hospital at Dr. v. Haunersches Kinderspital, Munich, Germany, †M. D. Anderson Cancer Center, The University of Texas, Houston, TX, USA, ‡School of Medicine and Children's Hospital, University of Washington, Seattle, WA, USA, §Baylor College of Medicine, Texas Children's Hospital, Houston, TX, USA*

Purpose/Objective: Comël-Netherton syndrome is a rare autosomal recessive disorder characterized by ichthyosis, bamboo hair, atopic diathesis, recurrent infections, and a 20% fatality rate in the first year of life. Mutations in *SPINK5* lead to reduced expression or complete absence of the protein it encodes the serine protease inhibitor LEKTI. In 2009 we defined the Comël-Netherton syndrome as a primary immunodeficiency disorder. This fact drew our attention to LEKTI's role in immune defense and to its potential effect on one of the most important serine proteases granzyme B (GZMB). LEKTI is expressed in epithelial cells but not in leukocytes. LEKTI fragments, however, have been isolated from human blood.

Materials and methods: We investigated the influence of the full length LEKTI protein and its various fragments (domains 1−6, 6−9, 9−12 and 12−15) on GZMB activity using an enzymatic assay and performed flow cytometric analysis using Annexin V-7AAD co-staining to examine a possible apoptotic effect by LEKTI.

Results: High amounts of LEKTI protein resulted in increased GZMB activity while low concentrations showed a mild reduction of GZMB activity suggesting a direct influence of LEKTI on GZMB. Since GZMB is an important player in T cell and NK cell mediated apoptosis we investigated a possible role of LEKTI on GZMB mediated cell death. Our experiments so far suggest a dose-dependent influence on GZMB mediated apoptosis by LEKTI.

Conclusions: We conclude that LEKTI secreted by epithelial cells may contribute to the induction of apoptosis in skin infiltrating T cells preventing unlimited cytotoxicity by these skin infiltrating cells against epidermal cells and hence play an important role in the maintenance of homeostasis in inflammatory skin processes. Thus the defective regulation of apoptosis may explain the increased incidence of recurrent infections, severe allergic manifestations and skin inflammation characteristic for the Comël-Netherton syndrome.

P1214

The Spain national registry of primary immunodeficiency diseases

N. Lanio,* V. Daza,* N. Martinez Pomar,* E. Villegas,* J. Pons de Ves,* J. Iglesias,* N. Matamoros* & The Spanish PID group†

**Son Espases Hospital, Immunology, Pañlma de Mallorca, Spain, †Members of the REDIP, Spain*

Purpose/Objective: Primary immunodeficiency diseases (PIDs) are acknowledged as important medical and social issues. Registries of PIDs are essential for improving our knowledge of many features of these rare disorders. The Spanish Registry for Primary Immunodeficiency Diseases (REDIP) was established in 1993. The online open-access database version was launched in 2005 and since 2009 REDIP contributes to the European Society for Immunodeficiencies (ESID) Registry.

Materials and methods: Demographic and clinical data of PID patients were registered by physicians from all over Spain. Collected data is anonymous and in agreement with ethic and protection guidelines.

Results: REDIP nowadays comprises 1890 patients from 27 regional centres located in 11 autonomous communities, with an overall prevalence of 4 PIDs per 100.000 inhabitants. Selective immunoglobulin IgA deficiency represents the most common entity (n = 722; 38.3%), followed by common variable immunodeficiency (n = 400; 21%), C1-inhibitor deficiency (n = 234; 12.4%), IgG subclass deficiency (n = 87; 4.6%), X-linked agammaglobulinemia (n = 61; 3.2%) and DiGeorge anomaly (n = 51; 2.7%). Consanguinity and familial antecedents were reported in 3.4% and 23.7% of cases, respectively. Autoimmunity was the most frequent complication (248; 13%) and celiac disease the most prevalent condition (41; 16.5% of total autoimmune disorders). The most frequent long-term therapy was immunoglobulin replacement (629; 33% of patients).

Conclusions: Overall prevalence of PIDs in Spain is similar to that observed in other national registries. However, the prevalence of Complement deficiency is higher than others registries, related to the incorporation of National C1inhibitor Registry to REDIP. Registries are powerful tools to understand different aspects of PIDs and promoting collaboration among healthcare professionals.

P1215

Why don't to do severe combined immunodeficiency newborn screening in Europe?

E. García Moreno, A. Nieto, M. Vilches, R. López Blanco, R. de la Varga Martínez, J. A. Brieva & A. Sampalo

Hospital Puerta Del Mar, Inmunología, Cádiz, Spain

Purpose/Objective: Infants affected by Severe combined immunodeficiency (SCID) die of infectious complications in the first years of life, unless an early diagnosis and a hematopoietic stem cell transplantation (HSCT) have been performed. They are not often diagnosed promptly. The delay in diagnosis and treatment has awful consequences. SCID infants receiving HSCT before 2 months of age show 95% of survival, whereas those receiving HSCT after 5 months show 70% of survival and 30% after 8 months. Early diagnosis is not always easy, and many of these patients die without being diagnosed.

Lymphopenia is the most constant sign of SCID. Its detection by T cell receptor excision circles quantification (TRECs) is the used method for screening.

The USA experience on SCID Newborn screening have been successful. We propose and discuss the convenience of introduce it in Europe based on clinical benefits and cost-effectiveness.

Materials and methods: A systematic literature review of published report was performed using the internet database Pubmed. Search criteria were; 'severe combined immunodeficiency', 'neonatal screening', 'T cell receptor excision circles' 'Hematopoietic stem cell transplantation', 'cost-effectiveness analysis' and 'QALY'. All retrieved papers were screened for additional references.

Results: Sixty three papers were analyzed and the main findings were:

Screening for SCID began in Wisconsin and Massachusetts in 2009. Following the recommendation of the USSHHS, California, Louisiana, New-York, Florida and Puerto Rico have implemented screening programs from 2010 to 2011 and, it has been extended to all states in 2012.

Main clinical results: of the widest study, carried out in California: 10 SCID has been detected among 507.000 newborns (two γc chain deficiency, two IL7Rβ deficiency, two RAG1 deficiency, one omenn syndrome and three SCID variants). Implementation of the program allowed to get 880 life years. Cost-effectiveness: the program show an incremental cost-effectiveness ratio of 25.429 $/life year, and of 27 907$/Quality adjusted life year (QALY), and allowed to get 802 QALYs.

Conclusions: American experience on SCID screening program has shown clinical benefits and suitable cost-effectiveness balance. Why Europe countries appear not to be so interested in it?

11ß-hydroxysteroid dehydrogenase-1 amplification of glucocorticoid action in myeloid cells promotes resolution of K/BxN arthritis in mice

Z. Zhang,* A. E. Coutinho,* D. G. Brownstein,† M. Gray,‡ J. R. Seckl* & K. E. Chapman*
*Endocrinology Unit, University of Edinburgh, Edinburgh, UK, †Mouse Pathology Core Laboratory, University of Edinburgh, Edinburgh, UK, ‡Centre for Inflammation Research, University of Edinburgh, Edinburgh, UK

Purpose/Objective: Glucocorticoids (GCs) have been widely used to treat arthritis. However, despite the efficacy of synthetic GCs, the role played by endogenous GCs in arthritis remains obscure. *In vivo*, endogenous GCs exist in active (cortisol and corticosterone) and inactive (cortisone and 11-dehydrocorticosterone) forms, the latter with negligible affinity for receptors. 11β-hydroxysteroid dehydrogenase 1 (11β-HSD1) converts inactive GCs into active GC, thereby amplifying GCs action within cells, *in vivo*. Macrophages express 11β-HSD1 and mice deficient in 11β-HSD1 (*Hsd11b1*$^{-/-}$) show delayed acquisition of macrophage phagocytosis. Compared to wild-type (WT) controls, *Hsd11b1*$^{-/-}$ mice show an earlier onset of inflammation in the K/BxN serum transfer model of arthritis, which is dependent on myeloid cells. *Hsd11b1*$^{-/-}$ mice also show delayed resolution of K/BxN arthritis, with greater exostosis of the bone. To dissect contributions of 11β-HSD1 in myeloid cells to this inflammatory phenotype, we have crossed *LysM-cre* with *Hsd11b1*$^{flox/flox}$ mice to generate *LysM-Cre Hsd11b1*$^{flox/flox}$ (MKO) mice.
Materials and methods: MKO mice show ~82% reduction of 11β-HSD1 enzyme activity in peritoneal resident macrophages, but little or no reduction in thioglycollate elicited macrophages. To induce arthritis, MKO and control *Hsd11b1*$^{flox/flox}$ and *Hsd11b1*$^{-/-}$ mice (male, aged 7–10 weeks, $n = 6–7$) were injected with K/BxN serum (125 μl/mouse). Clinical scoring of the joints was carried out blind to genotype for 21 days.
Results: Whereas *Hsd11b1*$^{-/-}$ mice showed an earlier onset of arthritis, as previously described, there was no difference in the onset or peak phrases of arthritis (day 1–12) in MKO mice compared to WT. However, inflammation was significantly worse in MKO mice between day 13–18, similar to *Hsd11b1*$^{-/-}$ mice.
Conclusions: These data demonstrate that resident macrophage 11β-HSD1 promotes the resolution of inflammation in K/BxN serum induced arthritis, but plays no role in the initial worse inflammation seen with global 11β-HSD1 deficiency in this model. In the future it will be important to elucidate the mechanisms underlying the pro-resolution role for resident macrophage 11β-HSD1, including whether its role in promoting macrophage phagocytosis of apoptotic cells is important in rheumatoid arthritis.

P1217

A novel method for investigating macrophage phagocytosis in juvenile systemic lupus erythematosus using the pH sensitive dye pHRodo

L. Ballantine, D. Harris & M. W. Beresford
Institute of Translational Medicine, University of Liverpool, Liverpool, UK

Purpose/Objective: Phagocytosis is the regulated cellular uptake of pathogens, cellular debris, and apoptotic cells in a non-inflammatory manner. There is increasing evidence that systemic lupus erythematosus (SLE) autoimmunity could be related to impaired or delayed clearance of apoptotic cells since key autoantigens are found on the surface of apoptotic cells [1]. Studies have also shown macrophages derived from SLE patients to have impaired phagocytic ability [2]. Juvenile-onset SLE (JSLE) is a more severe form of adult-onset SLE and at present there are no studies into the role of phagocytosis within JSLE. The use of pHRodo is a novel method of investigating phagocytosis as it is a pH sensitive dye with a low fluorescent signal at the neutral pH but will emit a red fluorescence in the acidic environment of the phago-lysosome once it is engulfed by the phagoctye.
Materials and methods: CD14$^+$ cells were isolated from healthy control patients and used immediately or differentiated into macrophages in the presence of M-CSF. Following optimisation, macrophages from 3 donors and monocytes from 1 donor were incubated with 50 μl pHRodo stained *E. coli* in the presence of 10% JSLE [($n = 5$ macrophages) ($n = 3$ monocytes)] or control serum [($n = 4$ macrophages) ($n = 4$ monocytes)] for 30 min at 37°C (phagocytosis assay) or at 4°C (negative control). The cells were washed and analysed on a flow cytometer. The percentage of *E. coli* phagocytosis was determined by measuring the number of macrophages or monocytes emitting red fluorescence. Non-specific background fluorescence was removed by subtracting the percentage of phagocytosis in the 4°C negative control from the 37°C phagocytosis assay.
Results: Macrophages had a lower level of phagocytosis when incubated in JSLE serum compared with control serum (33.8 ± 5.0% versus 42.0 ± 7%). Monocytes had a lower level of phagocytosis in JSLE serum compared to control (33.0 ± 8.9% versus 42.7 ± 6.2%), although these differences were not statistically significant.
Conclusions: These results correspond with literature from adult-onset SLE patients suggesting that the serum environment within JSLE patients is able to inhibit effective macrophage phagocytic uptake. Further work analysing JSLE monocyte and macrophage phagocytosis rate and their ability to phagocyte apoptotic cells is underway.

P1218

A role for the autoantigen La in the regulation of IFN production and progression of SLE?

R. Mahony,* R. J. Maraia† & C. A. Jefferies*
*Molecular & Cellular Therapeutics, Royal College of Surgeons in Ireland, Dublin, Ireland, †National Institutes of Health, National Institute of Child Health and Human Development, Bethesda MD, USA

Purpose/Objective: SLE is characterised by chronic inflammation driven by immune complexes against autoantigens and overproduction of inflammatory cytokines and type I IFNs. La is a 48 kDa RNA-binding protein well documented as an autoantigen in SLE, with a known role in binding and stabilising nascent RNA polymerase III (RNA pol III) transcripts. Recent studies have shown that RNA pol III transcribes dsDNA into 5'ppp-dsRNA, a potent activator of cytosolic receptor, RIG-I, thus contributing to the production of type I IFNs in an antiviral response. Due to this recently uncovered role for RNA pol III, as well as the role of La in binding RNA pol III transcripts, we hypothesise that La may play an important role in regulating IFN production.
Materials and methods: Luciferase assays.

HeLacells were transiently transfected with a luciferase reporter construct containing the IFN-β p125 promoter (40 ng). TK Renilla (40 ng), and 50 ng of RIG-I, IPS-1, TRIF and TBK-1, Cells were assayed for reporter gene activity 18 h post-transfection.

Interaction studies.

Immunoprecipitation studies in HEK293T cells were carried out using Protein G sepharose beads pre-coupled to either monoclonal La. Pulldown was carried out using nickel agarose beads coupled to either full-length or truncated recombinant La. HEK293T lysates overexpressing RIG-I domains were added to these beads. All samples were analysed by western blotting.

Results: Our results indicate a novel role for La in directly and specifically inhibiting RIG-I-dependent IFN production. Transient transfection of HeLa cells with increasing amounts of La inhibits both RIG-I- and IPS-1- induced IFN-β promoter activity, whilst IFN-β promoter activity driven by TRIF, an adaptor downstream of TLR3 and TLR4, or the downstream effector kinase TBK-1 was unaffected. Co-immunoprecipitation and pulldown experiments demonstrated that La and RIG-I interacted via the N-terminal domain of La directly and the CARD domain of RIG-I, suggesting that the inhibitory effect of La on IFN-β activity is due to direct binding.
Conclusions: This work demonstrates that La is a novel negative regulator of IFN responses and may be important in protecting cells from recognising and responding inappropriately to self-dsRNA motifs that may potentially activate RIG-I. Future work aims to characterise the RIG-I/La interaction in SLE patients in order to establish the potential influence of this complex within the context of disease.

P1220
Angiogenic T cells and endothelial progenitor cells depletion in rheumatoid arthritis patients

J. Rodriguez-Carrio,* B. de Paz Cazón,* C. Prado,* P. López,* M. Alperi-López,† F. J. Ballina-García† & A. Suárez*
**Department of Funcional Biology, Area of Immunology, University of Oviedo, Oviedo, Spain, †Department of Rheumatology, Hospital Universitario Central de Asturias, Oviedo, Spain*

Purpose/Objective: To study the Angiogenic T Cells (Tang) in rheumatoid arthritis patients and their relationships with Endothelial Progenitor Cells (EPC), clinical and immunological parameters and traditional cardiovascular risk factors.
Materials and methods: Tang, defined as $CD3^+$ $CD31^+$ $CD184^+$ cells, were quantified in peripheral blood samples from 35 patients with long-standing RA and 17 healthy controls (HC) and related to EPC population, determined by flow cytometry based on CD34, VEGFR-2 and CD133 markers. Clinical and immunological data and traditional cardiovascular risk factors were obtained by reviewing clinical records. DAS28 score was used for measuring disease activity.
Results: RA patients showed significant Tang and EPC depletions compared with HC ($P < 0.001$, in both cases). As expected, both populations were positively correlated in HC ($r = 0.833$, $P < 0.001$) and inversely related to traditional cardiovascular risk factors. In RA patients, however, these associations were missing but Tang cells were negatively correlated with disease activity (DAS28: $r = -0.552$, $P = 0.003$). Moreover, RF-, anti-CCP- and ANA-positive patients exhibited a higher Tang depletion than their negative counterparts ($P = 0.006$, $P = 0.098$ and $P = 0.001$, respectively), thus linking disease-specific autoantibodies with lower endothelial-repair ability.
Conclusions: Tang and EPC depletion could have a role in determining the increased endothelial damage in RA patients. Particularly, Tang depletion could be impairing EPC functionality in RA patients. Additionally, autoantibody profile could be an interesting tool to determine specific-patient cardiovascular risks.

P1222
Anti-carbamylated protein antibodies are present in mice with collagen induced arthritis

J. N. Stoop, J. Shi, D. T. S. L. Jansen, T. W. Huizinga, L. A. Trouw & R. E. Toes
Leiden University Medical Center, Rheumatology, Leiden, The Netherlands

Purpose/Objective: Antibodies against citrullinated proteins (ACPA) are a characteristic of rheumatoid arthritis (RA). Carbamylation is a different type of post translational modification, where a Lysine amino acid is converted into a homocitrullin. Recently, we identified antibodies binding to carbamylated proteins (anti-CarP) in a subgroup of RA patients. In ACPA negative RA patients anti-CarP antibodies associate with joint damage. The aim of this study was to determine whether these anti-CarP antibodies are present in animal models of arthritis.
Materials and methods: Collagen induced arthritis (CIA) was induced in DBA/1 ($n = 28$) and C57Bl/6 ($n = 19$) mice by immunization with type II collagen in CFA. Arthritis severity was monitored using a clinical scoring system. Non-immunized animals ($n = 9$) served as negative controls. After disease onset serum was collected and antibody levels were determined by ELISA. The specificity of our anti-CarP ELISA was validated using dotblots.
Results: Whereas no anti-CarP antibodies could be detected in non-immunized DBA/1 mice, anti-CarP total Ig was present in 93% of the arthritic DBA/1 mice. Of those mice 36% had IgG1 and 79% had IgG2a anti-CarP antibodies. Antibodies to citrullinated proteins could not be detected. The levels of mouse collagen-specific IgG2a correlated with the clinical score. However, the levels of the different anti-CarP isotypes did not. Around 60% of the immunized C56Bl/6 mice developed arthritis. Anti-CarP IgG2c could be detected in 55% of those mice and could not be detected in the mice that did not develop CIA. Anti-CarP IgG1 was detected in 27% of the arthritic mice. Interestingly, mouse collagen specific IgG2c antibodies were detected in 100% of the immunized C57Bl/6 mice. Dotblot analysis, using carbamylated and non-modified proteins confirmed the ELISA results regarding the specificity of the antibodies for homocitrulline containing proteins.
Conclusions: Mice with CIA have antibodies to carbamylated proteins and their presence associated with disease development. All immunized mice have anti-mouse CII antibodies, indicating that the presence of anti-CarP antibodies could be a disease specific marker for arthritis in mice. Further studies will be required to determine the role of anti-CarP in the pathogenesis of arthritis.

P1223
Anti-inflammatory effects of phosphodiesterase 4 inhibitor roflumilast in experimental arthritis

B. P. Leung,* D. S. Bundschuh,† R. Beume† & J. Barsig†
**Physiology, National University of Singapore, Singapore, Singapore, †Nycomed Takeda, Portfolio Project and Alliance Management, Konstanz, Germany*

Purpose/Objective: Inhibitors of cyclic AMP (cAMP)-specific phosphodiesterase (PDE) are potential therpeutic agents with board anti-inflammatory and immuno-modulatory activities. PDE4 is the predominant family of PDEs expressed in a variety of inflammatory cells, and implicated in a number of immune responses including pro-inflammatory cytokine TNFα production.
Materials and methods: Using roflumalist, a potent and selective PDE4 inhibitor recently launched for the treatment of chronic obstructive pulmonary disease (COPD), we studied the therapeutic potential and immuno-modulatory effects of PDE4 inhibition in murine collagen-induced arthritis (CIA).
Results: Roflumilast significantly reduced the levels of TNFα in lipopolysaccharide (LPS) – primed BALB/c mice *in vivo* and RAW 264.7 macrophages *in vitro*. In a murine CIA model, oral administration of roflumilast (5 mg/kg) significantly inhibited disease severity, reduced articular inflammation and joint destruction. Treatment of roflumilast also reduced pro-inflammatory cytokine IL-6, TNFα, and IFNγ production in response to type II collagen *in vitro* and down-regulated serum levels of IgG1 and IgG2a anti-collagen antibodies. Moreover, marked reduction in disease activity and articular destruction was observed in mice treated with a combination of suboptimal doses of roflumilast and methotrexate (MTX; 1 mg/kg respectively).

Conclusions: These data demonstrate PDE4-sensitive inflammatory pathways in experimental arthritis and may provide a novel approach of using roflumilast in treating chronic autoimmune conditions such as RA.

P1224

Antiribosomal autoantibodies: three cases reported by a Madrilenian Hospital

M. A. Ortiz Rosales, L. M. Medrano Dios, A. López-Larios, G. Ruiz de Garibay, R. Dieli Crimi, L. Fernández-Paredes & M. A. Figueredo
Clinical Immunology Deparment, Hospital Clínico San Carlos, Madrid, Spain

Purpose/Objective: In this work, we present the cases of antiribosomal autoantibodies observed in our department from March 2.010 to Abril 2.012. These autoantibodies are presented in 10−35% of patients with systemic erythematosus lupus (SLE) and they have been associated with a special form of SLE characterized by neurological and psiquiatric manifestations.
Materials and methods: From March 2010 to Abril 2012 were studied 8.005 consecutive sera samples received in our laboratory to be studied by indirect immunofluorescense (Mosaic: Basic Profile 3A, Euroimmune). Only 5 samples were considered as possible positive for antiribosomal autoantibodies and were confirmed by ImmunoLisa™ Ribosomal P Antibody Kit (Immco Diagnostics). PCR, Complement component C3 and C4 were quantified by nefelometry. Antinuclear specificities were studied by Luminex Technology.
Results: Three of the five sera that were suspected of anti-ribosomal autoantibodies were positive. Parallel analysis by Luminex Technology revealed their coexistence with other antinuclear antibodies such as, anti-SSB in case 1 and anti-RNP, -Sm, -dsDNA, -histones, in case 2. Anti- cardiolipin autoantibodies were positive in all the cases. The review of the clinical history of each patient revealed that these autoantibodies were present in patients with clinical manifestations of SLE, such as haematological manifestations (anemia: Hemoglobi n = 8.6 g/dl, trhombocytopenia: Platelets = 128.000/uL and leukopenia: Leukocytes = 2.200/uL) in the case 1 and a well defined nephritis lupic type V in case 2. The third case, a VIH-positive woman with no clinical manifestations of any autoimmune disease only elevated transaminases were reported (ALT = 61 U/l, AST = 62 U/l, GGT = 414 U/l). In none of them a neurological or psiquiatric manifestation was reported.
Conclusions: Antiribosomal autoantibodies are highly specific of patients with SLE. The patients studied in our laboratory present hamaetological or renal manifestations but not a neuropsiquiatric form typically associated with these autoantibodies. However, in the third case it is unknown that they play a special role or if are presented as a cause of a false cross-reaction against own antigens.

Association of MHC class III to animal models of rheumatoid arthritis

A. C. Y. Yau, J. Tuncel, U. Norin, S. Haag & R. Holmdahl
Medical Inflammation Research, Karolinska Institutet, Stockholm, Sweden

Purpose/Objective: Rheumatoid arthritis (RA) is a multifactorial, chronic inflammatory joint disease. The HLA-DRB1 locus within the major histocompatibility complex (MHC) at 6p21.3 has been identified as a major susceptibility gene. Several human genetic association studies have suggested that, in addition to the DRB1, at least one other susceptibility gene for RA exist in the MHC class III. However, MHC class III has been difficult to study in human due to the strong linkage disequilibrium (LD) and high gene density. Our aim is, by isolating MHC class III congenic fragments in arthritis-prone DA/Han rats, to study the association of MHC class III to animal models of arthritis, independent of the HLA-DRB1 effect.
Materials and methods: Pristane-Induced Arthritis (PIA) and Oil-Induced Arthritis (OIA) were induced by pristane and incomplete Freund's adjuvant (IFA) respectively. Collagen-Induced Arthritis (CIA) was induced with type II collagen emulsified in IFA. TNF level was measured in peritoneal macrophages and blood by standard ELISA. In cell transfer experiment, IFA-primed inguinal lymph node cells were cultured and stimulated with concanavalin A for 65 h before transferring to F1 recipient rats.
Results: MHC class III congenic rat, DA.1HR56T, developed less severe disease ($P < 0.01$, day 13−20) with less weight loss ($P < 0.05$, day 16−20) compared to DA rats in OIA. Similar results were seen in PIA ($P < 0.05$, day 11−20) but not CIA. Despite the importance of TNF in the pathogenesis of RA and being one of polymorphic genes in the congenic fragment, we found no association between TNF and our disease phenotype. Adoptive transfer of T cells from OIA rats shows that this MHC class III locus controls the immune priming of the disease ($P < 0.01$, day 14−20). These disease phenotype differences are mapped to a 215-kb region in MHC class III. Real-time PCR identified MHC class III genes in the region with differential expression ($P < 0.01$) which could regulate the disease phenotype. We have recently split this 215-kb region further into 3 smaller subcongenic fragments which will take us closer to identifying the MHC class III arthritis-regulating gene.
Conclusions: We have shown the association of MHC class III to T-cell mediated arthritis disease models OIA and PIA, but not antigen-induced model CIA. We have presented the congenic approach to study arthritis in the gene-dense HLA class III which has traditionally been difficult to study in human.

P1227

Association of NLRP3 and CARD8 genetic polymorphisms with juvenile idiopathic arthritis in a Taiwanese population

C. A. Yang,* S. T. Huang* & B. L. Chiang†
**Department of Pediatrics, National Taiwan University Hospital, Taipei, Taiwan, †Departments of Pediatrics and Medical Research, National Taiwan University Hospital, Taipei, Taiwan*

Purpose/Objective: Juvenile idiopathic arthritis (JIA) is a multi-genetic, chronic autoimmune disease of childhood. Elevated plasma IL-1βlevel had been observed in JIA, suggesting a possible role of inflammasome in pathogenesis. We determined if genetic polymorphisms of components of NLRP3 inflammasome confer risk for JIA.
Materials and methods: Of the 134 JIA patients and 103 healthy controls were genotyped for rs4353135 OR2B11/NLRP3 and rs2043211 CARD8 polymorphisms. Clinical laboratory data and serum IL-1β of JIA group were evaluated via medical chart review and ELISA, respectively.
Results: The variant rs4353135 G allele carrier had increased risk for JIA ($P = 0.036$) and elevated level of serum IL-1β ($P < 0.001$). Homozygous rs2043211 minor allele carrier was associated with the presence of rheumatoid factor (RF) ($P = 0.038$); while rs4353135 G/G genotype increased the need for Etarnercept (Enbrel) treatment ($P = 0.015$).
Conclusions: Our data suggest that functional genetic polymorphism affecting NLRP3 inflammasome components might contribute to the pathophysiology of JIA.

Cell-type specific type I interferon signatures in autologous stem cell transplanted lupus patients: IFN imprint remains in CD4+ T cells

C. Kyogoku,* J. R. Grün,* T. Alexander,† R. Biesen,† F. Hiepe,† T. Häupl,† A. Radbruch* & A. Grützkau*
*German Rheumatism Research Centre Berlin (DRFZ), an Institute of the Leibniz Association, Berlin, Germany, †Department of Rheumatology and Clinical Immunology, Charité University Hospital Berlin, Berlin, Germany

Purpose/Objective: Systemic lupus erythematosus (SLE) is a chronic inflammatory autoimmune disease that affects multiple organs, whose pathology is mainly caused by the augmented interferon (IFN) signaling pathway. The aim of this study was to analyze the particular contribution of CD4+ T cells and monocytes with respect to cell type-specific IFN signatures detectable in SLE by global gene expression profiling. The major focus was set on the comparison of disease-active and -inactive patients either by standard drug treatment or by autologous stem cell transplantation (ASCT) that is assumed to completely reset the autoreactive immunologic memory.
Materials and methods: Affymetrix Human Genome U133 Plus 2.0 Array were made from purified peripheral CD4+ T cells from six active SLE, 2 inactive SLE by standard drug treatment and 3 inactive SLE who underwent ASCT as well as 3 healthy donors (ND). In addition, using the same donors, arrays were made from purified peripheral monocytes from one active SLE, 1 inactive SLE, 3 ASCT-treated SLE and 3 ND. A reference list of 2220 IFN pathway-related genes was obtained from a recent publication and used to estimate IFN imprints in SLE patients.
Results: In CD4+ T cells, it was obvious that inactive SLE showed a marginal IFN-imprint characterized by 233 only weakly expressed probe sets compared to active SLE characterized by 573 probe sets. Unexpectedly, 562 differentially expressed probe sets were also identified in ASCT-treated patients who are under long-term remission. However, considering the absolute magnitude of expression of IFN-regulated transcripts, the imprint in ASCT-treated patients was much weaker than in active SLE. It was obvious that monocytes showed a more complex IFN response characterized by 918 differentially expressed probe sets in active SLE. Different from CD4+ T cells, monocytes from ASCT-treated patients showed no apparent IFN signatures.
Conclusions: We could show for the first time detailed cell type-specific IFN signatures for CD4+ T cells and monocytes isolated from active and inactive SLE patients. Most interestingly, the intriguing question comes up, why only CD4+ T cells, but not monocytes of ASCT-treated patients, are characterized by an apparent IFN imprint although patients are under long-term remission. Our results indicate for a cell type-specific pro-inflammatory cytokine memory in T helper lymphocytes even after ASCT-therapy in SLE.

P1229

Comparison of synovial tissue cytokine mRNA profiles in very early arthritis patients with divergent outcomes

L. Yeo, C. D. Buckley, A. D. Filer, K. Raza & D. Scheel-Toellner
Rheumatology Research Group, University of Birmingham, Birmingham, UK

Purpose/Objective: In the earliest clinically apparent phases of arthritis, it is difficult to distinguish patients who will develop rheumatoid arthritis (RA) from those whose disease will resolve. We sought to determine whether synovial tissue cytokine mRNA expression at presentation differed between early patients with these distinct outcomes.
Materials and methods: Synovial tissue biopsies were obtained within 12 weeks of symptom onset from 18 early synovitis patients who developed RA within 18 month follow-up, and 13 early synovitis patients with self-limiting disease. In addition, 12 patients with established RA, and 12 control subjects undergoing arthroscopy with no evidence of inflammatory pathology were studied. mRNA expression of 135 cytokines and related molecules was determined by real-time PCR using microfluidic cards. The Kruskal-Wallis test and principle component analysis were used for analysis. Synovial tissue sections were stained with haematoxylin and eosin and graded by infiltrate type. Synovial tissue sections were stained for CD3, CD4, CD8, CD68, CD20, CD15, mast cell tryptase and CD106 using immunofluorescence and cell counts were performed.
Results: Of the 135 cytokines analysed, 20 genes were differentially expressed between the 4 patient groups, 99 genes did not show significant differences, and 16 genes were not detected. Significant differences included higher levels of IFN-b and TNF in established RA compared to early RA, and higher levels of IL-2, IL-12b and IL-21 in established RA compared to early resolving synovitis. Principle component analysis showed early RA and resolving synovitis patients had overlapping cytokine mRNA profiles. mRNA expression of several cytokines correlated with leukocyte infiltrate grading and presence of leukocyte subsets. However, the type of leukocyte infiltrate and presence of leukocyte subsets were not significantly different between patient groups.
Conclusions: Cytokine mRNA expression patterns are similar in early synovitis patients who have resolving synovitis or develop RA. In addition, the clinical outcome of early synovitis patients is not reflected in the type of leukocyte infiltrate. These findings highlight the importance of alternative factors in determining resolution versus persistence in early synovitis.

P1230

Comparison of the peptide repertoires associated to hla-dr molecules differentially associated to rheumatoid arthritis

E. Scholz,* G. Espinosa,* J. Collado,* M. Carrascal,† F. Canals‡ & I. Álvarez*
Laboratory of Cellular Immunology, Institute of Biotechnology and Biomedicine, Autonomous University of Barcelona, Barcelona, Spain, †IIBB-CSIC/IDIBAPS, CSIC/UAB Proteomics Laboratory, Bellaterra, Spain, ‡Department Biochemistry and Molecular Biology, Institute of Biotechnology and Biomedicine, Autonomous University of Barcelona, Barcelona, Spain

Purpose/Objective: Rheumatoid arthritis (RA) is a chronic and systemic inflammatory autoimmune disorder that principally attacks synovial joints. The prevalence of RA is about 1% in the total population, being women more affected than men, in a ratio of approximately 2.3:1. The aetiology remains unknown, although it is known that environmental and genetic factors are involved in the pathogenesis of the disease. The strongest genetic association is with some human leukocyte antigens (HLA), including some subtypes of HLA-DR4 (DRB1*04:01, *04:04, *04:05 and *04:08), DR1 (DRB1*01:01) and DR10 (DRB1*10:01). Some alleles, as HLA-DR7 (DRB1*07:01) and DR15 (DRB1*15:01) are non-associated with the disease. A major feature shared by the RA-associated HLA*DR alleles is the presence of a basic consensus sequence in the third hypervariable region of DRB1, spanning residues 70–74 of the DRb chain. The presence of this basic 'motif' led to the proposal of the 'shared epitope' (SE) hypothesis, which postulates that the side chains of several of these amino acids could be involved in disease pathogenesis by either, defining the peptide preference or directly interacting with the T cell receptor (TCR), influencing the selection of the T cell repertoire. The objective of this work was to define if the peptide repertoires of HLA-DR associated molecules (DR1, DR4

and DR10) are more similar between them than with a non-associated molecule (DR15).
Materials and methods: HLA-DR molecules were immunoprecipitated from homozygous lymphoblastoid cell lines, using a mAb specific for a common epitope of the HLA-DR molecules. After acid elution, peptides were separated from HLA molecules by ultrafiltration. The peptide pool was fractionated by RP-HPLC in basic conditions and peptides were sequenced by mass spectrometry.
Results: A total of 843 peptides have been identified: 207 from DR1, 246 from DR4, 232 from DR10 and 158 from DR15. In these samples: DR10 shares 28 peptides with DR1, 10 with DR4 and 1 with DR15; DR15 shares 7 ligands with DR1 and 2 with DR4; finally, DR1 and DR4 bind 6 common peptides.
Conclusions: The direct mass spectrometry analysis of the HLA-DR natural ligands confirmed that the similarity between the peptide repertoires from DR1, DR4 and DR10 is higher that with that from DR15. Clearly, the two most similar peptide repertoires were those associated to DR1 and DR10, showing a prevalence of Leu en P4.

P1231
Cystamine ameliorates lupus-associated ventricular hypertrophy by modulating IL-6-mediated mitogen-activated protein kinase pathways

B. S. Tzang,* T. C. Hsu,† S. H. Kao* & S. L. Li*
**Institute of Biochemistry and Biotechnology, Chung Shan Medical University, Taichung, Taiwan, †Institute of Microbioloby and Immunology, Chung Shan Medical University, Taichung, Taiwan*

Purpose/Objective: Left ventricular (LV) hypertrophy is prevalent in patients with systemic lupus erythematosus (SLE), possibly because of inflammation-related arterial stiffening. We previously demonstrated that cystamine ameliorates physiological functions of hepatocyte and macrophage in lupus-prone mice NZB/W-F1. Present study was aimed to investigate effect of cystamine on alleviation of LV hypertrophy in lupus mice and to elucidate underlying mechanisms.
Materials and methods: Hypertrophy was assessed by mass change. Tissue morphology was examined by histochemical staining and Masson's trichrome staining. Expression and phosphorylation of protein was determined and quantitated by immunoblotting using specific antibodies and densitometric analysis.
Results: Our results revealed that cystamine treatment decreased both LV mass and LV mass/tracheobronchial remnants (TBR) in NZB/W-F1 mice, whereas slight effects were observed in Balb/c mice. Moreover, cystamine treatment reduced levels of atrial natriuretic peptide (ANP), C-reactive protein (CRP), heart type-fatty acid-binding protein (h-FABP), creatine kinase-MB (CK-MB) and IL-6 in LV tissues of NZB/W-F1 mice. Additionally, in LV tissues of NZB/W-F1 mice, suppression of hypertrophic signaling mediated by IL-6 in response to administration of cystamine was revealed, including phosphorylation of MEK5, ERK5, c-Jun N-terminal kinase (JNK) and p38 mitogen-activated protein kinase (p38).
Conclusions: Taken together, our results suggest that cystamine treatment alleviated LV hypertrophy in NZB/W-F1 mice as result of decrease in hypertrophic mediators and suppression of IL-6 mediated hypertrophic signaling. These findings indicate that cystamine has potential to be effective therapy for lupus associated cardiac hypertrophy in clinical setting.

P1232
Cytomegalovirus drives the expression of inhibitory NK cell receptor LIR1 on CD8+ T cells in RA patients

K. Rothe, D. Quandt, M. Klingner, K. Schubert, C. Baerwald & U. Wagner
Sektion Rheumatology, University of Leipzig, Leipzig, Germany

Purpose/Objective: Rheumatoid arthritis (RA) is a chronic inflammatory disease which is accompanied by a dysregulated T cell homeostasis that leads to an expansion of autoreactive T cell clones. These cells show a late memory phenotype characterized by the loss of the costimulatory receptor CD28 and an increased expression of inhibitory natural killer (NK) cell receptors. LIR1 (also known as CD85j or ILT2) belongs to the family of inhibitory NK receptors; it is widely expressed among different immune cells and has been associated to autoimmunity before. Furthermore, it has been shown that a chronic viral infection like Cytomegalovirus (CMV), contributes to an expansion of autoreactive T cell clones. LIR1 seems to be increased in T cells in CMV+ as compared to CMV- healthy donors (HD).
Materials and methods: We were interested in the role of LIR1+ T cells in RA patients, which potentially contribute to the autoreactive T cell pool, especially in CMV+ patients. Therefore we investigated the frequency of LIR1 on T cells in peripheral blood mononuclear cells (PBMC) from patients with RA and HD. LIR1 and $CD28^-$ T cells on $CD8^+$ $CD3^+$ T cells were analyzed by flow cytometry.
Results: Flow cytometry analysis of 37 RA patients as well as 39 HD reveal a significant higher frequency of LIR1 on $CD8^+$ T cells ($P = 0.043$) in RA patients ($n = 37$, mean%: 9.43) compared to HD ($n = 39$, mean%:5.98).

Beyond that, we found a higher frequency of $CD8^+LIR1^+$ T cells in CMV+ compared to CMV- donors, in RA patients as well as in healthy controls. $LIR1^+$ T cell frequencies of CMV+ healthy controls ($n = 29$, mean%: 7.29) are significantly higher ($P = 0.017$) than in CMV- HD ($n = 10$, mean%:2.17). In RA patients this difference is even more pronounced ($P = 0.0027$), (CMV+ RA patients, $n = 32$, mean%: 10.6; CMV- RA patients, $n = 5$, mean%:1.74).

Importantly, we found a significant correlation ($P = 0.034$) of high numbers of $CD8^+LIR1^+$ with high disease activity score (DAS28) in RA patients without medical treatment ($n = 14$, $r = 0.568$). In addition also the numbers of $CD8^+LIR1^+$ T cells significantly ($P = 0.012$) correlate with the numbers of $CD8^+$ $CD28^-$ T cells in RA ($n = 37$, $r = 0.41$).
Conclusions: We are the first to demonstrate a significant increase of LIR1 expression on $CD8^+$ T cells of RA patients compared to HD. Furthermore this LIR1 expression profile associates with CMV infection in RA patients and is correlated to disease severity.

P1233
Cytotoxic T cell epitope in Brucellosis-induced murine spondyloarthropathy

V. Adarichev,* E. T. Lyons,* T. S. Forde,* D. Magnani,† M. T. Shekhani* & G. A. Splitter†
**Albert Einstein College of Medicine, Medicine, Bronx, NY, USA, †Pathobiological Sciences, University of Wisconsin, Madison, WI, USA*

Purpose/Objective: Brucellosis is one of the most common bacterial zoonosis and causes significant human morbidity worldwide. Osteoarticular complications such as arthritis and spondylitis are the most frequent clinical manifestations. The goal of the study was to establish a murine model for human Brucellosis to better understanding the mechanisms of association between Brucellosis and spondyloarthropathy (SpA).
Materials and methods: BALB/c mice were infected with an intraperitoneal injection with 1−100 M CFU of the virulent bioluminescent *B. melitensis* strain GR023 or *B. abortus* vaccine strain S19. Mice were

sacrificed 3 and 26 weeks post-infection. Bacterial dissemination was monitored using biophotonic imaging and immunohistochemistry (IHC). Axial skeleton, paws, spleen, and liver tissue sections were stained for macrophage markers and for Brucella cell wall.
Results: *In vivo* biophotonic imaging showed accumulation of *B. melitensis* in paws and knees, but the strongest signal was detected in the axial skeleton. Upon IHC staining, intracellular bacteria were found in the spleen, liver, and bone marrow of peripheral joints and vertebrae. Three weeks post-infection, bacteria-infected cells were found in the subchondral bone marrow, but not present in the synovium, and infiltration by inflammatory cells was undetectable. Despite the general absence of infection in 26 weeks, mice developed arthritis in ankle and spine facet joints. We found that immunodominant Brucella-derived peptide from methionine sulfoxide reductase is presented by murine macrophages in context of MHC class I molecule to cytotoxic T cells. Homologous mouse/host protein carries a sequence that is 100% identical to Brucella epitope. Analysis indicates that Brucella epitope binds to human HLA-B27 class I molecules that are strongly associated with human SpA.
Conclusions: Arthritis was not associated with acute *Brucella* infection in this murine model. Inflammation in joints and changes in skeleton were found weeks after the bacteria were cleared from tissues. Murine Brucellosis demonstrated features that are typical to reactive arthritis with a potential involvement of cytotoxic T cells.

P1235
Effect of B CELL depletion by Rituximab in T cell subpopupulations from the peripheral blood of patients with rheumatoid arthritis

J. López-López,* M. Alfonso-Pérez,* S. Castañeda,† J. M. Alvaro-Gracia,† T. Velasco,† L. Vega Piris,‡ F. Rodríguez Salvanés,‡ V. López Huete,§ A. Ramírez Mengíbar,§ R. García-Vicuña,† I. González-Alvaro† & C. Muñoz-Calleja†
**Immunology, Instituto de Investigación Sanitaria Hospital, Universitario de la Princesa, Madrid, Spain, †Rheumatology, Hospital Universitario de la Princesa, Madrid, Spain, ‡Methodology, Hospital Universitario de la Princesa, Madrid, Spain, §Immunology, Hospital Universitario de la Princesa, Madrid, Spain*

Purpose/Objective: Rheumatoid arthritis (RA) is a chronic disease that leads to inflammation of the joints and other tissues. Rituximab (Rtx) is a therapeutic monoclonal antibody directed against CD20 that induces an important depletion of B cells and has been successfully used in RA. Although the efficacy of Rtx in RA is well documented, little is known about how it modifies the homeostasis of lymphoid subpopulations.

The objectives of the study were to know whether Rtxmodifies the ratio of the different T lymphocyte subpopulations from peripheral blood of RA patients.
Materials and methods: We studied 23 RA patients that underwent treatment with Rtx because of active RA and failure to at least one previous anti-rheumatic drug. The patients were divided into those naïve for Rtx treatment (Rtxn $n = 5$ patients) and those who had received at least one previous cycle of treatment with Rtx (Rtxs $n = 18$ patients). The treatment protocol consisted of two 1 g i.v. infusions, 2 weeks apart from each other. Peripheral blood samples for lymphoid subpopulation analysis were obtained at different times in both Rtxn and Rtxs patients: baseline (previous to the first infusion of Rtx) and at 3 and 6 months since baseline (t1 and t2 respectively) We studied different combinations of the following molecules: CD62L CD45RA CD45RO CD27 CD25 CD279 CCR5 CCR6 CCR7 CXCR5 CXCR6 that allowed us to calculate the percentage of memory and naïve T cells, effector and central memory T cells, follicular T helper cells and regulatory T cells, at each visit. Differences between groups were analyzed by ANOVA test.
Results: At baseline, there was a significant difference in the percentage of a considerable number of T cell subsets, standing out those regarding the memory and naïve differentiation stages. In particular, we observed a significant decrease of naïve T CD8 cells and a significant increase of memory T CD8 and memory T CD4 cells in Rtxs patients. During follow up period the differences in T cells observed at baseline became much smaller presumably because of the effects ofRtx, and no significant differences between the above mentioned T cell subsets were detected at t2.
Conclusions: Depletion of B cells through Rtx treatment leads to a profound change in the subpopulations of peripheral blood T lymphocytes, suggesting that mature B cells play a relevant role in the homeostasis of T cells in patients with RA.

P1237
Effect of Methotrexate in antigen-induced arthritis depends on regulatory T cells expression

R. Sanches Peres,* J. Talbot,* V. Carregaro,* R. D. R. Oliveira,† S. L. Almeida,† L. G. Pinto,* R. F. O. França,* J. C. Alves-Filho,* T. M. Cunha,* F. Y. Liew‡ & F. Q. Cunha*
**Pharmacology, Faculdade de Medicina de Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, †Internal Medicine, Faculdade de Medicina de Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, ‡Immunology, University of Glasgow, Glasgow, UK*

Purpose/Objective: Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic inflammation of the joints. The therapeutic approach of first choice for the RA treatment is the use of low doses of Methotrexate (MTX), an inhibitor of dihydrofolate reductase. Although its mechanism of action in RA is still poorly understood, MTX potentially acts via antiproliferative and anti-inflammatory means. Moreover, it is suggested that the suppressive effects of MTX in the disease may be related with suppressive activity of regulatory T (Treg) cells. Objective: To investigate the MTX effect on the population of Treg cells in experimental model of antigen-induced arthritis (AIA).
Materials and methods: mBSA-immunized C57BL/6 mice were pretreated with MTX (2 mg/kg) weekly for 5 weeks before challenge i.a. with 30 μg of mBSA at day 21 after first immunization. Articular hypernociception, cell migration, Treg cells frequency in the spleen and draining lymph nodes was evaluated 7 h after antigen challenge. Additionally, for depletion of Treg cells, mBSA-immunized C57BL/6 mice pretreated or not with MTX were undergoing administration of anti-CD25 (250 μg/ml) four times per week during the whole immunization protocol. After 7 h of the challenge with 30 μg i.a. of mBSA at 21 day, articular hypernociception was evaluated.
Results: MTX-treated animals showed an increase in hypernociception threshold and decrease in migration of neutrophils to the joint when compared to untreated animals. Interestingly, while the frequency of Treg cells ($CD4^+FoxP3^+$) in the draining lymph nodes were similar between groups; animals treated with MTX had an increase of this cell type in the spleen. In addition, Treg cells depletion with anti-CD25 monoclonal antibody treatment reversed the effect on articular hypernociception triggered by MTX.
Conclusions: These findings show that Treg cells are required for triggering anti-inflammatory effect of MTX in AIA model, and the drug still causes an increase of this cell population in treated animals.

P1238

Effect of therapy on the Th1/Th17 balance and cytokine profile in patients with juvenile idiopathic arthritis (JIA)

G. Almanzar, K. Sustal, R. Trippen, K. Höfner & M. Prelog
Department of Pediatrics Pediatric Rheumatology Special Immunology and Osteology, University of Würzburg, Würzburg, Germany

Purpose/Objective: Juvenile idiopathic arthritis (JIA) is an inflammatory disorder with heterogeneous clinical presentation. Recently discovered IL-17-producing T-cells (Th17) have been identified as pro-inflammatory cells in several autoimmune conditions. This study evaluated the phenotype and the cytokine-production profile on Th1: IFNgamma and Th17:IL-17 cells in JIA patients with different treatments.
Materials and methods: T-cells of fifty-seven JIA patients (mean age: 12.9 ± 4.3 years) under therapy (non-steroidal-anti-inflammatory-drugs, ($n = 29$), disease-modifying-anti-rheumatic-drugs ($n = 25$), TNFalpha inhibitors ($n = 3$), and 14 JIA patients without therapy, and 28 healthy donors (HD) (mean age: 10.4 ± 4.4 years) were investigated by flow cytometry.
Results: IFNgamma-production by memory $CD4^+$ $CD45RO^+$ $CD28^+$ $CCR7^{+/-}$ (9.7%), $CD8^+$ $CD45RO^+$ $CD28^+$ $CCR7^{+/-}$ (8.5%), effector $CD4^+$ $CD45RO^+$ CD28-$CCR7^{+/-}$ (13.7%) and $CD8^+$ $CD45RO^+$ CD28-$CCR7^{+/-}$ (11.2%) T-cells were significantly lower in JIA patients than in HD (CD4+: 16.3%, 14.6%; CD8+: 27.2%, 18.2%, respectively) ($P < 0.05$). JIA patients showed a higher expression of IL-17 in memory (1.86%) and effector T-cells (1.02%) compared to HD (0.37%, 0.3%, respectively) ($P < 0.001$). IFNgamma-production was strongly reduced in effector T-cells in JIA patients under therapy (1.8%) compared to the non-treated JIA group (3.4%) ($P < 0.005$). IL-17-production in memory CD4+ T cells was lower in treated patients (0.44%) compared to non-treated patients (0.74%) ($P < 0.05$).
Conclusions: Overall, this study suggests an imbalance in the IFNgamma- and IL-17-production in memory and effector T-cell subsets in JIA patients. Whether specific therapy is able to permanently drive the cytokine profile to a less inflammatory function remains to be determined.

P1239

Effect of TLR8-deficiency on lupus pathogenesis in a spontaneous mouse model

M. L. Santiago-Raber & N. L. Tran
Pathology and Immunology, University of Geneva Medical School, Geneva, Switzerland

Purpose/Objective: SLE is a systemic autoimmune disorder characterized by increased B and Th cells activation, increased DCs presentation, by the formation of various autoantibodies and subsequent development of immune complex glomerulonephritis. The role of endosomal TLR7 and TLR9 in the development of anti-nuclear autoantibodies, because of their respective recognition of RNA and DNA, respectively, has been extensively studied. Little is known on the TLR8 activation *in vivo* in mice, we therefore conducted an innovating study on its possible implication in autoimmune responses in a murine model of lupus.
Materials and methods: To better define the contributions of TLR8 to the development of SLE, we introduced the TLR8 null mutation into C57BL/6 mice congenic for *Nba2 (NZB autoimmunity 2)* locus (B6.Nba2) and followed the development of the disease, B, T cells and DCs activations, autoantibody production and mortality due to glomerulonephritis.
Results: TLR8-deficiency resulted in an accelerated SLE characterized by increased total IgM and IgG levels in the sera, increased MHCII expression on APCs and higher tlr7 mRNA expression on APCs. DC capacity to present allogenic antigens to CD4 T cells was also improved after TLR7 ligation.
Conclusions: TLR8 deficiency in lupus-prone mice induces acceleration of SLE due to up-regulation of TLR7-dependent APC activation. DCs function seems to be the key player of the TLR8 deficiency effect.

P1240

Elevated soluble E-cadherin levels in chronically inflamed joints favour TNF production by KLRG1 expressing T cells

L. Melis, K. Venken, L. Van Praet & D. Elewaut
Rheumatology, University Hospital Ghent, Ghent, Belgium

Purpose/Objective: The killer cell lectin-like receptor G1 (KLRG1) is a NK cell marker that is also expressed on antigen-experienced T cells showing an immune senescent phenotype. KLRG1 binding to its ligand E-cadherin results in inhibition of cytokine-producing and cytotoxic T cell responses. Recently, the soluble form of E-cadherin (sE-cadherin) has been shown to influence KLRG1 signaling. Furthermore, it has been hypothesized that senescent T cells play a role in development of autoimmunity but the potential involvement of KLRG1 in an arthritic/rheumatic disease has not been investigated yet.
Materials and methods: PBMC/SFMC from 21 chronic arthritis patients [rheumatoid arthritis (RA) or spondyloarthritides (SpA)], 8 patients with crystal induced acute arthritis (gout and chondrocalcinosis) and 10 healthy controls were obtained. T cells were characterized for KLRG1 expression directly *ex vivo*, while TNF/IFN-γ-production was assessed after 4 h PMA/CaI stimulation by flow cytometry. In addition, sE-cadherin levels in paired plasma − SF were determined. Moreover, TNF/IFN-γ production by T cells was compared in the presence/absence of sE-cadherin in a 7-day *in vitro* culture system.
Results: More T cells were KLRG1+ in the SF as opposed to the PB of patients with chronic arthritis (RA and SpA), which contrasts strikingly with results obtained in crystal induced arthritides. The KLRG1+ T cell subset had a functionally more active phenotype, characterized by increased capacity to produce proinflammatory cytokines such as TNF or IFN-γ. Levels of sE-cadherin were found to be markedly higher in the SF of all arthritides. Unexpectedly, the presence of sE-cadherin enhanced TNF but not IFN-γ production by KLRG1+ T cells.
Conclusions: Both KLRG1+ T cells and its ligand sE-cadherin were increased in the SF of chronic arthritis patients. Surprisingly, sE-cadherin is likely to contribute to the local proinflammatory environment in the joint by favouring TNF production by KLRG1+ T cells. Importantly, this pathway seems to be operational in both RA and SpA, but not in acute crystal induced forms of arthritis.

Enhanced megakaryopoiesis as a pro-pathogenic factor in a mice model for Systemic Lupus Erythematosus

O. Winter,* K. Moser,† R. A. Manz‡ & F. Hiepe*
**Department of Rheumatology and Clinical Immunology, Charité University-Medicine Berlin, Berlin, Germany, †Department of Humoral Immunology, German Arthritis Research Center (DRFZ), Berlin, Germany, ‡Institute for Systemic Inflammation Research (ISEF), University of Lübeck, Lübeck, Germany*

Purpose/Objective: Autoantibodies contribute to the pathogenesis of the autoimmune disease Systemic Lupus Erythematosus (SLE) by stimulating the immune response. Further, deposits of immune complexes in the kidneys can lead to severe nephritis. The source for autoantibodies is short- and long-lived plasma cells located in the bone marrow and -differently to protective plasma cells − in the spleen. In

NZB/W mice – a mouse model for SLE – both parental strains New Zealand Black (NZB) and New Zealand White (NZW) contribute different *sle-loci* to the formation of SLE. The NZB strain passes the *sle2c locus* in which the gene for the Thrombopoietin (TPO)-receptor (*c-mpl*) is located. According to the relevance of megakaryocytes for the plasma cell niche and the correlation between plasma cell and megakaryocyte numbers as reported earlier by us, we wanted to elucidate whether c-Mpl and/or megakaryopoiesis is altered in auto-immune mice.

Materials and methods: Therefore, we examined in wild type, NZB and NZW mice the amount of megakaryocytes in spleen and bone marrow, the occurence of genetic variations for *c-mpl* and the degree of megakaryopoiesis upon TPO stimulation by histological survey, flow-cytometric and genetic analysis and by *in vitro* studies.

Results: We found, that in the spleen of NZB mice plasma cell and megakaryocyte numbers are 10-times higher than in wild type while in NZW mice the numbers are equal. We detected a missense mutation in the *c-mpl* gene of NZB mice leading to an amino acid replacement within the essential TPO-binding site. Upon TPO stimulation of spleenocyte and bone marrow cultures NZB cultures responded significantly stronger resulting in the double amount of megakaryocytes compared to NZW cultures.

Conclusions: In summary, our data indicate that the mutated *c-mpl* gene located within the *sle2c-locus* is leading to an augmented megakaryopoiesis which enables the accumulation of a greater number of autoreactive plasma cells and thus is contributing to the development of SLE.

P1242
Evidence for spontaneous type I interferon release in SAMHD1 deficient mice

R. Behrendt,* T. Schumann,* U. Berka,† D. Lindemann,† W. Muller,‡ D. Alexopoulou,§ A. Dahl,§ R. Naumann,¶ U. Dittmer & A. Roers***

**Medical Faculty Carl Gustav Carus TU Desden, Insitute of Immunology, Dresden, Germany, †Medical Faculty Carl Gustav Carus TU Desden, Insitute of Virology, Dresden, Germany, ‡Bill Ford Chair of Cellular Immunology, University of Manchester, Manchester, UK, §BIOTEC Dresden, Deep Sequencing Facility, Dresden, Germany, ¶MPI CBG, Transgenic Core Facility, Dresden, Germany, **Department of Virology, University of Duisburg Essen, Essen, Germany*

Purpose/Objective: The term 'interferonopathies' designates a group of diseases in which an uncontrolled chronic type I interferon (IFN) response is considered a key pathogenic mechanism, a prominent member of this group being systemic lupus erythematosus (SLE). Also Aicardi-Goutières syndrome (AGS), an early-onset inflammatory encephalopathy which clinically and pathogenetically overlaps with SLE, is characterized by IFN production in the absence of detectable viral infection. AGS is caused by genetic defects of any of three intracellular enzymes, Trex1, RNase H2 or SAMHD1, all involved in intracellular nucleic acid metabolism. The finding that Trex1-deficient mice develop typ I IFN-dependent autoimmune multi-organ inflammation stimulated a new concept of autoimmunity caused by intracellular nucleic acid accumulation, which triggers IFN production. SAMHD1, a phosphohydrolase which cleaves dNTPs and thereby prevents retroviral (HIV) reverse transcription in human cells. Our aim was to elucidate the pathogenesis of SAMHD1-associated AGS.

Materials and methods: We generated mice with complete deficiency for SAMHD1.

Results: SAMHD1$^{-/-}$ mice were macroscopically normal and aged without any sign of systemic autoimmunity. We did not find evidence for SAMHD1-dependent retroviral restriction *in vitro* or *in vivo*. However, SAMHD1$^{-/-}$ peritoneal macrophages showed a type I IFN-induced gene expression signature indicative of spontaneous type I IFN production, similar to the interferon signature of Trex1$^{-/-}$ mice.

Conclusions: Although SAMHD1 deficiency in mice is not sufficient to trigger systemic autoimmunity, the animals recapitulate an early key feature of AGS pathogenesis, which is likely relevant also for SLE. We think that the animals will be useful for the investigation of mechanisms precipitating a pathogenic IFN response.

P1243
FKBP, a new gene involved in systemic lupus erythematosus?

J. Ruer-Laventie, J. N. Schickel, A. Soley, M. Duval, L. Marcellin, A. M. Knapp, T. Martin, A. S. Korganow, J. L. Pasquali & P. Soulas-Sprauel

Immunologie et Chimie Thérapeutiques, Institut de Biologie Moléculaire et Cellulaire, Strasbourg Cedex, France

Purpose/Objective: Systemic lupus erythematosus (SLE) is a severe autoimmune disease, characterized by the production of various autoantibodies and multiorgan damages. SLE involves both genetic and environmental factors. Several studies have mapped some autoimmune susceptibility regions in the genome in humans and mice, but most of the candidate genes are disputed or unconfirmed at this time. Several arguments strongly suggest that genetic defects in B cells pre-exist in the development of the disease. However, only a few genes among the published SLE susceptibility genes are linked to B cell functions. We propose to characterize one genetic intrinsic B cell abnormality found in a group of lupus patients, by functional genomics studies.

Materials and methods: We have performed a B cell transcriptoma analysis in quiescent SLE patients in comparison to normal subjects. A short list of interesting over- or under-expressed genes has been established. We pointed an overexpression of a member of FKBP peptidyl/prolyl cis/trans isomerases family (here named 'FKBPO'), which catalyzes the folding of proline-containing polypeptides. This family can regulate cellular mechanisms due to conformational changes of key proteins. The role of this protein in B cells is completely unknown. Thus we developed lentigenic mice overexpressing FKBP in order to reproduce the variation of gene expression that we observed in patients, and to evaluate its effect on B cell phenotype and lupus development.

Results: The analysis of B cell phenotype in 8 months-old FKBP lentigenic mice has shown: (1) an increase of total cell number in spleen and lymph nodes, (2) a higher production of IgG3, (3) a production of autoantibodies in subsets of animals. Moreover we observed a higher B cell response *in vivo*, by immunization with a T-cell independent antigen. Finally, the differentiation of B cells into plasmocytes is increased in FKBP lentigenic mice, compared to control mice, after stimulation with LPS *in vitro*.

Conclusions: Our results show that the overexpression of FKBP increases the risk to develop autoimmunity. Experiments are in progress in order to evaluate if FKBP overexpression can exacerbate the development of autoimmunity in autoimmune-prone mice or can modify the establishment of B cell tolerance in a transgenic model of B cell tolerance.

P1244
Foxp3+ regulatory T cells that lack CD25 expression might serve as a marker to diagnose and monitor Systemic Lupus Erythematosus (SLE) patients with kidney involvement

L. Göschl, M. Bonelli, J. S. Smolen & C. Scheinecker

Rheumatology, Medical University of Vienna, Vienna, Austria

Purpose/Objective: $CD4^+$ $CD25^-$ $Foxp3^+$T cells have been shown to be a population of regulatory T cells which are increased in SLE pa-

tients. So far their detailed role in SLE patients has not been elucidated. We therefore investigated the role of disease activity, treatment and organ involvement on proportions of $CD4^+$ $CD25^-$ $Foxp3^+$T cells in SLE patients.

Materials and methods: Percentages of $CD4^+$ $CD25^-$ $Foxp3^+$T cells-were determined in peripheral blood mononuclear cells (PBMC) in HC ($n = 21$) and SLE patients ($n = 61$) by FACS. In selected SLE patients suffering from active glomerulonephritis, proportions of $CD4^+$ $CD25^-$ $Foxp3^+$T cells were analyzed in urine samples. Percentages of $CD4^+$ $CD25^-$ $Foxp3^+$T cells were correlated with clinical data, therapy and disease activity indices. Time course analyses of proportions of $CD4^+$ $CD25^-$ $Foxp3^+$T cells were performed in patients suffering from active glomerulonephritis before and after treatment with cyclophosphamide and in patients with active skin involvement before and after cortisone treatment.

Results: Proportions of $CD4^+$ $CD25^-$ $Foxp3^+$T cells were significantly increased in patients as compared to HC and proportions of $CD4^+$ $CD25^-$ $Foxp3^+$T cells were significantly higher in active as compared to inactive patients. We observed a significant correlation of % $CD4^+$ $CD25^-$ $Foxp3^+$ T cells with the disease activity scores SLEDAI, ECLAM and SIS and with the daily cortisone dose. Time course analysis revealed no influence of cortisone treatment on the percentage of $CD4^+$ $CD25^-$ $Foxp3^+$T cells in patients with active skin involvement, whereas cyclophosphamide treatment of patients with active glomerulonephritis led to a decrease in $CD4^+$ $CD25^-$ $Foxp3^+$T cells. Further analyses of the different organ involvements revealed that only patients with renal involvement had significantly higher proportions of $CD4^+$ $CD25^-$ $Foxp3^+$T cells among SLE patients. Proportions were even increased in active nephritis patients as compared to patients with chronic kidney disease. Furthermore we observed a significant correlation between proportions of $CD4^+$ $CD25^-$ $Foxp3^+$T cells and the extent of proteinuria and could detect $CD4^+$ $CD25^-$ $Foxp3^+$T cells in urinary samples of patients suffering from active nephritis.

Conclusions: Proportions of $CD4^+$ $CD25^-$ $Foxp3^+$T cells are significantly increased in SLE patients with renal involvement. Since $CD4^+$ $CD25^-$ $Foxp3^+$T cells also correlate with the extent of proteinuria and were found to be decreased after cyclophosphamide treatment in long time course analyses, $CD4^+$ $CD25^-$ $Foxp3^+$ T cells might represent a new biomarker to recognize and monitor patients with renal involvement.

P1245
Functional analysis of a genetic variant of ITGAM (CD11b/Mac-1) associated with systemic lupus erythematosus

C. Sevier-Guy, M. MacPherson & S. Fagerholm
Division of Medical Sciences, University of Dundee, Dundee, UK,

Purpose/Objective: Systemic lupus erythematosus (SLE) is a clinically diverse autoimmune inflammatory disease, with a strong genetic component. There is no cure for SLE and treatment often utilises antimalarial and anti-inflammatory drugs, both of which can cause deleterious health effects with prolonged use. Therefore, greater understanding of SLE pathogenesis in individual cases may lead to the development of more specific therapies that focus on the underlying causes of the disease and reduce reliance on anti-inflammatories.

Our research concerns a genetic variant of the ITGAM (CD11b) gene that has been found to be associated with the incidence of SLE. The ITGAM gene codes for CD11b which is the alpha-chain of the Mac-1 (CD11b/CD18) integrin. This integrin is expressed on myeloid cells and binds several ligands, including members of the ICAM family and the complement factor iC3b. It is involved in immunological processes, such as leukocyte extravasation and phagocytosis. In addition, Mac-1 has been described to negatively regulate immune cell signalling. The SLE-associated genetic variant in ITGAM leads to a single amino acid substitution at position 77 in the extracellular domain of the integrin where an arganine is replaced with a histidine (R77H CD11b).

Materials and methods: We have used R77H CD11b transfected cells and primary human monocytes isolated from buffy coats to analyse CD11b surface expression, activation state, adhesion to ligands, phagocytosis and cytokine production.

Results: We have shown using R77H-CD11b transfected cells that this amino acid substitution does not affect the surface expression of the integrin. However the function of the integrin is severely impaired. R77H CD11b expressing cells display defects in cell adhesion to ICAM-1 and iC3b and phagocytosis of iC3b coated beads. In addition, R77H-CD11b transfected cells display increased IL-6 production as compared to WT-CD11b expressing cells.

Conclusions: We are currently isolating leukocytes from buffy coats from a healthy population, and examining Mac-1-dependent functions in these cells to esablish if the H77 alelle is associated with defects in hese cells. The H77 allele occurs at a frequency of 1 in 10 in the European population so we expect to be able to obtain sufficient heterozygotes and homozygote H77 monocytes to compare with the R77 variant (R77). It is hoped that this work will ultimately provide an insight into the pathogenesis of SLE.

P1246
G-modified inhibitory oligonucleotides for treatment of TLR-mediated autoimmune diseases such as systemic lupus erythematosus

F. Roemmler,* M. Jurk,† M. Hammel,* J. Vollmer† & T. Miethke*
**Medicine, Institute for Medical Microbiology Immunology and Hygiene TU Munich, München, Germany, †Coley Pharmaceuticals, Pfizer, Düsseldorf, Germany*

Purpose/Objective: Inappropriate or excessive activation of TLR7/8 and 9 by self RNA or self DNA complexes is presumably involved in the pathogenesis of SLE. Stimulation of both TLRs activates pDCs to secrete IFN-alpha and autoreactive B-cells to produce autoantibodies. Up to date, there are rather unspecific immune modulators available for treatment, such as corticosteroids and cytostatics. These drugs are limited in their efficiency and side effects restrict their use. Inhibitory synthetic oligonucleotides (INH-ODN) block DNA-mediated TLR9 and RNA-mediated TLR7/8 stimulation, and can prevent autoimmunity as shown in several lupus mouse models. However, many INH-ODNs generate G4-stacks which lead to higher order structures making them unsuitable for further pharmaceutical development. Our goal was to design INH-ODNs which do not form these structures without losing any inhibitory capacity.

Materials and methods: We modified guanosine residues of INH-ODNs in such a way that G4-stacks were no longer formed and compared their efficiency to classical INH-ODNs *in vitro* and *in vivo*.

Results: Upon stimulation of TLR7 and 9, these new INH-ODNs inhibited the secretion of TNF-alpha and IL-12 by bone marrow derived-macrophages (BMDM) and -dendritic cells (BMDC) *in vitro* and were at least as effective as the classical INH-ODNs. Furthermore, they appeared to be more potent in the inhibition of cells considered as relevant in autoimmunity. Thus, INF-alpha secretion by plasmacytoid dendritic cells and IL-6 secretion and proliferation of B-cells derived from WT and lupus-prone MRL^{lpr} mice was more efficiently inhibited compared to classical INH-ODNs. Our most promising candidate based on our *in vitro* studies, INH-ODN 24888, was also able to inhibit TLR7- and TLR9-mediated stimulation *in vivo* in Balb/c mice more potently than the established INH-ODN 2088. Additionally, we could show that mucosal application of INH-ODNs was sufficient to prevent systemic consequences of CpG stimulation and INH-ODN 24888 appeared again to be more effective than INH-ODN 2088.

Conclusions: In conclusion, our new modified INH-ODNs do not form unfavorable higher orders and show higher inhibitory capacity *in vitro* and *in vivo*.

P1247
GARP and miR142-3p expression in patients with rheumatoid arthritis

J. T. Kreuzer, Q. Zhou, H. Schulze-Koops & A. Skapenko
Division of Rheumatology and Clinical Immunology, Medizinische Klinik und Poliklinik IV University of Munich, München, Germany

Purpose/Objective: The function of regulatory T cells (Tregs) is diminished in patients with autoimmune diseases, such as rheumatoid arthritis (RA). GARP is a surface protein specifically expressed on activated Tregs. Diminished expression of GARP attenuates the function of Tregs. In a previous study, we could document that GARP expression is regulated by miR142-3p. To evaluate whether reduction of Treg function in RA might be caused by insufficient regulation of GARP expression by miR142-3p, we examined the expression of miR142-3p and GARP in patients with RA.
Materials and methods: CD25+ CD4 T cells were isolated from the peripheral blood of early, treatment naïve RA patients ($n = 6$) and healthy individuals (HC) ($n = 16$). The cells were stimulated for 2 days with anti-CD3/CD28 Dynabeads. GARP surface expression was assessed by FACS staining on days 0, 1 and 2. Total RNA was isolated daily. GARP mRNA and miR142-3p expression were assessed using TaqMan gene expression and miRNA expression assays.
Results: Consistent with the previous findings, CD25+ Tregs purified from RA patients and from healthy individuals did not express detectable GARP levels on the surface. In response to activation, both Treg populations upregulated GARP. The upregulation was, however, greater in CD25+ Tregs from RA patients. At day 0, expression of miR142-3p was comparable between Tregs from HCs and RA patients. Upregulation of miR142-3p in response to stimulation was, however, again greater in cells from the patients.
Conclusions: The data indicate a deregulated expression of GARP and miR142-3p in RA and suggest that so imbalanced miR142-3p expression might influence GARP expression on Tregs and thereby the function of Tregs in RA.

P1248
Genetic associations to germinal centre formation in primary Sjögren's syndrome

T. R. Reksten,* M. V. Jonsson,† R. Jonsson* & G. Nordmark‡
**Broegelmann Research Laboratory, The Gade Institute, Bergen, Norway, †Department of Clinical Dentistry, Section for oral and maxillofacial radiology, Bergen, Norway, ‡Department of Medical Sciences, Section of Rheumatology, Uppsala, Sweden*

Purpose/Objective: Primary Sjögren's syndrome (pSS) is an autoimmune rheumatic disease mainly affecting the salivary and lacrimal glands causing xerostomia and keratoconjunctivitis sicca. Focal mononuclear cell inflammation in the form of germinal center-like structures (GC) is found in the minor salivary glands of 20–25% of patients. We have previously shown that GC+ pSS patients presented with elevated serum levels of IL-1RA, IL-4, IL-17 and MCP compared to GC$^-$patients. In this follow-up study, we aimed to assess the genetic variations in GC+ and GC$^-$ pSS patients.
Materials and methods: In a Swedish-Norwegian pSS cohort ($n = 540$), GC+ ($n = 76$) and GC$^-$ ($n = 244$) patients were identified. Of the 1536 single-nucleotide polymorphisms (SNPs) were analysed in whole blood DNA by the Illumina GoldenGate assay (Illumina Inc.). Minor allele frequencies in GC+ and GC$^-$ patients were compared using Fisher's exact test and associations were considered significant when $P < 0.001$ and suggestive when $P < 0.01$. Statistical analysis were performed using the PLINK software.
Results: In this case-only analysis of 320 pSS patients with known GC status, we identified two SNPs in *Eotaxin* associated with GC+ patients with OR 0.45 and 0.41. Furthermore, we found suggestive associations with *BANK-1*, *ICA-1*, *IL-17, PRKCL1, CARD-8, Bcl-2, TANK, IKBKE, AID* and *APRIL*. We also detected weak associations ($P < 0.05$) with SNPs in the BLK, STAT1, STAT4, SSA1, SSB, IL15RA, IL-6 and TNF-a genes. Serum eotaxin (CCL11) has previously been identified as a key discriminator between GC+ and GC$^-$ pSS patients. The formation of GCs depends on B cell stimulation by helper T cells via the CD40-CD40L system, which also contribute to the expression of activation induced deaminase (AID). Genetic variations in *CD40L* and *AID* suggest that GC+ patients may be genetically predisposed for ectopic GC formation. B lymphoid kinase (BLK) has a role in the development and activation of marginal zone B cells present in the GC formations, and Bcl-2 is an anti-apoptotic protein which gene is implicated in a number of cancers and autoimmunity. CARD-8, IKBKE and TANK are regulators of the NF-κB pathway, a pathway with a well-established role in secondary lymphoid organ development.
Conclusions: Taken together, our findings suggest that genetic variations may help explain why ectopic GC-like structures are present in some pSS patients but not all.

P1250
Hypoxia and hypoxia-inducible factor-1a exacerbate Toll-like receptor signalling-engaged inflammatory response in rheumatoid arthritis synovial fibroblasts

F. Hu,* J. Zhu,* R. Mu,* Y. Li,* W. Shao,† P. Cohen,‡ X. Qiu† & Z. Li*
**Department of Rheumatology and Immunology, People's Hospital, Peking University, Beijing, China, †Department of Immunology, Peking University Health Science Center, Beijing, China, ‡Department of Medicine, Temple University, Philadelphia, PA, USA*

Purpose/Objective: Hyperplasia of synovial fibroblasts, infiltration with lymphocytes, and tissue hypoxia are the major characteristics of rheumatoid arthritis (RA). Much data support a key role for toll-like receptors (TLRs) in RA. Little is known regarding the impact of hypoxia on TLR signalling-induced inflammatory response in RA. The aim of this study was to reveal the effect of hypoxia and its regulator hypoxia-inducible factor-1α (HIF-1α) on the inflammatory response in rheumatoid arthritis synovial fibroblast (RASF) upon the recognition of pathogen molecules.
Materials and methods: Hypoxia was induced in RASF by incubation with $Na_2S_2O_4$. The TLR3 ligand polyIC, TLR2 ligand PGN, TLR4 ligand LPS, and TLR9 ligand CpG were used to stimulate the cells. Effects of hypoxia on TLR-induced inflammatory cytokines and matrix metalloproteinases (MMPs) were determined by RT-PCR, real time PCR, and ELISA. Overexpression of HIF-1α as well as knocking-down its expression by siRNA were used to reveal its fundamental role. RASF-induced inflammatory T cell population expansion was determined by flow cytometry, real time PCR, and ELISA analyses after RASF/T cell co-culture.
Results: Hypoxia potentiated the expression of inflammatory cytokines, MMPs, and VEGF in RASF stimulated by different TLR ligands, especially polyIC, a synthetic mimic of dsRNA from virus or apoptotic cells. HIF-1α played a fundamental role in this synergy. Moreover, HIF-1α overexpression enhanced RASF-mediated inflammatory T cell proliferation, inducing more proinflammatory IFN-γ and IL-17 production.
Conclusions: Our findings suggest that hypoxia and HIF-1α may function in conjunction with TLR-engaged innate immune responses to exacerbate the pathogenesis of RA. This pathway may serve as a therapeutic target for disease.

P1251

IFNa enhances TNFa-stimulated production and STAT4 expression in monocytes. *In vivo* and *in vitro* effect of antimalarial drugs

P. Lopez, J. Rodríguez-Carrio & A. Suárez
Functional Biology Immunology Area, University of Oviedo, Oviedo, Spain

Purpose/Objective: IFNα plays an important role in the etiopathogenesis of systemic lupus erythematosus (SLE) and other autoimmune diseases and is involved in the production of several pro-inflammatory cytokines in humans. Thus, we wanted to analyse the influence of IFNα on the production of TNFα by human peripheral blood mononuclear cells (PBMCs) as well as the possible interference of this cytokine on the effect of antimalarial drugs, TNFα inhibitors widely used in the treatment of SLE.
Materials and methods: PBMCs were incubated with IFNα (1000 U/ml), alone or in combination with other stimuli (PHA, LPS), as well as in the presence or absence of chloroquine. Supernatants from such cultures were collected to quantify TNFα levels by ELISA, while TNFα and STAT4 expression in cultured cells were analysed by intracellular flow cytometry. In addition, TNFα and IFNa serum levels were quantified in 171 SLE patients and 109 healthy donors by ELISA and STAT4 expression was analyzed in 60 SLE patients and 25 controls by real time RT-PCR.
Results: IFNα treatment of PBMC did not induce a significant increase of the TNFα secretion respect to untreated cells; however, this cytokine produced a strong increase in TNFα levels in LPS or PHA-stimulated cells. Moreover, when we investigated the cellular population responsible of this effect we detected an increased secretion of TNFα by stimulated monocytes but not by T lymphocytes. In addition, we observed an increase of the intracellular STAT4 levels in monocytes stimulated with LPS in the presence of IFNα, suggesting that this effect could be mediated by STAT4. The analysis of antimalarial effect showed that chloroquine was able to inhibit the expression of TNFα enhanced by IFNα in activated cells as well as the STAT4 levels. Finally, the analysis of SLE patients, which presented a positive correlation between IFNα and TNFα serum levels, showed that antimalarial treatment, in addition to decrease TNFα, could be able to reduce STAT4 gene expression but only in patients with high IFNα serum levels.
Conclusions: IFNα treatment in *in vitro* cultures enhances the induction of TNFα by stimulated monocytes, an effect that seems to be mediated by STAT4 and inhibited by chloroquine treatment. However, the consequence of antimalarial treatment on SLE patients could be different depending on their IFNα serum levels.

P1252

IFNa serum levels are associated with poor prognosis markers, Endothelial Progenitor Cells imbalance and proinflammatory cytokine profile in Rheumatoid Arthritis patients

J. Rodriguez-Carrio,* B. de Paz Cazón,* C. Prado,* P. López,* M. Alperi-López,† F. J. Ballina-García† & A. Suárez*
**Department of Funcional Biology, Area of Immunology, University of Oviedo, Oviedo, Spain, †Department of Rheumatology, Hospital Universitario Central de Asturias, Oviedo, Spain*

Purpose/Objective: As a role for IFNα in endothelial damage and endothelial progenitor cell (EPC) disturbances in autoimmune disorders has been proposed, the main aim of this study was to evaluate the potential associations of IFNa serum levels on EPC populations and cytokine profiles in RA patients.
Materials and methods: EPC populations were quantified by flow cytometry in peripheral blood samples from 50 healthy controls (HC) and 100 RA patients based on their CD34, VEGFR2 and CD133 expression. Cytokine serum levels were measured by immunoassays and clinical and immunological data, including cardiovascular events and cardiovascular risk factors, were obtained by reviewing clinical records.
Results: We found that IFNα serum levels were associated with EPC populations in RA. However, only 33% of patients displayed high levels of this cytokine, using the percentile 90 in HC as cut-off. In fact, patients with low IFNa levels displayed a significant EPC depletion, whereas the IFNα-high group exhibited higher mature EPC (mEPC) and EC counts, and an increased mEPC/EPC ratio. Moreover, high IFNα serum levels were associated with higher disease activity (DAS28), poor prognosis markers (Rheumatoid Factor and anti-CCP autoantibodies) and higher levels of proinflamatory cytokines (IL-1β, IL-12 and IL-6) accompanied with lower amounts of VEGF, thus suggesting higher rates of endothelial damage and an endothelial repair failure. Finally, the increased frequency of cardiovascular events found in patients with high IFNα levels ($P < 0.05$) seems to support this hypothesis.
Conclusions: IFNα serum levels could isolate a group of RA patients with an enhanced proinflamatory profile which may impair endothelial repair through an EPC imbalance, thus leading to higher cardiovascular risk.

P1254

IL-6 trans-signaling drives collagen production in fibroblasts

G. Febriana, S. O'Reilly & J. van Laar
Musculoskeletal Research Group, Institute of Cellular Medicine, Newcastle upon Tyne, UK

Purpose/Objective: In this study, we set out to determine the role of Signal Transducer and Activator of Transcription 3 (STAT-3) in the pathogenesis of systemic sclerosis (SSc), a rare connective tissue disease characterized by vasculopathy, inflammation, and fibrosis.
Materials and methods: Healthy dermal fibroblasts were cultured from a healthy donor after punch biopsy of involved skin. Fibroblasts were treated with IL-6 (25 ng/ml) andsIL-6R (20 ng/ml) alone and a combination of both cytokines. Collagen I transcripts were quantified by Q-RT-PCR. We also performed immunocytochemistry, using antibody against α-SMA, and Western blot analyses to determine whether STAT-3 and Smad3 phosphorylation were affected by *in vitro* culture of fibroblasts with IL-6 and/or sIL-6R.
Results: These experiments showed that the combination of IL-6 and sIL-6R induced the strongest collagen fold increase, which was 7.76 times higher ($n = 2$) compared to control (untreated fibroblast). Western blot analysis confirmed the direct contribution of IL-6 in STAT-3 phosphorylation and indirect contribution in Smad3 phosphorylation. Immunocytochemistry showed a direct effect of IL-6 on α-SMA levels.
Conclusions: We conclude that IL-6 trans-signaling affects collagen expression in dermal fibroblasts and postulate that a similar mechanism is operative in SSc.

P1255

Incidence and significance of Antibodies to ribosomal P proteins in lupus without neuropsychiatric manifestations

K. Djenouhat,* A. Tahiat,* S. S. Salah,* F. Haddoum,† M. Boucelma‡ & M. C. Abbadi*
**Immunology, Institut Pasteur of Algeria, Algiers, Algeria, †Nephrology, Hôpital Parnet, Algiers, Algeria, ‡Internal medicine, CHU Bab El Oued, Algiers, Algeria*

Purpose/Objective: Several studies showed a strong association between elevated titers of serum anti-ribosomal P antibodies andneuropsychiatric manifestations (NM) of Systemic Lupus Erythematosus (SLE). The aim of this work is to assess frequency of anti-ribosomal P

proteins antibodies and then study their clinical significance in SLE without NM.

Materials and methods: Eighty SLE patients without NM were included in this study. Among them 47SLE patients with biopsy-proven nephritis. Clinical activity was measured according to the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI index). For detecting antibodies to ribosomal P proteins, serum samples were tested using the multiplex method (Luminex and AtheNA Multi-Lyte).

Results: Sera from 24 patients were positive for anti-P, which represents 30% of our patients. This rate is consistent with the literature data. Among these 24 positive subjects, 17 of them have renal impairment (17/24) whereas only 6 of patients (6/33) without renal involvement were positive (36%vs18%, $P < 0.01$). Stratification of positive anti-P patients with lupus nephritis according to disease activity revealed that 14 from the 17 one of these categories of patients are in clinical relapse (74%vs26%, pc < 0.01). Our findings correlated with the results of some studies showing that these antibodies represent a marker of lupus nephritis flare.

Conclusions: Even if antibodies to ribosomal P proteins occur in approximately one third of lupus patients without MN, they seem to have high specificity for monitoring lupus nephritis flare. However, their low sensitivity is the main parameter limiting their search in daily practice.

P1256

Increased genomic ribonucleotide content and spontaneous DNA damage response in mice with defects of the Aicardi-Goutières syndrome-associated endonuclease RNase H2

R. Behrendt,* B. Hiller,* S. Glage,† R. Naumann‡ & A. Roers*
**Medical Faculty Carl Gustav Carus TU Desden, Insitute of Immunology, Dresden, Germany, †Hannover Medical School, Institute for Laboratory Animal Science, Hannover, Germany, ‡Max Planck Institute of Molecular Cell Biology and Genetics, Transgenic Core Fcility, Dresden, Germany*

Purpose/Objective: RNases H cleave the RNA moiety of RNA/DNA hybrids. RNase H2 mutations cause Aicardi-Goutières Syndrome (AGS), a neonatal inflammatory disease, which shows clinical overlap with systemic lupus erythematosus (SLE). Like SLE, AGS patients are characterized by a spontaneous type I IFN response, which presumably plays a key role in pathogenesis.

Materials and methods: We generated mice with complete or cell type-specific RNase H2 deficiency or with hypomorphic expression of the enzyme.

Results: We show that RNase H2 deficiency is embryonic lethal. RNase H2-deficient cells show proliferative impairment and accumulate in G2/M phase of the cell cycle due to a spontaneous DNA damage response. Embryonic fibroblasts with reduced RNase H2 activity featured increased frequency of genomic single strand breaks, increased numbers of nuclear gH2AX foci and induction of p53-target genes, most prominently the cyclin-dependent kinase inhibitor 1 gene encoding cell cycle inhibitor p21. DNA from RNase H2-deficient embryos featured an increased load of ribonucleotides in the genomic DNA. These findings suggest that unrepaired ribonucleotides trigger the DNA damage response in RNase H2-deficient cells.

Conclusions: Collectively, we show that RNase H2 is essential to remove ribonucleotides from the mammalian genome to prevent DNA damage. Our findings raise the question, whether a chronic DNA damage response is of relevance in the pathogenesis of AGS and related conditions including SLE.

Inflammation and bone erosion in the delayed-type hypersensitivity (DTH) arthritis model

S. M. Atkinson,* M. Thorn,† P. A. Usher,‡ B. Fox,§ K. Serikawa,§ S. Biswas,§ C. Haase† & A. Nansen†
**Veterinary Disease Biology, University of Copenhagen, Frederiksberg, Denmark, †Novo Nordisk A/S, Immunopharmacology, Måløv, Denmark, ‡Novo Nordisk A/S, Histology, Måløv, Denmark, §Novo Nordisk A/S, Molecular Immunology, Seattle, WA, USA*

Purpose/Objective: Rheumatoid arthritis (RA) is a chronic inflammatory and destructive autoimmune disease, characterised by joint inflammation and bone erosion. To better understand the underlying immune mechanisms of RA various models of arthritis have been developed in different inbred mouse strains. Delayed-type hypersensitivity (DTH) arthritis is a mono-paw arthritis model in C57BL/6 mice affecting one hind paw. DTH-arthritis is induced by modifying a protein antigen induced DTH response by administration of anti-type II collagen antibodies between immunisation and challenge. Onset is synchronised, incidence is ≥100% and intra-group variation is low. The mono-paw arthritic phenotype makes the model suitable for analysis of inflammation and bone destruction, as the unaffected control hind paw can be used as an intra-animal control. The purpose of this study was to improve our understanding of DTH arthritis-associated inflammation and bone destruction by exploring different biomarkers of disease using various state of the art techniques.

Materials and methods: Leukocyte subsets were analysed by flow cytometry, and paw homogenates and serum by ELISA/Bioplex. A gene expression analysis was performed using deep sequencing (mRNA expression) techniques. Fluorescence molecular tomography was used to *in vivo* image enzyme activities and bone remodeling. Finally, a histopathological scoring system was established to assess pathological changes in the affected paw.

Results: In the affected paw, we observed marked infiltration of neutrophils and macrophages as well as osteoclast activation, bone erosion and remodelling, cartilage destruction and increased activity of enzymes associated with these processes. Serum analysis revealed an increase of systemic levels of several inflammatory markers. Analysis of paw homogenates revealed an increase of several markers associated with inflammation and bone erosion. Moreover, gene expression analysis revealed an increase in mRNA expression of several genes associated with inflammation and bone erosion.

Conclusions: We have performed analyses of biomarkers for disease in DTH arthritis, which indicate that DTH arthritis shares features with RA. We believe that the applied state of the art techniques provide highly valuable model insights from which efforts into development of novel biologics targeting RA can benefit.

Intrarenal FOXP3+ regulatory T cells expansion and decreased number of infiltrating CD4+ T cell in murine lupus nephritis by IL-2 therapy

A. Rose, R. Undeutsch, L. Kloke, J. Y. Humrich & G. Riemekasten
Rheumatology and Clinical Immunology, Charité University-Medicine Berlin, Berlin, Germany

Purpose/Objective: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by an acquired IL-2 deficiency, which leads to a homeostatic imbalance between regulatory T cells (Treg) and effector T cells (Tcon). Humrich *et al.* (2010) demonstrated that the IL-2 deficiency in diseased NZB/W mice can be rebalanced in lymphoid organs using a treatment with recombinant IL-2 (IL-2) by promoting the homeostatic proliferation of regulatory T cells. The aim of this study was to investigate the impact of IL-2 therapy on intrarenal

Foxp3+ Treg and kidney infiltrating CD4+ T cells in (NZBxNZW) F1 mouse model of lupus nephritis.
Materials and methods: (NZBxNZW) F1 mice with active nephritis were treated with recombinant IL-2 either over a short period of 24 h or over a long period of 20 days with PBS as control. Absolute numbers, phenotype and proliferation of kidney infiltrating CD4+ T cells were determined by flow cytometry.
Results: (NZBxNZW) F1 mice treated over a short term with IL-2 showed an enhanced proliferation of FoxP3+ Treg and increased numbers and frequency of CD4+Foxp3+ Treg compared to PBS treated control mice. On the other hand, long term IL-2 treatment did not result in a persistent expansion of the intrarenal Foxp3+ Treg population. Nevertheless, total numbers of kidney infiltrating CD4+ T cells were diminished and the CD4+ Tcon showed reduced signs of cellular activation.
Conclusions: Our data indicates that short term IL-2 treatment is able to expand the size of the intrarenal Treg pool. In contrast, long term IL-2 treatment decreases the numbers of kidney infiltrating CD4+ T cells. These results may in part explain the delay of disease progression induced by treatment with IL-2 and underline the important role of intrarenal Treg for the suppression of kidney disease in lupus mice. These results also provide additional rationales for an IL-2 based immunotherapy of human disease.

Lactobacillus rhamnosus KL-37 – derived, highly purified, exopolysaccharide (EPS) inhibits adjuvant effect of LPS on the development of CIA in DBA/1 mice

B. Nowak,* M. Ciszek,* M. Sróttek,* A. Lazar,† S. Fraczek-Górska,‡ A. Gamian‡ & J. Marcinkiewicz*
**Immunology, College of Medicine, Jagiellonian University Kraków, Poland, †Pathomorphology, College of Medicine, Jagiellonian University, Kraków, Poland, ‡Medical Microbiology, Ludwik Hirszfeld Institute of Immunology and Experimental Therapy, Wroclaw, Poland*

Purpose/Objective: We have shown that crude exopolysaccharide (EPS), produced by *Lactobacillus rhamnosus KL-37* has immunomodulating activity both *in vitro* (cytokine production by mouse peritoneal macrophages) and *in vivo* (antigen-specific antibody production). The aim of present study was to examine the effect of highly purified EPS, free of LTA, DNA and bacterial proteins, on the onset of CIA induced in DBA/1 mice by collagen in the presence of bacterial adjuvant (LPS).
Materials and methods: To induce CIA DBA/1 male mice were given subcutaneous injection of chicken collagen type II (CII) emulsified in Complete Freud's Adjuvant (CFA). Twenty-one days later mice were boosted with CII in the presence of LPS (given intraperitoneally). EPS (or PBS as control) was given systemically (intravenously or intraperitoneally) or locally by subcutaneous injection every other day starting at the day of boost immunization. In some experiments EPS was given prior immunization. The development of CIA was evaluated by visual observation of joint inflammation and measurement of paw thickness. At the end of the experiment (day 42–45), hind paws were collected for histological evaluation of joint damage or MPO level in inflamed joints. Additionally, the level of proinflammatory cytokines (IL-6, TNF-alpha) and anti-CII antibodies were measured in serum by ELISA.
Results: Highly purified EPS, given to DBA/1 mice intravenously or intraperitoneally, ameliorated the onset of CIA. The incidence and severity of joint inflammation was reduced in mice receiving EPS during and after boost immunization (CII+LPS). Additionally, when given systemically, EPS reduced the level of anti-CII antibodies in serum. The incidence of CIA and clinical symptoms of joint inflammation were also ameliorated by subcutaneous injections of pure EPS although the level of anti-CII antibodies in serum was comparable to control mice (given PBS). The inhibiting effect of EPS on CIA development was not observed when EPS was given prior boost immunization with CII+LPS.
Conclusions: *Lactobacillus rhamnosus KL-37* derived EPS, devoid of other bacterial components (LTA, DNA, bacterial peptides), inhibits LPS, but not CFA, adjuvant effect on the development of CIA in DBA/1 mice.

Maternal systemic lupus erythematosus affects neonatal circulating plasminogen activator inhibitor-1 levels

U. Holmlund,* G. Heidari-Hamedani,* S. Björkander,* M. Ekström† & K. Bremme‡
**Department of Immunology, Wenner-Gren Institute, Stockholm University, Stockholm, Sweden, †Department of Medicine, Hospital Solna, Karolinska Institutet, Karolinska University, Stockholm, Sweden, ‡Department of Women and Child Health, Hospital Solna, Karolinska Institutet, Karolinska University, Stockholm, Sweden*

Purpose/Objective: During pregnancy changes in hemostasis takes place including a reduced fibrinolysis. Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by pronounced systemic inflammation and many patients have a disturbed fibrinolytic activity. Since pregnancy as such, is a condition with substantial impact on both inflammation and coagulation, women with SLE might be particularly exposed to pregnancy-associated complications. Therefore we have investigated fibrinolytic activity in pregnant women with SLE. In addition, fibrinolytic activity in cord blood of children to women with SLE or the closely related autoimmune disease anti-phospholipid syndrome (APS) was investigated, to elucidate if the disease of the mother affects fibrinolysis in the newborn child.
Materials and methods: To investigate the fibrinolytic activity we measured serum PAI-1 and PAI-2 concentrations with ELISA. Placental tissue was stained for PAI-1 and PAI-2 using immunohistochemistry.
Results: PAI-1 concentrations in serum from SLE patients were significantly higher during pregnancy and post partum compared to controls. Pregnant SLE patients also tended to have increased PAI-2 in serum compared to healthy women. However, no significant differences were found in placental PAI-1 or PAI-2 expression between SLE and controls. Finally, children to SLE and APS patients had the highest cord blood serum concentrations of PAI-1 when compared to children to healthy women.
Conclusions: PAI-1 and PAI-2 have been attributed to immune response modulation; PAI-1 has been proposed to enhance Th2 immune responses and PAI-2 is associated with suppression of Th1 immune responses. The pregnant SLE patients had increased *in vivo* concentrations of both PAI-1 and PAI-2, which might contribute to the proposed Th2 skewing in SLE patients. Finally, newborn children to women with SLE or APS seem to have a decreased fibrinolytic activity, which might have implications for these children during the neonatal period.

P1261

Membrane-bound and soluble BAFF expression by human rheumatoid fibroblast-like synoviocytes in response to TLR stimulation

N. W. Kam,* A. Filer,† C. Buckley,† M. Bombardieri* & C. Pitzalis*
**Experimental medicine and Rheumatology, William Harvey Research Institute, London, UK, †Division of Immunity and Infection, College of Medical and Dental Sciences, Birmingham, UK*

Purpose/Objective: B cell activating factors of TNF family (BAFF) is associated with the survival and maturation of B cells. BAFF is widely expressed in the rheumatoid arthritis (RA) synovium which is characterized by the presence of synovial niches of autoreactive B cells and

sustain *in situ* autoantibody production. Importantly, B cell niches remain functional in the RA-SCID model in the absence of recirculating cells, suggesting that autocrine mechanisms support ongoing B cell activation in the RA synovium. BAFF exerts its functional role both as a membrane bound protein and in soluble form. Here we investigated whether resident stromal cells in the RA synovium, synovial fibroblasts (RASF), are capable of producing either forms of BAFF and thus contribute to local B cell activation.

Materials and methods: mRNA BAFF in RASF stimulated with Toll-like receptors (TLR) 2, TLR3 and TLR4 ligands was assessed by quantitative Taqman PCR. RA dermal fibroblasts (RADF) and osteoarthritis SF (OASF) were used as controls. The cytoplasmic, membrane bound and/or soluble forms of BAFF were investigated by (1) Western blot using total and membrane-enriched protein extracts, (2) flow cytometry, (3) ELISA and (4) immunocytochemistry.

Results: *In vitro* stimulation of TLR3, and to a significantly lesser extent TLR4, but not TLR2 on RASF led to strong induction of BAFF mRNA. In response to TLR3, soluble BAFF was time-dependently released in the supernatant of RASF (~600 pg/ml) and, to a lesser extent, OASF and RADF. RASF constitutively expressed both cytoplasmic and membrane bound BAFF as demonstrated by Western blot, flow cytometry and immunocytochemistry which was upregulated upon TLR3 stimulation and was significantly increased as compared to RADF.

Conclusions: Here we provide conclusive evidence that SF in the RA synovium are a pivotal source of the B cell survival factor BAFF at both mRNA and protein level. In addition to their significant constitutive expression, RASF can further up-regulate cytoplasmic, membrane-bound and soluble BAFF in response to TLR3 stimulation. Overall, our data strongly support a fundamental role for RASF in sustaining functional B cell activation and antibody production in the inflamed RA synovium.

P1262

Modulation of rheumatoid adipose-derived mesenchymal stem cells function by adipocytokines

U. Skalska, E. Kontny & W. Maslinski
Department of Pathophysiology and Immunology, Institute of Rheumatology, Warsaw, Poland

Purpose/Objective: To investigate whether selected adipocytokines i.e. leptin, low (LMW) and high (HMW) molecular weight adiponectin isoforms and TNF affect indoleamine 2,3-dioxygenase (IDO) and hem oxygenase-1 (HO-1) mRNA expression and cytokines (IL-6, IL-8) secretion by rheumatoid adipose-derived mesenchymal stem cells (RA-ADSCs). To determine if conditioned media from RA-ADSCs treated with above mentioned adipocytokines, influence mRNA expression (APRIL, Cadherin-11, MMP-13), cytokine secretion (IL-6, IL-8, MMP-3) by FLS and FLS and PBMC apoptosis.

Materials and methods: Articular adipose tissue (AAT) and synovial membrane were obtained from rheumatoid arhritis (RA) patients during total knee joint replacement surgery. ADSCs were isolated and cultured with/without human recombinant leptin, TNF, adiponectin (LMW, HMW) and IFNγ. After 24 h, secretion of IL-6 and IL-8 and IDO, HO-1 mRNA expression was measured. Moreover, conditioned media from ADSC cultures were used to stimulate FLS (for 24 h) and PBMC from healthy donors (for 3 h). After stimulation, FLS and PBMC apoptosis was determined as well as gene expression and cytokine secretion in FLS. mRNA expression was assessed by Real Time PCR, cytokines concentration by ELISA and apoptosis by flow cytometry. The Wilcoxon signed-rank test was used for statistical analysis.

Results: Unstimulated RA-ADSCs did not express IDO mRNA. All applied stimuli triggered IDO expression, but with different potency. RA-ADSCs expressed HO-1 mRNA spontaneously and there were no significant differences after the treatment. IL-6 and IL-8 secretion were significantly up-regulated after HMW adiponectin ($P = 0.018$ and $P = 0.028$, respectively) and TNF treatment ($P = 0.018$). RA-ADSC-conditioned media exerted only slight effect: we did not observe any regularity in cytokines secretion by FLS, except IL-6 which was decreased after stimulation with media from HMW adiponectin-treated ADSCs ($P = 0.018$). mRNA expression for Cadherin-11, APRIL and MMP-13 stayed unchanged. No statistically significant differences in FLS and PBMC apoptosis after RA-ADSC-conditioned media treatment were observed.

Conclusions: Adipocytokines may influence RA-ADSCs function; however we did not prove it in all studied aspects. Further studies are needed to elucidate the hypothesis that the specific milieu of rheumatoid joint formed by pro-inflammatory cytokines and adipokines may affect properties of ADSCs from AAT.

Funding: Grant No. N/NZ5/00932 from National Science Center, Poland

Over-expression of 5-alpha reductase in B cells from systemic lupus erythematosus patients suggests disease related difference in androgen activation

F. Ali,* W. Arlt,† C. Gordon* & D. Scheel-Toellner*
**Rheumatology Research Group, University of Birmingham, Birmingham, UK, †Endocrinology, University of Birmingham, Birmingham, UK*

Purpose/Objective: The prevalence of many autoimmune conditions is higher in women compared to men. These differences may be explained by the conflicting effects androgens and estrogens have on the immune system; androgens such as 5α-dihydrotestosterone (5α-DHT) have an anti-inflammatory effect, whereas estrogens such as 17β-estradiol enhance immune responses. Five-alpha reductase (SRD5A1) plays an important role in the regulation of androgen activity by converting testosterone into the more active 5α-DHT. Here, we have explored the expression of SRD5A1 in peripheral blood mononuclear cells from patients with SLE and in age and gender matched healthy controls.

Materials and methods: Cells were investigated with and without *in-vitro* stimulation using beads coated with anti-CD3 and CD28 antibodies. PBMC were labelled for SRD5A1 and cell populations were identified by expression of CD19, CD14, CD4, CD8 and CD45RO and analysed by flow cytometry.

Results: Both in healthy controls (HC) and in SLE patients T cell activation lead to an increase in SRD5A1 expression (HC $P = 0.002$, SLE $P \leq 0.0001$). Also, CD45RO+ T cells consistently showed a higher expression of 5-alpha reductase when compared to the CD45RO- subset.

We then investigated whether this mechanism is altered in autoimmune conditions by measuring the expression of SRD5A1 in various immune cells from SLE patients ($n = 30$) and healthy controls ($n = 16$) using flow cytometry. There was a significantly higher expression of SRD5A1 in B cells from SLE patients compared to healthy controls ($P = 0.005$).

Conclusions: So far, the data suggest that T cells up-regulate their capacity to activate testosterone to 5α-DHT upon activation and keep it stably up-regulated in the CD45RO+ subset. B cells from SLE patients are increasing their exposure to more potent androgens, which maybe an attempt to reduce B cell hyper-reactivity. As SRD5A1 inhibitors are used clinically to treat prostate cancer, it will be important to investigate the consequences of their use on the immune system.

P1268

Phenotypic and homeostatic abnormalities of Foxp3+ Treg in Systemic Lupus Erythematosus are associated with IL-2 deficiency

C. von Spee, N. Wassermann, J. C. von Glischinski, T. Alexander, J. Y. Humrich & G. Riemekasten
Rheumatology, Charité University-Medicine Berlin, Berlin, Germany

Purpose/Objective: Systemic lupus erythematosus (SLE) is characterized by uncontrolled activation of T and B cells resulting in loss of tolerance towards self antigens. Regulatory T cells (Treg) are important players in the maintenance of self-tolerance. Phenotypic and quantitative abnormalities of Treg have been associated with human and murine SLE. Further, it was shown that SLE T cells have an impaired production of IL-2, which is the essential cytokine for Treg homeostasis. In order to substantiate a link between IL-2 deficiency and Treg abnormalities in SLE we investigated the phenotype and homeostasis of CD4+Foxp3+ Treg and CD4+Foxp3- conventional T cells (Tcon) in view of abnormalities associated with an IL-2 deficiency.
Materials and methods: Phenotype, frequency and proliferative status of Treg and Tcon subsets were analyzed in peripheral blood from 90 SLE patients and 40 healthy donors by flow-cytometry. Disease activity was determined according to the SLE activity index (SLEDAI). Two-tailed Mann−Whitney *U*-test was used for statistical analysis between SLE and control groups, Spearman's rank coefficient was used to calculate correlations with disease activity.
Results: The frequency of Foxp3+ Treg is significantly increased in SLE patients compared to healthy controls ($P = 0.015$). However, their phenotype is considerably altered: We found a significantly reduced frequency of CD25 expressing cells among Foxp3+ Treg in SLE ($P = 0.0001$) and the frequency of cells with a memory phenotype was increased ($P = 0.003$). Analysis of Ki67 expression revealed an increased percentage of proliferating Treg and Tcon, which correlated with disease activity ($r = 0.36$, $P = 0.012$ and $r = 0.46$, $P = 0.001$ resp.). The ratio of proliferating Treg versus proliferating Tcon, however, was significantly reduced in SLE compared to controls ($P = 0.0001$) and inversely correlated with disease activity ($r = -0.33$, $P = 0.02$).
Conclusions: Although the frequency of Foxp3+ Treg is increased in SLE patients, their loss of CD25 expression and their shift to the memory compartment together with the homeostatic imbalance between Treg and Tcon indicate a profound disorder in Treg biology in SLE. These phenotypic and homeostatic abnormalities of SLE Treg are very similar to those observed in IL-$2^{-/-}$ and lupus-prone mice, suggesting an IL-2 deprivation of Treg also in human SLE.

P1271

Positive double-stranded DNA antibodies: it is not always lupus

V. García López,* V. García López,* B. Tejera,† E. Ruiz-Ortiz,* A. Teniente-Serra,* S. I. Lozano-Ramos,* O. Bernaus,* A. Soriano,* A. Olivé† & E. Martínez-Cáceres*
**LIRAD (Immunology Laboratory) Germans Trias i Pujol Hospital, Blood and Tissue Bank, Badalona, Spain, †Rheumatology, Germans Trias i Pujol Hospital, Badalona, Spain*

Purpose/Objective: Systemic Lupus Erythematosus (SLE) is a systemic autoimmune disease with relevant clinical and immunological manifestations in which double-stranded DNA (anti-dsDNA) antibodies have been considered the serological hallmark. About 75−95% of patients with active and non-active disease produce anti-dsDNA antibodies. The aim of this study is to evaluate different assays for anti-dsDNA antibodies detection.
Materials and methods: Retrospective study with seventy two sera from Germans Trias i Pujol Hospital. All sera were positive for anti-nuclear antibodies (ANA, homogeneous pattern with a title higher than 1:80). Each serum sample was analyzed with QUANTA Lite®dsDNA ELISA (test A) and QUANTA Lite®dsDNA SC ELISA (test B) in order to determine the presence of anti-dsDNA antibodies and with QUANTA Lite™Chromatin ELISA (test C) and Anti-dsDNA-NcX ELISA (test D) to detect antibodies against the dsDNA-nucleosomes complex. All corresponding clinical notes were reviewed.
Results: Fifty four sera with test A and sixty sera with test B were positive for anti-dsDNA antibodies test showing a sensibility of 68.4% and 80.7% respectively but very low specificity (≤ 6.6%). In relation to antibodies anti-dsDNA-nucleosomes complex: sixty five sera with test C and fifty three sera with test D were positive with a sensibility of 91.2% and 82.4% respectively and a specificity of 13.3% and 60% respectively. False positive Results: (patients without SLE but with a positive anti-dsDNA determination) were less common in test detecting anti-dsDNA-nucleosomes antibodies ($n = 13$ (18%) and $n = 6$ (8.3%), respectively), than those detecting anti-dsDNA antibodies ($n = 15$ (18%) and $n = 14$ (20%), respectively). False positive results were mostly from patients with infection (HBV, HCV and HIV).
Conclusions: The determination of antibodies against the dsDNA-nucleosomes complex displays higher specificity for SLE than the determination of anti-dsDNA antibodies alone. The selection of the antigen should be taken into account for the diagnosis and follow up of SLE patients.

P1272

Protective role of MAP kinase phosphatase 2 (MKP-2) in a model of collagen antibody induced Arthritis

J. Schroeder, K. Ross, J. Alexander, C. E. Lawrence & R. Plevin
Strathclyde Institute for Pharmacy and Biomedical Sciences, University of Strathclyde, Glasgow, UK

Purpose/Objective: MAP kinase phosphatase 2 (MKP-2) is a nuclear phosphatase which negatively regulates the MAP kinase signalling pathway by dephosphorylating MAP kinases ERK, JNK and to a lesser extend p38. The involvement of the MAPK pathway in the development of Arthritis has been previously shown and a protective role has been established for the related phosphatase MKP-1 in macrophages (Salojin *et al.* 2006). MKP-1 and MKP-2 share many properties and consequently we investigated the role of MKP-2 in Arthritis development.
Materials and methods: We recently generated MKP-2 deficient mice and utilised these to study the role of MKP-2 in the development of collagen antibody induced arthritis (CAIA). In addition we measured neutrophil infiltration into the joints using an *in vivo* imaging system (IVIS), myeloperoxidase expression and further analysed cytokine and chemokine levels in joints and serum of mice.
Results: We found that MKP-2 deficient mice were particularly responsive to collagen antibody induced arthritis and developed severe signs of disease marked by earlier onset, stronger and prolonged symptoms (weight loss, swelling of joints, especially front paws and ankles) compared with their wild type counterparts. This was accompanied with a drastically enhanced infiltration of neutrophils into the joint cavities, increased pathology of the joint and higher levels of monocyte chemotactic protein MCP-1 in the joints and the serum.
Conclusions: We show that MKP-2 plays a protective role in arthritis, as the absence of this molecule results in severe disease.

P1273

Regulatory T cell function is influenced and partly restored by commonly used biologicals in rheumatoid arthritis (RA)

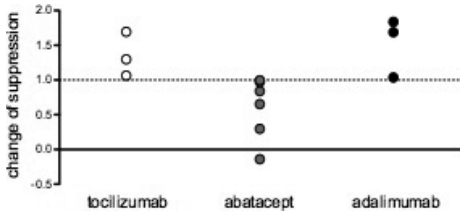
J. Herrath, M. Müller & V. Malmström
Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden

Purpose/Objective: Rheumatoid arthritis (RA) therapy includes a variety of biologicals that either block different pro-inflammatory

cytokines such as IL-1 (anakinra), TNF (etanercept, infliximab, adalimumab) or IL-6 (tocilizumab), modulate the adaptive immune system by depleting B cells (rituximab) or interfere with T cell activation and antigen presentation (abatacept). Regulatory T cells (Treg) are a crucial T cell subset in controlling autoimmune disorders and inflammatory responses in general. Here, we aim to understand the effect of three different biologicals, namely adalimumab, tocilizumab and abatacept on the functionality of Treg.

Materials and methods: Peripheral blood (PB) of RA patients was collected at baseline and after 3 month of abatacept ($n = 8$) or tocilizumab ($n = 10$) therapy. Specific T cell and Treg marker were determined *ex vivo* by multi-parameter flow cytometry. In addition, adalimumab, tocilizumab or abatacept was added to *in vitro* co-culture assays to assess the influence on synovial-fluid derived Treg and T effector cells (T eff) from chronic RA patients ($n = 12$).

Results: RA patients treated with abatacept showed a diminution of Treg-associated marker such as FOXP3 ($p \leq 0.05$), Helios ($p \leq 0.05$) and CD39 ($p \leq 0.05$). Tocilizumab therapy increased CD25high T cells ($p \leq 0.05$), but did not change FOXP3 frequency. Functional studies of synovial Treg with added adalimumab or tocilizumab showed an enhancement of their suppressive capacity when compared to control co-cultures. However, no beneficial effect on Treg suppressive capacity was seen when functional studies were performed in the presence of abatacept. Moreover, adalimumab and abatacept but not tocilizumab reduced the proliferative capacity of T eff cells when administrated *in vitro*.



Conclusions: All investigated biologicals do influence Treg function, but by different means. Abatacept did not increase Treg suppressive capacity, most likely due to its dual effect on T eff and Treg. Adalimumab increased suppression by its profound effect on T eff while tocilizumab also enhanced suppression but probably by affecting antigen-presenting cells in the culture. These data emphasize the need to understand Treg function in a context, which also takes into account the inflammatory milieu. Hence, many therapies can promote Treg function without directly interacting with this cell subset.

Role of CCR2 expression in neutrophils on development o arthritis

J. Talbot,* F. J. Bianchini,* F. O. S. Souto,† D. C. B. Nascimento,† L. G. Pinto,* R. S. Peres,† R. D. Oliveira,‡ S. L. Almeida,‡ J. R. Silva,† S. H. Ferreira,* P. L. Louzada-Junior,‡ T. M. Cunha,* F. Q. Cunha* & J. C. Alves-Filho*

**Pharmacology, Faculdade de Medicina de Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, †Immunology, Faculdade de Medicina de Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, ‡Medical Clinic/Rheumatology, Hospital das Clínicas/Faculdade de Medicina de Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil*

Purpose/Objective: Rheumatoid Arthritis (RA) is an autoimmune disease characterized by articular pain and progressive bone damage. These disease features have been associated with neutrophil infiltration on articular cavity. Blood neutrophils (PMN) trafficking during inflammation is a complex process with participation of several types of chemotactic factors. In general, PMN interact directly with CXC chemokines, as CXCL2 and monocytes and lymphocytes interact predominantly with CC chemokines (CCLs). However, our group showed that PMN from mice and patients with sepsis express a CCL receptor type 2 (CCR2). In sepsis, CCR2 expression has an essential role in neutrophil tissue infiltration. Here, we investigate the role of CCR2 on neutrophil infiltration on antigen-induced arthritis (AIA).

Materials and methods: PMN from healthy or RA patients, or from AIA mice were purified and used to chemotaxis assay and evaluation of CCR2 expression by qRT-PCR and immunofluorescence. AIA was induced in wild-type (WT) and CCR2 deficient mice ($CCR2^{-/-}$) 21 days after first mice sensitization by intra-articular injection (i.a.i) of antigen (mBSA) or CCL2. Some mice were also treated with CCR2 antagonist (RS504393) before challenges. PMN migration was assessed 7 h after i.a.i. articular hyperalgesia was evaluated at this same time using an electronic version of von Frey test. *In vitro* PMN chemotaxis in response to CXCL2 or CCL2 was performed in a Boyden microchamber. All experiments were approved by Human Ethics Committee (2981/2009) and Animal Ethics Committee (nordm; 181/2008) from HCFMRP/USP.

Results: PMN from RA patients and from arthritic mice express CCR2 and migrates to CCL2. Furthermore, CCL2 was able to induce PMN intra-articular infiltration in immunized mice. PMN recruitment to joints and articular hyperalgesia was significantly reduced in $CCR2^{-/-}$ mice or by treatment with RS504393. To ensure that CCR2 were directly responsible of PMN infiltration to the joint cavity we performed the adoptive transference of WT PMN from immunized mice to $CCR2^{-/-}$ immunized mice. This transference restored arthritis phenotype (PMN infiltration and articular hypernociception) to $CCR2^{-/-}$ mice after mBSA challenge.

Conclusions: Our findings suggest that CCL2-CCR2 chemotaxis pathway is involved directly in the detrimental infiltration of PMN to the joints in experimental arthritis.

P1275
Selective infiltration of CD6-CD56bright NK cells into the synovial fluids of rheumatoid arthritis and osteoarthrosis patients

B. Müller,* B. Simm,† M. Braun,‡ B. Mosetter,§ M. Witt,¶ H. Lorenz, G. O. Hofmann†† & C. S. Falk‡‡**

**Transplant Immunology, Hannover Medical School, Hannover, Germany, †DKFZ, Immune Monitoring, Hannover, Germany, ‡Karolinska Institutet, Microbiology and Immunology, Stockholm, Sweden, §Molecular Immunology, Helmholtz Centre for Environment ahnd Health, Munich, Germany, ¶Rheumatology, LMU Munich, Munich, Germany, **Rheumatology and Hematology, University Heidelberg, Heidelberg, Germany, ††Surgery & Traumatology, University Jena, Jena, Germany, ‡‡Transpklant Immunology IFB-Tx, Hannover Medical School, Hannover, Germany*

Purpose/Objective: Natural killer (NK) cells are part of the innate immune system and respond rapidly to a variety of stimuli via cytolytic activity and cytokine secretion. In the periphery, human NK cells can be divided into two major subsets defined as $CD16^+$ CD56dim and CD16-CD56bright NK cells. In this study, we wanted to demonstrate whether NK cells characterized by a clearly defined phenotype participate in the inflammatory process that is driving inflammation in rheumatoid arthritis but absent in osteo arthritis.

Materials and methods: Peripheral blood and synovial fluid of RA and OA patients was analysed by flow cytometry in order to define the distribution of NK cell subsets in this compartment, in addition, the microenvironment in plasma versus SF (synovial fluid) was analyzed by mutliplex based protein arrays for 50 cytokines, chemokines and growth factors. SF ofRheumatoid arthritis (RA) patients: $n = 33$ and Osteoarthritis (OA) patients: $n = 36$.

Results: Amongst all tested markers, the absence of CD6 represented the strongest correlation regarding NK cell infiltration, independently

from their CD16 expression. One reason for this reversed NK cell distribution could be the selective recruitment of CD56bright NK cells by chemokines. As shown in other publications, CD56bright NK cells express CXCR3 and CCR5 at higher levels whereas CD56dim NK cells express more CXCR1. Therefore the most important cytokines, chemokines and growth factors in synovial fluids and sera were determined by the Luminex-based multiplex method. As expected for CD56bright NK cells, two ligands for CXCR3 i.e. CXCL10 (IP-10) and CXCL9 (MIG) where found in significantly high concentrations in the SF of RA and OA patients compared to autologous sera. The same is true for the CCR5 ligand CCL4 (MIP-1b), however CCL5 (Rantes) was significantly decreased in the SF of RA and OA patients compared to sera. The CXCR1 ligands CXCL8 and CXCL1 are also present at significantly high concentrations while CXCL5 (ENA-78) is significantly reduced in SF compared to sera of both patient cohorts. Therefore the lack of the $CD16^+$ CD56dim NK cell infiltration is not due to the absence of their recruiting chemokines.

Conclusions: Our results indicate that CD6 is differentially expressed on NK cell subsets and represents a novel NK cell marker for infiltration into synovial fluid. Furthermore, the infiltration of CD6-CD56bright NK cells seems to be supported by high concentrations of the ligands CXCL10 (IP-10) and CXCL9 (MIG).

P1276

Serum and urinary IL-18 levels are associated with SLE and lupus nephritis activity

H. S. Howe,* K. O. Kong,* B. Y. T. Thong,* T. Y. Lian,* H. H. Chng,* E. T. Koh,* W. G. Law,* T. T. S. H. Lupus Study Group* & B. P. L. Leung†

**Rheumatology Allergy and Immunology, Tan Tock Seng Hospital, Singapore, Singapore, †Physiology, National University of Singapore, Singapore, Singapore*

Purpose/Objective: IL-18, a proinflammatory cytokine released predominantly by antigen presenting cells, is elevated in association with SLE disease activity; and its glomerular expression is increased in lupus nephritis. The purpose of this study was toexamine the association of serum IL-18 with SLE disease activity and urinary IL-18 with lupus nephritis.

Materials and methods: SLE patients and healthy controls were recruited in accordance with institutional review board guidelines. SLE patients were from our longitudinal study cohort where demographics, disease manifestations, treatment regimes, disease activity indices (SLAM-R and SLEDAI) and SLE damage index (SDI) are prospectively recorded. Renal disease activity was defined as a score of more than zero for renal related criteria in SLEDAI (range 0−16). Serum and urine IL-18 levels (in pg/ml) were determined by ELISA. The correlation of serum IL -18 with disease activity, anti-dsDNA antibody (ab), C3, C4 and CRP levels, and disease manifestations was analyzed.

Results: Levels of serum IL-18 were significantly higher in SLE patients ($n = 891$) than normals ($n = 50$); 311.1 (IQR: 0−969.7) versus 159.6 (IQR: 86.0−217.3); $P = 0.03$ respectively. Serum IL-18 levels positively correlated with SLAM-R [inactive: 330.6 (IQR: 0−938.5), mild: 325.6 (IQR: 0−1068.7), moderate: 500.5 (IQR: 175.0−573.6), and severe 1620.7 (IQR: 243.9−2395.5), $P = 0.0055$], and median levels were higher in patients with active neurological [305.7 (IQR: 0−964.1) versus 574.5 (IQR: 186.9−1439.0); $P = 0.040$] and mucocutaneous [279.1 (IQR: 0−954.1) versus 449.9 (IQR: 0−1136.9); $P = 0.036$] manifestations. Significant correlation was found with ESR and CRP but not anti-dsDNAab or complement levels. Detectable urinary IL18 was found in 163 of 246 SLE patients, median 24.38, and inter-quartile range: 15.9−46.54, range: 10.16−550.6, mea $n = 42.40 \pm 58.50$, with a markedly skewed distribution. Healthy controls ($n = 21$) had lower urinary IL-18; mea $n = 29.41$, SD 21.68, SEM 4.73. A significant difference ($P = 0.015$) was found between different renal SLEDAI groups (modified Kruskal-Wallis tests for Trend across Ordered Groups), and a clear difference found also between renal SLEDAI = 0 compared to renal SLEDAI = 4 (Wilcoxon rank sum test, $P = 0.029$). However the number of patients with higher grades of renal activity was too few for meaningful comparison.

Conclusions: Serum IL-18 levels are increased in SLE, particularly in those with active neurological and mucocutaneous manifestations, and correlate with disease activity. Urine IL-18 levels significantly correlated with renal lupus disease activity. Further studies are warranted to determine the usefulness of this cytokine in assessing activity of lupus nephritis.

Severe defects of complement regulator CD46-mediated IL-10 producing regulatory T cells in patients with systemic lupus erythematosus

U. Ellinghaus*, C. L. Pinder,* G. Le Friec,† C. Kemper† & T. J. Vyse*

**Department of Medical & Molecular Genetics, King's College London, London, UK, †MRC Centre for Transplantation, King's College London, London, UK*

Purpose/Objective: SLE is a complex autoimmune disease characterised by the breakdown of tolerance. Although the pathogenesis of SLE is not entirely understood, evidence suggests a strong genetic component. We have identified the TNF superfamily member *OX40L* as a candidate risk gene. It has been shown that OX40L completely inhibits the generation of IL-10-producing $CD4^+$ T cells resembling an adaptive regulatory T cell type (Tr1). IL-10 is key to the maintenance of peripheral tolerance. We therefore became interested in the examination of these $CD4^+$ T effector cells in SLE.

Materials and methods: Thirty seven SLE patients and 20 healthy controls were recruited for this study. Purified $CD4^+$ T cells were stimulated with antibodies to CD3 and CD46 in the presence of IL-2 and cytokine production was measured using the human IFN-γ or IL-10 Cytokine Secretion Assay kit (Miltenyi). Suppression assays were performed by monitoring cell proliferation of freshly isolated CD3/CD28 stimulated T cells cultured in the supernatant of CD3/CD46 stimulated cells.

Results: We found a striking difference in the cytokine profile of CD3/CD46 stimulated T cells from SLE cases compared to healthy controls. T cells in the majority of patients lacked an $IL\text{-}10^+$ population, produced up to 10 times more IFN-γ compared to healthy controls ($P < 0.0001$) and switching into an $IFN\text{-}\gamma^+/IL\text{-}10^+$ regulatory phase was defective. These results were consistent in a subset of patients when repeated 1 month later. Furthermore we showed that the IL-10 dependent suppressive activity of Tr1 cells was impaired in SLE. A neutralizing antibody was used to determine the contribution of OX40L to the development of Tr1 cells. We could not replicate the previously shown involvement of OX40L.

Conclusions: We have demonstrated that the CD46-mediated production of IL-10 producing effector T cells is dysregulated in SLE, a novel mechanism that might contribute to the development of the disease. Impaired Tr1 cell function is also observed in other autoimmune diseases like multiple sclerosis and rheumatoid arthritis. Together with our results it seems very likely that a defect in the CD46-mediated pathway is a common autoimmune phenotype. Thus understanding the precise signalling pathway in T cells associated with the production of IL-10 may lead to promising targets for the development of novel therapies for the treatment of autoimmune diseases.

P1279

Succinate enhances experimental arthritis

A. L. Saraiva,* J. Talbot,* R. F. França,* R. S. Peres,† F. P. Veras,* J. Raymond,† T. M. Cunha,* F. Q. Cunha* & J. C. Alves-Filho*
*Pharmacology, Faculdade de Medicina de Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, †Immunology, Faculdade de Medicina de Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil

Purpose/Objective: It has been shown that succinate, a citric acid-cycle intermediate, is released in the extracellular space upon cellular energy supply-demand imbalance or cell damage and can act as a mediator signaling through the G protein coupled receptor-91 (GPR91). Interestingly, activation of GPR91 on dendritic cells (DCs) by succinate enhances DC-mediated T cell activation and cytokine production. DCs play a key role in inducing and perpetuating the immune response in autoimmune diseases. The aim of present study was evaluate the effect of succinate on the development of experimental arthritis.
Materials and methods: Arthritis was induced by immunization of male C57BL/6 mice with methylated bovine serum albumin (mBSA) and completes Freund's adjuvant (CFA). Some mice received 2.5 mg of succinate in the antigen emulsion. Twenty-one days later, arthritis was triggered by intra-articular mBSA injection and articular hyperalgesia; leukocyte infiltration and cartilage proteoglycan loss was determined. Titers of serum anti-mBSA IgG and expression of IL-17/IFN by draining lymph node lymphocytes were also determined. All experiments were performed in accordance with protocols approved by the institutional Ethics Committee (protocol 146/2011).
Results: mBSA challenge into the femurtibial joint induced articular hyperalgesia and leukocyte infiltration. The inclusion of succinate in the antigen emulsion enhanced articular hyperalgesia ($t_8 = 4.48$, $P < 0.05$) and increased leukocyte infiltration in the joint cavity ($t_7 = 1.75$, $P < 0.05$) compared to control-immunized group. Serum from succinate-treated mice contained significantly higher concentrations of mBSA-specific IgG ($t_7 = 2.54$; $P < 0.05$). Moreover, succinate-treated mice had higher cartilage proteoglycan loss ($t_7 = 2.4$, $P < 0.05$). The expression of IL-17 lymphocytes was higher in succinate-treated mice ($t_7 = 3.16$, $P < 0.05$) while there are not change in lymphocytes producing IFN ($t_7 = 0.31$, $P < 0.05$).
Conclusions: We show here that succinate given together with the antigen emulsion potentiates specific immune response, enhancing articular inflammation during antigen-induced arthritis. Although the exact mechanisms by which succinate mediates its effects was not elucidated yet, our data suggest that the release of succinate could be an important component for the self-tolerance breaks down in autoimmunity.

P1280

Targeting the autoreactive memory using a new therapy combining plasma cell depletion with inhibition of activation and differentiation of B cells

A. Taddeo,* B. F. Hoyer,† H. D. Chang,‡ F. Hiepe† & A. Radbruch‡
*Deutsches Rheuma-Forschungszentrum Berlin, Cell Biology and Autoimmunology Group, Berlin, Germany, †Charité, Universitätsmedizin Berlin, Medizinische Klinik III mit Schwerpunkt Rheumatologie & klinische Immunologie, Berlin, Germany, ‡Deutsches Rheuma-Forschungszentrum, Cell Biology Group, Berlin, Germany

Purpose/Objective: In Systemic lupus erythematous (SLE) autoreactive plasma cells (PC) producing autoantibodies can survive in dedicated niches where they are resistant to immunosuppression and cytotoxic drugs. Therefore these cells represent a promising target for new therapies. It has been shown that the proteasome inhibitor bortezomib is able to deplete PC in NZB/W mice leading to an amelioration of the renal disease. However, it is likely that after PC-depletion new autoreactive PC can be generated from B cells and contribute to the maintenance of phatogenic memory. Therefore in this study we tested a new treatment approach aimed at depleting PC and, at the same time, preventing the generation of new autoreactive PC that results from B cell-hyperreactivity. We combined bortezomib with an anti-CD20 antibody or with the immunosuppressive drug cyclophosphamide (CY) and analyzed the PC-B cells dynamics in bone marrow (BM) and spleen of NZB/W mice.
Materials and methods: Mice were injected i.v. or not with 250 μg of a murine anti-CD20 antibody or 35 mg/kg body weight (BW) CY at various time intervals. All the mice where then injected twice whit 0.75 mg/kg BW bortezomib. The mice were sacrificed at different time points after the treatment, and PC and B cells subsets were characterized by FACS and ELISPOT.
Results: The selective depletion of PC using bortezomib without depletion of their precursor's leads only to transient effects as production of newly formed PC continues throughout life and the PC-niches are refilled quickly. Therefore, we treated NZB/W mice with bortezomib in combination with a murine anti-CD20 antibody or CY. The groups treated with the combination therapies showed a heterogeneous grade of B cell depletion and a slower repopulation of the PC pool. However, the supply of newly generated autoreactive PC from hyperreactive-B cells was not completely suppressed.
Conclusions: In this study, we observed that the PC niches in spleen and BM were refilled within few days after bortezomib mediated depletion, which is caused by persisting B cell hyperactivity. Due to the observed resistance of NZB/W mice to B cell depletion, neither anti-CD20 nor CY therapies were able to completely prevent the differentiation of autoreactive B cells in PC after depletion. Therefore, for sustained depletion effects and thereby sustained remission in patients the combined depletion of autoreactive PC and their precursor cells (i.e. B cells) is necessary.

P1282

The role of miR-155 in monocyte migration in Rheumatoid arthritis

A. Elmesmari, D. Gilchrist, A. Fraser, J. Brewer, I. McInnes & M. Kurowska-Stolarska
Immunology, Institute of Infection Immunity and Inflammation, Glasgow, UK

Purpose/Objective: Rheumatoid arthritis (RA) is a chronic autoimmune disease that leads to joint destruction. The recruitment of effectors cells, including monocytes to the joint space is an important step in RA progression and is mediated by chemokines (Ch) and their receptors (ChR). MicroRNAs are a recently discovered class of post-transcriptional regulators. Many members of the miR family are implicated in the regulation of cell movement and migration. Our previous study showed miR-155 is upregulated in RA synovial fluid (SF) monocytes suggesting that this miR may be involved in activation of these cells, including their migration into joint space. We hypothesized that miR-155 could regulates migration of monocytes in RA by modulating the expression of the chemokine and chemokine receptor system.
Materials and methods: Peripheral blood (PB) $CD14^+$ cells from healthy controls (HC) and RA patients were transfected with miR-155 mimic or scramble mimic using N-TER nanoparticles and cultured for 48 h. TaQman Low Density Array and multiplex assay was used to evaluate ChR expression and Ch production, respectively. Similar analysis was carried out on bone marrow monocytes (BMM) from miR-$155^{-/-}$ and WT mice. In addition, absolute copy numbers of miR-155 transcripts in PB and SF $CD14^+$ of RA and HC were assessed by QPCR.
Results: PB and SF monocytes in RA patients showed higher copy number of miR-155 compared to HC. Overexpression of miR-155 in HC and RA monocytes did not affect the production of CCL2, CCL7,

CCL21, CXCL5, CXCL8, CXCL7, CXCL10 and CX3CL1. In contrast, overexpression of miR-155 induced the production of chemokines such as CCL4, CCL5 and CCL22 in RA monocytes and CCL3 in both RA and HC. Analysis of chemokine receptors in BMM of miR-155$^{-/-}$ and WT mice revealed significantly higher levels of CCR1, CCR2, CCR5 and CXCR4 in miR-155 deficient cells suggesting that miR-155 can act as a negative regulator of these receptors in homeostatic state. As expected, TLR-4 ligand significantly suppressed expression of these receptors in both WT and miR-155$^{-/-}$ cells. Analysis of 3'UTRs of Ch/ChR (TargetScan) suggests that miR-155 is likely interfering with signaling pathways implicated in Ch/ChR system expression.
Conclusions: Deregulation of miR-155 in RA monocytes can contribute to the production of pro-inflammatory chemokines by these cells and to their accumulation at sites of inflammation.

P1283
The role of TNFa in the maintenance of joint inflammation in the CAIA model of Rheumatoid Arthritis

S. Allden, Z. Stencel, A. Vugler, G. Watt, S. Shaw & M. Catley
UCB, Pharmacology, Slough, United Kingdom

Purpose/Objective: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterised by synovitis, systemic inflammation and production of autoantibodies. The introduction of treatment with biologics, such as those targeting TNFα, have revolutionised the treatment of RA. Here we investigate the role of TNFα in the collagen antibody induced arthritis (CAIA) model of inflammatory arthritis.
Materials and methods: Male Balb/C mice were administered with 4 mg of anti-collagen II mAb cocktail on day 0. On day 1 the mice are administered with 25 μg LPS. Animals were weighed and scored for clinical signs of arthritis (swelling) daily. Using MSD multiplex ELISAs, cytokines, including TNFα, levels were measured in the paws and serum in the CAIA model at time points prior to and post LPS administration. To investigate TNFα inhibition mice were treated with either a anti-TNF Ab, 100 mg/kg i.v. 1× weekly, etanercept 30 mg/kg q.a.d. s.c., or anti-p55 Ab 30 mg/kg i.v. 2× weekly. To determine a dose response and to establish a time frame of efficacy the anti-TNF Ab was administered 1 h prior to Ab cocktail at 100 mg/kg, 6 h post LPS at 100, 3 and 0.01 mg/kg, and 24 h post LPS at 100 mg/kg.
Results: In the CAIA model TNFα levels were at their highest around 1 h post LPS in the serum and 2.5 h post LPS in the paws. Serum TNFα levels fall to baseline 24 h post LPS and were not detected in the paw from 6 h post. Treatment with Anti-TNF, etanercept and anti-p55 in this model significantly inhibit clinical scores by 100%, 99.5% and 96.5% respectively. Dosing prior to LPS and 6 h post LPS significantly inhibited clinical score. A dose dependent inhibition was observed with administration of anti-TNF, 100 mg/kg and 3 mg/kg, significantly inhibiting clinical score 98% and 75.8% respectively and 0.01 mg/kg showing a 17.8% non significant increase. Dosing 24 h post LPS with 100 mg/kg of anti-TNF did not significantly reduce clinical scores.
Conclusions: Through analysis of TNFα levels in the CAIA model and the administration of anti-TNF Abs we have determined that TNFα is essential in initiating disease but its role is less critical 24hrs post LPS and as such in the progression of inflammation in the paws. It is possible that other cytokines such as IL-1β are key in driving the inflammatory process in the latter stages.

P1284
TLR9-independent and immune complex-independent interferon-alpha production by neutrophils upon netosis in response to circulating chromatin

D. Lindau,* A. Rabsteyn,† J. Mussard,‡ M. Ribon,‡ I. Kötter,§ A. Igney,§ G. J. Adema,* M. C. Bossier,‡ H. G. Rammensee† & P. Decker‡
**Department of Tumor Immunology, Nijmegen Center for Molecular Life Sciences, Nijmegen, The Netherlands, †Department of Immunology, Institute for Cell Biology, Tübingen, Germany, ‡Sorbonne Paris Cité EA 4222 Li2P université Paris-13, Service de rhumatologie, Paris, France, §Internal Medicine II, University Hosptial Tübingen, Tübingen, Germany*

Purpose/Objective: Chromatin represents a major autoantigen in systemic lupus erythematosus (SLE). Interferon (IFN)-α plays an important role in lupus development. Plasmacytoid dendritic cells (pDC) are believed to be the main producers of IFN-α in SLE, although they represent a minor cell population. In contrast, neutrophils represent 50% of total blood leukocytes and are activated in SLE, especially by chromatin. Toll-like receptor (TLR) 9 recognizes certain forms of DNA but its role in SLE is still not elucidated. We therefore sought to determine the cellular source of IFN-α as well as the natural stimuli in SLE and the impact of TLR9.
Materials and methods: Chromatin was purified from calf thymus. PBMC and neutrophils were isolated from healthy individuals, SLE and rheumatoid arthritis patients. Mouse neutrophils were purified from the bone marrow. Cells were activated with different stimuli. Cell activation and IFN-α production/secretion was verified by flow cytometry and ELISA. Gene expression was analyzed by qPCR. Neutrophil extracellular trap (NET) induction was estimated by confocal microscopy.
Results: IFN-α secretion by neutrophils was observed with steady-state and not pro-inflammatory neutrophils, from both healthy donors and patients whereas pDC were less efficient. Neutrophil-derived IFN-α was detected in response to free chromatin, and not chromatin-containing immune complexes, as well as TLR9 agonists. Nucleosome induced IFN-α production by neutrophils was associated with IL-8 secretion, CD66b up-regulation, ROS production and NET formation. Neutrophil priming is not required. PBMC sustain IFN-α secretion by chromatin-activated neutrophils in co-cultures. Importantly, chromatin-induced IFN-α secretion occurs independently of TLR9. Finally, chromatin increases gene expression levels of IFN-α and several DNA sensors, e.g. AIM2 and STING.
Conclusions: Neutrophils represent a major source of IFN-α. This is the first report showing both that steady-state neutrophils can secrete IFN-α and identifying a natural lupus stimulus involved. A key event is thus the presence of increased concentrations of circulating nucleosomes in SLE patients. Chromatin-activated neutrophils may secrete IFN-α early during SLE development, before immune complexes are produced. The generation of NET and the expression of genes involved in the recognition of DNA may strengthen pDC activation and DNA-mediated activation.

P1286

ZNF334 – a new molecular marker of rheumatoid arthritis – sensitive to proinflammatory cytokines

M. Soroczynska-Cybula, I. Henc, E. Bryl & J. M. Witkowski
Pathophysiology, Medical University of Gdansk, Gdansk, Poland

Purpose/Objective: We have shown before thatthe expression of ZNF334 gene, coding for a new zinc finger protein, is extremely reduced in the $CD4^+$ lymphocytes of RA patients regardless their age and sex and thus can be considered a new molecular marker of the disease (Soroczynska-Cybula *et al. Immunology* 2011, 132(1):78–86). Based on the promoter sequence of the gene we speculated that it might be regulated by TNF, similarly to regulation of CD28 and Klotho genes described earlier. Here we have tested that hypothesis.

Materials and methods: The objectives were achieved by studying the *in vitro*influence of TNF, IL-1 and IL-6 on the levels of expression (by real-time PCR) and contents ofZNF334 protein (by Western blot) in the $CD4^+$ cells of healthy volunteers, both *ex vivo* and after 24–120 h of anti-CD3 stimulation *in vitro*.

Results: We have confirmed that TNF modifies the expression of ZNF334 in the CD4+ cells *ex vivo*; however, the effect varied for different individuals and reduction of expression was seen only for those cell samples that initially exhibited high transcriptional activity of the gene, while for those exhibiting initially very low expression, some increase in the transcriptive activity of the gene could be shown. On the other hand, both IL-1 and IL-6 had variable, but negligible-to-increasing effect on ZNF334 expression, never showing an inhibitory effect. The expression of ZNF334 in $CD4^+$ lymphocytes isolated after various periods of anti-CD3 stimulation was also variable, but generally increased with longer culture times, both with and without TNF treatment. Finally, incubation with TNF significantly reduced the amounts of two isoforms of ZNF334 protein in the $CD4^+$ cells of healthy volunteers.

Conclusions: Our Results: , albeit preliminary, seem to confirm the regulatory effect of TNF (and possibly also IL-1 and IL-6) on the expression and protein levels of ZNF334 zinc finger protein in healthy helper T lymphocytes and to stress that this effect varies in different individuals, at least regarding the gene expression. It is too early now to speculate what might be the meaning of our observations (other than a general remark that it might regulate the expression of as yet unknown gene(s) and that its regulatory properties would be modified in RA lymphocytes), as no specific functions for ZNF334 had been reported yet.

This work was fundedby the Polish Ministry of Science and Higher Education 'Iuventus Plus' grant IP2010 0387 70 to MSC.

CD44-deficiency delays LPS-induced acute renal injury

E. Rampanelli, G. J. D. Teske, N. Claessen, J. Leemans & S. Florquin
Pathology, Academic Medical Center, Amsterdam, Netherlands

Purpose/Objective: Sepsis is a progressive syndrome associated with a disseminated inflammatory response that leads to multiorgan failure, including acute kidney injury (AKI), which occurs in 20−50% of septic patients. CD44 is a cell-surface transmembrane glycoprotein expressed on a variety of cell types such as haematopoietic, epithelial, endothelial cells and it is upregulated in the renal cortex upon injury. CD44 plays a role in proinflammatory cytokines production, leukocytes migration and adhesion, and TLRs-signalling regulation and it forms a complex with TLR-4 and MD-2.
Materials and methods: In order to understand the role of CD44 in sepsis-induced acute kidney injury, we compared Wt and CD44 KO mice (n = 8/group), which received an intraperitoneal injection of 10 μg/g body weight of LPS. 2, 4, and 24 h after LPS injection, mice were sacrificed and both kidneys and blood were collected for analysis of kidney function, damage and inflammatory state.
Results: At 2 and 4 h after LPS injection, the plasma and renal levels of the pro-inflammatory cytokines MCP-1, TNF-α, IL-1β were lower in CD44 KO mice in respect to the Wt, and the opposite was found for the anti-inflammatory cytokines IL-10 and HGF. This was associated with decreased T cells influx in the CD44 KO kidneys. Furthermore, TLR4 gene expression in the CD44 KO kidneys was induced later and to a lesser extent than in the Wt; while the mRNA expression of the protective HO-1 (heme oxygenase-1) was higher in the CD44 KO kidneys than in the Wt. This could explain the cytokines pattern of the CD44 KO mice, as TLR4 signaling leads to secretion of pro-inflammatory molecules and HO-1 controls the balance pro-/anti-inflammatory cytokines. LPS-induced iNOS expression in renal tubules is parallel to the time course of capillary dysfunction and the iNOS levels found in the CD44 KO renal tissue remained low at 2 and 4 h compared to the Wt. This was associated with preserved renal function and decreased apoptosis rate of tubular and interstitial cells in the CD44 KO kidneys compared to Wt at 2 and 4 h.
Conclusions: In conclusion, these data suggest that the lack of CD44 protects against sepsis-induced AKI by impairing the leukocytes influx in the kidney parenchyma, the production of nitric oxide, the pro-inflammatory cytokines secretion via HO-1 induction and delayed TLR4 expression and therefore maintaining a better renal function.

Chitohexaose activates macrophages by alternate pathway through TLR4 and blocks Endotoxemia

S. K. Panda,* S. Kumar,* N. Tuperware,† T. Vaidya,† A. George,‡ V. Bal,‡ S. Rath‡ & B. Ravindran§
**Infectitious Disease Biology Laboratory, Institute of Life Sciences, Bhubaneswar Orissa, India,* †*Parasite Biology, Center for Cell and Molecular Biology, Hyderabad, India,* ‡*Immunobiology, National Institute of Immunology, NewDelhi, India,* §*Infectitious disease Biology Laboratory, Institute Of Life Sciences, Bhubaneswar, India*

Purpose/Objective: Sepsis is one of the leading causes of death contributing to half of mortality in intensive care units across the world. LPS present in the cell wall of gm-negative bacteria signals through TLR4 and activates macrophages to produce inflammatory mediators such as TNF-α, IL-1β, IL-6 etc, is a critical factor inducing endotoxemia and shock in most cases of sepsis. This study aimed to develop an antagonist to inhibit the LPS mediated inflammation and to test its efficacy in protection from endotoxic shock.
Materials and methods: Preparation of filarial extracts and labelling Bone marrow cells culture Mouse Model of Endotoxemia Isolation of human PBMCs and *in vitro* culture Quantification of Cytokines Flow Cytometry, Nitrite analysis and Arginase assay Quantitative real timePCR analysis.
Results: In this study we report that a filarial glycoprotein (AgW) binds to TLR4 of human monocytes and murine macrophages through a carbohydrate residue (i.e. chitohexaose) present in AgW. LPS mediated induction of TNF-α, IL-1β and IL-6 by macrophages/monocytes was effectively inhibited both *in vitro* and *in vivo* by AgW as well as chitohexaose. Inhibition of LPS mediated inflammation by chitohexaose appeared to be a consequence of activation of macrophages into alternate pathway by the carbohydrate. Intraperitoneal administration of chitohexaose protected mice from lethal endotoxic shock. More crucially, therapeutic administration of chitohexaose after 6, 24 or 48 h of onset of endotoxemia also protected mice from lethal endotoxic shock and death. Ex-vivo analysis of monocytes filarial parasite infected humans revealed significantly lower numbers of inflammatory monocytes in comparison to endemic controls. Futher monocytes of filarial infected individuals expressed canonical markers of alternate activation were refractory to inflammatory response when stimulated with LPS. The significance of this finding in the context of Hygiene Hypothesis will be discussed.
Conclusions: We demonstrate thatchitohexaose delicately balances the storm of inflammation induced by LPS while concurrently activating macrophages into a non inflammatory alternate pathway through TLR4. Administration of chitohexaose protected mice from endotoxemia prophylactically as well as therapeutically. The study also offered evidence for induction of two diverse activation pathways of macrophages through a single receptor, TLR4.

P1290
Epigenetic profile in lipopolysaccharide-stimulate macrophages

E. C. S. Rios, T. M. Lima-Salgado & F. G. Soriano
Clínica Médica, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Purpose/Objective: Sepsis remains a clinical challenge for the intensive care units. However, it is known that the tolerance mechanism using low doses of lipopolysaccharide (LPS) reduces the expression of proinflammatory genes and involves epigenetic regulation. The chromatin openness is regulated by Histone Acetyltransferases (HATs) and these enzymes could be modulated by Nitric Oxide (NO) interaction. In the present work, we demonstrate the pathway of tolerance to LPS from HAT activity and level of histone openness to production of cytokines as well as the influence of NO inhibition.
Materials and methods: THP1 differentiated into macrophages (with 2.5 nM PMA treatment) were cultivated in RPMI medium (Control group), submitted to tolerance (500 ng/ml of LPS 24 h before challenge with 1000 ng/ml of LPS * Tolerant group) and challenge (1000 ng/ml of LPS * D group) during 24 h. NO production was inhibited by addition of 100 μM of LNAME. The HAT activity and cytokine production (IL-6) were measured with biochemistry kits. Histone acetylated H3 and H4 were analyzed by western blotting.
Results: Tolerance reduced HAT activity compared with group directly challenged ($P < 0.05$). The H4 acetylated was maintained at basal levels in the tolerant group and increased in the D group ($P < 0.05$). However, the tolerance increases the acetylation of Histone H3 in a NO-dependent response. Similarly, the IL-6 release was reduced by induction of tolerance ($P < 0.05$ versus D). However, this effect was abolished by inhibition of NO production.
Conclusions: The induction of tolerance reduces HAT activity and cytokine production. The tolerance triggers a complex epigenetic modulation dependent of Nitric Oxide.

P1291

Epigenetic regulation of cytokine production in endotoxin tolerance and sepsis

C. Reschke,* M. Krüger,* J. Hecht,† H. D. Volk* & G. Grütz*
*Institute of Medical Immunology, Charité – University Medicine Berlin, Berlin, Germany, †Max Planck Institute for Molecular Genetics, Max Planck Society, Berlin, Germany

Purpose/Objective: One mechanism for host protection is endotoxin tolerance (ET), defined by a transient unresponsiveness to endotoxin (LPS) following a first exposure to this stimulus. While ET seems to be a protective mechanism against excessive inflammation, it plays a major role in death of sepsis patients suffering from secondary infections. In clinics, a reactivation of the immune system is necessary to overcome ET.

A recent publication suggested epigenetic modifications on histones which determine gene expression in endotoxin-tolerant murine macrophages. The aim of our study is to understand ET on the chromatin level in human monocytes and how the production of specific cytokines (e.g. IL6 and TNFα) is switched off during tolerance induction. This would give new insights in the reactivation of the immune system leading to new biomarkers or treatment strategies of sepsis patients.

Materials and methods: For induction of ET, human $CD14^+$ monocytes were desensitized with a preliminary treatment of LPS overnight followed by a second LPS challenge on day two. Subsequently, chromatin remodeling involving histone modifications was analyzed by chromatin-immunoprecipitation (ChIP).

Results: In contrast to murine macrophages, our results did not reveal differences between endotoxin responsive and endotoxin tolerant human monocytes in the methylation of histone 3 at lysine 4 (H3K4me3) – a marker for open chromatin. It was still present in the promoter regions of IL-6 and TNFα in desensitized cells. ChIP-Sequencing using an antibody directed to H3K4me3 confirmed that there are no differences in the promotor region of IL-6 and TNFα between the control group (unstimulated) and the LPS-treated group in terms of this particular modification. However, the promotor region of interleukin-1 receptor antagonist (IL1RN) and IL-1β showed an enrichment of H3K4me3 in the LPS-treated group indicating a positive feedback in transcription.

Conclusions: These results suggest that histone modifications (here H3K4me3) seem to play a role in induction of cytokine production in at least a subset of cytokines also in human monocytes. However, a combination of different ChIP assays combining positive and negative histone markers and key transcription factors (e.g. NF-κB) is necessary to understand the complex picture of induction and/or inhibition of cytokine production in ET.

P1293

Immune suppression in sepsis: is there a role of regulatory T cells?

K. Kleinfeldt,* C. Poetschke,* T. Sparwasser† & B. M. Bröker*
*Department of Immunology, Institute for Immunology and Transfusion Medicine, Greifswald, Germany, †Institute for Infection Immunology, Twincore, Hannover, Germany

Purpose/Objective: Despite progress in intensive care therapy, sepsis remains the third common cause of death in Germany. While the hyperinflammatory first phase of sepsis (SIRS) can be controlled by supportive therapies, many patients die in the subsequent hypoinflammatory phase (CARS). We are interested in CARS as it is less well described but characterized by high susceptibility to secondary infections. It is well documented that in sepsis many lymphocytes undergo apoptosis contributing to the hypoinflammatory milieu. The innate immune response is impaired as demonstrated in mice by a reduced capacity of TNF production after sepsis. Moreover, the fraction of regulatory T cells (Tregs) is increased and the cells are activated early after sepsis induction.

Materials and methods: To investigate CARS, we have immunized animals after sepsis induction (AP, acute peritonitis, CASP, colon ascendens stent peritonitis) and analyzed the antigen-specific humoral immune response. To investigate if regulatory T cells play a role in the observed immune suppression we depleted Tregs after sepsis induction and before antigen-specific priming.

Results: The antigen-specific humoral immune response was strongly impaired in septic mice, indicated by a decrease of specific antibody titres. Additionally, the affinity maturation of the produced antigen-specific IgG antibodies was reduced and the migration of specific plasma cells into the bone marrow was impaired in these mice. Moreover, also T cells were affected, indicated by a reduced antigen-specific recall response *in vitro*.

Retrospective comparison of immune suppressed and immune competent animals showed not only a more severe course of disease but also an increase of total IgG concentration in immune suppressed animals. Moreover, splenic Tregs were more activated in these mice.

Treg-depletion before priming partially restored antigen-specific humoral immune response and increased affinity maturation. Additionally, the antigen-specific T cell recall response was also re-established.

Conclusions: The results indicate a role of Tregs in immunoparalysis after sepsis. However, other regulatory mechanisms appear to be involved as the antigen-specific humoral and T cell response was not restored completely.

P1294

LPS internalization mediated by Syk signals in lung epithelial cells

H. Zhang & A. S. Slutsky
Critical Care Medicine, St. Michael's Hospital University of Toronto, Toronto, Canada

Purpose/Objective: Toll-like receptor 4 (TLR4) was identified as a receptor for lipopolysaccharide (LPS) because mouse strains with nonfunctional or deficient TLR4 are endotoxin hyporesponsive. However, clinical trials using either anti-LPS antibodies or TLR4 inhibitors failed to save patients with LPS-induced sepsis. Mechanisms other than TLR4 may be responsible for the sustained inflammatory responses induced by LPS.

Materials and methods: Human lung epithelial cells were cultured on glass chamber slides overnight, incubated with the spleen tyrosine kinase (Syk) inhibitor BAY 61-3606 for 30 min, and then stimulated with BODIPY-LPS for 4 h. Cells were fixed for F-actin staining with Rhodamin-Phalloidin. Fluorescen images were taken under a confocal microscope and analyzed by the microscopy software ZEN lite 2011. IL-8 production was measured in culture supernatant from additional experiments without cell fixation. C57BL/10ScSnJ mice (Tlr4 wild type) were anesthetized with sevofluorane and divided into three groups. (1) LPS intratracheally administered concurrently with BAY 61-3606, with a second dose of BAY 61-3606 administered 2 h later. (2) LPS intratracheal instillation administered concurrently with saline I.P. injection, followed by a second I.P. administration of saline 2 h later. (3) BAY 61-3606 administered alone at time 0 and 2 h. Mice were sacrificed 4 h after LPS instillation. Immunohistochemistry of lung histology was analyzed for LPS internalization (goat anti-LPS antibody) and colocalization with the epithelial cell marker cytokeratin 8 (mAb), followed by Alexa-conjugated anti-goat IgG and Cy3 anti-mouse IgG). The nuclei were counterstained with DAPI.

Results: We demonstrate that human lung epithelial cells do not express surface but intracellular TLR4 and these cells still produce cytokines in response to stimulation with LPS. LPS was internalized

and co-localized with F-actin by human lung epithelial cells, leading to sustained IL-8 production. The LPS internalization was attenuated by the administration of BAY 61-3606. *In vivo* conditions, the LPS internalization and cytokine production were largely attenuated in Syk deficient mice. Furthermore, the LPS-induced cytokine response is reduced by the pharmacological intervention with BAY 61-3606 *in vivo* mouse model of endotoxemia.
Conclusions: These results suggest that Syk may act as a key molecule for LPS internalization that mediates subsequent inflammatory responses through TLR4-independent mechanisms.

LPS/endotoxemia leads to an altered activation threshold and signal transduction in splenic T-cells

R. P. Requardt,* R. Markwart,* K. Schubert,* M. Förster,† M. Bauer‡ & I. Rubio§
**Center for Sepsis Control and Care, University Hospital Jena, Jena, Germany, †Internal Medicine I Pneumology, University Hospital Jena, Jena, Germany, ‡Department of Anesthesiology and Intensive Care Medicine, Center for Sepsis Control and Care, University Hospital Jena, Jena, Germany, §Center for Sepsis Control and Care & Center for Molecular Biomedicine, University Hospital Jena, Jena, Germany*

Purpose/Objective: Systemic inflammation or sepsis is a fatal condition that often literally overruns the patients« natural defense system. Following an initial burst of the innate immune system, the patients« adaptive immune system enters a protracted stage of paralysis. It is generally assumed that T-cells are compromised in their ability to fight infections in later stages of sepsis but if and how T-cell function affects sepsis outcome is still disputed. We have characterized T-cell paralysis/behaviour in LPS induced endotoxemia in an attempt to decipher the molecular mechanisms underlying this process and the role of T-cell paralysis in disease progression.
Materials and methods: Sublethal LPS doses were injected in CL57/B6 mice. Animals were continuously monitored and sacrificed 9 days after insult. CD4/CD8 positive T-cells were isolated from the spleen via automated magnetic separation and extensively characterized by FACS (phenotype, proliferation). To discern subtle changes in the sensitivity of T-cell signalling the isolated T-cells were challenged with a range of TCR-agonists including stimuli that are physiologically inert owing either to too low or too high TCR activation potency as well as physiologically active stimuli with intermediated TCR stimulation strength.
Results: Total splenic CD4/CD8 T-cell numbers were unaltered in LPS-treated mice, as were Treg ($CD4^+$, $CD25^+$, $Foxp3^+$) numbers, but there was a slight reduction of the CD4/CD8 ratio. As expected, the pattern of activation marker induction (CD25, CD69, CD137) and proliferation following *ex vivo* stimulation with the various agonists reflected the gradual increase in TCR stimulation strength of the individual cues. Importantly, only stimuli with intermediate, 'physiological' affinity for the TCR lead to expansion and proliferation of T-cells from mock-treated animals. Notably, T-cells from the LPS treated mice proliferated in response to unphysiologically 'weak' agonists and showed no signs of paralysis. This remarkable behaviour is accompanied by unconventional signalling downstream of the TCR which can, in part, explain the altered characteristics of the T-cells.
Conclusions: We propose that LPS/endotoxemia primes T-lymphocytes leading to a lower signal threshold for TCR stimulation and T-cell activation. Recapitulation of the same experimental program in *bona fide* animal models for sepsis/peritonitis is currently underway.

P1296
MyD88 is crucial for inflammation during obesity and for severity of sepsis

A. Castoldi,* V. Andrade-Oliveira,* E. J. Bassi,* C. Fávero-Aguiar,† M. T. Amano,* A. Caricilli,* P. M. Moraes-Vieira,* M. A. Cenedeze,† M. I. Hiyane* & N. O. Saraiva-Camara*
**Immunology, Instituto de Ciências Biomédicas, University of São Paulo, São Paulo, Brazil, †Medicine, Division of Nephrology, Federal University of São Paulo, São Paulo, Brazil*

Purpose/Objective: Obesity is a complex condition, affecting individuals of all ages and is characterized by a moderate state of chronic inflammation, with increased levels of several pro-inflammatory cytokines and acute phase proteins that maintain this inflammatory state. Obesity has also been shown to be a risk factor 'dose dependent' for morbidity and mortality in sepsis; although, little is known about the specific role of obesity in innate immunity activation, cellular and tissue dysfunction that are observed in sepsis. Our goal is to study the relationship between obesity and the regulation of immune response in sepsis in order to contribute for the understanding of the mechanisms involved in immune regulation of the inflammatory response of sepsis in obese individuals.
Materials and methods: We used a model of obesity induced by high fat diet in C57BL/6 and MyD88 knockout (KO) mice 60 days, and then they were submitted to sepsis by caecal ligation and puncture (CLP) with two perforations using 23G needles and sacrificed 24 h after sepsis induction.
Results: MyD88 KO mice showed higher weight gain and increased adipocyte size and reduced inflammation as compared to wild type mice. After sepsis, these mice were protected with longer survival, decreased of systemic inflammation, less macrophage infiltration in white adipose tissue and decreased gene and protein expression of pro-inflammatory molecules IL-1β, TNF-α, IL-6 and KC. In addition, we observed a significant increase in gene expression of arginase-1 and decreased of MCP1. The inflammation in these mice after sepsis appears to be reduced by a significant increase in gene expression of PPAR-γ, Glut4, LPL and FABP4, possibly by inhibiting NF-κB pathway.
Conclusions: Here, we concluded that the innate immunity mainly through MyD88 that plays an important role in obesity and inflammatory status in adipose tissue and after a severe inflammatory stimulus.

Obesity alters sepsis induced pulmonary inflammation

T. Lima-Salgado, T. P. Fungaro, R. C. Petroni, S. J. S. Oliveira, D. F. Barbeiro & F. G. Soriano
Emergency Medicine, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Purpose/Objective: Sepsis is a severe disease that represents a significant healthcare burden worldwide, while obesity has reached epidemic proportions over the last few decades. Although the mechanism is uncharted, it is known that obesity increases morbidity and mortality in sepsis through its multiple effects on many organ systems, including pulmonary function. Our aim was to investigate the effects of obesity in systemic and pulmonary inflammatory process in an experimental model of endotoxemic shock.
Materials and methods: Animals were fed a high fat diet (30% of fat) for 6 weeks and then injected with 15 mg/kg LPS i.p. They were euthanatized after 6, 24 and 48 h. Inflammation was characterized by measurement of plasma and pulmonary cytokines. The mRNA

expression of cytokines and tissue remodeling proteins was determined by real time PCR.
Results: Obesity decreased the survival rate of the animals 24 h after LPS injection. There was higher plasma concentration of IL1-beta, IL-6 and TNF-alpha in these animals. Furthermore, there was higher concentration of IL-6 in the obese mice's lungs after 6 h of endotoxemia. However, the mRNA expression of pro-inflammatory factors (IL-6, TNF-alpha, IL-1beta and MMP9) was lower, suggesting they may be converted to proteins. Obese mice presented higher mRNA expression of TGF-beta after 6 h, indicating a reparative process.
Conclusions: Obesity may be an additional complication factor in sepsis induced pulmonary inflammation.

P1299
Sepsis increases autoantibody titers in mice – antibody repertoire analysis at the single cell level

O. Nicolai,* C. Pötschke,* J. van der Linde,† C. Berek,‡ S. Maier† & B. Bröker*
**Immunology, Immunology and Transfusion Medicine, Greifswald, Germany, †Surgery General Surgery Visceral Thoracical and Vascular Surgery, Ernst Moritz Arndt University, Greifswald, Germany, ‡Institut der Leibniz Gemeinschaft, Deutsches Rheuma Forschungszentrum, Berlin, Germany*

Purpose/Objective: Sepsis is associated with immunosuppression due to lymphocyte apoptosis. Especially $CD4^+$ T cell-, B cell- and dendritic cell numbers decrease dramatically. Interestingly, in our polymicrobial sepsis model (Colon ascendens stent peritonitis, CASP) there is a strong increase in serum IgM and, a few days later, of IgG concentrations that reach maximal values 14 days after sepsis induction. Here, we investigated the specificity of the antibody response.
Materials and methods: For this, sera of septic mice were tested for IgM and IgG bindingto bacterial, foreign and self-antigens. Futhermore, splenocytes of septic mice were fused with myeloma cells to generate monoclonal B cell hybridomas. The resulting monoclonal antibodies were tested for binding to HEp-2 cells by immunofluorescence microscopy (a diagnostic tool for autoantibody screening) and for binding to a panel of bacterial, foreign and self-antigens (ELISA). In addition, immunoglobulin (Ig)-genes were sequenced to determine (1) whether the hybridomas were really monoclonal, (2) the usage of Ig-gene segments and (3) the frequency of somatic hypermutations.
Results: In serum we found autoreactive antibodies as well as antibodies directed against antigens (e.g. TNP, OVA) that mice had never been in contact with. Because it is impossible to discriminate between a polyclonal response and polyreactive antibodies in serum, monoclonal hybridomas of splenic B-cells were generated. These cells produced a large variety of autoreactive IgM and fewer autoreactive IgG. ELISA showed polyreactive IgM for the tested antigens. No antibodies with a unique specificity for any of the tested bacterial antigens were found. Sequencing revealed germ line or near germ line Ig-sequences for IgM and IgG.
Conclusions: We conclude, that sepsis activates B cells, which mostly produce polyreactive IgM binding to bacterial, self and foreign antigens. These data raise the question to which degree the humoral immune response in peritoneal sepsis is driven by specific antigen recognition (BCR) or by polyclonal stimuli (PRR), and which B cell subsets get activated.

P1302
Vav1 guards against excessive acute macrophage immune response in experimental septic shock and peritonitis

S. Zenker,* S. Wirtz,* M. Waldner,* T. Kishimoto,† M. F. Neurath* & I. Atreya*
**Department of Intestinal Medicine 1, Medical Clinic, University of Erlangen-Nuremberg, Erlangen, Germany, †Immunology Frontier Research Center, Osaka University, Suita City, Japan*

Purpose/Objective: Overwhelming immune responses mediated by activated macrophages (MΦ) play a key role in acute inflammations and septic shock. Vav1, a family member of RhoGEFs, is mainly expressed in hematopoetic cells and exhibit scaffold protein function, GEF activity and participates in transcriptional active complexes. Furthermore, compared to the well characterized function of Vav1 in T cells, Vav1 mediates migration and cytoskeleton reorganization of MΦ. However, the capacity of Vav1 to influence early MΦ activity in the context of sepsis and acute inflammation has not been investigated extensively.
Materials and methods: In order to characterize Vav1 in MΦ, we analyzed $Vav1^{-/-}$ mice in LPS induced septic shock. ELISA, ChIP, Co-Immunoprecipitation and FACS analysis were used to specify behavior of *in vivo* or *in vitro* LPS stimulated peritoneal $CD11b^+$ $Vav1^{-/-}$ MΦ.
Results: Unexpectedly, in LPS induced septic shock Vav1 deficiency resulted in increased susceptibility and $Vav1^{-/-}$ mice could be characterized by increased systemic levels of IL-6. FACS analysis of whole blood and peritoneal lavage confirmed MΦ as source of IL-6. In accordance with our *in vivo* data, *in vitro* LPS stimulated peritoneal $CD11b^+$ $Vav1^{-/-}$ MΦ secreted significantly more IL-6 than WT MΦ, while in the same setting TNF-α secretion was not markedly affected. LPS/Actinomycin D treatment of WT- and $Vav1^{-/-}$ MΦ emphasized that Vav1 modulated IL-6 release on a transcriptional level. Our data excluded classical IL-6 regulation factors, like NFκB, as source of enhanced IL-6 secretion in $Vav1^{-/-}$ MΦ. Interestingly, Vav1 was located in the cytoplasm as well as in nuclei of MΦ and showed an association with HSF1 and the IL-6 promoter. Using a mutated IL-6 promoter construct, we were able to stress the functional relevance of Vav1/HSF1 association and DNA interaction for regulation of IL-6 expression.
Conclusions: Vav1 emerges as a crucial regulator protein of the early state of peritonitis and thus sepsis via dampening LPS induced IL-6 expression in MΦ. Strengthening of Vav1 signalling in the innate immune system might therefore represent an effective tool to regulate overwhelming IL-6 secretion in the context of septic peritonitis.

A 24 h-HBHA-specific interferon-gamma release assay for the detection of latent tuberculosis

C. Wyndham-Thomas,* V. Corbière,* V. Dirix,* K. Smits,* M. Libin,* S. Vanderseypen,* M. Loyen,† C. Locht† & F. Mascart‡
*Laboratory of Vaccinology and Mucosal Immunity (LoVMI), Université Libre de Bruxelles (ULB), Brussels, Belgium, †INSERM, U1019, Lille, France, ‡Laboratory of Vaccinology and Mucosal Immunity (LoVMI), Immunobiology Clinic of the Erasme Hospital, Université Libre de Bruxelles (ULB), Brussels, Belgium

Purpose/Objective: Treatment of latent tuberculosis infection (LTBI) in target populations is one of the current WHO strategies to prevent active tuberculosis (TB) and reduce the *Mycobacterium tuberculosis (Mtb)* reservoir. Powerful LTBI screening tools are therefore indispensable. An interferon-gamma release assay (IGRA) in response to 4 day stimulation by the latency antigen Heparin-binding haemagglutinin (HBHA) has proven its potential. Adapting this assay for routine laboratory testing is essential. We evaluated its possible optimization through reduction of incubation time and the addition of co-stimulatory cytokine IL-7. These upgrades were analyzed in terms of immunological response and efficacy.
Materials and methods: A total of 95 patients were recruited from three Brussels based university hospitals, and divided into LTBI patients (defined according to CDC tuberculin-skin test guidelines), TB patients, healthy controls and patients with undetermined *Mtb* infection status. HBHA-specific IGRAs, with the classical 4 day stimulation and a 24 h stimulation with concomitant IL-7, were performed simultaneously on peripheral blood mononuclear cells isolated from participants' blood samples.
Results: Optimal IL-7 dosage, determined by dose-response curves, was 1 ng/ml. Correlation between the classical 4 day assay and the 24 h/IL-7 assay was high. Phenotypes of IFN-γ producing cells are currently being investigated through flow cytometry.
Conclusions: A 24 h/IL-7 interferon gamma release assay in response to HBHA is a promising candidate for the detection of latent tuberculosis. Greater numbers of LTBI and TB patients are presently being recruited to achieve statistically significant numbers and establish discriminatory IFN-γ concentration cut-offs between LTBI, TB and healthy controls.

A role for macrophage arginase-1 expression in immunopathology in tuberculosis granulomas

M. Duque,* P. Rodriguez,† K. C. Faé,* U. Zedler,* S. Schommer-Leitner,* P. J. Murray,‡ S. H. E. Kaufmann* & S. T. Reece*
*Immunology, Max Planck Institute for Infection Biology, Berlin, Germany, †Microbiology, Louisiana State University, New Orleans, LA, USA, ‡Immunology, St. Jude Children's Research Hospital, Infectious Diseases, Memphis, TN, USA

Purpose/Objective: Granulomas in the lung are organized aggregates of immune cells and the hallmark of human tuberculosis (TB). These aggregates contain mainly non-infected and *Mycobacterium tuberculosis (Mtb)*-infected macrophages as well as *Mtb*-specific T cells. *Mtb* can persist within macrophages in granulomas due to insufficiencies of macrophage anti-microbial mechanisms. One such mechanism, the production of nitric oxide (NO) by nitric oxide synthase-2 (NOS2) via L-arginine and oxygen (O_2) is thought to be suboptimal in hypoxic regions in granulomas. Arginase-1 (Arg-1) also metabolizes L-arginine but does not require O_2 as a substrate and can thus function in hypoxic conditions. Arg-1 can act as a suppressor of acquired immune responses by depriving proximal T cells of L-arginine. We investigated the role of Arg-1 in tuberculosis pathogenesis using a murine model of granuloma formation.
Materials and methods: $NOS2^{-/-}$ C57BL6 mice, but not WT mice, develop lung granulomas similar to humans on *Mtb*- dermal infection and temporary blocking of IFN-γ. Using this model, we evaluated the role of Arg-1 in immunopathology in TB granulomas by flow cytometry analysis, histopathology, western blot, HLPC, enzymatic activity assay, measurement of local cytokine and chemokine production and quantification of bacterial burden.
Results: We found Arg-1-expressing cells in potentially hypoxic regions of lung TB granulomas in humans and non-human primates. Macrophages expressing Arg-1 were analogously present in human like-hypoxic TB granulomas in the lungs of $NOS2^{-/-}$ mice. Expression and activity of Arg-1 in this model correlated with decreased L-arginine and increased L-ornithine, spermidine and putrescine levels in the lung. Decreased expression of Ki-67 by T cells in hypoxic regions of granulomas indicated inhibition of T cell activation and proliferation in these locations. Furthermore, reduced IL-2 and elevated IL-10 production by lung cells in response to ESAT-6 stimulation support a micro-environment of T cell suppression.
Conclusions: These and preliminary data suggests that macrophages expressing Arg-1 modulate immunopathology and tissue destruction in TB granulomas by dampening T cell activity in hypoxic regions.

P1305

A two-compartment system allows lymphatic tissues to control *M. tuberculosis* infection in the peripheral organs

C. Vilaplana,* C. Prats,† E. Marzo,* C. Barril,† I. Llopis,* J. Diaz,* Q. Valls,† D. L. Codina† & P. J. Cardona*
*UTE (Experimental Tuberculosis Unit), Fund Institut Germans Trias i Pujol-Universitat Autònoma de Barcelona-CIBERES, Badalona, Spain, †MOSIMBIO Group, Universitat Politecnica de Catalunya, Castelldefels, Spain

Purpose/Objective: There is a paradox in the low dose aerosol model of experimental murine model of TB. At week 3, the bacillary load (BL) growth is controlled in lungs, but still grows in spleen, where the immune response is thought to be triggered. A '2-compartment' hypothesis has been raised, in which lymphoid tissues infection shall take place in a compartment, 'previous' to where the specific lymphocytes are generated. This proliferation shall not protect their origin organs: for being released to the efferent vessels, the lymphocytes are attracted in those organs with a more intense inflammatory response, thus where the BL is higher. Only when the BL is controlled and the attraction capacity is reduced, the lymphocytes will come back to the infected compartment of the origin organs to control the BL.
Materials and methods: 6-weeks old female C57BL/6 mice were infected via aerosol (aer) with 20–50 bacilli using a Middlebrook device or ev (10^2, 10^4, 10^5 CFU/ml with *M. tuberculosis* H37Rv Pasteur strain. The animals were sacrificed at sequential timepoints: aer experiment (exp) everyday from day 10 to 22 post infection (pi); ev exp at days 0 and 2, 5, 8, 11, 14, 17, 20, 28 and 42 pi. The BL and specific immune responses were measured in lungs, spleens and lymph nodes, by culturing them in 7H11 agar plates and ELISPOT assays, respectively. An 'in silico' model was designed considering the generation and life of lymphocytes, the immune response and BL in tissue, and the flows among lymph and blood vessels of the 3 organs.
Results: The use of the highest infective dose ev (10^5 CFU) demonstrated 5 days is the elapse time needed to trigger the proliferation of effector lymphocytes in spleen, while the other experiments suggested the presence of a BL threshold around 10^3 CFUs in tissue needed to be overcome. The experiments confirmed that even when the lymphatic tissues are able to generate specific lymphocytes, the BL can still grow

there at the same time. Integration of this data in a mathematical model explains this paradox after considering the dynamics of fluxes among the three organs.

Conclusions: The results confirm the original hypothesis of the two compartment system in lymphatic tissues, which prioritizes the control of the infection in lungs and avoids the self-resolution of their own infection processes which would leave non-lymphatic organs defenseless.

P1306

Apoptosis and TNF receptor expression in alveolar macrophages during *Mycobacterium bovis* infection in mice

H. C. Teixeira, M. F. Rodrigues, B. B. F. Figueiredo, A. B. Rezende, C. C. S. Alves & A. P. Ferreira

Department of Parasitology Microbiology and Immunology, Federal University of Juiz de Fora, Juiz de Fora, Brazil

Purpose/Objective: Apoptosis of infected macrophages has been reported as an effective host strategy to control the growth of intracellular pathogens, including pathogenic mycobacteria. TNF-α may play an important role in the modulation of apoptosis of infected macrophages. TNF-α exerts its biological activities via two distinct cell surface receptors, the 55-kDa receptor (TNF-R1) and the 75-kDa receptor (TNF-R2) whose extracellular domain can be released by proteolysis forming soluble TNF receptors (sTNFR-1 and sTNFR-2). The signaling through TNF-R1 initiates the majority of the biological functions of TNF-α, leading to either cell death or survival whereas TNF-R2 mediates primarily survival signals. In the present work, the expression of TNF-α receptors and the apoptosis of alveolar macrophages were investigated during infection with virulent and avirulent mycobacteria in mice.

Materials and methods: C57BL/6 mice were intratracheally infected with avirulent (BCG Moreau) and virulent (ATCC19274) strains of *M. bovis*. Mice were killed 3 and 7 days after infection and lung cells obtained by *Bronchoalveolar* lavage (BAL). Alveolar macrophages were differentiated according to their CD11b/CD11c profiles and apoptosis was assessed by flow cytometry using Annexin V-FITC/PI labeling. Cell surface TNFR1 and TNFR2 were studied using FITC-conjugated anti-mouse CD120a (TNFR1) and PE-conjugated anti-mouse CD120b (TNFR2). Levels of soluble TNF receptors (sTNF-R1 and sTNFR2) in BAL were measured by ELISA.

Results: A significant increase of apoptosis and high expression of TNFR1 were observed in alveolar macrophages at 3 and 7 days after infection with *M. bovis* BCG but only on day 7 in mice infected with the virulent *M. bovis*. Low surface expression of TNFR1 and increased levels of sTNFR1 on day 3 after infection by the virulent strain were associated with reduced rates of apoptotic macrophages. TNFR2 expression was lower on days 3 and 7, which was accompanied by increased levels of sTNFR2 in mice infected with both strains of *M. bovis*.

Conclusions: These results suggest a potential role for TNFR1 in mycobacteria induced alveolar macrophage apoptosis *in vivo* in a strain dependent manner.

Financial support: FAPEMIG (CBB PPM 0216/10) and CNPq (305941/2007-7), Brazil.

BCG vaccination inducing long-term protection against *Mycobacterium tuberculosis* correlates with the differentiation of IL-17/IL-2/TNF producing T cells

A. Cruz,* J. Carmona,* A. G. Fraga,* C. Sousa,* D. Pereira,* P. Costa,* F. Rodrigues,* R. Appelberg,† M. Correia-Neves,* A. M. Cooper,‡ M. Saraiva,* J. Pedrosa* & A. G. Castro*

**Microbiology and Infection Research Domain, Life and Health Sciences Research Institute (ICVS), University of Minho ICVS/3B's – PT Government Associate Laboratory Braga/Guimarães Portugal, Braga, Portugal, †IBMC, Microbiology and Immunology of Infection, Porto, Portugal, ‡Trudeau Institute, Trudeau Intitute, Saranac Lake, NY, USA*

Purpose/Objective: Tuberculosis is responsible for approximately 2 million deaths each year. *Mycobacterium bovis* BCG is the only available vaccine to prevent Tuberculosis. The re-emergence of the disease, as well as the appearance of high rates of multidrug resistant strains, makes the development of novel vaccines imperative.

It is documented that the differentiation of polyfunctional Th1 cells, namely those producing IFN-g/IL-2/TNF, or IL-2/TNF, are of utmost importance in the control of *M. tuberculosis* infection. However, recently a new T cell population, producing IL-17 (Th17) has also been reported to play a role in both primary and secondary immune responses to *M. tuberculosis* infection.

Materials and methods: To dissect further the role of Th17 cells in vaccination, C57BL/6 mice were vaccinated with BCG for 21 or 120 days prior to *M. tuberculosis* intranasal infection. At different days post-infection, the number of ESAT-6 and Ag85-specific T cells producing IFN-g or IL-17 was measured by ELISPOT and the frequency of IFN-g, IL-2, TNF and IL-17 producing T cells was analysed by flow cytometry.

Results: Our results show that protection was associated with a reduction in the number of both Th1 and Th17 cells specific for Ag85 or ESAT-6, as compared to non-vaccinated mice. Moreover, the differentiation of Ag85 specific effector/memory $CD4^+$ T cells, induced by BCG vaccination, influenced the primary response to ESAT-6, from *M. tuberculosis*.

In addition, our results show that although the frequency of the IFN-g/IL-2/TNF producing T cells was increased early after infection in both vaccinated and unvaccinated mice, a sustained increase in the frequency of polyfunctional T cells producing IL-17/IL-2/TNF was only seen in mice vaccinated with BCG 120 days prior to infection.

Conclusions: These data suggest that the period between vaccination and challenge can impact the longevity and type of the polyfunctional response, with influence in the level of protection.

Correlates of immune protection in *Mycobacterium tuberculosis*

R. Metcalf,* S. A. Clark,* C. Graeme,* M. Loebinger† & P. Kelleher*

**Immunology, Imperial College London, London, UK, †Respiratory Medicine, Chelsea and Westminster NHS Foundation Trust, London, UK*

Purpose/Objective: Current T cell based interferon-gamma release assays (IGRA) to detect TB antigen specific responses cannot distinguish between active and latent TB infection. In addition, more robust biomarkers of active TB are needed in immune-compromised populations such as those with HIV/TB co-infection. Our lab has recently shown that Th1Th17 CD4 T cells are significantly reduced in HIV-1 infected patients. Also, IFN-γ and IL-2 PPD responses are significantly reduced in ART naïve patients but are partially restored with successful ART. Therefore, we sought to determine whether the loss of Th1Th17

CD4 T cells and reduced cytokine responses were also found inpatients with TB infection, with the aim of identifying potential biomarkers to distinguish active and latent TB.

Materials and methods: Study participants comprised of healthy controls ($n = 12$), active tuberculsosis (ATB) ($n = 10$), latent tuberculosis (LTB) ($n = 10$), HIV-1 patients with ATB (HIV/ATB) ($n = 10$), and LTB (HIV/LTB) ($n = 7$). Whole venous blood was used to look at CD4 T cell subsets (Th1, Th2, Th17, Th1Th17, and memory) via flow cytometry. ELISPOT (Gen-probe) was used to measure IFN-g and IL-2 cytokine responses to PPD, ESTAT-6 and CFP-10.

Results: We found no significant differences in the proportion of TH1, Th2, TH17 or Th1Th17 cells between patients with ATB and LTB for both HIV-1 positive and negative individuals. CD4 T cell expression of CXCR3 was increased in HIV/ATB patients compared to HIV/LTB (media $n = 46.2\%$ versus 35.0%) ($P < 0.05$).

ELISPOT analysis showed that there were no differences in IFN-g or IL-2response to ESTAT-6, CFP-10 or PPD for ATB/HIV patients compared to HIV/LTB. In contrast, among HIV negative individuals, LTB patients had significantly increased IFN-g (media $n = 388$ versus 50 SFC/10^6 PBMCs) responses to ESTAT-6 compared with ATB patients ($P < 0.01$). Patients with LTB had consistently higher cytokine responses compared to HIV/LTB co-infected patients. Median IFN-g responses to ESTAT-6 were 388 versus 13 and CFP-10 were 930 versus 16 SFC/10^6 PBMCs ($P < 0.01$). Median IL-2 responses to ESTAT-6 were 291 versus 18 andCFP-10 were 304 versus 4 SFC/10^6 PBMCs ($P < 0.01$).

Conclusions: Preliminary data suggest that ESTAT-6 ELISPOT counts of IFN-g responses may enablethe distinction between active and latent TB in HIV-1 negative individuals.

P1310

M2 macrophages and LTB_4 are factors associated with the lower lung *Mycobacterium tuberculosis* counts in the infected and allergic mice

A. Piñeroz,* L. Campos,* A. F. Gembre,* T. Bertolini,* R. Prado,* S. Ramos,† D. Fonseca* & V. Bonato*

**Biochemistry and Immunology, FMRP-USP, Ribeirão Preto São Paulo, Brazil, †Pathology, FMRP-USP, Ribeirão Preto São Paulo, Brazil*

Purpose/Objective: Epidemiological data show that the incidence of allergic response is lower in Tuberculosis Skin Test positive individuals. However, Th2 immune response, characteristic of allergy, may down modulate the protection mediated by Th1 cellular immune response in tuberculosis (TB).

Materials and methods: In attempt to study how it would be the outcome of the allergic response in the *Mycobacterium tuberculosis* infection, we sensitized and challenged BALB/c mice with Ovalbumin (OVA) after 30 days of intra-tracheal *M. tuberculosis* infection.

Results: Infected, allergic mice (TB/OVA group) presented bacterial load significantly lower than infected mice (TB group) 54 and 80 days post-infection. Because the decrease in the bacterial load was not dependent on IFN-gamma and IL-17 secretion or alum adjuvant, we hypothesized that this phenomenon was dependent on leukotrienes production, that play a role in TB and asthma. There was a significant higher secretion of LTB_4 between TB/OVA and TB groups. Treatment with MK-886 compound, which inhibits the 5-Lipoxygenase pathway, abolished the reduction of CFU counts, previously observed when compared to respective non-treated groups. A histological analysis showed a reduction in cell influx in the lung granuloma areas of TB/OVA mice. Because foamy macrophages are predominant leukocytes in the TB granuloma, we evaluated populations of M1 and M2 macrophages. There was a significant increase in the transcription of genes associated with the M2 phenotype in the lungs of TB/OVA group compared to TB group.

Conclusions: Therefore, the reduction in the lung CFU counts of infected and allergen sensitized mice appears to be dependent on LTB_4 and M2 macrophage. Further experiments are undergoing to depict the biological meaning of these findings.

P1311

Macrophage bioenergetics is differentially regulated by *M. tuberculosis* virulence factors

F. J. Sanchez-Garcia,* A. Garedew,† C. Espitia,‡ N. Frakich† & S. Moncada†

**Inmunologia, Escuela Nacional de Ciencias Biologicas-Instituto Politecnico Nacional, Mexico City, Mexico, †Pharmacology, Wolfson Institute for Biomedical Research-UCL, London, UK, ‡Immunology, Instituto de Investigaciones Biomedicas-UNAM, Mexico City, Mexico*

Purpose/Objective: To analyse the bioenergetic consequences of macrophage stimulation with different *M. tuberculosis* proteins, regarded as posible virulence factors.

Materials and methods: J774 cells were stimulated with *M. tuberculosis* recombinant proteins p27, PE_PGRS1, PE_PGR33, and MT_1866 or left untreated. Nitric Oxide (NO) and ATP synthesis, glycolysis (lactate production), mitochondrial respiration, and mitochondrial dynamics were evaluated at different time points post-stimulation.

Results: p27 and PE_PGRS1 induced NO synthesis, diminished mitochondrial respiration and enhanced glycolysis. In contrast, PE_PGRS33 failed to induce NO production and glycolysis but increased mitochondrial respiration. MT_1866 induced NO production and glycolysis only slightly. PE_PGRS33 induced hyperfusion of mitochondrial networks by 4 h post-stimulation, whereas P27 induced mitochondrial fragmentation. These mitochondrial dynamics correlated with the rate of oxygen consumption.

Conclusions: Results suggest that different virulence factors from the same pathogen (*M. tuberculosis*) have different and seemingly opposing effects on the bioenergetics of the host cell; the interplay of these actions could ultimately determine the outcome of host-pathogen interactions.

P1312

MMP-10 is increased in respiratory secretions in pulmonary TB and is specifically upregulated by pathogenic Mtb in human macrophages

T. Sathyamoorthy, L. Stuttaford, S. Singh, N. Walker, P. Elkington & J. S. Friedland

Infectious Diseases and Immunity, Imperial College London, London, UK

Purpose/Objective: Morbidity in *Mycobacterium tuberculosis* (*Mtb*) infection results from pulmonary matrix destruction. Matrix metalloproteinases (MMPs) degrade all lung extracellular matrix components and are implicated in tissue destruction in tuberculosis (TB). MMP-10 is a stromelysin which can activate the collagenases, MMPs -1, -8, -13. Therefore we hypothesise that MMP-10 has a critical role in immunopathology in human tuberculosis. We investigated MMP-10 concentrations in patients with pulmonary TB and MMP-10 regulation in a cellular model of *Mtb* infection.

Materials and methods: MMP-10 in induced sputum and bronchoalveolar lavage fluid (BALF) of patients with TB ($n = 38$) and controls ($n = 35$) was measured by Luminex bead array. Human macrophages (MDMs) were infected with live virulent H37Rv *Mtb* or attenuated vaccine Bacillus Calmette-Gu*rin (BCG). p38/ERK MAP kinase and Pi3 kinase signalling pathways were inhibited chemically with SB203580, PD98059 and LY294002 respectively. MMP-10 and TNF alpha secretion was measured by ELISA and MMP-10 mRNA by RT-PCR.

Results: The median level of MMP-10 in sputum/BALF of TB patients was 5173 pcg/ml (interquartile range 883−13286 pcg/ml) compared to

2217 pcg/ml (interquartile range 528–4940 pcg/ml) in controls ($P = 0.01$). *Mtb* upregulates MMP-10 gene expression and secretion from MDMs 14-fold relative to uninfected cells ($P < 0.005$) in a dose and time dependent manner. Inhibition of the p38 and ERK MAPK signalling pathways suppresses *Mtb* driven MMP-10 secretion in a dose dependent manner ($P < 0.005$ for each inhibitor), due to suppressed mRNA synthesis. Inhibition of the Pi3 kinase pathway has no effect on *Mtb* driven MMP-10 secretion. *Mtb* driven upregulation of MMP-10 secretion from MDMs is 3.5-fold greater than that by BCG ($P < 0.005$) and is secondary to reduced mRNA accumulation. In contrast, TNF alpha secretion by *Mtb* and BCG infected cells is equal.

Conclusions: MMP-10 concentration is increased in the respiratory secretions of patients with active pulmonary TB. Live virulent *Mtb* but not attenuated vaccine strain BCG specifically upregulates MMP-10, although both upregulate TNF alpha secretion equally. *Mtb* driven MMP-10 secretion is under the control of the p38 and ERK MAP kinase pathways. To our knowledge, these are the first data implicating MMP-10 in tissue destruction in pulmonary TB.

P1313

Mycobacterium tuberculosis strains are differentially recognized by TLRs with an impact on innate immune responses and the outcome of infection

J. Carmona,* A. Cruz,* C. Sousa,* N. Osorio,* A. L. Saraiva,† S. Svenson,‡ G. Kallenius,‡ J. Pedrosa,* F. Rodrigues,* A. G. Castro* & M. Saraiva*

**Microbiology and Infection Research Domain, Life and Health Sciences Research Institute (ICVS), University of Minho ICVS/3B's – PT Government Associate Laboratory Braga/Guimarães Portugal, Braga, Portugal, †EUVG – Escola Universitária Vasco da Gama Coimbra Portugal, Escola Universitária Vasco da Gama, Coimbra, Portugal, ‡Department of Clinical Science and Education, Karolinska Institutet Södersjukhuset, Stockholm, Sweden*

Purpose/Objective: Tuberculosis (TB) is characterized by a wide spectrum of disease outcomes. The Beijing (Bj) family of *Mycobacterium tuberculosis* (Mtb) strains is suggested to be more virulent than other Mtb genotypes and prone to elicit non-protective immune responses. Highly heterogeneous immune responses were reported upon infection of innate immune cells with Bj strains, but the molecular mechanisms underlying this heterogeneity are largely unknown. With this study, we aimed at investigating whether differential recognition of Mtb strains by toll-like receptors (TLRs) contributes to distinct innate immune responses with an impact on the outcome of infection.

Materials and methods: Bone marrow-derived macrophages generated from wild-type, TLR2 deficient or TLR4 deficient mice were infected with a panel of Mtb strains. At specific time-points post-infection the cytokine response was measured at the mRNA and protein levesl, by qPCR and ELISA respectively. Activation of specific signaling cascades was also assessed by Western Blot. Experimental infections were performed intra-nasally and the progression of infection measured by colony forming units counting, lung mRNA expression of specific genes and lung histology.

Results: We found Mtb strains that preferentially activate TLR2, and others that activate TLR4. This differential recognition is not unique to the Bj family, as we also found it within the Euro-American lineage of Mtb. Recognition of Mtb strains by TLR4 resulted in a distinct cytokine profile *in vitro* and *in vivo*, with specific production of Type I IFN. We also uncovered a novel protective role for TLR4 *in vivo* when infecting with TLR4 activating Bj Mtb strains.

Conclusions: Our findings provide the first molecular basis in host innate immune cells to, at least in part, explain the heterogeneity of responses to Mtb strains.

P1314

Mycobacterium tuberculosis-specific CD8 T cells are functionally and phenotypically different between latent infection and active disease

V. Rozot,* S. Vigano,* J. Mazza-Stalder,† M. Perreau,* D. Goletti,‡ P. A. Bart,* L. Nicod,† G. Pantaleo* & A. Harari*

**Division of Immunology and Allergy, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, †Division of Pneumology, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, ‡Department of Epidemiology and preclinical Research, National Institute for Infectious Diseases, Rome, Italy*

Purpose/Objective: Tuberculosis (TB) is the second worldwide leading cause of death from an infectious disease after HIV infection. Protective immunity to *Mycobacterium tuberculosis* (*Mtb*) remains poorly understood and the role of *Mtb*-specific CD8 T-cells is controversial. We performed comprehensive functional and phenotypic characterizations of *Mtb*-specific CD8 T-cell responses in 273 subjects with either latent *Mtb* infection (LTBI) or active TB disease (TB) to assess their profile and relevance in TB.

Materials and methods: Using multi-parametric flow cytometry, we assessed *Mtb*-specific CD8 T-cell functional (production of IFN-gamma, IL-2 and TNF-alpha; proliferation capacity and cytotoxicity) and phenotypic (T-cell differentiation and exhaustion) profiles in cells isolated from peripheral blood and correlated these profiles with distinct clinical presentations.

Results: *Mtb*-specific CD8 T-cells were detected in most TB patients and few LTBI subjects (65% and 15%, respectively; $P < 0.00001$) and were of similar magnitude with a comparable cytokines profile (IFNg+TNFa+IL2-) in both groups. *Mtb*-specific CD8 T-cells were mostly T_{EMRA} (CD45RA$^+$ CCR7-) co-expressing 2B4 and CD160 in LTBI subjects and mostly T_{EM} (CD45RA-CCR7-) lacking PD-1/CD160/2B4 in TB patients. Furthermore, *Mtb*-specific CD8 T-cells mostly expressed very little perforin and granulysin but contained granzymes A and B or lacked all these cytotoxic markers in TB and LTBI subjects, respectively. However, *in vitro* expanded *Mtb*-specific CD8 T-cells acquired perforin, granulysin and granzymes. Finally, *Mtb*-specific CD8 T-cell responses were more robust and prone to proliferate in patients with extrapulmonary compared to pulmonary TB.

Conclusions: The clinical status and TB presentation are associated to specific profiles of *Mtb*-specific CD8 T-cell responses, thus indicating distinct dynamics between the mycobacteria, the CD8 T-cell response and the clinical outcome. Our data shed light on the controversial reached by studies performed in human and animal models, thus advancing the current knowledge on the complex dynamic of TB immunity.

P1315

Phagosome maturation induces the activation of NALP3 inflammasome which enhances the immunogenicity of BCG

D. Mohanan,* T. Kündig,* P. Sander,† E. Böttger† & P. Johansen*

**Department of Dermatology, University Hospital of Zurich, Zurich, Switzerland, †Insitiute for Meidcal Microbiology, University of Zurich, Zurich, Switzerland*

Purpose/Objective: Since *Mycobacterium bovis* Bacille Calmette-Gu*rin (BCG) is poorly efficient against TB, we have developed a mutant BCG with potentially stronger immunogenicity than wild-type BCG.

Materials and methods: Wild-type *M. bovis* BCG and deletion mutant deficient in the zinc-metalloprotease 1 (D*zmp1*) were grown in 7H9 broth. Bone-marrow dendritic cells (BMDCs) were cultured from femurs of mice as previously described. For *in-vitro* studies, BMDCs were infected with BCG of both strains overnight. In part, inflamma-

some inhibitors were added 30 min before addition of BCG to the BMDCs. For *in vivo* studies, 2×10^6 CFU for subcutaneous (s.c) immunisations and 10^5 CFU for intraperitoneal (i.p) infection were used. Twelve days (DM1) after s.c immunisations, mice were sacrificed and splenocytes restimulated. Analysis of restimulation was done by FACS and ELISA. Forty-eight hours after i.p infection, flow cytometric characterisation of cells within the peritoneal lavage was done.

Results: We found that the activation of the inflammasomes, was stronger in the *zmp1*-deficient strain. BCGD*zmp1* facilitated secretion of IL-1b from BMDCs was dependent on the NALP3 inflammasome. The inflammasome activation was dependent on cathepsin B while ROS played a minor role. Neutrophils have been suggested to affect specific T-cell responses against BCG and the recruitment of neutrophils is regulated by the inflammasome. In mice infected i.p. with BCG and BCGD*zmp1*, we indeed found that the *zmp1*-deficient strain had higher numbers of neutrophils in the peritoneal lavage. Moreover, animals that were s.c. immunised with BCGD*zmp1* had higher frequencies of IFNg-producing CD4 and CD8 T cells when compared to mice immunised with wild-type BCG. Also, re-stimulation of splenocytes *in vitro* showed increased antigen-specific IL-17 secretion in cells from mice immunised with BCG*zmp1*. When caspase-1-deficient mice were immunised, the increased Th1 and Th17 immune responses seen in wild-type mice were dampened further supporting that the presence of Zmp1 in BCG prevents efficient immune responses through inactivation of inflammasome.

Conclusions: By inhibiting inflammasome activation, BCG was unable to be an efficient vaccine against TB. We have clearly shown that with increased inflammasome activation we were able to induce better memory T cell response.

P1318

Relationship of IL-10 gene polymorphism (-1082A/G) with cytokine production and tuberculosis (TB) suceptibility in Polish population

M. Druszczynska,*M. Wlodarczyk,* M. Slomczynska,* B. Janiszewska-Drobinska,† P. Trzepinski* & W. Rudnicka*

**Department of Immunology and Infectious Biology, University of Lodz, Lodz, Poland, †Department of Tuberculosis Treatment, Center Hospital for Tuberculosis Lung Diseases and Rehabilitation, Tuszyn, Poland*

Purpose/Objective: Several genes coding for different cytokines may affect complex interaction between *M. tuberculosis* and host immune system. The aim of this study was to investigate the relationship of the single base change polymorphic variants identified in the promoter region of interleukin-10 gene (-1082 A/G) with cytokine production in whole blood cultures and TB susceptibility.

Materials and methods: We studied a Polish population of 191 volunteers including 32 patients with culture-proven pulmonary TB, 41 patients with non-mycobacterial lung diseases (non-TB), 71 healthy close TB contacts and 47 healthy control subjects. The QuantiFERON-TB Gold In Tube (QFT) assay was performed for all participants. Genotype frequencies for IL-10 (-1082G/A) polymorphism were analyzed using allele specific PCR method. The levels of IL-10 in whole blood cultures stimulated with mycobacterial antigens (PPD, ESAT-6, *M. bovis* BCG and *M. tuberculosis* $H_{37}R_v$ bacilli) were tested by ELISA.

Results: The frequency of latent *M. tuberculosis* infections was significantly increased among TB contacts (46%) as compared with non-TB patients (20%) and healthy volunteers unexposed to TB (13%). The distribution of the IL-10 genotypes (A/A, A/G and G/G) was similar in all groups being under the study. The 31% TB patients, 37% non-TB patients and 29% healthy controls were A/A homozygous. However, A/A homozygosity was found more frequently in QFT (+) than QFT(-) TB contacts (47% versus 10%, respectively).

The association between stimulated with mycobacterial antigens IL-10 levels and *IL-10* promoter polymorphism was noticed for neither healthy groups nor patients, however we observed significantly higher concentrations of the cytokine in cultures of blood from TB patients compared with healthy control subjects.

Conclusions: We conclude that polymorphic variants of *IL-10* gene may have possible impact on susceptibility to *M. tuberculosis* infection, but this polymorphism was not associated with progression of TB infection to disease. Mycobacteria driven IL-10 activity was not related to IL-10 gene variants. In contrast, an enhanced cytokine production in the group of TB patients was probably a consequence of disease manifestation.

Supported by the grant from the Polish Ministry of Science and Higher Education (N N402 098539).

Risk stratification of latent tuberculosis defined by combined interferon gamma release assays

V. Corbière,* G. Pottier,* F. Bonkain,† K. Schepers,‡ V. Verscheure,* S. Lecher,§ T. M. Doherty,¶ C. Locht§ & F. Mascart**

**Laboratory of Vaccinology and Mucosal Immunity (LoVMI), Université Libre de Bruxelles (ULB), Brussels, Belgium, †Department of Nephrology of the Erasme Hospital, Université Libre de Bruxelles (ULB), Brussels, Belgium, ‡Immunodeficiency Unit of the Erasme Hospital, Université Libre de Bruxelles (ULB), Brussels, Belgium, §INSERM, U1019, Lille, France, ¶Department of Tuberculosis Immunology, Statens Serum Institute, Copenhagen, Denmark, **Immunobiology Clinic & Laboratory of Vaccinology and Mucosal Immunity (LoVMI), Université Libre de Bruxelles (ULB), Brussels, Belgium*

Purpose/Objective: Most individuals infected with *Mycobacterium tuberculosis* develop latent tuberculosis infection (LTBI). Some may progress to active disease and would benefit from preventive treatment yet no means currently exists to predict who will reactivate. Here, we provide an approach to stratify LTBI based on IFN-g responses to two antigens, the Early-Secreted Antigen Target-6 (ESAT-6) and the latency antigen Heparin-Binding Haemagglutinin (HBHA).

Materials and methods: We retrospectively analyzed results from in-house IFN-g-release assays (IGRA) with HBHA and ESAT-6 performed during a 12-year period on serial blood samples (3−9) collected from 23 LTBI subjects in a low-TB incidence country. Both the kinetics of the absolute IFN-g concentrations secreted in response to each antigen and the dynamics of HBHA/ESAT-6-induced IFN-g concentrations ratios were examined.

Results: This analysis allowed the identification among the LTBI subjects of three major groups. Group A featured stable IGRA profiles with an HBHA/ESAT-6 ratio persistently higher than 1, and with high HBHA- and usually negative ESAT-6-IGRA responses throughout the study. Group B had changing HBHA/ESAT-6 ratios fluctuating from 0.0001 to 10 000, with both HBHA and ESAT-6 responses varying over time at least one time during the follow-up. Group C was characterized by a progressive disappearance of all responses.

Conclusions: By combining IGRAs with early and latency antigens, LTBI subjects can be stratified into different risk groups. We propose that disappearing responses indicate cure, that persistent responses to HBHA with HBHA/ESAT-6 ratios ≥1 represent stable LTBI subjects, whereas subjects with ratios varying from ≥1 to <1 should be closely monitored as they may represent the highest-risk group, as illustrated by a case report, and should therefore be prioritized for preventive treatment.

P1321

The degree of CD4 T cell differentiation as marker of tuberculosis severity and progression

I. Y. Nikitina,* E. N. Tsiganov,* I. A. Vasilyeva† & I. V. Lyadova*
*Immunology, Central Tuberculosis Research Institute, Moscow, Russia, †Phtisiology, Central Tuberculosis Research Institute, Moscow, Russia

Purpose/Objective: For many infections, especially, chronic, evaluation of disease progression is an important objective. Antigenic and inflammatory stimuli released during infections induce T cell activation and differentiation from naïve to effector lymphocytes. Thus, it was hypothesized that the degree of T cell differentiation depends on infection severity (activity) and may be used for disease monitoring. In this study we addressed how the differentiation status of CD4 T cells changes during pulmonary tuberculosis (TB) and whether its evaluation may be used to monitor TB progression.
Materials and methods: The differentiation status of CD4 T cells was evaluated by analyzing the expression of CD45RO, CD62L, CD27, CD28, and CD57 markers on CD4 T cells. Based on the co-expression of these markers, naïve ($CD45RO^-$ $CD62L^+$), central memory (T_{CM}, $CD45RO^+CD62L^+$) and effector memory (T_{EM}, $CD45RO^+CD62L^-$) cells were identified; within the population of T_{EM} cells, early ($CD27^+$), late ($CD27^-$), senescent ($CD27^-$ $CD28^-$) and terminally differentiated ($CD27^-$ $CD57^+$) lymphocytes were detected.
Results: In TB patients a tendency towards a lower content of naïve CD4 T cells and an increase in the frequency of T_{EM} cells was registered. Within T_{EM} cells, different populations of cells predominated in patients with different TB severity. In patients with mild TB, early T_{EM} cells were increased; in patients with severe TB, late T_{EM} cells and their different subsets (i.e. senescent and terminally differentiated) accumulated ($P < 0.05$). Within a population of *Mtb*-specific cells, accumulation of late ($CD27^-$) T_{EM} cells was also observed in patients with more severe TB ($P < 0.0001$). Following effective TB treatment the frequencies of late T_{EM} decreased ($P < 0.01$).
Conclusions: Severe TB is associated with the accumulation of highly differentiated effector CD4 T cells. Evaluation of the degree of CD4 T cell differentiation represents a means to monitor TB progression and patient responsiveness to TB treatment.

P1322

TNFa/IL2 ratio discreminates latent from active tuberculosis in immunocompetent children

N. Gourgouillon,* A. De Lauzanne,† C. H. Cottart,‡ E. Curis,§ C. Debord,* V. Guerin-El Khourouj,* B. Pedron,* A. Faye† & G. Sterkers*
*Laboratory of Immunology, Robert Debre Hospital, Paris, France, †Department of Pediatrics, Robert Debre Hospital, Paris, France, ‡Department of Biochemistry and Hormonology, Charles Foix Hospital, Paris, France, §Laboratory of Biomathematics, Paris V Descartes University, Paris, France

Purpose/Objective: In clinical practice, distinguishing children with LTB from those with active early disease is of key importance in order to initiate an appropriate management of the patient. The aim of the study was to identify cytokine profiles that could differentiate LTB from TB disease.
Materials and methods: A Luminex assay was used to compare Th1 (IFNγ, TNFα, IL2) and Th2 (IL4, IL10, IL5, IL13) *in vitro* lymphocyte responses to *Mycobacterium tuberculosis* antigens (ESAT-6 CFP-10 and TB 7.7). Eighteen immunocompetent children were included. Six presented LTB (median age: 6.2 years) and 8 TB disease (median age: 5.7 years) following recent contact (≤3 months) with TB. Four age-matched children with recent contact but uninfected were also analysed as reference.
Results: Poor induction, by antigens, of IL4 and IL10 precluded analysis of these cytokines. IFNγ, TNFα, IL2, IL5 and IL13 were however clearly induced by antigens in 14/14 infected but in 0/4 uninfected children. Th1 cytokine levels were similar in LTB and TB disease (IFNγ: 12254 and 10495 pg/ml, IL2: 2097 and 1869 pg/ml, TNFα: 1020 and 2875 pg/ml, respectively). Th2 cytokine levels were similar or even higher in LTB (IL5:23 and 10 pg/ml, IL13: 284 and 109 pg/ml in LTB and TB disease, respectively). A positive correlation (spearman's rank correlation) between all cytokine levels, whatever Th1 or Th2, was observed in the 14 infected children. A higher (linear regression, $P < 0.01$) TNFα/IL2 ratio in TB disease discriminated 6/8 TB diseases from 6/6 LTB.
Conclusions: We do not confirm previous reports that suggested an association between progression and a biais toward Th2 responses. Instead, a higher TNFα response (involved in effector function) related to IL2 response (involved in protection) was found. The TNFα/IL2 ratio could help in staging *M. tuberculosis* infection following recent contact in immunocompetent children.

Vaccination with the Δmce2 mutant *M. bovis* strain induced in cattle protective immune response against *Mycobacterium bovis* challenge

F. Bigi,* F. Blanco,* V. Montenegro,* M. Gravisaco,* L. Vagnoli,* S. Garbaccio† & A. Cataldi*
*Instituto de Biotecnología, CICVyA, Buenos Aires, Argentina, †Instituto de Patobiología, CICVyA, Buenos Aires, Argentina

Purpose/Objective: Bovine tuberculosis (bTB) is not only serious animal and zoonotic disease that causes significant financial loss but also a public health hazard. Vaccination of cattle to control bTB is particularly demanding in high-prevalence zones where it is economically unfeasible to slaughter animals. Although previous studies with BCG in cattle have demonstrated reductions in disease severity to subsequent experimental challenge with virulent *M. bovis* strains, the protection induced by BCG was, in general, not complete. In this study we explore another attractive alternative that is to vaccinate cattle with a *M. bovis* mutant strain in the *mce2* operon of virulence. The protection efficacy of the candidate vaccine against *M. bovis* challenge as well the immune responses induced by the vaccine were tested in cattle and the results were compared to that obtained with BCG vaccination.
Materials and methods: Three groups of 5–6 Holstein-Fresian calves (3–4 months old) were inoculated subcutaneously in the side of the neck with either Δmce2, BCG Pasteur or vehicle. Eight weeks after vaccination, animals were infected with an *M. bovis* field strain by intratracheal instillation of 10^6 CFU as described previously. Sixteen weeks after infection, the calves were euthanized and then thin slices of lungs and lymph nodes of the head and pulmonary region were analyzed looking for granuloma formations. Macroscopic lesions were scored as previously described. At different points, post vaccination and prior to challenge, and post challenge, blood samples were taken for cytokines quantification, and T cell population analysis.
Results: The group of animals vaccinated with *M. bovis* Δmce2strain showed significantly reduced number of lesion as compared to the non vaccinated group. By contrary, the group vaccinated with BCG did not showed significantly differences to the non vaccinated group. By cross-sectional analysis of responses from those animals that presented lung lesions compared to animals that did not, we found that IL-17 was statistically higher expressed, before challenge, in blood of protected animals than in those non protected.
Conclusions: We found that *M. bovis* Δmce2strain better protected cattle against virulent *M. bovis* challenge than the vaccine strain BCG, in term of number and severity of lesions in lungs and lymph nodes.

A dual role for the inflammatory chemokine CCL2/CCR2 pathway in controlling the infiltration of pro-tumor and anti-tumor leukocyte subsets

B. Silva-Santos,* T. Lança,* N. G. Sousa,* M. F. S. Costa† & C. Penido†

*Molecular Immunology, Instituto de Medicina Molecular, Lisbon, Portugal, †Fundação Oswaldo Cruz, Farmacologia, Rio de Janeiro, Brazil

Purpose/Objective: The identification of tumor-infiltrating leukocyte (TIL) subsets that either inhibit or promote tumor growth has been an important development in tumor immunology. It is thus critical to characterise the molecular cues that determine the balance between anti- versus pro-tumor leukocyte subsets within the tumor bed. In this study we aimed at identifying the chemokine signals that control leukocyte infiltration and the outcome of tumor development in experimental models.

Materials and methods: We transplanted the melanoma B16 cell line s.c. in wild-type and chemokine/chemokine receptor-deficient mice. We analysed B16 lesions for leukocyte infiltrates (including $CD8^+$, $CD4^+$ $Foxp3^-$ and $CD4^+$ $Foxp3^+$, and $\gamma\delta$ T cells; NK cells; macrophages and myeloid-derived suppressor cells, MDSCs) by FACS. Chemokines were profiled in B16 tumor extracts using a Quantibody Chemokine Array, and their functions were tested in chemotaxis assays *in vitro*.

Results: The chemokine CCL2 accumulated in B16 lesions from T cell-deficient mice, suggesting an unanticipated role in controlling T cell migration and tumor infiltration. Interestingly, this was specific to the $\gamma\delta$ T cell subset, which produced high levels of interferon-g and cytotoxic mediators (perforin and granzymes) within the tumor bed. Moreover, $\gamma\delta$ T cells expressed the counter-receptor CCR2 and migrated towards CCL2 *in vitro*, while CCL2 neutralization in B16 protein extracts completely inhibited $\gamma\delta$ T cell chemotaxis. To determine the functional relevance of CCL2/CCR2 *in vivo*, we established B16 tumors in CCR2-deficient versus WT mice. Analysis of TILs revealed significantly reduced numbers of $\gamma\delta$ T cells, macrophages and MDSCs in CCR2-deficient hosts. By contrast, the recruitment of $CD8^+$ or $CD4^+$ $Foxp3^+$ T cells was similar in both strains. To assess the impact of $\gamma\delta$ T cell infiltration on tumor development, we implanted B16 tumors in $\gamma\delta$ T cell-deficient mice, and observed increased (and more rapid) tumor growth.

Conclusions: Our data identified a novel anti-tumor role of CCL2/CCR2 based on the migration and infiltration of $\gamma\delta$ TILs endowed with potent interferon-γ production and cytotoxicity, which inhibited tumor growth *in vivo*. Moreover, since CCL2 also recruited pro-tumor leukocytes (macrophages and MDSCs), this work establishes a complex dual function of CCL2 in cancer immunity.

Activity of endoplasmic reticulum aminopeptidase 1 in malignant melanoma influences tumor recognition by autologous CD8+ T Cells

F. Zhao,* C. Seifert,* S. Lubojanski,† U. Seifert,‡ D. Schadendorf* & A. Paschen*

*Dermatology, University Hospital Essen, Essen, Germany, †Department of Medicine III, University Medical Centre, Mainz, Germany, ‡Institute for Molecular and Clinical Immunology, University Magdeburg, Magdeburg, Germany

Purpose/Objective: Endoplasmic reticulum aminopeptidase 1 (ERAP1) plays an important role in the generation of viral and parasitic $CD8^+$ T cell epitopes by trimming N-terminally elongated peptide precursors to the correct epitope length. In cervical carcinoma, low ERAP1 expression is associated with reduced overall survival, suggesting its involvement in tumor immune escape. However, the significance of ERAP1 in the generation of tumor antigen epitopes and anti-tumor immune responses remains still unclear.

The aim of the current study was to investigate if ERAP1 activity in melanoma cells influences autologous $CD8^+$ T cell activation.

Materials and methods: First, ERAP1 expression in two melanoma cell lines (Ma-Mel-86a, -86c) established from different metastasis of patient Ma-Mel-86 was confirmed by quantitative RT-PCR and Western Blot. By shRNA transfection of tumor cells, ERAP1 was downregulated. To determine if dowregulation of ERAP1 expression influences autologous T cell activation, bulk $CD8^+$ T lymphocytes from the peripheral blood were stimulated with ERAP1-shRNA transfected Ma-Mel-86 cells in comparison to control shRNA or empty vector transfected melanoma cells. T cell activation was analyzed by IFN-γ ELISA assay.

Results: IFN-γ ELISA assays, performed after 24 h coculture, revealed significantly impaired IFN-γ production of bulk $CD8^+$ T cells in the presence of ERAP1 knockdown Ma-Mel-86 cells.

To get knowledge about ERAP1-dependent tumor antigen epitopes, autologous $CD8^+$ T cell clones of known specificity were incubated with the indicated melanoma target cells. Three of four analyzed T cell clones were significantly less activated by ERAP1-knockdown melanoma cells.

Conclusions: ERAP1 activity in melanoma cells influences specific T cell activation via the amount of the generated epitopes suggesting that tumor cells might escape from efficient T cell activation by alterating ERAP1 expression.

P1327

Adaptive immunity contributes to leukemia progression by activating the Wnt-pathway in leukemia stem cells via the CD70-CD27-interaction

C. Schürch,* C. Riether,† M. S. Matter,‡ A. Tzankov‡ & A. F. Ochsenbein§

*Department of Clinical Research, Institute of Pathology, University of Bern, Bern, Switzerland, †Department of Clinical Research, University of Bern, Bern, Switzerland, ‡Institute of Pathology, University Hospital Basel, Basel, Switzerland, §Medical Oncology and Department of Clinical Research, University of Bern, Bern, Switzerland

Purpose/Objective: Chronic myelogenous leukemia (CML) is a myeloproliferative neoplasia that arises from leukemia stem cells (LSCs) harboring the oncogenic BCR/ABL translocation. Clinically, CML is characterized by a chronic phase that inevitably evolves into acute leukemia. During the chronic phase, a leukemia-specific immune response is thought to contribute to disease control, but whether the immune system can also promote the disease is unknown.

Materials and methods: Retroviral transduction of BCR/ABL-GFP into murine bone marrow (BM) cells, followed by transplantation into sublethally irradiated congenic recipients, was used to establish CML-like disease in mice. Sublethal irradiation (4.5 Gy) preserved the endogenous adaptive immune system of the recipients, allowing analysis of anti-leukemic immune responses.

Results: In the present study, we document that BCR/ABL^+ LSCs express the TNF receptor family member CD27. CD70-expressing T cells ligated CD27 on LSCs in the BM, which increased the expression of Wnt target genes in LSCs by enhancing nuclear localization of active β-catenin and the TRAF2- and NCK-interacting kinase (TNIK). This resulted in increased proliferation and differentiation of LSCs. Blocking CD27 signaling by transplanting LSCs from $CD27^{-/-}$ mice or by monoclonal antibody treatment delayed disease progression and prolonged survival. Furthermore, CD27 was expressed on $CD34^+$ cells in the bone marrow of CML patients and healthy controls, and CD27

signaling promoted growth of BCR/ABL$^+$ human leukemia cells by activating the Wnt pathway.
Conclusions: Here, we describe a novel signaling axis in leukemia, the CD27-TRAF2-TNIK-Wnt pathway. Activated immune cells promoted LSC proliferation and differentiation via the CD70-CD27-interaction. Our results reveal a novel mechanism by which adaptive immunity contributes to leukemia progression. Targeting CD27 on LSCs may represent an attractive therapeutic approach to block the Wnt/β-catenin pathway in leukemia.

P1328
B and T lymphocyte attenuator mediates inhibition of tumor-reactive CD8+ T cells in patients after allogeneic stem cell transplantation

F. Maas,* W. Hobo,* W. J. Norde,* H. Fredrix,* J. H. F. Falkenburg,† A. J. Korman,‡ N. Schaap,§ D. Olive,¶ R. van der Voort* & H. Dolstra*
*Department of Laboratory Medicine, Laboratory of Hematology, Radboud University Medical Centre, Nijmegen, The Netherlands, †Department of Hematology, Leiden University Medical Center, Leiden, The Netherlands, ‡Department of Biologics Discovery, Bristol-Myers Squibb, Milpitas, CA, USA, §Department of Hematology, Radboud University Medical Centre, Nijmegen, The Netherlands, ¶Institute Paoli Calmettes, IBiSA Cancer Immunomonitoring platform, Marseille, France

Purpose/Objective: Allogeneic stem cell transplantation (alloSCT) can cure hematological malignancies by inducing alloreactive T cell responses targeting minor histocompatibility antigens (MiHA) expressed on malignant cells. Despite induction of robust MiHA-specific T cell responses and long-term persistence of alloreactive memory T cells specific for the tumor, often these T cells fail to respond efficiently to tumor relapse. Previously, we demonstrated the involvement of the coinhibitory receptor programmed death-1 (PD-1) in suppressing MiHA-specific CD8$^+$ T cell immunity. In this study, we investigated whether B and T lymphocyte attenuator (BTLA) plays a similar role in functional impairment of MiHA-specific T cells after alloSCT.
Materials and methods: In order to examine the role of BTLA and PD-1 in T cell dysfunction after alloSCT, we analyzed T cells from transplanted patients and healthy donor. Furthermore, we stained tumor cells for ligands. Importantly, we performed *ex vivo* stimulation assays with MiHA-specific T cells in the presence of anti-BTLA and/or anti-PD-1 blocking antibodies (Ab). Subsequently, cell proliferation, IFN-γ and TNF-α secretion and degranulation upon Ag challenge was investigated.
Results: In addition to PD-1, we observed higher BTLA expression on MiHA-specific CD8$^+$ T cells compared with that of the total population of CD8$^+$ effector-memory T cells. In addition, BTLA's ligand, herpes virus entry mediator (HVEM), was found constitutively expressed by myeloid leukemia, B cell lymphoma, and multiple myeloma cells. Interference with the BTLA-HVEM pathway, using a BTLA blocking Ab, augmented proliferation of BTLA$^+$PD-1$^+$ MiHA-specific CD8$^+$ T cells by HVEM-expressing dendritic cells. Notably, we demonstrated that blocking of BTLA or PD-1 enhanced *ex vivo* proliferation of MiHA-specific CD8$^+$ T cells in respectively 7 and 9 of 11 allo-SCT patients. Notably, in 3 of 11 patients, the effect of BTLA blockade was more prominent than that of PD-1 blockade. Furthermore, these expanded MiHA-specific CD8$^+$ T cells competently produced effector cytokines and degranulated upon Ag reencounter.
Conclusions: Together, these results demonstrate that BTLA-HVEM interactions impair MiHA-specific T cell functionality, providing a rationale for interfering with BTLA signaling in post-stem cell transplantation therapies.

P1329
B-1 cells expressing CCR5 can modulate the development of murine melanoma

B. Vivanco,* M. G. Guereschi,* F. T. C. Konno,* E. C. Perez,* P. Xander,† J. S. da Silva‡ & J. D. Lopes§
*Departamento de Micro Imuno e Parasitologia, Universidade Federal de Sao Paulo, Sao Caetano do Sul, Brazil, †Departamento de ciencias biologicas, Universidade Federal de Sao Paulo, Campus Diadema, Sao Caetano do Sul, Brazil, ‡Departamento de medicina, Faculdade de Medicina da Universidade de Sao Paulo, Ribeirao Preto, Brazil, §Departamento de Micro Imuno e Parasitologia, Faculdade Federal de Sao Paulo de Sao Paulo, Sao Paulo, Brazil

Purpose/Objective: Melanoma is a type of skin cancer which can acquire invasive behavior. In the tumor microenviroment, inflammatory cells can influence almost every aspects of cancer progression, but the knowledge on the cellular and molecular mechanism are not completely clarified. Studies have attributed an important role to B-1 cells, a subset of B lymphocytes, in melanoma progression. Objective: The aim of this work was evaluate the influence of CCR5 expressed in B-1 cells on the course of murine melanoma progression.
Materials and methods: Experimental metastasis assay were performed by injecting intravenously 1x10^5 B16 melanoma cells in C57Bl/6, CCR5$^{-/-}$ and CCR5$^{-/-}$ that received adoptive transfer of B-1 cells from C57Bl/6. After 14 days, lung tumoral colonies were counted in each group. The same experimental groups were used to evaluated subcutaneous tumor growth and survival rate.
Results: The present study demonstrated that B16 cells release soluble factors that are chemoattractant for B-1 cells. It was demonstrated that 10% of peritoneal B-1 cells express the chemokine receptor CCR5 on their surface. These cells, when inoculated into animals CCR5$^{-/-}$, led to 10-fold decrease in the number of metastatic nodules. Moreover, this approach reduced subcutaneous tumor growth maintaining a stable volume of tumor whereas control animal presented exponential tumor growth. In addition, this treatment significantly increased the survival of the animals.
Conclusions: Our data suggest that B-1 cells expressing CCR5 can modulate the development of murine melanoma. So, this work may contribute to a better understanding of B-1 cells chemotaxis and the influence of migration in evolution of melanoma.

P1331
CCR2-dependent VEGF-A production by infiltrating macrophages sustains Kaposi sarcoma growth

N. Caronni,* B. Savino,* A. Anselmo,* F. Pasqualini,* M. Nebuloni,† A. Mantovani,‡ M. Locati‡ & R. Bonecchi‡
*Department of Translation Medicine, Istituto Clinico Humanitas, Rozzano, Milan, Italy, †Department of Clinical Science 'Luigi Sacco', University of Milan, Milan, Italy, ‡Department of Translation Medicine, Istituto Clinico Humanitas, Rozzano, Milan, Italy

Purpose/Objective: Inflammatory chemokines are overexpressed in several tumors where they exert different protumoral functions such as monocyte recruitment at tumor site, tumor-associated macrophage polarization and promotion of metastasis. Here we want to assess the involvement of the atypical chemokine receptor D6, that drives to degradation several inflammatory CC chemokines, in a cancer model.
Materials and methods: An *in vivo* model of Kaposi sarcoma was performed using a cell line (KS-IMM) overexpressing the atypical chemokine receptor D6 injected subcutaneously in nude mice.
Results: D6 overexpression did not influence KS-IMM *in vitro* proliferation rate while significantly reduced its *in vivo* growth when compared to mock cells. Leukocyte infiltrate of D6 overexpressing tumors was mainly composed by Ly6C^{high}/F480$^+$ monocytes with strong reduction of both neutrophils and tumor-associated macro-

phages when compared to mock tumors. D6 overexpressing tumors had decreased amount of mVEGF-A and reduced angiogenesis compared to mock tumors. The use of a CCR2 antagonist reduced monocyte recruitment at tumor site, impaired their differentiation to TAM and inhibited tumor growth. KS-IMM conditioned medium enhanced VEGF-A production by bone marrow-derived macrophages with a CCR2 and COX_2 dependent mechanism.
Conclusions: The regulation of CCR2 ligands bioavailability by D6 overexpression at tumor site inhibits monocyte differentiation and VEGF-A production resulting in reduced tumor growth.

P1332
CD27-signaling increases the frequency of regulatory T cells and promotes tumor growth

C. Riether,* C. Claus,* C. Schürch,† M. S. Matter,* T. Hilmenyuk* & A. F. Ochsenbein‡
*Tumor Immunology/Department of Clinical Reserach, University of Bern, Bern, Switzerland, †Tumor Immunology/Department of Clinical Reserach, University of Bern, Institute of Pathology, Bern, Switzerland, ‡Tumor Immunology/Department of Clinical Reserach, University of Bern, Institute of Medical Oncology, Bern, Switzerland

Purpose/Objective: Signaling of the TNF-receptor superfamily member CD27 activates costimulatory pathways to initiate T and B cell responses. CD27-signaling is regulated by the expression of its unique ligand CD70 on subsets of activated immune cells. In this study, we analyzed the role of the CD27-CD70-interaction in the immunological control of solid tumors.
Materials and methods: To investigate the role of CD27-signaling in tumor growth in the context of an already established tumor stroma, we transplanted solid fragments of MC57 fibrosarcoma s.c. into the flanks of wild-type and CD27-deficient mice.
Results: In tumor-bearing wild-type mice, the CD27-CD70-interaction reduced apoptosis of intratumoral regulatory T cells (Tregs). This resulted in an increase ofTreg frequencies, reduction of tumor-specific T cell responses, increase in angiogenesis and in promotion of tumor growth. Consequently, the frequency of Tregs and growth of solid tumors were reduced in CD27-deficient mice or in wild-type mice treated with the CD70 blocking monoclonal antibody FR70. CD27-signaling induced $CD4^+$ effector T cells to produce interleukin-2, a key survival factor for Tregs. Furthermore, in patients with non-small cell lung cancer (NSCLC), the serum concentration of soluble CD27, a marker of the CD27-CD70 interaction *in vivo*, correlated with poor prognosis.
Conclusions: Our findings therefore provide a novel mechanism by which the adaptive immune system enhances tumor growth. In combination with other therapeutic regimens, blocking CD27-signaling is a promising approach to reduce Treg formation in the tumor environment and to improve tumor control.

P1334
Changes in TGF-beta concentration in bone marrow plasma in the course of common acute lymphoblastic leukemia (cALL) treatment

K. Popko,* E. Górska* & I. Malinowska†
*Departament of Laboratory Diagnostics and Clinical Immunology of Developmental Age, Medical University of Warsaw, Warsaw, Poland, †Department of Pediatrics Hematology and Oncology, Medical University of Warsaw, Warsaw, Poland

Purpose/Objective: Transforming growth factor β is a multipotent cytokine with a great impact on cellular homeostasis. It plays an important role in cellular differentiation, senescence, regulation of cell growth, migration and apoptosis. These actions determine TGF β influence on oncogenesis, progression and metastasis. TGF β signaling pathway has a defined role in regulation of normal hematopoesis and is frequently impaired in hematologic malignancies. In same types of leukemia, blastic cells demonstrate decreased sensitivity to TGF β action. It may be connected with a lack of TBR-I and TBR-II receptors.

The aim of this study was the evaluation of TGF β concentration in bone marrow plasma in the course of common limfoblastic B leukemia treatment.
Materials and methods: 46 children with cALL, hospitalized in The Department of Pediatrics, Hematology and Oncology Medical University of Warsaw, were enrolled to the study group. The concentration of TGF β was measured using immunoenzymatic ELISA technique in the bone marrow plasma before and in 15, 33 and 72 day of treatment.
Results: Results of our analyses revealed significant difference in TGF β concentration before introduction of the therapy and in subsequent (15, 33, 72) days of treatment. Statistical significance reached the value $P < 0.0001$ in each case. Differences were also found between subsequent days when compared. The median of TGF β in 0, 15, 33 and 72 day was of: 3180.355pg/ml; 5444.645pg/ml; 11451.5pg/ml and 9645.78pg/ml respectively.
Conclusions: Gradual increase of TGF β concentration up to the 33 day and decrease in 72 day observed in the course of treatment confirm essential role of transforming growth factor in cellular proliferation and apoptosis. It suggests also possible influence of this cytokine on hematopoesis. However influence of chemotherapy on TGF β secretion has to be further evaluated.

P1335
Chemotherapy by dacarbazine improves antitumor immunity induced by a DNA vaccine targeting telomerase

M. Dossets* M. C. Lienafa,† C. Neuveut,‡ C. Vauchy,* L. Beziaud,* Y. Godet,* J. Medioni,§ C. Liard,¶ P. Langlade-Demoyen,¶ C. Borg* & O. Adotevi*

Purpose/Objective: Given its widespread expression in cancers, telomerase reverse transcriptase (TERT) is an attractive target for cancer vaccine. Recently it has been shown that chemotherapy can kill cancer cells by causing them to elicit an immune response or alternatively, by interfering with host immunity to promote immune attack. In this study we evaluated TERT-based DNA vaccine combined to immunomodulating chemotherapy.
Materials and methods: A mutated TERT DNA vaccine encoding a non-functional telomerase was used in HLA-A2/DR1 transgenic mice bearing B16-HLA-A2 melanoma. Vaccine was combined to Dacarbazine (DTIC), a reference chemotherapy used in advanced melanoma.
Results: TERT DNA vaccine induces T cell responses against multiple TERT-derived CD4 and CD8 epitopes *in vivo*. These responses are strongly enhanced by the association of DTIC to the vaccine and effectively eradicates B16-HLA-A2 tumor growth in mice. An increased level of activated immune cells (dendritic cells, NK cellsÉ) was found in mice treated by DTIC. Furthermore, mice treated by vaccine plus DTIC exhibit high frequency of functional tumor-infiltrative lymphocytes (TILs).
Conclusions: In this study, we showed that DTIC chemotherapy combined with TERT-based vaccine significantly increases TERT-specific T cell responses and provides efficient tumor protection in mice. Altogether these results underline the interest of combining TERT-based DNA vaccine to immunostimulating chemotherapies.

Chronic hepatitis B co-infection, with hepatitis C and detection of carcinogenic markers

R. Issa & M. Elbassiouni
Molecular Diagnostic, Institute of Genetic Engineering and Biotechnology, Cairo, Egypt

Purpose/Objective: Thedetection of occult HBV infection in chronic hepatitis C patients using qualitative PCR. Detection of $CD45^{-}$ $CD90^{+}$, as a biomarker in hepatocellular carcinoma patients.
Materials and methods: From 30 patients suffering from HCVdisease, samplescollected and histopathologically verified, 10 healthy control subjects. Patientsclassified into two groups according to serological tests for viral hepatitis markers (HBsAg, HCV-ab), the clinical findings, laboratory findings, and alpha-fetoprotein. Total DNAextracted from 100ul of serum. Samples assayed for HBVusing three PCR assays with primer pairs, their sequences were taken from the surface, core, and X-genes of the viral genome. CD90 purified and analysed by flow cytometry.
Results: Out of forty patients,30 had serological positive HCV infection, all negative for HBsAg. Using PCR, off 4 0 patients, seranine were positive for HBV DNA (15%), byPCR assays, documentingoccult HBV infection. Fivesamples, positive for HBV DNA (surface gene) (12.5%), three werepositive for HBV, DNA (X gene) (7.5%), andone patient samplepositive HBV DNA (core gene) (2.5%). Two fromnine positive samples were positive for both X-gene and surface gene. In 5 of 15 cases more than 0.2%in liver cirrhosis, one case only 0.1%, in healthy group expression is 0%.
Conclusions: data suggest that occult HBVinfection may have clinical significance in chronic hepatitis C patients.

P1339

Composition, organization and clinical impact of the adaptive and innate immune microenvironments in lung metastases from colorectal and renal cell carcinoma

R. Remark,* M. Alifano,† I. Cremer,* A. Lupo,‡ M. C. Dieu-Nosjean,* H. Ouakrim,* J. Goc,* C. Sautès-Fridman,* W. H. Fridman* & D. Damotte*
Cordeliers Research Center UMRS872, Team 13, Paris, France, †Thoracic Surgery Department, Hôtel-Dieu Hospital, Paris, France, ‡Department of Pathology, Hôtel-Dieu Hospital, Paris, France

Purpose/Objective: It is now well established that the immune microenvironment of primary tumors impacts clinical outcome. During cancer progression, cancer cells undergo genetic alterations and the composition and organization of the immune microenvironment may differ between metastatic and primary tumors. Moreover, it could be expected that if metastatic cells underwent immunoediting and escaped immunosurveillance, immune infiltrates in metastases might not be associated with clinical outcome.
Materials and methods: Human lung metastatic colorectal (CRC-MET, $n = 140$), lung metastatic renal cell carcinoma (RCC-MET, $n = 52$), primary CRC ($n = 12$) and primary RCC ($n = 14$) tumors were analyzed for immune cell infiltrates (CD3+ and CD8+ T cells, mature dendritic cells (mDCs) and natural killer (NK) cells) using immunohistochemistry techniques. qPCR was implemented to investigate the gene expression profiles related to immune populations and their functions in lung metastases from both CRC ($n = 19$) and RCC ($n = 13$).
Results: We show for the first time that lung metastases from CRC and RCC have different immune infiltrates. Elevated mDCs ($P < 0.0001$) and reduced densities of NK cells ($P < 0.0001$) were observed in CRC-MET as compared to RCC-MET, whereas densities of CD3+ and CD8+ T cells were similar in both metastases. Interestingly, the densities of immune cells correlated significantly ($R > 0.6$, $P < 0.05$ for all comparisons) between coincident or relapsing metastases and between metastases and primary tumors from the same patient. This indicates that tumor cells induce a characteristic and reproducible immune pattern in the primary tumor and associated metastases. A high infiltration of CD8+ T cells and mDCs was a good prognosticator of prolonged survival in CRC-MET ($P = 0.008$), whereas it is associated with poor survival in RCC-MET ($P < 0.0001$). A high density of NK cells was associated with longer survival in metastatic RCC patients ($P = 0.002$). A Th1 orientation was found in CRC-MET whereas a more complex immune genes profile with a Th1 orientation mixed with genes linked to Th2, inflammation and immunosuppression were detected in RCC-MET.
Conclusions: Our findings revisit the 'seed and soil' theory and highlight the role of the tumor cell in shaping the tumor-associated immune microenvironment. The immune signature appears to be a phenotypic marker for the disease and is remarkably reproduced between primary and metastatic sites in the same patient. It is the most powerful prognostic marker for overall survival in lung metastases from CRC and RCC.

Cross-talk between p53 and CXCR5 in breast carcinoma cells

D. Kuprash,* N. Mitkin,* C. Hook,* D. Kochetkov,† J. Kravchenko† & A. Schwartz*
Laboratory of Immunoregulation, Engelhardt Institute of Molecular Biology, Moscow, Russia, †Regulation of Genome Transcription, Engelhardt Institute of Molecular Biology, Moscow, Russia

Purpose/Objective: Elevated expression of chemokine receptors by tumors has been reported in many instances and is related to a number of survival advantages for tumor cells including abnormal activation of prosurvival intracellular pathway. The objective of this study was to see whether impairment of p53 function may be directly related to expression of chemokines and their receptors by tumor cells.
Materials and methods: p53 expression in MCF-7 cells was suppressed by lentiviral expression of an shRNA for p53. Chemotaxis was assessed using agarose spot assay.
Results: The suppression of p53 expression led to increased expression of CXCR5 and to increased cell chemotaxis along CXCL13 gradient.
Conclusions: We have established the relationship between the expression of tumor suppressor p53 and the chemokine receptor CXCR5 in breast cancer cells MCF-7. Transcriptome changes in p53-supressed MCF-7 cells and possible direct role of p53 in CXCR5 gene regulation are under investigation. The study was supported by grant 10-04-92657 from Russsian Foundation for Basic Research and by contract 16.740.11.0006 with the Ministry of Education and Science of the Russian Federation.

Cytokine Induced Killer cells immunotherapy overcomes the resistance to MET tyrosine kinase inhibitors in nonsmall cell lung cancer

M. Todorovic, S. Corso, L. Gammaitoni, V. Leuci, G. Mesiano, L. Giraudo Diego, S. Capellero, S. Giordano, M. Aglietta & D. Sangiolo
Cell Therapy, Institute for Cancer Research and Treatment, Candiolo, Italy

Purpose/Objective: Prognosis for late stage lung cancer under conventional therapies remains poor. We hereby investigated whether immunotherapy approach with CIK (Cytokine Induced Killer) cells might overcome acquired resistance to MET tyrosine kinase inhibitors

(TKI) in NSCLC. CIK cells are a subset of *ex -vivo* expanded T lymphocytes with T-NK phenotype and MHC-unrestricted antitumor activity which is mediated by the interaction of CIK's membrane receptor NKG2D with MIC A/B and ULBPs ligands expressed on the tumor cells. We hypothesized that acquired resistance and consequent acquisition of more aggressive characteristics of NSCLC cells might be associated with upregulation of MIC A/B and ULBPs ligands.

Materials and methods: MET inhibitor resistant cells are generated by treating MET -addicted cells with increasing concentrations of the MET small-molecule inhibitors PHA-665752 OR JNJ38877605. CIKs were expanded from 10 healty donors, starting from PBMC, with the timed addition of IFN-gamma, Ab anti-CD3 and IL2. Cytotoxicity assays were preformed to detect antitumor activity of CIK cells.

Results: The median expansion of CIK cells was 29-fold (range, 7−43). Expanded CIKs included a median of 39% $CD3^+$ CD56+ cells (range, 21−74). Median expression of NKG2D receptor was 87% (range, 60−95). NSCLC cells sensitive to MET TKI (EBC 1 WT) had 51% membrane expression of MIC A/B. Such expression was upregulated on the cells that acquired resistance (EBC 1R125) reaching 100%. There was no difference observed in ULBPs ligands expression between both cell lines. CIK cells efficiently killed both, sensitive and resistant cell lines. Specific killing was significantly higher against resistant cells comparing to sensitive cells. An average specific killing of resistant line was 55%, 51%, 43% and 37% at 40:1, 20:1, 10:1 and 5:1 effector/target ratio respectively. The sensitive line had, at the same ratio, an average specific killing of 38%, 34%, 26%, 23%, respectively ($n = 14$).

Conclusions: Our data describe for the first time the association of MIC A/B upregulation and MET TKI resistance in NSCLC. Acquired resistance is a common and limiting problem for chronic therapy with many TKI, including MET TKI. CIK cells adoptive immunotherapy might address this issue targeting MET TKI resistant tumor cells.

P1343

Cytotoxic T cells induce proliferation of chronic myeloid leukemia stem cells by secreting interferon-y

C. Riether,* C. Schürch,† M. A. Amrein* & A. F. Ochsenbein‡

**Tumorimmunology/Department of Clinical Reserach, University of Bern, Bern, Switzerland, †Tumorimmunology/Department of Clinical Reserach − Institute of Pathology, University of Bern, Bern, Switzerland, ‡Tumorimmunology/Department of Clinical Reserach − Institute of Medical Oncology, University of Bern, Bern, Switzerland*

Purpose/Objective: Chronic myelogenous leukemia (CML) is a clonal myeloproliferative neoplasia arising from the oncogenic BCR/ABL translocation in hematopoietic stem cells (HSCs), resulting in a leukemia stem cell (LSC). Cure of CML depends on the eradication of LSCs. Unfortunately, LSCs are resistant against current treatment strategies. The host's immune system is thought to contribute to disease control and several immunotherapy strategies are under investigation. However, the interaction of the immune system with LSCs is poorly defined. Therefore, we analyzed the interaction of leukemia-specific $CD8^+$ effector cytotoxic T cells (CTLs) with LSCs.

Materials and methods: In order to analyze the interaction of CTLs with defined antigen specificity with LSCs, we used donor BM of H8 transgenic mice ubiquitously expressing the LCMV glycoprotein epitope gp33 under the control of an MHC class I promoter to generate a CML in BL/6 mice (H8 CML). In this setting, BCR/ABL-GFP-expressing cells co-express the LCMV-gp33 antigen. However, results may differ if a relevant leukemia antigen is targeted. Therefore, we additionally induced CML using HLA-A2tg mice. In this setting, BCR/ABL-GFP-expressing cells co-express the BCR/ABL-derived junctional peptide b3a2 on HLA-A2.1.

Results: In the present study, we document that LSCs express major histocompatibility complex (MHC) and costimulatory molecules and are recognized and killed by specific CTLs *in vitro*. In contrast, therapeutic infusions of effector CTLs to CML mice *in vivo* failed to eradicate LSCs but paradoxically increased LSC numbers. LSC proliferation and differentiation was induced by CTL-secreted interferon (IFN)-γ. Effector CTLs were only able to eliminate LSCs in a situation with minimal leukemia load where CTL-secreted IFN-γ levels were low.

Conclusions: Our study reveals a novel mechanism by which the immune system contributes to leukemia progression and may be important to improve T-cell-based immunotherapy against leukemia.

P1344

Dendritic cell editing by activated natural killer cells results in a more protective cancer-specific immune response

G. Ferlazzo,* B. Morandi,† I. Bonaccorsi,* L. Moretta,‡ A. Moretta† & M. C. Mingari§

**Department of Human Pathology, University of Messina, Messina, Italy, †Department of Experimental Medicine, University of Genoa, Genoa, Italy, ‡Istituto G. Gaslini, Direzione Scientifica, Genoa, Italy, §IRCCS A.O.U. San Martino-IST-Istituto Nazionale per la Ricerca sul Cancro, Immunology, Genoa, Italy*

Purpose/Objective: Over the last decade, several studies have extensively reported that activated natural killer (NK) cells can kill autologous immature dendritic cells (DCs) *in vitro*, whereas they spare fully activated DCs. This led to the proposal that activated NK cells might select a more immunogenic subset of DCs during a protective immune response. However, there is no demonstration that autologous DC killing by NK cells is an event occurring *in vivo* and, consequently, the functional relevance of this killing remained elusive. Here we aimed to elucidate whether NK cell-mediated DC killing indeed takes place *in vivo* and investigate its possible role on antigen specific immune response.

Materials and methods: NK cells were activated in a mouse model by injecting MHC-devoid cells. Draining lymph nodes were collected and lymph node DCs functions analyzed. Finally, in a model of anti-cancer vaccination, the functional relevance of DC editing by NK cells was investigated.

Results: A significant decrease of $CD11c^+$ DCs was observed in draining lymph nodes of mice inoculated with MHC-devoid cells. Residual lymph node DCs displayed an improved capability to induce T cell proliferation. In addition, during anti-cancer vaccination, the administration of MHC-devoid cells together with tumor cells increased the number of tumor-specific CTLs and resulted in a significant increase in survival of mice upon challenge with a lethal dose of tumor cells. Depletion of NK cells or the use of perforin knockout mice strongly decreased the tumor-specific CTL expansion and its protective role against tumor cell challenge.

Conclusions: Our data indicate that NK cell-mediated DC killing takes place *in vivo* and is able to promote expansion of cancer-specific CTLs. The results also show that cancer vaccines could be improved by strategies aimed at activating NK cells.

P1345

Density of tertiary lymphoid structures is associated with T lymphocyte infiltration and protective immune signature in human lung tumors

J. Goc, L. De Chaisemartin, A. Lupo, D. Damotte, P. Validire, P. Devi, I. Cremer, W. H. Fridman, C. Sautès-Fridman & M. Dieu-Nosjean

Cordeliers Research Center Inserm UMRS 872, Team 13, Paris, France

Purpose/Objective: An important number of studies have demonstrated a strong correlation between density of tumor infiltrating T

cells (TIL) and clinical outcome in several types of human solid cancers. Nevertheless, the mechanisms governing T-cell infiltration and activation into tumors remain poorly characterized. In lung cancer, our team has observed the presence of tertiary lymphoid structures called Ti-BALT (Tumor-induced Bronchus-Associated Lymphoid Tissues). These structures present features of an ongoing immune response and their density is associated with long-term survival for lung cancer patients, suggesting their implication in local T cell recruitment and activation. Our aim was to study the influence of these structures on the infiltration, composition, density and functionality of the immune infiltrate in lung tumors.

Materials and methods: The expression of relevant molecules was assessed on fresh TIL by multicolor flow cytometry, on tissue sections by immunohistochemistry and on frozen tumors by Low Density Array analysis.

Results: We identified presence of intra-tumoral PNAd$^+$ high endothelial venules (HEVs) exclusively associated with Ti-BALT. We also report that CD62L$^+$, the PNAd ligand, is specifically expressed on Ti-BALT T cells. Moreover, a specific chemoattractant gene expression signature associated with T cell presence was identified in Ti-BALT, which strongly argue for an active recruitment of CD62L$^+$ T cells from HEVs to Ti-BALT. We also observed that TIL located in Ti-BALT had a naïve and early memory T cell phenotype, as observed in canonical secondary lymphoid organs. Moreover, we detected presence of DC-Lamp$^+$ mature dendritic cells in Ti-BALT, which could be in close contact with Ki-67$^+$ proliferating TIL, suggesting a local priming of T cells in these structures. Finally, Ti-BALT density was associated with increased activated effector-memory T cell infiltration and upregulation of genes related to T-helper 1 adaptive immunity and T-cell cytotoxicity.

Conclusions: All Together, these data suggest that Ti-BALT represent a privileged area for T cell recruitment and activation in the primary site of the tumor. This mechanism could lead to the establishment and maintenance of a protective anti-tumor immune response directly in the tumor.

P1346

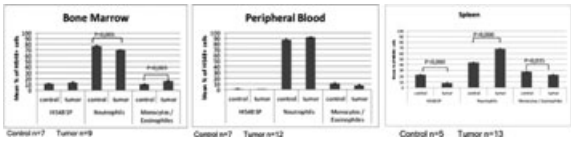
Differences of myeloid cell subsets in a chemically induced rat breast carcinoma model

Y. Dolen, G. Gunaydin, G. Esendagli & D. Guc
Basic Oncology, Hacettepe University Institute of Oncology, Ankara, Turkey

Purpose/Objective: The aim of this study is to identify the distribution of the myeloid cells at different immune compartments in a rat breast cancer model. In addition, we intend to reveal novel myeloid derived suppressor cell subsets in rats. At the first stage of our study, amounts and distributions of myeloid cell populations were determined.

Materials and Methods: Four injections of *N*-Methyl N-Nitrosourea (NMU) were performed to 21 days old female Sprague−Dawley rats at a dose of 50 mg/kg/week and mammary adenocarcinoma development was observed in about 40 days post injection. Following sacrifications, cells were isolated employing erythrocyte lysis from the spleen, peripheral blood and bone marrow tissues of tumor bearing and healthy control animals. CD11b/c, HIS48, CD172a, HIS36, CD103, RP1, CD80, CD86, CD40, RT1B (MHC-II) and CD161 antibodies were used for staining and data acquisition was performed by FACS ARIA II flow cytometer. Kaluza and SPSS softwares were used to analyse the data and Mann−Whitney *U*-tests were used to determine statistical significances.

Results: Rp-1$^+$ cells defining Neutrophils are found to be co-expressing HIS48 target and CD11b/c at all tissues. The number of neutrophils were diminished at tumor bearing animals' bone marrow ($P = 0.001$), whereas HIS48$^+$, CD11b/c$^+$, Rp-1$^-$ monocytes numbers were elevated respectively ($P = 0.003$). The most dramatic difference was observed in tumor bearing rats' spleen. At this tissue, the accumulation of neutrophils at tumor bearing rats was apparent ($P = 0.000$), being complementary, HIS48 single positive cells and monocytes were slightly lower at tumor bearing rats' spleen ($P = 0.000$, $P = 0.035$). In addition, macrophage numbers do not differ between control and tumor bearing rats at any tissue. Rp-1$^+$ cells of spleen origin have also been found to suppress PHA induced CD4$^+$ T cell proliferation of control splenocytes.



Conclusions: The dramatic increase detected in neutrophil population at spleen might be related to premature migration of these cells from bone marrow of tumor bearing animals. Furthermore, the remarkable decrease of HIS48 single positive cells and the elevation of neutrophil numbers at spleen might be related with a distorted maturation process among these cells in this microenvironment

P1347

Dominant and cryptic CD4 T cell epitopes reside in the signal peptide of the tumor-shared antigen Midkine

B. Maillere, J. Kerzerho, A. Schneider, E. Favry & F. A. Castelli
CEA-Saclay, Institute of Biology and technologies SIMOPRO, Gif Sur Yvette, France

Purpose/Objective: We have previously shown that the angiogenic factor Midkine (MDK) induced HLA-A2 restricted and tumor-specific CTL responses. Because of its wide expression in malignant cells and its vaccine potential, we investigated the CD4 T cell response specific for MDK.

Materials and methods: By weekly stimulations of T lymphocytes harvested in HLA-DR-typed healthy donors, we derived CD4 T cell lines specific for several Midkine peptides.

Results: Most of the T cell lines reacted with the peptides 3 and 4, which were located in the MDK signal peptide and overlapping with it, respectively. Accordingly, the MDK signal peptide appears as especially rich in good binders to the most frequent HLA-DR molecules in Europe. Peptide 3-specific T cell lines were specifically stimulated by autologous dendritic cells loaded with lysates of MDK-transfected cells or of tumor cells naturally expressing MDK. One T cell line was stimulated by HLA-compatible MDK-transfected tumor cells. In contrast, the peptide 4-specific T cell lines were not stimulated in these conditions.

Conclusions: Peptide 4 did not seem therefore to be displayed at the surface of the APC from MDK expressed in tumor cells. It might be cleaved during the MDK processing. This peptide behaves as a cryptic epitope since it does not elicit a MDK-specific T cell response but a peptide-specific response, only. We therefore conclude that peptide 3, which is present in the signal peptide of MDK leads to a tumor-specific CD4 T cell response demonstrating that signal peptide can be accessible to recognition by CD4 T cells, while peptide 4, which overlaps the joining region with the signal peptide, is not. Our data illustrate how CD4 T cell epitopes residing in the signal peptide could contribute to tumor immunity.

P1348

Effective anti-tumor vaccination by CIITA-transfected tumor cells as result of optimal CD4+ T helper cell stimulation

R. Accolla, L. Merello, L. Lombardo & G. Tosi
General Pathology and Immunology, Surgical and Morphological Sciences, Varese, Italy

Purpose/Objective: Most of the poor protection of present vaccination approaches against cancer is due to inefficient stimulation of MHC class II-restricted CD4+ T helper cells (TH). Thus newly conceived anti-tumor vaccination strategies based on optimal stimulation of TH cells are urgently needed.
Materials and methods: Murine tumor cell lines of different histotype were stably transfected with the MHC-II transactivator CIITA and CIITA-dependent MHC-II-positive cells were isolated by cell sorting. Immunocompetent mice were injected with CIITA-tumor cells or with parental cells. Immune response against the tumor was evaluated by: (1) the kinetics of tumor growth *in vivo*, (2) the anamnestic response to a parental tumor cell challenge; (3) the anti-tumor specificity of distinct lymphocyte subpopulations evaluated by *in vitro* and *in vivo* transfer assays; (4) the characterization of the tumor microenvironment and infiltrate by immunohistochemistry.
Results: Tumor rejection and/or retardation of growth was found for CIITA-transfected mammary, colon, renal carcinomas and for sarcomas. Animals rejecting CIITA-transfected tumors acquired specific immunological memory as demonstrated by resistance to challenge with untransfected parental tumors. Adoptive cell transfer experiments demonstrated that tumor immunity was the result of optimal priming of CD4+ T cells and consequent triggering of CD8+ T lymphocytes. Importantly, CIITA-tumors were rapidly infiltrated by TH cells and subsequently by dendritic cells and CD8+ T cells. T cells from CIITA-tumor vaccinated mice used in an adoptive immunotherapy model showed the cure at early stages and significantly prolonged survival at later stages of tumor progression. Importantly, CD4+ T cells were clearly superior to CD8+ T cells in anti-tumor protective function. Interestingly, the protective phenotype was associated to both a Th1 and Th2 polarization of the immune effectors and to reduction of Tregs in spleen and draining lymphonodes.
Conclusions: These results establish the general application of our tumor vaccine model as a superior model to induce anti-tumor $CD4^+$ TH, key cells for triggering anti-tumor effector mechanisms, and disclose the additional application of this strategy for producing better lymphocyte effectors for adoptive anti-tumor immunotherapy.

P1349

Effects of the hypoxia-inducible factors inhibitor 'topotecan' on the suppressive activity of tumor-associated myeloid cells

S. Morlacchi,* E. Riboldi,† F. Zitelli† & A. Sica†
Istituto Clinico Humanitas, Molecular Immunology, Milano, Italy, †Research Laboratory of Pathology, DiSCAFF University of Piemonte Orientale A. Avogadro, Novara, Italy

Purpose/Objective: Areas of low oxygen levels (hypoxia) are frequently found in solid tumors. Hypoxia has an important impact on myeloid cells with opposite effects on the innate and adaptive immunity. Hypoxia promotes the recruitment, activation and survival of innate immunity while inhibiting the adaptive immunity. Responses to hypoxia are mostly orchestrated by activation ofHypoxia-Inducible Factors (HIFs), which represent suitable targets for cancer therapy. Several HIF inhibitors have been identified. Among them Topotecan (TPT), a topoisomerase I inhibitor, is currently used in clinic for the treatment of ovarian cancer|, small-cell lung cancer| and cervical cancer|. Noteworthy, tumor development is also paralleled by a strong expansion of suppressor myeloid cell populations, including both suppressor dendritic cells (DC) and myeloid-derived suppressor cells (MDSC). Here, we evaluated whether targeting HIFs activation in both DC and MDSC may be an integrant part of the therapeutic activity of HIFs inhibitors, including TPT.
Materials and methods: Cell culture.

DCs were differentiated *in vitro* from either peripheral blood monocytes of healthy human donors or mouse bone marrow cells. MDSCs were differentiated *in vitro* from bone marrow too.

MLR.

Purified allogeneic T-cells or OVA-specific splenocytes were added to graded doses of DCs or MDSCs in 96-well plates. T cells proliferation was assessed by Thymidine incorporation.

ELISA.

Cytokine levels were measured using Duo-Set kits (R&D).
Results: On both mouse and human DCs, TPT displays an immunogenic effect by up-regulating their *in vivo* production of IL-1β and IL-12, associated with an increased Th1response (increased T cell-mediated Interferon-g production in draining lymph nodes). On the contrary, TPT restrains the immunosuppressive capacity of MDSCs by reducing both their NO production and capacity to inhibit T cell proliferation *in vitro*. These effects of TPT on DC and MDSC functions were observed in both hypoxic and normoxic conditions and appear, at least partially, independent from HIFs activation.
Conclusions: Our data indicate a possible effect of TPT as immune-stimulant drug. We wish to confirm these preliminary results *in vivo* and to establish the potential use of TPT in a combined chemotherapeutic/adjuvant preclinical approach.

P1350

Establishment and characterization of a tumor cell line from bone marrow of patient with myelodysplastic syndrome

B. Tsai,* J. Tang,† C. Li,† C. Lin† & B. Chiang‡
Pediatrics, National Taiwan University Hospital, Taipei, Taiwan, †Tai Cheng Stem Cell Therapy Center, National Taiwan University Hospital, Taipei, Taiwan, ‡Graduate Institute of Clinical Medicine, National Taiwan University, Taipei, Taiwan

Purpose/Objective: Myelodysplastic syndrome (MDS) that ineffectively produces myeloid class of blood cells is formerly known as preleukemia. Many patients with MDS are at risk of developing leukemia. However, the mechanism of cells from MDS transformed into leukemia is unclear. To study the tumorigensis of cells form MDS, we established and characterized a tumor cell line from the bone marrow of patient with MDS.
Materials and methods: A tumor cell line, BML01, was established from the bone marrow of patient with MDS. To determine the tumorigenecity of BML01, the cells were implanted into the DOS-SCID mice and cultured in serum-reduced culture medium *in vitro*. To define the surface marker expression of the cells, many different kinds of specific antibodies were used to stain and analyses by flowcytometry. And also, the tumor cells were stimulated with PHA, LPS, mitomycin or IL-2 to test the characteristics of cells.
Results: The BML01 cells are of a hematopoietic cell as demonstrated by the expression of CD45 surface marker. BML01 cells posses characteristics of tumor cells based on the cell are tumorigenic in NOD-SCID mice and reduced serum requirements for *in vitro* cultivation. The doubling time of BML01 cell is 16 h, and the cells have been successfully cultured *in vitro* for more than 50 generations. In addition, FACs analysis shows the BML01 cells also express surface molecules including CD14, CD30, CD44, CD81, CD107a, CD135, CD138, CD146, CD235 and CD274. The result of Liu's stain for the BML01 suggested the cells are mononuclear. Furthermore, the cells can be stimulated with PHA but not LPS, mitomycin or IL-2 in terms of the proliferation assay.
Conclusions: The new cell line provides us an *in vitro* system for the study on the oncogenesis of leukemia.

P1351

Ethanol effects MICA/B protein expression and release from the cells

A. A. Kuchukova, M. A. Streltsova, L. M. Kanevskiy & E. I. Kovalenko
Department of Immunology, Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russia

Purpose/Objective: MICA and MICB proteins (MHC class I chain-related proteins A/B) participate in regulation of immune reactions during tumorogenesis and some infections. The basic mechanism of MICA/B functioning is the interaction of MICA/B with the activating receptor of cytotoxic lymphocytes NKG2D. Recognition of MICA/B exhibited on the cellular surface leads to increase of cytotoxic activity of NK and T cells and the subsequent liquidation of the affected cell. At the same time, the circulating MICA/B forms releasing from the cells is capable to reduce the cytotoxic immune answer.

The aim of the work was to analyze effects of ethanol on MICA/B surface expression and shedding in several hemopoietic tumor cell lines with different levels of MICA/B surface expression.

Materials and methods: Surface expression of MICA/B was analyzed by flow cytometry and confocal microscopy. Intracellular proteins and colocalization were registered by confocal microscopy. Soluble MICA/B forms were detected by ELISA. Cells were incubated with ethanol for 18 h and then stained with fluorescent-labeled antibodies.

Results: The surface expression of MICA/B increased under the influence of ethanol (100–400 mM) in all types of investigated cells. Alcohol induced also MIC protein moving from the cytoplasm to the cell surface and releasing from cells in different forms. In normal conditions at the cell membrane there was a considerable level of colocalization of MIC protein with HSP70 that was previously shown to be exposed within lipid rafts. Under the action of ethanol location of these proteins became less coordinated.

Conclusions: We suggested that ethanol resulted in membrane domain reorganization. After cholesterol removing by incubation with methyl-β-cyclodextrin, the release of MIC from cells increased, which may indicate a role of lipid rafts in keeping MIC on the plasma membrane.

P1353

Expression of claudin-10 on B-1 cells triggers the higher metastatic potential of b16 murine melanoma cells

E. Pérez,* P. Xander,† R. Novaes e Brito,‡ M. Laurindo,* L. Osugui,* B. Vivanco,* M. Mariano* & J. Lopes*
Microbiology Immunology and Parasitology, Universidade Federal de São Paulo, São Paulo, Brazil, †Biological Sciences, Universidade Federal de São Paulo, São Paulo, Brazil, ‡Medicine, Centro Universitário São Camilo, São Paulo, Brazil

Purpose/Objective: B-1 cells comprise a small fraction of the B cell family found preferentially in peritoneal and pleural cavities. Considering that B-1 cells are one of the main sources of interleukin-10 (IL-10), we previously demonstrated that cocultivation of B16 melanoma cells with B-1 cells from C57BL/6 mice (wt), but not with C57BL/6 IL-10 knockout B-1 cells (IL-10KO), increases the metastatic potential of melanoma cells. However, the molecule expressed on B-1 wt cells able to affect the metastatic potential of B16 cells has not yet been fully addressed. Therefore, the aim of this work was to identify the molecule expressed by B-1 wt, but absent in B-1 IL-10KO cells, which triggers increased metastatic potential of melanoma cells.

Materials and methods: To investigate differential gene expression between B-1 cells from wt and IL-10KO mice, expression profiles were generated using the *Affymetrix GeneChip Mouse Genome 430 2.0 Array*. Results were validated by western blot analysis and interference RNA assays were realized to evaluate biological function of differentially expressed molecules.

Results: Three independent experiments of microarrays analyses demonstrated differential mRNA expression of seven (7) genes between wt and IL-10KO B-1 cells. Among these genes, claudin-10, involved with cell communication and cell adhesion, was upregulated in B-1 wt cells. Data was confirmed by western blot analysis and interference RNA assays were performed to evaluate the biological function of claudin-10 in this model. Interestingly, silencing of claudin-10 expression on B-1 wt cells prevent their capacity to increase the metastatic potential of melanoma cells.

Conclusions: These results suggest that claudin-10 is one of the molecules present on B-1 cells responsible for the interaction that triggers the phenotypic changes of melanoma cells during coculture.

Functional analysis of neutrophils cultured in supernatant of CXCL7 overexpressing lung cancer cells

N. Unver, G. Esendagli & D. Guc
Department of Basic Oncology, Institute of Oncology, Hacettepe University, Ankara, Turkey

Purpose/Objective: CXCL7 is a chemoatractant for the effector cells of innate immune system, neutrophils. The objective of this study is to analyze the function of neutrophils cultured in supernatant of lung cancer cells (Lewis Lung Carcinoma cells, LLC1) transfected with pCXCL7-IRES2EGFP plasmid.

Materials and methods: CXCL7 gene was cloned into the pIRES2EGFP vector. LLC1 cells were transfected by liposomal transfection agent. Stable CXCL7 overexpression of LLC1 cells was confirmed by using RT-PCR and ELISA. C57Bl6 mouse neutrophils were sorted from bone marrow by flow cytometry. Sorted neutrophils were cultured in supernatants of control or CXCL7 gene modified LLC1 cells. ROS production and phagocytic activity of neutrophils were evaluated by flow cytometry. Chemotactic activity of neutrophils was analysed using transwell insert system.

Results: Supernatant of CXCL7 gene modified LLC1 cells increased chemotaxis of neutrophils compared to the controls. ROS synthesis of neutrophils cultured in tumor supernatants was increased independent of CXCL7 gene modification. Phagocytic activity of neutrophils cultured in the presence of 10 ng/ml of recombinant CXCL7 was found to decrease.

Conclusions: CXCL7 gene modification affects neutrophil migration *in vitro*. CXCL7-gene modified LLC1 cells will be used for the establishment of LLC1 tumor in order to analyze immune responses against tumor *in vivo*.

P1357

Higher prevalence of LAP+ (latency TGFß-associated peptide) T cells in patients with early gastric cancer

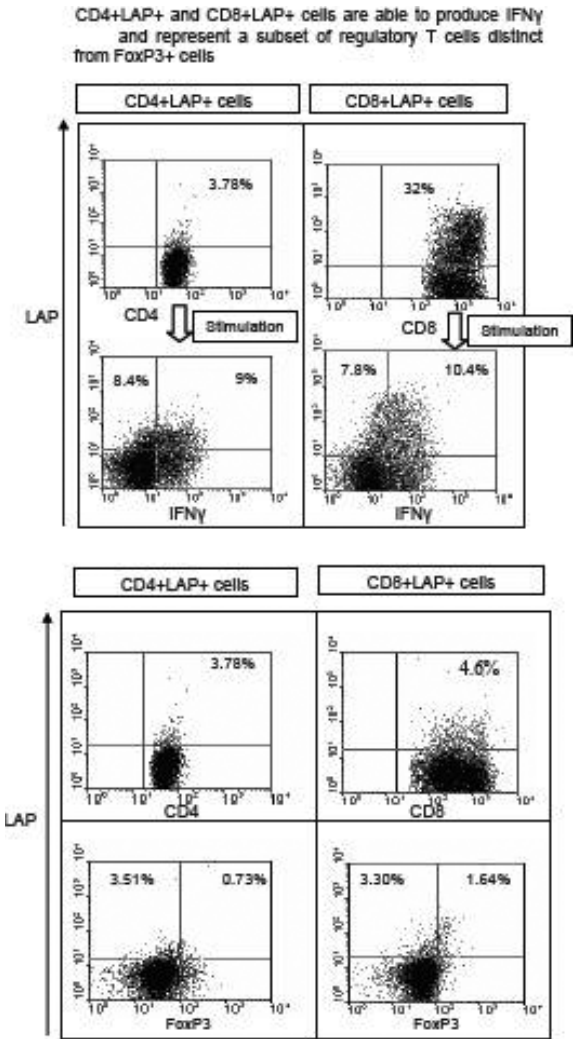
J. M. Martin-Villa,* A. Aguinaga-Barrilero,* A. Gutiérrez-Calvo,† I. Lasa† & A. López†
Facultad Medicina Universidad Complutense, Microbiology I-Immunology, Madrid, Spain, †Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Servicio de Cirugía General y Aparato Digestivo, Alcalá de Henares, Spain

Purpose/Objective: The literature reports that regulatory T cells, identified as FoxP3+ cells, have a role in the progression of cancer. New immunoregulatory FoxP3-, TGFβ-producing cell subpopulations other than the well characterized FoxP3+ subset are now emerging. These subpopulations express the latency TGFβ-associated peptide (LAP) on their surface. In fact, two different immunoregulatory T-cell subpopulations have been recently described: CD4+LAP+ in humans

and CD8+LAP+ in a mice EAE model. Given the regulatory properties of these populations, we wished to analyze the prevalence of LAP+ T cells in gastric cancer patients.

Materials and methods: To this aim, enriched T cell populations were achieved from blood or gastric tissue (tumoral, TT or tumor-free, TF) samples from 22 patients, 6 with early (EGC) and 16 with advanced disease (AGC). Blood samples from 23 healthy control individuals (H) were also used. The expression of the CD4, CD8, LAP (inactive membrane-bound TGFβ) and FoxP3 markers was measured by cytometry. IFN-γ production by T cells upon stimulation was also measured by cytometry.

Results: The results reveal the presence of LAP+ T cells (both CD4+ and CD8+) subpopulations for the first time in cancer. CD8+LAP+ cells are increased in patients, especially in early cancer, in blood (H 2.8 ± 2.8%; EGC 7.1 ± 9.7%; AGC 4.9 ± 8.3%) and tumour samples (TF 3 ± 1%; EGC 6.6 ± 4.5%*; AGC 3.6 ± 3.1% *$P < 0.05$ versus TF). Likewise, the LAP+/CD8+LAP- ratio (a measure of the immunosuppression exerted on CTLs) is also increased in patients with early disease (blood: H 0.14 ± 0.14%; EGC 0.44 ± 0.6%; AGC 0.24 ± 0.4%, tissue: TF 0.23 ± 0.2%; EGC 0.37 ± 0.12%*, AGC 0.2 ± 0.3% *$P < 0.05$ versus AGC). Upon stimulation, these cells, different from the FoxP3+ cells, produce IFN-γ, a finding in keeping with previous published data stressing the role for IFN-γ production in the immunoregulatory function of LAP+ T-cells.



Conclusions: Results suggest that disease progression is accompanied by a decreased LAP membrane expression and, therefore, an increased LAP secretion for subsequent TGFβ activation, promoting tolerance to the tumour. LAP measurement in blood or tissue-derived T cells may be useful to evaluate the immune status of cancer patients.

P1358

Identification of posttranslationally modified tumour antigens in colorectal carcinoma reveals functional tumour-resident immunity targeting phosphoantigens

S. A. Penny,* J. G. Abelin,† J. Shabanowitz,† D. F. Hunt† & M. Cobbold*

**School of Immunity and Infection, University of Birmingham, Birmingham, UK, †Department of Chemistry, University of Virginia, Charlottesville, VA, USA*

Purpose/Objective: Multiple large studies have shown that an adaptive immune response, particularly infiltration of $CD8^+$ T cells, is associated with a positive clinical outcome in both primary and metastatic colorectal cancers (CRC). This suggests that there is a functional cytotoxic T cell response against the tumour. However, the tumour antigens that these $CD8^+$ tumour-infiltrating lymphocytes (TILs) are recognising have not been identified.

We have previously shown that posttranslationally modified peptides represent attractive tumour-specific antigens, as they are differentially expressed by tumour and normal tissues and may not be subject to central tolerance. Since dysregulation of signalling in cancers leads to aberrant phosphosphorylation, phosphorylated epitopes are a potential target.

Here, we identify CRC-associated phosphopeptides and assess the tumour-resident immunity against these novel antigens.

Materials and methods: CRC tumours and matched normal tissues were lysed, the MHC class I complexes affinity purified, and bound peptides eluted. Phosphopeptides were enriched using immobilised metal affinity chromatography and characterised using mass spectrometry. TILs, from the same tumours, were extracted and expanded, and their responses to the phosphopeptides assessed using ELISpot and multiplexed intracellular cytokine staining. Cytolytic activity was observed by staining for surface upregulation of CD107. Healthy donor PBMC responses were also assessed.

Results: We have identified over 20 tumour-specific, MHC class I associated phosphopeptides from CRCs. These include phosphopeptides from proteins that contribute to key CRC-associated oncogenic pathways, including the MAP-kinase, interleukin and p53 signalling pathways. TILs were found that responded to approximately a third of the phosphopeptides identified from the same tumour, producing IL-2, IFNg and TNFa. These TILs also exhibit cytolytic activity. In addition, immune responses to a small proportion of these phosphopeptides are seen in healthy donors.

Conclusions: We have identified over 20 novel tumour-specific CRC-associated phosphopeptide antigens. A functional cytotoxic T cell response to these phosphopeptide antigens is present in tumours. These novel tumour-specific antigens represent key targets for future tumour immunotherapy strategies in CRC.

P1359

IL17-producing CD161$^+$ CCR6+ T cells are associated with graft-versus-host disease after allogeneic stem cell transplantation

A. B. van der Waart,* W. J. F. M. van der Velden,† A. G. S. van Halteren,‡ M. J. L. G. Leenders,* T. Feuth,§ N. M. A. Blijlevens,† R. van der Voort* & H. Dolstra*

*Department of Laboratory Medicine, Lab of Hematology, Radboud University Medical Centre, Nijmegen, The Netherlands, †Department of Hematology, Radboud University Medical Centre, Nijmegen, The Netherlands, ‡Immunology Laboratory Department of Pediatrics, Leiden University Medical Center, Leiden, The Netherlands, §Department of Epidemiology Biostatistics and Health Technology Assessment, Radboud University Medical Centre, Nijmegen, The Netherlands

Purpose/Objective: The C-type lectin-like receptor CD161 is a well-established marker for human IL17-producing T cells, which have been implicated to contribute to the development of graft-versus-host disease (GVHD) after allogeneic stem cell transplantation (allo-SCT).

Materials and methods: In this study, we analyzed CD161$^+$ T cell recovery, their functional properties and association with GVHD occurrence in allo-SCT recipients.

Results: While CD161$^+$ CD4$^+$ T cells steadily recovered, CD161^{hi}CD8$^+$ T cell numbers declined during tapering of Cyclosporine A (CsA), which can be explained by their initial growth advantage over CD161$^{neg/low}$CD8$^+$ T cells due to ABCB1-mediated CsA efflux. Interestingly, occurrence of acute and chronic GVHD was significantly correlated with decreased levels of circulating CD161$^+$ CD4$^+$ as well as CD161^{hi}CD8$^+$ T cells. In addition, these subsets from transplanted patients secreted high levels of IFNγ and more IL17 than healthy controls. Moreover, we found that CCR6 co-expression by CD161$^+$ T cells mediated specific migration towards CCL20, which was expressed in GVHD biopsies. Finally, we demonstrated that CCR6$^+$ T cells indeed were present in these CCL20$^+$ GVHD-affected tissues.

Conclusions: In conclusion, we showed that functional CD161$^+$ CCR6$^+$ co-expressing T cells disappear from the circulation and home to GVHD-affected tissue sites. These findings support the hypothesis that CD161$^+$ T cells actively participate in the pathophysiology of GVHD.

P1360

Immunological targeting of deregulated signalling in lymphoma: targeting a phosphorylated antigen derived from CD19

R. Buka,* H. De La Peña,* T. Butler,* S. Penny,* D. Millar,* O. Goodyear,* G. Pratt† & M. Cobbold*

*MRC Centre for Immune Regulation, University of Birmingham, Birmingham, UK, †Heartlands Hospital, Heart of England Foundation Trust, Birmingham, UK

Purpose/Objective: The nature of the antigens targeted by effective immunotherapeutic strategies is largely undefined. Cancer genome and epigenetic studies have revealed the importance of signal transduction pathway deregulation in the pathogenesis of cancer. Therapeutic strategies targeting these have been highly successful in the clinic, providing a powerful argument for aligning immunotherapeutic approaches to target signal transduction. The discovery that phosphorylation of serine and threonine residues is preserved during MHC class-I and II antigen processing suggests that phosphopeptide antigens derived from cancer-related phosphoproteins could serve as immunological signatures of 'transformed self'.

Materials and methods: Memory CD4$^+$ and CD8$^+$ T cells, which recognise a phosphorylated antigen derived from the cytoplasmic tail of CD19 (pCD19), can be isolated from the peripheral blood of healthy donors and grown as a T cell line. ELISpot and cytotoxicity assays have been used to determine the *in vitro* specificity and efficacy of T cells from both healthy donors and 11 patients with Chronic Lymphocytic Leukaemia (CLL). We are currently undertaking immunohistochemistry with a phosphospecific antibody to determine the distribution of the pCD19 epitope in B cell malignancies.

Results: Incubation of circulating lymphocytes with leukaemia cell lines, HLA-matched primary CLL cells, and mitogenically activated B cells leads to proliferation and expansion of pCD19-specific T cells, yet incubation with normal, healthy B cells does not. These expanded T cells are effective killers of cell lines, primary CLL cells and mitogenically activated B cells. Moreover, when compared to healthy controls, patients with CLL display diminished pCD19 specific immunity and immunohistochemistry has revealed the presence of the pCD19 epitope in a number of B cell malignancies.

Conclusions: These data show, for the first time, the presence of T cells which exhibit cytotoxicity against primary B-CLL cells through recognition of a posttranslationally modified antigen. Healthy individuals exhibit robust pCD19-specific immunity and abrogation of this is associated with CLL. The data increase our understanding of mechanisms within the adaptive immune response that target cells with underlying deregulated signalling, and validate the potential of phosphopeptides as immunotherapeutic targets.

Immunoreactivity to food antigens and changes in peripheral blood white cells subsets in patients with non-Hodgkin lymphoma

I. Matic,* M. Djordjic,* N. Grozdanic,* A. Damjanovic,* B. Kolundzija,* I. Besu Zizak,* D. Ristic,† M. Puric,† N. Milanovic,† S. Ristic‡ & Z. Juranic*

*Department for Experimental Oncology, Institute of Oncology and Radiology of Serbia, Belgrade, Serbia, †Department for Medical Oncology, Institute of Oncology and Radiology of Serbia, Belgrade, Serbia, ‡Department for Hematology, KBC 'Dr Dragisa Misovic', Belgrade, Serbia

Purpose/Objective: The aim of research was to determine the intensity of humoral and cellular immunity to food antigens: phytohemagglutinin (PHA), cow's milk proteins (CMP) and gliadin in patients with non-Hodgkin lymphoma (NHL). To evaluate the possible relationship of enhanced immunity with changes in peripheral blood white cells subsets, the percentages of lymphocytes, monocytes and granulocytes were determined.

Materials and methods: This study involved 48 patients with NHL before oncological therapy. The control group consisted up to 50 healthy volunteers. Levels of IgM, IgG and IgA antibodies to food antigens were determined by ELISA test. MTT test was used for examination of *in vitro* stimulation of peripheral blood mononuclear cells (PBMC) by food antigens. Flow cytometry was performed for analysis of white blood cells.

Results: Enhanced levels of anti-CMP and anti-PHA IgA antibodies were found in patients with NHL (14 out of 44 and 10 out of 44, respectively). Furthermore, in 8 patients who had higher levels of anti-PHA IgA antibodies, reduced ability of PHA to stimulate proliferation of PBMC was found. Higher frequency of NHL patients (10 out of 18) with increased ratio of percentage of granulocytes and percentage of lymphocytes (GLR) had enhanced humoral immunity to food antigens. Decreased percentage of lymphocytes was observed in 19 out of 41 patients. In 11 mentioned patients enhanced levels of immunoglobulins to food antigens were determined. Our preliminary *in vitro* analysis of human leukocytes in 30% autologous plasma showed decrease in the percentage of lymphocytes treated with tested food antigens in comparison to the percentage of lymphocytes in control sample and sample exposed to antigen and N-acetylcysteine, indicating that oxidative reaction mediated by neutrophils could be the basis of observed lymphocyte destruction.

Conclusions: Data from our study demonstrate high frequency of NHL patients with increased GLR and with elevated humoral

immunity. These data suggest the need to elucidate to what extent presence of enhanced immunoreactivity to food constituents contribute to immune disturbances found in NHL patients. It is important to clarify the molecular mechanisms responsible for decrease in the percentage of lymphocytes and changes in GLR, observed in examined patients.

P1362

Increased AMPK phosphorylation and enhanced effector function following low dose ionising radiation of T cells

Z. Tabi, L. K. Spary, J. Salimu, S. Al-Taei, M. D. Mason, A. Clayton & J. Staffurth
Oncology, Cancer and Genetics, Cardiff, UK

Purpose/Objective: Radiation therapy (RT) is a standard treatment in many haematological and solid cancers aiming to cause irreparable damage to tumour cell DNA. However, circulating or tumour-resident immune cells are also exposed to ionising radiation (IR) during RT but this effect is less well studied. We previously observed that T cell responses to recall antigens were enhanced by low dose IR of PBMC *in vitro* (Tabi *et al.* J Immunol 2010, 185:1330). Here we study the characteristics and mechanism of low dose IR-induced enhancement of T cell function.
Materials and methods: The cells used in these experiments were PBMC from healthy donors or prostate cancer patients, T cells purified from PBMC, and peptide-specific $CD8^+$ T cell lines. Irradiation was carried out using a ^{137}Cs-source (0.637 Gy/min). T cell function was assessed by measuring cytokine production or CFSE dilution following stimulation with antigenic peptides or CD3/CD28 antibody coated beads. T cell cytotoxicity was measured by standard ^{51}Cr assay. The effect of IR and/or T cell stimulation on T cell signalling was tested by a phosphoprotein array and confirmed using phosphoflow antibodies.
Results: Low or standard dose IR (0.6−2.4 Gy) enhanced both peptide- and CD3/CD28 bead-induced T cell proliferation and IFNγ production. It also decreased the activation threshold of T cells by 10-fold following peptide stimulation and broadened the resulting Th1 cytokine profile. Cytotoxic activity displayed by a tumour antigen-specific T cell line was also elevated in a radiation dose-dependent and antigen-specific manner. T cells remained 'primed' to give enhanced responses to stimulation even 24 h after IR. A physiological parallel was observed in prostate cancer patients who received 2.0−2.4 Gy localised (pelvic) radiation. CD3/CD28 cross linking of the PBMC resulted in significantly elevated IFNγ and TNFα production 24 h after RT compared to that before radiation. T cells irradiated *in vitro* released ATP and displayed significant AMPK (T172) phosphorylation. This effect may contribute to the enhanced T cell function by altering the metabolic state of the irradiated cells.
Conclusions: We report here for the first time a direct effect of low dose radiation on T cells resulting in a significant enhancement of T cell function. This effect maybe exploited clinically to boost T cell responses in immunotherapeutic settings.

P1363

Increased CD4+ and CD8+ T cell differentiation in old melanoma patients

J. A. Seidel,* N. Riddell,* S. Henson,* M. Vukmanovic-Stejic,* M. Rustin,† F. Nestle,‡ K. E. Lacy‡ & A. N. Akbar*
**UCL, Infection and Immunity, London, United Kingdom, †Dermatology, Royal Free Hospital, London, UK, ‡Genetics and Molecular Medicine, Kings College London, London, UK*

Purpose/Objective: Constant antigen exposure is thought to drive end-stage T cell differentiation. This has been shown to be the case during chronic viral infections such as CMV and is particularly pronounced with age. Tumour burden may have a similar effect on T cell differentiation, especially in melanoma which is known to be highly immunogenic and to induce accumulation of tumour-specific T cells without evidence of disease amelioration. This study therefore sought to assess global T cell differentiation in stage I-III melanoma patients when compared to age matched healthy donors, aged between 60 and 90 years.
Materials and methods: Flow cytometry was used to analyse the T cells' CD45RA/CD27 phenotypic profile, CMV-specific T cell responses were measured via intracellular cytokine expression and Melan-A specific T cells were measured using peptide loaded MHC class I dextramers.
Results: When compared to healthy controls, melanoma patients had an inverted CD4:CD8 ratio. The CD4+ T cell compartment was shown to have a significant reduction in naïve ($CD27^+$ CD45RA+) cells that was accompanied by an increase in the central memory ($CD27^+$ CD45RA-) fraction (both $P < 0.05$). Among the CD8+ T cells, no change in naïve cell numbers could be detected, but a decrease in central memory cells was observed, with a slight increase in effector memory cells ($CD27^-$ CD45RA-) and a significant increase in effector memory cells re-expressing CD45RA ($CD27^-$ CD45RA+; $P < P < 0.05$). No concomitant increase in Melan-A specific CD8+ T cells was observed among HLA-A2 positive patients and donors. However, these trends were CMV independent and correlated in part with disease stage, affirming them to be a true attribute of melanoma burden.
Conclusions: In summary, CD8+ T cells seem more driven towards end-stage differentiation in melanoma patients. We are currently investigating both the functional characteristics of these highly differentiated cells and the differentiation profiles of skin resident T cells of melanoma patients and healthy controls.

P1365

Inflammation-driven intratumor lymphoid tissue in colo-rectal cancer

F. Bergomas,* G. Di Caro,† F. Grizzi,† P. Bianchi,† A. Doni,* A. Malesci,‡ L. Laghi,§ P. Allavena,* A. Mantovani¶ & F. Marchesi***
**Department of Immunology and Inflammation, Istituto Clinico Humanitas, Milano, Italy, †Laboratory of Molecular Gastroenterology, Istituto Clinico Humanitas, Milano, Italy, ‡Department of Gastroenterology, Istituto Clinico Humanitas, Milano, Italy, §Department of Gastroenterology, Laboratory of Molecular Gastroenterology, Istituto Clinico Humanitas, Milano, Italy, ¶Department of Immunology and Inflammation, Istituto Clinico Humanitas, Milano, Italy, **Department of Translational Medicine, Istituto Clinico Humanitas, Milano, Italy*

Purpose/Objective: Immune infiltration is a fundamental component of solid tumors, however its significance to human cancer is still controversial. In colo-rectal cancer, inflammatory mediators are undoubtedly involved in cancer initiation as well as progression, however, the analysis of T cell infiltration in large cohorts of tumor patients has indicated a clear role of T cells in the anti tumor immune response, resulting in more favourable prognosis. Our aim was to determine whether ectopic lymphoid tissue is present in colo-rectal cancer andits possible contribution to disease progression.
Materials and methods: CRC patient samples were analyzed by immunohistochemistry. Two models of CRC were used: a preclinical model of colitis-associated colon cancer (AOM/DSS model) and a genetic model of colon cancer not driven by an inflammatory reaction (APCMin/AOM model). In mice, lymphoid aggregates were analyzed by immunofluorescence on colon frozen sections and colon whole mounts.
Results: Here we show the presence of intratumor lymphoid tissue in colo-rectal cancer (CRC), organized in high compartmentalized follicle-like structures, comprising of B and T cells and a network of

CD21+ follicular dendritic cells. To address the impact of ectopic lymphoid aggregates on tumor development and progression, we have analyzed a murine model of colitis-associated cancer (AOM/DSS) and found an expansion of B cell follicles in the mucosa of mice developing intestinal neoplasia. The increase is likely to be driven by the chronic inflammatory reaction, as is not induced in a non inflammatory model of intestinal neoplasia (APCMin). In CRC patients, high density of lymphoid follicles correlates with better prognosis for colo-rectal cancer patients. The presence of intratumor lymphoid neogenesis occurs by formation of new vessels, including high endothelial venules and lymphatic vessels and correlates with increased T cell infiltration, suggesting an active contribution to T cell traffic to the tumor and the induction of an antitumor immune response.
Conclusions: Our results suggest that intratumor lymphoid tissue in CRC correlates with a more favorable patient clinical outcome, rising the hypothesis that it takes part to the anti tumor immune response, providing a suitable site for cell interaction, actively participating to immune cell recruitment and activation.

P1366
Inflammatory and regulatory T cells contribute to a unique immune microenvironment in tumour tissue of colorectal cancer patients

A. Girardin,* E. S. Taylor,* E. Dunn,* F. Munro,† J. McCall† & R. A. Kemp*
**Microbiology and Immunology, University of Otago, Dunedin, New Zealand, †Surgery, University of Otago, Dunedin, New Zealand*

Purpose/Objective: Colorectal cancer is one of the five leading causes of cancer mortality worldwide. The mechanisms of pathogen clearance, inflammation and regulation by T cells in the healthy bowel are also important in controlling tumour growth. The majority of studies analyzing T cells and their relationship to colorectal tumour growth have focused on individual T cell markers or gene clusters and thus the complexity of the T cell response contributing to the growth of the tumour is not clear.
Materials and methods: Using a novel analytical flow cytometric approach in concert with confocal microscopy, we have studied the T cells in colorectal cancer patients and have defined a unique T cell signature for colorectal tumour tissue.
Results: We have shown that the tumour has a lower frequency of effector T cells (CD69+), but a higher frequency of both regulatory (CD25hi Foxp3+) and inflammatory T cells (IL-17+) compared with associated non transformed bowel tissue. We have also identified minor populations of T cells expressing conventional markers of both inflammatory and regulatory T cells (CD4+IL-17+Foxp3+) in the tumour tissue. These cells may represent intermediate populations or they may dictate an inflammatory versus regulatory function in surrounding T cells. To study the functional relevance of these cell subsets, methods have been established to isolate functional T cell subsets from tumour tissue and non-transformed bowel tissue. Effector T cells, regulatory T cells and inflammatory T cells have been isolated from tumour tissue and non-transformed bowel tissue from colorectal cancer patients. Regulatory T cells isolated from non-transformed bowel tissue actively inhibit proliferation of T cells isolated from the same tissue.
Conclusions: Together, these data describe an immune microenvironment in colorectal cancer unique to the tumour tissue and distinct from the surrounding healthy bowel tissue, and this distinct environment is reflected by a gradient of T cells expressing markers of multiple T cell subsets.

P1368
Is there any autoimmune destruction of lymphocytes driven by the oxidative burst in melanoma patients?

Z. Juranic,* I. Matic,* M. Djordjic,* N. Grozdanic,* A. Damjanovic,* N. Babovic,* R. Dzodic,† S. Matkovic‡ & S. Nikolic‡
**Experimental Oncology, Institute of Oncology and Radiology of Serbia, Belgrade, Serbia, †Clinics for Surgery, Institute of Oncology and Radiology of Serbia, Belgrade, Serbia, ‡Medical Oncology, Institute of Oncology and Radiology of Serbia, Belgrade, Serbia*

Purpose/Objective: Decreased antitumor cellular immunity, (especially decreased percentage of lymphocytes), is reported to be present in many malignant diseases, while development ofTh2 immunity in general wasreported to be connected with bedprognosis of disease. Quantitative analysis of the serum immunoglobulins revealed that the enhanced levels of especially specificIgA immunoglobulins to tumor associated antigen calreticulin are presentin sera of majority of patients with hepatocellular, pancreatic, colorectal, or breastcancer. Pleass *et al.* 2007 showed that the interaction of Fc fragments of IgA or IgG (engaged with their antigens) with correspondingFc receptors on neutrophilstriggers theoxidative burst. The main proposal of this work is that metabolites of this oxidative reaction could nonspecifically damage neighboring lymphocytes. The aim of this work was to determine is there an increase in the ratio of the percentage of granulocyte and percentage of lymphocytes (GLR), present inpatients with melanoma, andis theobserved decrease of lymphocytes driven by the oxidative burst in melanoma patients?.
Materials and methods: Up to 90 melanoma patients and 36 healthy controls were included in the study. Determination of the percentages of white blood cell subpopulations was performed using flow cytometry.
Results: Of the 44 out from 90 melanoma patients had the enhanced (>5.10) GLR. Our preliminary analysis performed *in vitro* on the mixture of leucocytes in 30% autologous plasma obtained fromone melanoma patientshowed decrease in the percentage of lymphocytestreated with melaninin comparison to the percentage of lymphocytes in control sample and sample exposed to melanin and N-acetylcystein, inboth experiments :2 and 24 h after the beginning of incubation.
Conclusions: Data from this analysis are along with recent data on the presence ofenhanced GLRin some patients with malignant diseases andindicates that oxidative reaction mediated by the reaction of neutrophils with antibodies bound to their antigen may be the basis of the observed lymphocyte decreasein patients with melanoma.

P1371
Local complement activation abrogates the tumor-endothelial barrier and mediates T cell homing and tumor immune attack

A. Facciabene, F. Desanctis, J. Lambris, K. Blint, J. Facciponte, R. De Angelis, W. Song & G. Coukos
Ovarian Cancer Research Center, University of Pennsylvania, Philadelphia, PA, USA

Purpose/Objective: Cancer immune therapy does not only depend on the ability of the patients to mount a specific tumor immune response but also to the capability of the effector cells to infiltrate tumors through the endothelial barrier. In Ovarian Cancer this is mediated by the endothelin-B receptor (ET_BR) as we previously described. For this reason we investigated if the endothelial barrier was an innate and irreversible characteristic of certain tumors that allows them to resist immune attacks, or whether it could be overcome or reversed.
Materials and methods: CD3+ T cells harvested from W. T. C57BL/6, HPV16 E6-E7 DNA vaccinated mice were adoptively transferred in tumor bearing: 1. W. T. C57BL/6 $^{+/-}$ C5a Receptor inhibitor, 2. complement component C3 (C3KO) deficient mice, 3. Decay accelerating factor 1 deficient mice (DAF-KO), C5a receptor (C5aRKO)

deficient mice. E7 specific CD8+ T cells infiltration was correlated with Tumor growth and with complement activation on tumor endothelial surface.
Results: We demonstrated that an anti-tumor specific E7-CD8$^+$ T cells infiltration required *in vivo* a local endothelial complement activation by anaphylatoxin release. Moreover T cell-released Th1 cytokines *in vitro* induced an endothelial C3 expression that promoted T cell adhesion to endothelium up-regulatingboth ICAM-1 and VCAM-1 surface protein by complement activation (C3a and C5a anaphylatoxin release).
Conclusions: This data suggests that initial T cell recognition of cognate tumor antigen by a sufficient number of tumor-reactive T cells can lead, via local complement activation and release of anaphylatoxins, to the up regulation of endothelial adhesion molecules and facilitated homing of additional tumor-specific effector T cells to the tumors, thereby establishing a positive feed-back loop that tunes T cell infiltration.

P1372

Mesenchymal contribution to leukocyte entry, transit, and positioning within human melanoma tumor tissues

P. Sanchez-Mateos & R. Samaniego
Immunology, Hospital General Universitario Gregorio Marañón, Madrid, Spain

Purpose/Objective: Tumors are complex tissues that, in addition to cancer cells, contain many different cellular components (e.g. fibroblasts, endothelial cells and various types of leukocytes) and other non-cellular components (e.g. secreted soluble factors, collagens and fibronectin), that are collectively called tumor stroma or microenvironment. In order to understand factors that regulate leukocyte entry, migration and position within human cancer, we performed a comprehensive characterization of cellular and non-cellular components of human melanoma tissue microenvironment.
Materials and methods: We used a panel of tumor antigens to delineate the intratumoral area, and mesenchymal (cells and matrix), endothelial, and leukocyte markers to define stromal components by multicolor confocal microscopy. To systematize our study we quantified and analyzed separately two tissue regions: (1) the intratumoral area and (2) the peritumoral stroma.
Results: We found that peritumoral stroma contained a profusion of inflammatory postcapillary vessels, as indicated by the endothelial expression of the multichemokie receptor DARC, heavily surrounded by CD90 perivascular mesenchymal cells (MC). In addition, we purified CD90+ peritumoral mesenchymal cells by using multicolor fluorescence-activated cell sorting to further characterize this population *in vitro*, finding a secretory CCL2 stable proinflammatory phenotype. We show a complex interplay among tumor and non-tumor tissue cells resulting in general CCL2 expression in human melanoma, but restricted expression of its receptor CCR2 to blood monocytes and sparse leukocytes around peritumoral inflammatory vessels. Interestingly, CD90 expression was lost from a distinct intratumoral stromal network composed of FAP+ MC, which is a marker of activated tumor stroma, and extracellular matrix (ECM) proteins such as collagen 1 (COL1) and fibronectin (FN). A great heterogeneity among melanoma tissue samples was detected with regard to this intratumoral stromal network, showing areas with minimal, partial and high stromal infiltration. We found a positive correlation between intratumoral stromal components and leukocytes.
Conclusions: All together our results show that a variety of mesenchymal cells regulate tumor leukocyte recruitment, migration, and final positioning of leukocytes in human melanoma tissues, i.e. CD90+ cells surrounding peritumoral stroma vessels that express CCL2 and recruit inflammatory CCR2+ monocytes from peripheral blood, whereas specific intratumoral FAP+ MC organize a stromal scaffold that contact-guide invasion and final positioning of leukocytes within the tumor cell nests.

P1373

Mesenchymal sterm cells (MSCs) in head neck squamous cell cancer (HNSCC)

M. C. Rossi, V. Querci, V. Santarlasci, L. Maggi, M. Capone, L. Cosmi, F. Liotta & F. Annunziato
Internal Medicine, University of Florence, Florence, Italy

Purpose/Objective: It is well established that cancer is not simply a disease confined to transformed epithelial cells, but is deeply influenced by the stromal microenvironment. In this contest a major role is played by immune cells, and by cells of mesenchymal origin. One of the solid tumors in which a potential role of MSCs has been proposed, is HNSCC, that is the sixth leading cancer by incidence worldwide.

The aim of this study was to demonstrate MSCs' presence in HNSCC, to evaluate of their immunosuppressive properties *in vitro* and to correlate MSCs frequency tumors extent.
Materials and methods: Twelve HNSCC affected patients has been enrolled in the study. The frequency of epithelial-, endothelial-cells, leucocytes, MSCs and fibroblasts, was determined by flowcytometry on fresh single cell suspensions: of cells 12 tumors and 6 controls specimens.
Results: Cells of mesenchymal origin resulting significantly enriched in tumors ($P < 0.05$). Form 5 patients we derived homogeneous adherent cells sharing morphology, immunophenotype and, more importantly, *in vitro* differentation potential with bone marrow-MSCs. Interestingly tumor derived MSC (tumor-MSC) showed a significant inhibitory effect on T cell proliferation in *in-vitro* models, in a dose dependent manner; this activity was, in part, IDO dependent. Finally a positive and significant correlation was observed between tumor extent and the frequency of tumor-MSC.
Conclusions: In conclusion we demonstrated that MSCs are enriched in HNSCC and have *in vitro* immunosuppressive activity on CD4+ T cells.

P1374

Monocyte chemoattractant protein 1 (MCP-1/CCL2) is associated with thymus atrophy in a mouse model of acute myeloid leukemia

V. Driss, B. Quesnel & C. Brinster
Inserm, u837, lille, France

Purpose/Objective: Research works performed in acute myelogenous leukemia (AML)-affected patients have revealed T-cell immunodeficiency characterized by peripheral T lymphocytes unable to interact with blasts, reduced thymic emigrants and oligoclonal restricted repertoires. These observations suggest a profound thymic dysregulation which remains difficult to study in patients.
Materials and methods: As experimental limitations (absence of thymus biopsies, involution with age) in AML-affected patients hamper the study of T-cell immunodeficiency which could be associated with thymus dysregulation, we decided to address this question using an AML-inducible mouse model. Female C57BL/6-Ly5.1 mice were challenged intraperitonealy (IP) with a highly lethal, syngeneic AML cell line, C1498, transduced to express the Zsgreen fluorescent protein.
Results: Using the C1498 mouse AML model, we demonstrated that leukemia development was associated with thymus atrophy defined by abnormal weight, reduced cellularity and, increased necrosis. In addition, we observed a dramatic loss of peripheral CD4$^+$ and CD8$^+$ T cell numbers although the frequencies of CD4$^+$FoxP3$^+$ regulatory and memory CD3$^+$ T cells were increased. Investigating the mechanisms leading to this atrophy, we found significant intrathymic

levels of CCL2 chemokine, which was also highly expressed by leukemic cells when cultured *ex vivo*. Mice treated with a blocking anti-CCL2 antibody after leukemia induction revealed a lower tumor burden, no more thymic atrophy, augmented anti-leukemic T-cell responses and a better survival compared to AML-bearing mice.
Conclusions: These findings have potent implications for future immunotherapeutic strategies. In this study, a novel link between CCL2 and T-cell immunodeficiency in AML is proposed.

P1376
Nasopharyngeal carcinoma derived exosomes promote natural regulatory T cells (Treg) immunosuppressive properties

D. Mrizak,* N. Martin,* N. Wambre,* C. Barjon,† Y. De Launoit,‡ P. Busson,† O. Morales* & N. Delhem*
**Institut de Biologie de Lille, CNRS UMR 8161 IRCV team, Lille, France, †Institut Gussave Roussy, CNRS UMR 8126, Villejuif, France, ‡Institut de Biologie de Lille, CNRS UMR 8161, Lille, France*

Purpose/Objective: Exosomes are nano-vesicules found in large quantities in biological fluids and tumors of patients with nasopharyngeal carcinoma (NPC). These tumor exosomes play an important role in tumor progression due to their immunosuppressive properties. In addition, it has been reported that the frequency and suppressor functions of $CD4^+$ $CD25^{high}CD127^{low}FoxP3^+$ regulatory T cells (Treg) are also higher in NPC patients than healthy donors. As interections between NPC-derived exosomes and Tregs remain unknown, we investigated their ability to induce, expand, activate and recruit human Tregs.
Materials and methods: Human Tregs were isolated from blood of healthy donnors and co-incubated with exosomes purified from (1) culture supernatents of NPC cell lines (C15 exosomes) or (2) the plasma of healthy donnors (HD exosomes).
Results: C15 exosomes significantly increased Treg expansion and generated Treg Tim-3^{low} insensitive to the suppression induced by exosomes. C15 exosomes also significantly increased the level of expression of $CD25^{high}$ and $FoxP3^{high}$ on Treg and lead to the conversion of $CD4^+$ $CD25^-$ T cells into $CD4^+$ $CD25^{high}$ Treg. Moreover, co-incubation of C15 exosomes induces over expression of the genes associated with Treg phenotype (L-selectin, ICAM-1, OX40), their suppressive activity (IL10, TGF-β1, TNF-α, Tbet, Granzyme B), and recruitment (CCR6). These results are correlated with significant increase in the suppressive activity of Tregs in the presence of C15 exosomes ($p \leq 0.001$). Finally, the C15 exosomes are able to facilitate the recruitment of Treg cells via the chemokine CCL20.
Conclusions: Our results give new insights about NPC-derived exosomes immunoregulatory properties. They induce Treg expansion, up-regulate Treg suppressor function, enhance Treg chemo-attraction, and promote the conversion of $CD4^+$ $CD25^-$ T cells into Treg. Interactions of NPC-derived exosomes with $CD4^+$ regulatory T cells represent a newly-defined mechanism that might be involved in regulating peripheral tolerance by tumor cells and supporting immune evasion of human NPC.

P1377
Notch controls generation and function of human effector CD8 T cells

L. Kuijk,* M. Verstege,* N. Rekers,† S. Bruijns,* M. Kester,‡ B. Roep,† E. Hooijberg,§ T. de Gruijl,§ Y. van Kooyk* & W. Unger*
**Molecular Cell Biology & Immunology, VU Medical Center, Amsterdam, The Netherlands, †LUMC, Immunohematology and Blood Transfusion, Leiden, Netherlands, ‡LUMC, Hematology, Leiden, Netherlands, §Pathology, VU Medical Center, Amsterdam, The Netherlands*

Purpose/Objective: Generation of effector CD8 T cells with cytotoxic capacities is crucial for control of tumor growth. Dendritic cells (DC) provide important signals to promote activation and differentiation of naïve CD8 T cells into effective cytotoxic T lymphocytes (CTLs). In mice, Notch is known to regulate T cell responses. Our aim is to address how Notch affects human CD8 T cell priming and effector function.
Materials and methods: Primary human monocyte-derived dendritic cells (moDC) and naïve CD8 T cells were obtained from HLA-$A2^+$ donors. These cells were screened for the presence of Notch ligands and receptors, respectively. In addition, activation and differentiation of MelanA (Mart1)-specific CD8 T cells from these donors was studied in the presence or absence of Notch inhibitors. Additionally, a Mart1-specific T cell clone was used to address the role of Notch in activation of established effector T cells.
Results: Human moDC express Notch ligands Jagged1 and Delta-like4 upon maturation, whereas naïve CD8 T cells express Notch1. Inhibition of Notch during activation of CD8 T cells with autologous Mart1 peptide-pulsed moDC reduced the expansion of Mart1-specific CD8 T cells. This was accompanied by a decreased frequency of IFN-g-, TNF-a- and Granzyme B-producing CD8 T cells after antigen-specific activation, indicating that also effector functions of CD8 T cells are controlled by Notch. Furthermore, DC-mediated activation induced Notch signalling in the Mart1 specific T cell clone, increased surface expression of Notch1 and Notch2 and enhanced IFN-g secretion. Inhibition of Notch resulted in significant decreases in both the frequency of activated CD8 effector T cells as well as the amount of IFN-g secreted, demonstrating that Notch also modulates established effector cells.
Conclusions: The Notch pathway plays an important role in the priming of human naïve CD8 T cells as well as the activation of effector T cells. Enhancing Notch signaling between DC and naïve CD8 T cells could therefore promote anti-tumor responses.

P1379
Particular functional status of NK cells in melananoma patients: effect of chemotherapy

E. Neves,* M. Messaoudene,* J. Chanal,* G. Fregni,* S. Mazouz Dorval,* M. F. Avril† & A. Caignard‡
**Immno-Hematology, Cochin Institute Inserm U1016, Paris, France, †Dermatology, Cochin Hospital, Paris, France, ‡Immuno-Hematology, Institute Cochin INSERM U1016, Paris, France*

Purpose/Objective: There is a growing incidence of melanoma for several decades. Malignant melanoma has a high metastatic potential and is difficult to cure. At the metastatic stage, 15−20% of patients respond to conventional chiomiotherapies and despite the promising clinical responses to target therapies, there is still no efficient treatment for metastatic melanoma. Numerous arguments indicate that melanomas are immunogenic and that the immune system can control the tumor growth in certain patients. Immunotherapy is an alternative of choice for melanoma patients resistant to chemotherapy. Natural Killer (NK) cells are important innate immunity effectors and their role in solid tumors is actually evaluated. NK activation is regulated by a balance between activating receptors that detect stress related molecules on targets and HLA-I specific inhibitory receptors.
Materials and methods: We have studied the phenotype and function of blood NK cells from 32 donors and from 64 melanoma patients at different stages of the disease: 8 stage I-II, 15 stage III and 24 stage IV patients. In addition, 17 patients were analysed 1 month post-chemotherapy.
Results: We first showed that NK cells infiltrate primitive melanoma and that they display a peritumoral distribution. We showed that the NK/T ratio is increased and the $CD56^{bright}$ subset is decreased in patients. Patient NK cells exhibit a co-reduced expression of $NKp46^{dim}$/$NKG2A^{dim}$ that is associated with a reduced functionality (cytotoxicity and IFNg secretion towards K562). We show that

chemotherapy modulate the phenotype and function of NK cells. Purified NK cells from pre or post-chemotherapy patients display distinct functional status. Melanoma cells express NK ligands for NKG2D, NCR and DNAM-1 that are involved in the lysis by NK cells.
Conclusions: These results provide arguments and new clues to design NK cell based immunotherapeutic strategies for metastatic melanoma.

Positive immunosuppressive mechanisms correlate with adaptive immune reaction and survival

H. K. Angell,* B. Mlecnik,* G. Bindea,* T. Fredriksen,* A. Kirilovsky,* W. H. Fridman,† F. Pagès* & J. Galon*
**INSERM U872, Laboratory of Integrative Cancer Immunology, Paris, France,* †*Cordeliers Research Centre, Université Paris Descartes, Paris, France*

Purpose/Objective: Several studies in colorectal cancer (CRC) patients indicate a relationship between tumour immune infiltrates and clinical outcome. Here we analyse the correlation between immune cell prevalence with markers of co-inhibition or immune suppression. Our study aims to address the feasibility of three potential hypothesis; (1) increased immunosuppression and co-inhibition receptors are associated with tumour progression, increased relapse and poor survival; (2) patients with a strong adaptive immune signature and therefore good prognosis show a negative correlation with immunosuppression; or (3) patients exhibit both a strong immune response which positively correlates with increased levels of immunosuppression and cytotoxicity.
Materials and methods: Gene expression patterns of a panel of immunosuppression markers in 109 CRC patients were investigated using quantitative real-time PCR. Primary CRC (n = 109) FFPE tissue was analysed immunohistochemically for various immune cells at the tumour centre (CT) and invasive margin (IM). Fisher Exact-Test was used to assess the relationship between immune cell density and CRC TNM stage. ClueGO-cytoscape networking was implemented, along with an advanced correlation matrix, to achieve a comprehensive analysis of gene expression networks.
Results: Interestingly, we observed a strong positive correlation between infiltrating adaptive immune cells and markers of immunosuppression. A significant increase in the prevalence of programmed cell death 1 (PDCD1), programmed cell death 1 ligand (PD-L1), B- and T-lymphocyte attenuator (BTLA), CD80, CD86, CTLA4, Foxp3, B7H4 and IDO, positively correlated with markers of T cell activation, cytotoxicity (GNLY, GZMA/B/K, PRF1) and Th1 polarisation (IFN-g, Tbx21, IRF1). Furthermore, increased immunosuppression was observed in patients with the highest density of infiltrating cytotoxic T cells, memory T cells and Th1 cells. Thus, these data support the third hypothesis, showing a positive correlation between adaptive immunity and immunosuppressive entities in human tumours. Strikingly, despite elevated levels of immunosuppression, patients with a high adaptive immune response retained a correlation with low risk of relapse and prolonged survival.
Conclusions: The local *in situ* presence of high immunosuppression does not impair the beneficial effect of adaptive immune response on survival.

P1382

Potential tumor promoting effect of CD137 on Hodgkin lymphoma

W. T. Ho,* W. L. Pang,* S. M. Chong,† A. Castella,‡ S. Al-Salam‡ & H. Schwarz*
**Physiology, NUS Yong Loo Lin School of Medicine, Singapore, Singapore,* †*Pathology, NUS Yong Loo Lin School of Medicine, Singapore, Singapore,* ‡*Pathology, UAEU Faculty of Medicine and Health Sciences, Al Ain, United Arab Emirates*

Purpose/Objective: Hodgkin Lymphoma is a type of solid hematological malignancy which its principal malignant cells, Reed Sternberg (RS) cells, only accounting for a small fraction of the total tumor mass. Large numbers of inflammatory cells make up the major part of the tumor mass. It is now accepted that RS cells are most frequently derived from germinal center B cells, nonetheless, how RS cells survive in this inflammatory environment remains unknown. Here, we identified that CD137, a member of TNFR superfamily, is expressed by RS cells as a neoantigen. In addition, we further explored the beneficial effects of ectopic CD137 to RS cells.
Materials and methods: a. CD137 expression on primary Hodgkin lymphoma lesion was determined by IHC staining.

b. KM-H2, a RS cell line, was used as experimental model. CD137 on KM-H2 cells was neutralized by neutralizing antibodies or silenced by RNA interference, and then co-cultured with PBMC or T cells. IFN-g release was used as the indicator of T cells activation.

c. CD137 ligand (CD137L) expression on KM-H2 cells was determined by using flow cytometry after CD137 neutralization or silencing.
Results: RS cells in primary Hodgkin lymphoma tissue sections stained strongly for CD137. When CD137 on KM-H2 cells was silenced or neutralized, greater IFN-γ release was induced in PBMCs and T cells which were cocultured with the KM-H2 cells. This induction of IFN-γ could be abrogated by addition of CD137L neutralizing antibodies, demonstrating that it was indeed due to CD137L. We also observed that CD137L expression on KM-H2 was up-regulated following CD137 knock-down or neutralization.
Conclusions: It was shown previously that CD137 is a strong co-stimulator of T cells which shares a similar downstream mechanism as CD28. Hence, we propose that ectopic CD137 expression on RS cells down-regulates CD137L on RS cells, and subsequently assists RS cells in evading immune surveillance by reducing T cells co-stimulation.

P1383

PTEN/MAPKa pathway plays a key role in platelet-activating factor-induced tumor metastasis

S. Im,* H. Kim,* K. Kim,* K. Seo† & H. Lee‡
**Biological Sciences, Chonnam National University, Gwangju, Korea,* †*Immunology, Biopharmaceutical Research Center, Hwasun-gun Jeollanamdo, Korea,* ‡*Immunology, Medical School, Chonbuk National University, Jeonju, Korea*

Purpose/Objective: Platelet-activating factor (PAF), a potent inflammatory mediator, can enhance tumor growth and metastasis. In this study, we investigated the role of PTEN (Phosphatase and tensin homolog deleted on chromosome10), a dual specificity phosphatase with both lipid and protein phosphatase activities, in a PAF-induced experimental pulmonary tumor metastasis model.
Materials and methods: Immunoprecipitation and PTEN phosphatase assay, PI3K activity assay, *In vitro* Gene Transfection, *In vivo* Gene Delivery, Lung Colonization Assay.
Results: PAF injection resulted in an increase in AKT phosphorylation and a decrease in PTEN activity. Systemic administration of an adenovirus carrying PTEN cDNA (Ad-PTEN), but not the control Ad-LacZ, not only reversed PAF-induced changes in phosphorylation of PTEN and AKT, but also attenuated PAF-induced pulmonary metas-

tasis of B16F10. However, PAF-induced pulmonary metastasis was not inhibited by the PI3K inhibitor, Wortmannin. PAF injection resulted in phosphorylation of all three mitogen-activated protein kinases (MAPKs) in the lungs, and PAF-induced metastasis of B16F10 was inhibited by pretreatment of MAPKs inhibitors. Ad-PTEN abrogated PAF-induced MAPKs phosphorylation *in vivo* as well as *in vitro*.
Conclusions: These data indicate that PAF decreases PTEN activity, which, in turn, leads to phosphorylation of MAPKs, and, consequently, enhances tumor metastasis.

P1384
Regulation of the oncoprotein cortactin during CCR7 mediated breast cancer cells migration

C. Cuesta Mateos, B. Somovilla Crespo, B. Colom Fernández & C. Muñoz Calleja
Instituto de Investigación Sanitaria Hospital Universitario de la Princesa, Immunology, Madrid, Spain

Purpose/Objective: The G-protein-coupled-receptor CCR7 through the binding to its ligands, the chemokines CCL19 and CCL21, induces chemotactic and invasive responses of breast tumor cells *in vivo* and *in vitro* triggering the development of ganglionar and distant metastases. Although it is well known that CCR7 triggers various signalling pathways the molecular mechanisms underlying CCR7-mediated chemotaxis and metastasis in breast carcinomas are not well understood. It is acceptable that cytoskeletal proteins located in the cell cortex coupling membrane dynamics to cortical actin assembly have a crucial role in these processes. In this direction, the oncoprotein cortactin is an important node in the regulation of the actin network and a key signalling protein in many cellular processes. Nevertheless, many basic aspects of cortactin regulation are unknown and little is the knowledge of its role in the migration mediated by chemokine receptors.
Materials and methods: Our work has investigated several questions about how cortactin activity is regulated and participates in CCR7 signalling and our findings reveal that both molecules may contribute to breast cancer progression through promotion of structures and processes which are essential for metastases.
Results: With fluorescence microscopy we demonstrated that CCR7 lignads induce a temporary translocation of cortactin from cytoplasmic compartments to the cell cortex where it accumulates at thin flat membrane extensions containing actin filaments called lamellipodia. CCR7 ligands binding also promoted an increment of specialized actin and cortactin-rich protrusions focused on degrading extracellular matrix termed invadopodia. Biochemical approaches confirmed that cortactin is a novel downstream effector of CCR7 and suggest that ERK mediates different phosphorylation events responsible for cortactin regulation following CCR7 activation. In addition, chemotaxis assays using phospho-mutant forms of cortactin pointed out that these phosphorylation events are crucial for CCR7-mediated migration and invasion of breast cancer cells.
Conclusions: Our findings suggest a novel mechanism by which the CCR7-ERK-cortactin pathway mediates functional maturation of invadopodia and lamellipodia and breast cancer cell invasion bringing us closer to understanding the link between CCR7 and breast cancer.

P1385
Regulatory T cells (Tregs), but not Th17, are increased patients with gastric adenocarcinoma

J. Martin-Villa,* A. Aguinaga Barilero,* A. Gutiérrez-Calvo,† I. Lasa† & A. López†
**Facultad Medicina Universidad Complutense, Microbiology I-Immunology, Madrid, Spain, †Hospital Universitario Príncipe de Asturias., Servicio de Cirugía General y Aparato Digestivo, Alcalá de Henares, Spain*

Purpose/Objective: Cells of the immune system, such as regulatory T cells (Tregs) and Th17 have been involved in the surveillance or progression of tumours. Thus, we wished to investigate the prevalence of these subpopulations in a group of patients with gastric adenocarcinoma.
Materials and methods: Enriched T-cell populations were achieved from blood or gastric tissue (tumor and tumor-free) samples from 21 patients (14 with intestinal type and 7 with diffuse type disease). As a control, blood samples from 23 healthy subjects were used. The following cell markers were assessed by flow cytometry: CD4, CD8, CD25, FOXP3 and IL-17.
Results: The $CD4^+$ CD25+ (regulatory) population was found increased in T cell populations obtained from tissue samples, when comparing tumor with tumor-free gastric tissue in patients ($9 \pm 5.7\%$ versus $4 \pm 3\%$; $P = 0.014$). Likewise, intestinal type tumor shows higher FoxP3 and $CD4^+$ CD25+FoxP3+ percentages ($7.3 \pm 4.6\%$ and $2.7 \pm 2.4\%$, respectively) when compared to tumor-free tissue ($4.5 \pm 4.8\%$ and $1.6 \pm 2.6\%$; $P = 0.036$ and $P = 0.028$, respectively). Finally, the FoxP3+/IL17+ ratio is higher in blood samples of patients (2.2 ± 2.1) than in control subjects (1.1 ± 1.6; $P = 0.025$). No significant differences were found for CD4+ or CD8+ IL-17-producing cells.
Conclusions: Treg cells ($CD4^+$ $CD25^+$) and not Th17, seem to play a key role in tumor progression, more so in the intestinal type of gastric cancer.

P1386
Role of the tumor suppressor ARF in the alternative activation of macrophages

S. Hortelano,* S. Herranz,* P. G. Traves† & A. Luque‡
**Centro Nacional de Microbiología, Inflammation and Cancer Unit, Madrid, Spain, †Salk Institute, Molecular Neurobiology Laboratory, La Jolla, CA, USA, ‡CISA-INIA, Centro de Investigación en Sanidad Animal, Madrid, Spain*

Purpose/Objective: ARF is among the most widely inactivated gene in human cancer. The tumor suppressor activity of ARF is in part a result of its ability to prevent the degradation of p53. However, numerous evidences indicate that ARF also exhibits p53-independent functions and interestingly place ARF as a general sensor of different types of cellular stress. We previously demonstrated that ARF deficiency severely impairs inflammatory response *in vitro* and *in vivo*, establishing a role for ARF in regulation of innate immune responses. Based on these data, we postulated that ARF could modulate polarization of macrophages.
Materials and methods: Peritoneal macrophages were obtained from WT and $ARF^{-/-}$ mice. Basal expression of M2 markers were determined by quantitative PCRs in resting macrophages. Reverse transcription (RT)-PCR, microarray assays and Western blot analysis were employed to investigate the effects of M1 (LPS) or M2 (IL-4) activation on WT and $ARF^{-/-}$ macrophages.
Results: In this study, we demonstrate that resting $ARF^{-/-}$ macrophages express high levels of Ym1, and Fizz-1, two typical markers of alternative activation of macrophages. Additionally, $ARF^{-/-}$ cells showed an impaired production of proinflammatory cytokines/

chemokines in response to LPS. Moreover, after stimulation with IL-4, an inducer of alternative activation, well established M2 markers such as Fizz-1, Ym1, and arginase-1 were higher in $ARF^{-/-}$ cells compared with WT macrophages. Additionally, the cytokine and chemokine profile of $ARF^{-/-}$ macrophages was associated with a M2 phenotype. Interestingly, various pro-angiogenic factors such as VEGF and MMP-9 were also increased, suggesting the potential pro-tumoral action of $ARF^{-/-}$ macrophages.

Conclusions: In summary, these results indicate that ARF can contribute to the polarization and functional plasticity of macrophages.

This study was supported by grant PI11.0036 from the FIS and MPY 1410/09 from ISCIII to S. H.

Simultaneous co-expression of memory- and effector-related genes by individual human CD8 T cells depends on antigen specificity and differentiation

P. O. Gannon,* B. Gupta,* E. M. Iancu,* D. E. Speiser† & N. Rufer†

**Department Research, Lausanne University Hospital (CHUV), Lausanne, Switzerland, †Ludwig Center for Cancer Research, University of Lausanne, Lausanne, Switzerland*

Purpose/Objective: Phenotypic and functional T cell properties are usually analyzed at the level of defined cell populations. However, large differences between individual T cells may have important functional consequences. To answer this issue, we performed highly sensitive single-cell gene expression profiling, which allows the direct *ex vivo* characterization of individual virus- and tumor-specific T cells from healthy donors and melanoma patients.

Materials and methods: HLA-A*0201-positive patients with stage III/IV metastatic melanoma were included in a phase I clinical trial (LUD-00-018). Patients received monthly low-dose of the Melan-A^{MART-1}_{26-35} unmodified natural (EAAGIGILTV) or the analog A27L (ELAGIGILTV) peptides, mixed CPG and IFA. Individual effector memory CD28+ (EM28+) and EM28- tetramer-specific $CD8^{pos}$ T cells were sorted by flow cytometer. Following direct cell lysis and reverse transcription, the resulting cDNA was precipitated and globally amplified. Semi-quantitative PCR was used for gene expression and TCR BV repertoire analyses.

Results: We have previously shown that vaccination with the natural Melan-A peptide induced T cells with superior effector functions as compared to the analog peptide optimized for enhanced HLA binding. Here we found that natural peptide vaccination induced EM28+ T cells with frequent co-expression of both memory/homing-associated genes (*CD27*, *IL7R*, *EOMES*, *CXCR3* and *CCR5*) and effector-related genes (*IFNG*, *KLRD1*, *PRF1* and *GZMB*), comparable to protective EBV- and CMV-specific T cells. In contrast, memory/homing- and effector-associated genes were less frequently co-expressed after vaccination with the analog peptide.

Conclusions: These findings reveal a previously unknown level of gene expression diversity among vaccine- and virus-specific T cells with the simultaneous co-expression of multiple memory/homing- and effector-related genes by the same cell. Such broad functional gene expression signatures within antigen-specific T cells may be critical for mounting efficient responses to pathogens or tumors. In summary, direct *ex vivo* high-resolution molecular characterization of individual T cells provides key insights into the processes shaping the functional properties of tumor- and virus-specific T cells.

Targeted-Therapy attenuates local and systemic immune suppression in patients with Soft Tissue Sarcoma favoring the onset of adaptive tumor immunity

M. Tazzari,* T. Negri,† F. Rini,* V. Beretta,* B. Vergani,‡ P. Filipazzi,* A. Villa,‡ E. Fumagalli,§ A. Marrari,§ E. Palassini,§ P. Casali,§ S. Stacchiotti,§ L. Rivoltini,* S. Pilotti† & C. Castelli*

**Fondazione IRCCS Istituto Nazionale Tumori, Experimental Oncology, Milano, Italy, †Fondazione IRCCS Istituto Nazionale Tumori, Diagnostic Pathology and Laboratory Medicine, Milano, Italy, ‡Consorzio MIA, Microscopy Image Analysis, Monza, Italy, §Fondazione IRCCS Istituto Nazionale Tumori, Cancer Medicine Adult Sarcoma Medical Oncology Unit, Milano, Italy*

Purpose/Objective: Targeted-Therapies are designed to directly inhibit the growth of cancer cells. However it is becoming clear that this class of drugs can also exert multi-faced immune-related effects potentially contributing to their clinical efficacy. For Soft Tissue Sarcomas (STS), Targeted-Therapy has evolved as a standard treatment option. Nevertheless, little is presently known about nature and features of the immune response in these neoplasms and their possible contribution to treatment efficacy. The aim of this study is to characterize circulating immunoregulatory cell subsets and tumor immune infiltrates in patients with STS, to assess the immunomodulating potential of targeted-therapies in this clinical setting. Results observed in the subgroup of Solitary Fibrous Tumor (SFT) are here reported.

Materials and methods: Patients with malignant SFT receiving sunitinib, were enrolled in the study. PBMC were collected prior and at different time points during treatment and analyzed by multiparametric flow cytometry for the frequency and functional status of T regulatory cells (Treg) and myeloid-derived suppressor cells (MDSC). Local tumor immunity was evaluated by extensive immunoistochemical characterization in tumor specimens surgically removed before or after drug treatments.

Results: Peripheral Treg (defined as $CD4^+$ CD25hiFoxp3+) and MDSC (detected as $CD14^+$ CD11b+HLADRlo/neg cells), present at higher frequency with respect to healthy donors (Tregs 3.8% ± 0.5 versus 1.2% ± 0.2; MDCS 12.7% ± 4.99 versus 3.4% ± 0.9) were downmodulated by treatment, starting from the second week. However, disease progression occurring during treatment induced a boost in MDSC, that regained or exceed the pretreatment level. Immunohistochemical analysis showed the presence of a strong intratumoral CD3+ lymphocyte infiltration in the post-treatment tumor lesions, undetectable in untreated samples. Myeloid cells expressing M1 and M2 markers (i.e. CD68, CD163, CD209 and CD208) were present both in naïve and in treated tumors with enrichment in the M1 population in post-therapy specimens.

Conclusions: These data strongly suggest that sunitinib, revert a tolerogenic microenvironment in malignant SFT by parallel-immune mediate mechanisms, thus potentially favoring the setting of an adaptive immune response.

Temporally designed treatment of melanoma cells by ATRA and polyI:C results in enhanced chemokine and IFNß secretion controlled differently by TLR3 and MDA5

A. Szabo, R. M. Osman, I. Bacskai, B. V. Kumar, Z. Agod, A. Lanyi, P. Gogolak & E. Rajnavolgyi

Department of Immunology, Medical University of Debrecen, Debrecen, Hungary

Purpose/Objective: In the last three decades the incidence of melanoma has increased worldwide and no effective treatment modalities have yet been developed. ATRA and polyI:C are strong inducers of TLR3 and MDA5 expression, andpolyI:C-induced TLR3 andMDA5

signaling specifically causes cell death in melanoma cells *in vitro*. We addressed the question whether ATRA pre-treatment could enhance the efficacy of polyI:C and if so, would ATRA have any additional effects on this process.

Materials and methods: WM35 and WM983A human melanoma cells were obtained from ATCC and cultured according to the recommended protocol. Human dendritic cells (DCs) and macrophages were differentiated from blood-derived monocytes. $CD1a^-$ and $CD1a^+$ DCs were sorted by FACS DiVa. Relative mRNA expressions were analyzed by real-time Q-PCR. Protein expressions were measured by Western blot, the levels of secreted chemokines/cytokines were detected by ELISA. Small interfering RNA (siRNA) was introduced by electroporation. Migration assays were performed in transwell chambers.

Results: We found that combined treatment of human melanoma cells with ATRA and pI:C strongly increased the expression of TLR3 and MDA5 in both WM35 and WM983A cells associated to significantly higher mRNA and secreted levels of IFNβ, CXCL1, CXCL8/IL-8, CXCL9, and CXCL10 than cells treated with either ATRA or polyI:C. Silencing of MDA5 by siRNA moderately affected IFNβ secretion, whereas TLR3 knock down interfered with both CXCL chemokine and IFNβ production. Furthermore, supernatants of ATRA+polyI:C-activated cultures increased the migration of both human monocyte-derived macrophages and $CD1a^+$ dendritic cells significantly as compared to the supernatants of cells treated with either ATRA or polyIC, and this effect occured in a TLR3 dependent manner.

Conclusions: In conclusion, consecutive treatment with ATRA and polyI:C results in strong, TLR3/MDA5 mediated chemokine and interferon responses in cultured human melanoma cells, which triggers a functional migratory response in professional antigen-presenting cells. This novel mode of concomitant activation may offer a more efficient treatment option for future melanoma therapy.

P1391

The first encounter between tumor cells and immune system cells

M. G. Ruocco, T. Courau & D. Klatzmann
UMR7211, Departent of Immunology, Paris, France

Purpose/Objective: Regulatory T cells (Tregs) play a key role in the immune response to tumors. In cancer patients, a high number of Tregs is indicative of a poor prognosis as their abundance is inversely correlated with survival. In contrast, tipping the balance in favor of effector T cells (Teffs) has been associated to favorable prognosis. The suppressive function of Tregs is considered one of the main obstacles to successful immunotherapy.

We have previously shown that at the time of tumor emergence, activated memory Tregs (amTregs) are the first to be involved in the immune response (Darrasse-Jeze *et al.* JCI 2009). Prior to Teffs, amTregs mount a secondary memory response against self antigens expressed by the tumor that overpowers Teffs, suggesting that the activation status of Tregs and Teffs dictates the tumor outcome.

Here we characterized the first encounter between tumor cells, Tregs and Teffs.

Materials and methods: We used a combination of genetic tools, fluorescent markers and multiphoton intravital microscopy.

Results: We described the dynamics of immune system cells within the microenvironment of an emerging tumor. Furthermore, we analyzed different conditions aimed to perturb tumor growth in order to identify the spatio-temporal mechanisms and the cellular dynamics that determine tumor growth or tumor rejection.

Conclusions: A better understanding of the dynamic behavior of immune system cells during the very early stages of tumor emergence will allow to identify new strategies for immunotherapy.

P1392

The HIF-1alpha hypoxia response in tumor-infiltrating T lymphocytes induces functional CD137 (4-1BB) for immunotherapy

A. Palazon,* I. Martínez-Forero,* A. Teijeira,* A. Morales-Kastresana,* S. Hervás-Stubbs,* M. O. Landázuri,† J. Aragonés,† M. Jure-Kunkel‡ & I. Melero*
**CIMA, Gene therapy and Hepatology, Pamplona, Spain, †Hospital la Princesa, Immunology, Madrid, Spain, ‡Bristol Myers-Squibb, Research and Development, Princeton, NJ, USA*

Purpose/Objective: To study the effects of hypoxia in the tumor microenvironment, as sensed by the HIF-1α system, on the expression of CD137 on tumor-infiltrating lymphocytes (TILs). To take advantadge of CD137 being expressed selectively on TILs and check the efficacy of immunotherapy with agonist anti-CD137 mAb delivered intratumorally.

Materials and methods: Mice: OT-1, OT-2, CD45.1, $Rag^{-/-}$ and MMTVneuT, Hif-1α floxed-UBC-Cre-ERT2 mice. Cell lines: CT26, B16-OVA and MC38. *In vivo* tumor growth: $0.5x10^6$ tumor cells were injected subcutaneously. Tumor hypoxia was measured by positron emission tomography (PET) with the radiotracer fluorine-18-fluoromisonidazole (18^F-FMISO). Flow cytometry: FACSCantoII and FACSCalibur (BD Pharmingen) as indicated were used for cell acquisition and data analysis was carried out using FlowJo. Tissue immunofluorescence staining was performed on 10-μm thick cryosections. Monoclonal antibodies for *in vivo* experiments: agonistic mouse anti-CD137 (clone 2A) and blocking anti-B7-H1 (PD-L1) (clone 10B5).

Results: The tumor microenvironment of transplanted and spontaneous mouse tumors is profoundly deprived of oxygenation as confirmed by PET imaging. CD8 and CD4 tumor-infiltrating T lymphocytes (TILs) of transplanted colon carcinomas, melanomas and spontaneous breast adenocarcinomas are CD137 (4-1BB) positive, as opposed to their counterparts in tumor draining lymph nodes and spleen. Expression of CD137 on activated T lymphocytes is markedly enhanced by hypoxia and the prolyl-hydroxylase inhibitor DMOG. Importantly, hypoxia does not up-regulate CD137 in inducible HIF 1α knock-out T cells, and such HIF-1α-deficient T cells remain CD137-negative even when becoming TILs, in clear contrast to co-infiltrating and co-transferred HIF-1α-sufficient T lymphocytes. The fact that CD137 is selectively expressed on TILs was exploited to confine the effects of immunotherapy with agonist anti-CD137 monoclonal antibodies (mAb) to the tumor tissue. As a result, low-dose intratumoral injections avoid liver inflammation, achieve antitumor systemic effects and permit synergistic therapeutic effects with PD-L1/B7-H1 blockade.

Conclusions: CD137 (4-1BB) is an important molecular target to augment antitumor immunity. Hypoxia in the tumor microenvironment as sensed by the HIF-1α system increases expression of CD137 on tumor-infiltrating lymphocytes which thereby become selectively responsive to the immunotherapeutic effects of anti-CD137 agonist monoclonal antibodies as those used in ongoing clinical trials.

P1393

The identification of the Cancer Associated Fibroblasts and functional analyses for mechanisms of immune evasion in a rat chemical mammary carcinoma model

G. Gunaydin, Y. Dolen, S. A. Kesikli & D. Guc
Basic Oncology, Institute of Oncology, Hacettepe University Ankara, Turkey

Purpose/Objective: Seed-centric cancer models do not take into account the probable impact of the microenvironment, soil, that the tumor cells reside in. Fibroblasts are thought to be involved in a dynamic crosstalk with other cells of the tumor microenvironment. The

aim of this study is to characterize and effectively isolate cancer associated fibroblasts (CAFs) for further functional assays.
Materials and methods: N-Nitroso N-Methyl Urea (NMU) induced experimental mammary carcinogenesis model was utilized. Twenty-one days old female Sprague Dawley rats were injected once a week for 4 weeks with NMU. When the animals are about 3 months old, developed tumors were harvested surgically under sterile conditions for CAF isolation. Fibroblasts were isolated from breast tumor tissues using a protocol which utilizes collagenase and hyaluronidase. Enzymatically digested tissues were then cultured in fibroblast selective medium. The same protocol was also used to isolate normal tissue fibroblasts from healthy mammary tissues. These CAFs and healthy tissue fibroblasts were immunostained to show their differential expressions of surface markers such as α-Smooth Muscle Actin (αSMA) and Vimentin, in order to distinguish CAFs from their normal tissue counterparts. Probable DNA damage of peripheral blood cells due to the NMU injections were evaluated by Comet Assays at different time points. Coculture of CAFs with lymphocytes and Carboxyfluorescein succinimidyl ester (CFSE) proliferation assays were performed for functional analyses.
Results: The immunostainings clearly showed that CAFs had significantly higher levels of αSMA expression than normal fibroblasts. This finding of differential αSMA expression was shown to fade out with further passages of cultured CAFs. Histological examinations also revealed significant morphological differences between these cells. The Comet Assays showed that levels of DNA damage in peripheral blood cells of tumor bearing animals were similar to control levels after 2 months post injection. CFSE proliferation assays showed the immunosuppressive effects of CAFs on lymphocytes (see Fig. 1).

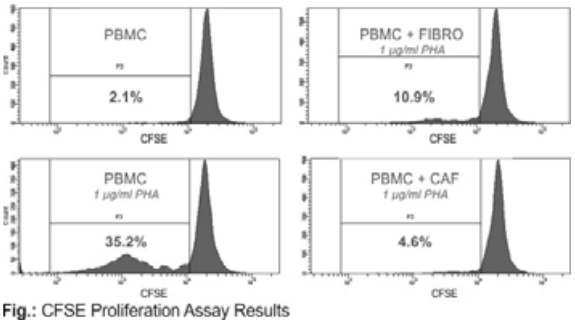

Fig.: CFSE Proliferation Assay Results

Conclusions: CAFs were successfully propagated using a rat chemical breast carcinogenesis model. Functional analyses with these CAFs were performed employing various coculture systems and showed their immunomodulatory roles on immunity against breast cancer.

P1394
The importance of epitope choice for adoptive T cell therapy

A. Jukica,* P. M. Kloetzel,† K. Schmidt,† B. Weißbrich,‡ C. Perez,* J. Charo,* K. Anders,* J. Sidney,§ A. Sette,§ C. Keller,† T. N. Schumacher,¶ D. Busch,‡ U. Seifert & T. Blankenstein***
**Max Delbrück Center for Molecular Medicine (MDC), Molecular Immunology and Gene Therapy, Berlin, Germany, †Charité-Universitätsmedizin Berlin, Institute for Biochemistry, Berlin, Germany, ‡Technical University Munich, Institute for Medical Microbiology Immunology and Hygiene, Munich, Germany, §La Jolla Institute for Allergy and Immunology, Division of Vaccine Discovery, La Jolla, CA, USA, ¶The Division of Immunology, The Netherlands Cancer Institute, Amsterdam, The Netherlands, **Otto-von-Guericke-Universität Magdeburg, Institute for Molecular and Clinical Immunology, Magdeburg, Germany*

Purpose/Objective: Due to high genetic instability large established tumors contain different cell variants, where some can be therapy resistant and lead to tumor escape. There are many factors contributing to the outgrowth of these escape variants that have to be taken into consideration for achieving optimal Results: . In this study we show the importance of epitope choice for a given target antigen by comparing rejection of large established SV40 Large T positive (T-Ag$^+$) tumors either by targeting subdominant epitope pI or immunodominant pIV.
Materials and methods: Retroviral transduction of mouse T cells, flow cytometry, cytokine release, MHC-peptide binding, T cell avidity, tumor challenge and adoptive T cell therapy, *in vivo* kill, *in vivo* bioluminescent imaging, western blot, proteasomal cleavage, mass spectrometry.
Results: T cells engineered to express pI or pIV specific T cell receptors (TCRs) were potent enough to long-term reject large established T-Ag$^+$ tumors. However, when tumors expressing low levels of MHC class I were treated, only TCR-I T cells rejected these tumors, while TCR-IV T cells selected IFNγ unresponsive escape variants. *Ex vivo* recognition of these escape variants was impaired for TCR-IV, but not for TCR-I T cells, indicating that in contrast to pI, pIV recognition was dependent on IFNγ stimulation. TCR-I and TCR-IV T cells had comparable avidity, and pI and pIV had similar affinity for the MHC class I molecule, therefore, the differential outcome of the two therapies could not be attributed to these factors. The difference was in the proteasomal cleavage of the two epitopes: pI was directly produced by the proteasome, while only N-terminal precursors were generated for pIV. Due to IFNγ unresponsiveness of the escape variants, ERAAP could not be upregulated by IFNγ stimulation.
Conclusions: We speculate that the N-terminal precursors could not be efficiently trimmed to generate the pIV epitope, allowing tumors to escape only TCR-IV but not TCR-I T cell therapy. We conclude that IFNγ independent epitopes might be better targets for adoptive T cell therapy of tumors expressing low levels of MHC class I.

P1395
The PD-1/PD-L1 axis contributes to T cell dysfunction in chronic lymphocytic leukemia

D. Brusa,* S. Serra,* M. Bianco,† M. Coscia,‡ D. Rossi,§ G. Gaidano,§ G. Fedele† & S. Deaglio*
**Hugef, Genetic biology and biochemistry, Turin, Italy, †Department of infectious parasitic and immuno-mediated deseases, Istituto superiore sanità, Rome, Italy, ‡Division of Hematology, San Giovanni Battista Hospital, Turin, Italy, §Division of Hematology, Department of Clinical and Experimental Medicine & BRMA, University of Eastern Piedmont and AOU Maggiore della Carità, Novara, Italy*

Purpose/Objective: Chronic Lymphocytic Leukemia (CLL) is characterized by the progressive accumulation of a population of mature B lymphocytes. It is marked by profound defects in T-cell functions. Programmed death-1 (PD-1) is a cell surface molecule that inhibits activation and is involved in tumor escape mechanisms through binding of the specific PD-L1 ligand. The aim of this work is to evaluate expression and function of the PD-1/PD-L1 axis in CLL.
Materials and methods: We compared T cell subpopulations of CLL patients (n = 120) to age- and sex-matched healthy donors (HD, n = 30) using multiparameter flow cytometry. Immunohistochemical analyses were used to study PD-1 and PD-L1 expression in the lymph node microenvironment. Functional assays were used to determine the involvement of the PD-1/PD-L1 axis in shaping T cell responses.
Results: The first finding of this work is that CD4$^+$ T lymphocytes from CLL patients express significantly higher levels of the PD-1 receptor, as compared to the same cells purified from age- and sex-matched donors (52% versus 34%, $P < .001$). In keeping with the notion that PD-1 is a marker of cell exhaustion, we found that CD4$^+$ T lymphocytes from CLL patients display increased numbers of effector

memory cells with a concomitant decrease in naïve and central memory cells, when compared to age- and sex-matched donors. The number of effector memory cells positively associated with a more advanced stage of disease, treatment requirements and unfavorable genetic aberrations. Leukemic lymphocytes expressed higher levels of PD-L1 than circulating B lymphocytes from normal donors. PD-1 and PD-L1 increased significantly when T or B lymphocytes were induced to proliferate, suggesting that this interaction might work efficiently in an activated environment. This hypothesis was tested by determining PD-1 and PD-L1 expression in the proliferation centers located in the lymph nodes of CLL patients. Results indicate that PD-L1$^+$ proliferating CLL cells are in close contact with CD4$^+$/PD-1$^+$ T lymphocytes. Lastly, functional experiments performed using anti-PD-1 antibodies or recombinant PD-L1 ligands clearly indicate that this axis contributes to driving IL-4 secretion and to the inhibition of IFN-γ production by CD8$^+$ T cells.
Conclusions: Considered together, these observations imply that pharmacological manipulation of the PD-1/PD-L1 axis might be relevant in restoring T cell functions.

P1396
The phytochemical apigenin downregulates the inducible expression of programmed death ligand 1 (PDL-1) by mouse mammary carcinoma cells

M. R. P. Coombs,* M. E. Hickey† & D. W. Hoskin‡
**Pathology, Dalhousie University, Halifax, NS, Canada, †Microbiology & Immunology, Dalhousie University, Halifax, NS, Canada, ‡Pathology Microbiology & Immunology and Surgery, Dalhousie University, Halifax, NS, Canada*

Purpose/Objective: PDL-1 is an inhibitory T cell molecule expressed by antigen presenting cells, activated T cells and various tumor types. PDL-1 expression by some breast cancer cell lines can be induced by the proinflammatory cytokine IFN-γ and is believed to contribute to immune evasion by breast cancer cells. Our goal is to determine the effect of the antiinflammatory dietary phytochemical apigenin on PDL-1 expression in a mouse model of breast cancer.
Materials and methods: The effect of apigenin on cell number and viability was determined using MTT assays and Annexin-V-FLUOS staining, respectively. The effect of apigenin on cell-surface PDL-1 was analyzed in mouse mammary carcinoma cell lines with IFN-γ-induced PDL-1 expression. Murine IFN-γ (1 ng/ml) was used to induce PDL-1 expression, which was measured by flow cytometry using PE-anti-human PDL-1 or isotype control antibodies.
Results: Apigenin at 10, 20 and 30 μM did not affect E0771 and 4T1 murine mammary carcinoma cell numbers by MTT assay; however, annexin V staining indicated a modest decrease in viability of both 4T1 and E0771 mammary carcinoma. IFN-γ-induced upregulation of PDL-1 on 4T1 and E0771 mammary carcinoma cells was significantly decreased by apigenin.
Conclusions: Apigenin and other phytochemicals that downregulate inducible PDL-1 expression may represent a new class of chemotherapeutics that will increase the vulnerability of breast cancer cells to antitumor immune responses.

P1397
The potential role of eosinophils in the microenvironment niche of Multiple Myeloma

D. M. Wong,* L. Meng,* V. T. Chu,† B. Bogen,‡ F. Jundt,§ K. Bommert,¶ C. Berek† & R. A. Manz*
**Institute for Systemic Inflammation Research, University of Luebeck, Luebeck, Germany, †Charite, Deutsches Rheuma Forschungszentrum, Berlin, Germany, ‡Immunology and Transfusion Medicine, Oslo University Hospital, Oslo, Norway, §Charite, Hematology and Oncology, Berlin, Germany, ¶Universitätsklinikum Würzburg, Hämatologie/Internistische Onkologie, Würzburg, Germany*

Purpose/Objective: Multiple myeloma (MM) is a B cell neoplasm characterised by aberrant expansion of plasma cells within the bone marrow. It is thought that survival of these neoplastic plasma cells, similar to 'normal' plasma cells require survival signals from their environment. Recently, we and others have shown that in addition to bone marrow stromal cells, hematopoietic cell types such as megakaryocytes and eosinophils also play an important role in the function of plasma cell niches. Here, we tested the hypothesis that MM cell growth is also supported by these components of plasma cell niches.
Materials and methods: A novel MM mouse model, i.e. a subclone of the BALB/c derived plasmacytoma cell line MOPC 315 that specifically homes to bone marrow of recipient mice, which lead to symptoms closely resembling the human MM disease was used in these studies. Eosinophils were depleted from wild type BALB/c mice by injection of the anti-IL5 blocking antibody. Serum were taken from mice every week and myeloma load was quantified by measuring MOPC specific dnp antibody titres by ELISA.
Results: Anti-IL5 treatment lead to approximately 30–50% reduction of bone marrow eosinophil counts for at least 4 weeks. There was a significant difference in dnp antibody titres after 2 weeks however this was not seen in the subsequent 2 weeks and there was no difference in the percentage of MOPC 315 after mice were sacrificed at 5 weeks.
Conclusions: This study shows that their could be a supportive role for eosinophils in the earlier stages of the disease, but not necessarily in the later stages. It would be interesting to test this further in a eosinophil depeleted mice to see if the changes seen is more drastic.

Purpose/Objective: Cells respond intrinsically to the perception of DNA damage by initiating the DNA damage response (DDR) pathway that leads to cell-cycle arrest, senescence or apoptosis. Telomeres protect chromosome extremities from being repaired and recognized as accidental double strand DNA breaks. For instance, loss of TRF2, a major telomere protein in mammals, triggers an ATM-dependent DDR, telomere fusion and growth arrest. As we observed during early stages of human colon cancer the progressive TRF2 upregulation correlated with a decrease in NK cells density, we address the question of a possible link between TRF2 dosage and cancer immunity.

Materials and methods: Two cellular models are used: (1) immortalized human fibroblast overexpressing or not the oncogenic form of Ras or (2) the mouse melanoma B16 cells. Using lentivirus, we modulated TRF2 expression (overexpression or knockdown), and we analyzed cellular effects of TRF2 modulation *in vitro*. Tumorigenicity of transduced cells was analyzed both in immunocompromised and immunocompetent mice. Immune microenvironment was analyzed 5 days after tumor engraftment. Finally, NK cells functionality was assayed by CD107a degranulation assay.

Results: In a Ras V12 contexture, we observed that TRF2 modulation do not impact neither tumor cell proliferation nor clonogenicity *in vitro and inhibit DDR pathway activation: not clear, I thought that TRF2 downregulation does not activate DDR*. We observed that TRF2 overexpression in both human transformed cells and mouse melanoma cells decreases their ability to activate NK cells *in vitro*. Conversely, a reduced TRF2 dosage can impair tumorigenicity without engaging a cell intrinsic program of proliferation arrest but by an ATM-independent mechanism activating natural killer (NK) cells in both models. In addition, we show that TRF2 dosage modulates NK cell infiltration within the tumor microenvironment and global modification of immune infiltrate.

Conclusions: We demonstrate here that TRF2 dosage in cancer cells modulates their ability to activate NK cels. We propose that the increased level of TRF2 measured in many human tumors can favor cancer progression by a cell extrinsic mechanism contributing to bypass immunosurveillance.

Tumor-infiltrating regulatory T cells favor tumor development by suppressing anti-tumor immunity in patients with primary and metastatic liver cancer

A. Pedroza-Gonzalez,* J. Kwekkeboom,* C. Verhoef,† J. N. M. IJzermans,† M. Peppelenbosch,* J. Verheij,‡ H. L. A. Janssen* & D. Sprengers*

Erasmus MC – University Medical Centre, Gastroenterology and hepatology, Rotterdam, The Netherlands, †Erasmus MC – University Medical Centre, Surgery, Rotterdam, The Netherlands, ‡Erasmus MC – University Medical Centre, Pathology, Rotterdam, The Netherlands

Purpose/Objective: The mechanisms that enable liver cancer to escape elimination by the immune system remain unclear, but their elucidation may provide novel therapeutic interventions.

Materials and methods: We investigated the impact of tumor-infiltrating regulatory T cells on tumor-specific T cell responses in patients with liver cancer, using *ex vivo* isolated cells from individuals with hepatocellular carcinoma (HCC) or liver metastases from colorectal cancer (LM-CRC).

Results: We observed the presence of tumor antigen specific responder CD4+ T cells in the blood of these patients, but they were undetectable in tumor infiltrating lymphocytes (TIL's). In both HCC and LM-CRC, $CD4^+$ CD25+Foxp3+ regulatory T cells (Treg) accumulate in the tumor milieu and are potent suppressors of autologous tumor-specific T cell responses. We show that tumor Treg up-regulate the expression of glucocorticoid-induced tumor necrosis factor receptor (GITR) and the inducible T-cell co-stimulator (ICOS) compared to Treg in tumor-free liver tissue and blood. Importantly, treatment with soluble GITR ligand (sGITRL) induces a decrease in the suppression mediated by the activated tumor-infiltrating Treg and restores the proliferative capacity and cytokine production of $CD4^+$ CD25- T cells.

Conclusions: Our results show that tumor-associated Tregs are critical for immune evasion in liver cancer and we propose that GITRL constitutes a rational treatment for this disease.

P1402

Tumor-specific CD4+ T cells develop cytotoxic activity and eliminate virus-induced tumour cells in the absence of regulatory T cells

I. Akhmetzyanova,* G. Zelinskyy,* S. Schimmer,* T. Sparwasser† & U. Dittmer*

Virology, University Hospital Essen, Essen, Germany, †TWINCORE, Infection immunology, Hannover, Germany

Purpose/Objective: The majorities of tumor viruses is well controlled by the immune system and therefore cause only transient or no disease in their hosts after infection. The important role of tumour-specific cytotoxic $CD8^+$ T cells (CTLs) is well-defined in the immune control of the tumours but the role of effector $CD4^+$ T cells is poorly understood. In addition, the significance of regulatory T cells (Tregs) in inhibiting tumor-specific $CD4^+$ T cell responses during tumor rejection *in vivo* has not been defined.

Materials and methods: In the current research we have used a murine retrovirus-induced tumour cell line of C57BL/6 mouse origin, namely FBL-3 cells, as a model to study basic mechanisms of immunological control and escape during tumour formation. In the present study we used Foxp3 transgenic mice (DEREG) expressing the diphtheria toxin receptor under the control of the Foxp3 promoter, which made it possible to selectively deplete Tregs *in vivo* and to determine the influence of $Foxp3^+$ Tregs on T cell responses during tumor regression. FBL-3 tumor cells were injected subcutaneously on the right flank of the mouse. Tumor size based on caliper measurements was calculated. At different time points mice were sacrificed, and

tumors and draining and non-draining lymph nodes were resected. Data were acquired on an LSRII flow cytometer. Analyses were done using FACSDiva software (Becton Dickinson) and FlowJo software (Treestar).

Results: This study shows that tumour-specific $CD4^+$ T cells are able to protect against virus-induced tumour cells. We show here that there is an expansion of tumour-specific $CD4^+$ T cells producing cytokines (IFN-γ, TNF-α and IL-2) and cytotoxic molecule granzyme B in the early phase of tumour growth. Importantly, we demonstrate that *in vivo* depletion of Tregs and $CD8^+$ T cells in FBL-3-bearing DEREG transgenic mice augments IL-2 and granzyme B production by $CD4^+$ T cells and increases FV-specific $CD4^+$ T-cell effector and cytotoxic responses leading to the complete tumour regression.

Conclusions: Therefore, the capacity to reject tumour acquired by tumour-reactive $CD4^+$ T cells largely depends on the direct suppressive activity of regulatory T cells. We suggest that a cytotoxic $CD4^+$ T cell immune response may be induced to enhance resistance against oncovirus-associated tumours.

P1403

Tumour hypoxia promotes tolerance and angiogenesis via CCL28 and Treg cells

A. Facciabene, X. Peng, I. Hagemann, K. Balint, L. Wang, P. Gimmoty, B. Glilks, P. Lal, L. Zhang & G. Coukos

Ovarian Cancer Research Center, University of Pennsylvania, Philadelphia, PA, USA

Purpose/Objective: Although immune mechanisms can suppress tumor growth, tumors establish potent and overlapping mechanisms that mediate immune evasion. Emerging evidence suggests a link between tumor immune tolerance and angiogenesis. Hypoxia, a condition known to drive tumor angiogenesis, results in release of damage-associated molecular pattern molecules, which can trigger tumor immune rejection. Thus, counter-activation of tolerance mechanisms at the site of tumor hypoxia would be a critical condition to maintain immunologic escape of tumors. Direct link between tumor hypoxia and tolerance through the recruitment of regulatory cells has not been established.

Materials and methods: We used early-passage primary cell lines from 4 solid ovarian cancers and 3 ascites and 10 established human ovarian cancer cell lines. ID8-ccl28 cells were derived from ID8 cells through transfection of codon-optimized *ccl28* cDNA cloned into pCDNA3 vector. For hypoxia experiments, cells were cultured for 16 h under hypoxic (1.5% O_2) or oxic conditions (21% O_2) and 5% CO_2 at 37°C. We used 6–8 week old female C57BL/6 mice to establish intraperitoneal ID8 or ID8-ccl28 tumours. *In vivo* depletion of $CD4^+$ $CD25^+$ cells was achieved with i.p. anti-CD25 Ab (PC61) or immunotoxin developed with anti-mouse CCR10 or CCR3 Ab, conjugated at equimolar ratio with Strep-ZAP. Two publicly available Affymetrix expression array datasets, comprising a total of 353 human ovarian cancer patients, were mined to analyze the interaction of *CCL28* with survival.

Results: Tumor hypoxic media recruited significantly more $CD4^+$ $CD25^+FoxP3^+$ cells relative to oxic media. The ability of hypoxic media to recruit preferentially $CD4^+$ $CD25^+FoxP3^+$ cells was abrogated by antibody neutralizing human CCL28. ID8-ccl28 tumors accumulated significantly more $CD4^+$ $CD25^+FoxP3^+$ cells *in vivo* relative to ID8 tumors. OrthotopicID8-ccl28 tumors exhibited significantly faster growth and ascites development relative to ID8 tumors. Depletion of CCR10 positive cells suppressed tumor growth and abrogated the effects of ccl28 overexpression.

Conclusions: Here we show that tumor hypoxia promotes T regulatory (Treg) cell recruitment via the CCL28 chemokine, which in turn promotes tumor tolerance and angiogenesis. Thus, peripheral immune tolerance and angiogenesis are intimately connected and cooperate to sustain tumor growth.

P1404

Tumour-Associated MDSC in Malignant Pleural Mesothelioma

S. Al-Taei,* J. F. Lester,† M. D. Mason* & Z. Tabi*

**Department of Oncology, Institute of Cancer and Genetics, Cardiff, UK, †Velindre NHS Trust, Velindre Hospital, Cardiff, UK*

Purpose/Objective: We previously identified 5T4, a 72 kDa oncofetal antigen, on all malignant pleural mesothelioma (MPM) cell lines, pleural fluid (PF)-localised tumour cells and tumour tissue tested by flow cytometry, immunohistochemistry and Western blotting ($n = 42$). We observed $CD8^+$ and $CD4^+$ 5T4-specific T cell responses in the peripheral blood, but to a lesser extent in the tumour associated PF of patients. This indicated that localised immunosuppression was possibly hindering immune interactions. The relevance of regulatory T cells (Tregs) in MPM is not proven, whilst the presence of suppressive monocytes, such as myeloid derived suppressor cells (MDSC) has not been previously addressed. We aimed to elucidate the presence and relevance of Tregs and MDSC in patients as they may need to be considered for optimal immunotherapy.

Materials and methods: Flow cytometry was used to detect Tregs ($CD4^+$ CD25hi$Foxp3^+$) or MDSC (defined here as $CD3^-$ $CD14^-$ HLA-DR^- cells located within the monocyte gate). Mixed lymphocyte reaction (MLR) was carried out by stimulating allogeneic T cells with either $CD14^+$HLA-DR^+ classical monocytes or with $CD3^-$ $CD14^-$ HLA-DR^- cells. T cell proliferation was measured with a thymidine incorporation assay. Antigen-specific T cell stimulation was conducted over 6 days using PF cells pulsed with viral, 5T4 or common tumour antigen peptide pools, followed by intracellular IL-2/IFN-γ flow cytometry staining.

Results: We found that the levels of Tregs in MPM patients were not significantly elevated above those found in healthy blood. However, we identified a $CD14^-$ HLA-DR^- subset of cells with highly upregulated CD11b, CD15 and CD33 in the PF, when compared to the same population in patient and healthy blood. These cells also showed upregulation of the suppressive marker CD200 and were shown to suppress T cell proliferation in a MLR. Furthermore, they were able to suppress T cell IL-2/IFN-γ production in response to antigenic stimulation in some patients.

Conclusions: We report here for the first time the presence of MDSC in MPM patients. These MDSC are functional in patient PF, significantly decreasing T-cell proliferation and cytokine production in response to both antigen-specific and non-specific stimulation. MDSC may contribute to tumour-related immunosuppression in the tumour environment in MPM.

P1405

Use of Telomerase-derived Universal Cancer Peptides for dynamic monitoring of CD_4 T cell responses and cancer vaccines improvement

M. Dosset,* Y. Godet,* C. Vauchy,* E. Levionnois,† L. Beziaud,* C. Sedlik,‡ P. Langlade-Demoyen,§ E. Tartour,† C. Borg* & O. Adotevi*

**Umr1098 inserm/efs/ufc, Thérapeutique Immuno-Moléculaire Des Cancers, Besançon, France, †Umr970 Inserm, Immunologie, Paris, France, ‡Inserm u93,2 Immunologie, Paris, France, §Invectys, Institut Pasteur Biotop, Paris, France*

Purpose/Objective: The stimulation of CD4+ T helper cell responses has gained considerable interest for cancer immunotherapy. We evaluate the antitumor potential of CD4 T cells specific of novel telo-

merase-derived peptides referred as universal cancer peptide (UCP) that bind to most commonly found HLA-DR alleles.
Materials and methods: We prospectively studied a cohort of 84 advanced NSCLC patients for the presence of naturally occurring UCP-specific CD4 T cells prior chemotherapy (CT). A relevant preclinical HLA-A2/DR1 transgenic mouse model was used to evaluate the potential of UCP-based cancer vaccine.
Results: Significant frequency (38%) of naturally occurring UCP-specific CD4 T-cell responses were detected before CT in advanced NSCLC but not in healthy volunteers. UCP-specific CD4 T-cell clones generated from cancer patients exhibited high avidity and are Th1 polarized. Interestingly, the presence of UCP-specific T cell response was shown to significantly increase overall survival (OS) of patients responding to CT (Median OS: 53 versus 40 weeks, $P < 0.034$). By using a HLA-A2/DR1 transgenic mouse model, we showed that UCP-specific CD4+ T cells induced after vaccination fulfilled helper features necessary to generate potent tumor-specific CTL responses. Furthermore the use of UCPs in therapeutic vaccination breaks self tolerance against telomerase and eradicates established mouse melanoma by promoting massive CD8+ T cells recruitment at the tumor site.
Conclusions: Together with the presence of natural UCP-specific T cell responses in many other cancers, these results support that the stimulation of UCP-specific CD4+ helper T cells is a powerful method to improve cancer vaccines efficiency and provides a new tool for comprehensive monitoring of antitumor responses in cancer patients.

P1406
VEGF-A-induced Treg proliferation, a novel mechanism of tumor immune escape in colorectal cancer: effects of anti-VEGF/VEGFR therapies

M. Terme, S. Pernot, E. Marcheteau, O. Colussi, F. Sandoval, N. Benhamouda, E. Tartour & J. Taieb
Université Paris-Descartes, Inserm U970, Paris, France

Purpose/Objective: Regulatory T cells (Treg) are suspected of hindering an effective antitumor immune response in cancer. Multi-target anti-angiogenic tyrosine kinase inhibitors (TKI) that are routinely used as first or second line treatment of cancer patients, have been shown to decrease Treg proportion in tumor-bearing mice and metastatic renal cancer patients. However, the role of VEGF/VEGFR blockade in this effect is still debatable, and the direct impact of VEGF-A on Treg has not been studied.
Materials and methods: Treg proportion, number were analyzed by flow cytometry in peripheral blood of metastatic colorectal cancer (mCRC) patients treated with bevacizumab, and in CT26 tumor-bearing mice treated with drugs targeting the VEGF axis. The direct impact of VEGF on Treg increase in cancer was also studied.
Results: Sunitinib (a TKI targeting VEGFR, PDGFR, c-kit), and anti-VEGF-A antibody both decreased Treg in CT26 tumor-bearing mice. Masitinib, a TKI that does not target VEGFR, did not reduce Treg proportion in CT26 bearing mice. Bevacizumab, an anti-VEGF-A monoclonal antibody, reduced Treg proportion in peripheral blood of mCRC patients. Proliferation of Treg was enhanced in CT26 tumor-bearing mice compared to tumor-free mice and was decreased after anti-VEGF-A treatment. Furthermore, *in vitro* experiments have shown that VEGF-A could directly induce Treg proliferation. VEGFR1 and 2 were expressed on Treg in the presence of a tumor. Anti-VEGFR2 antibody administration reduces Treg proportion and also proliferation in CT26 bearing mice, but anti-VEGFR1 antibody did not, suggesting that VEGF-A-induced Treg proliferation was dependent on VEGFR2 expression. In metastatic CRC patients, Treg proliferation was also enhanced compared to healthy volunteers and was blocked by bevacizumab treatment.
Conclusions: We identified a new mechanism by which VEGF-A induced by the tumor could stimulate Treg proliferation. VEGF-A/VEGFR2 blockade reduced Treg proportion and proliferation in tumor-bearing mice and metastatic CRC patients suggesting that combination of anti-VEGF-A/VEGFR2 therapies with immunotherapeutic approaches in the future might be particularly relevant in CRC patients.

P1407
IFN inducible genes, programmed cell death and cancer

Z. Alteber, E. Tzehoval & L. Eisenbach
Immunology, The Weizmann Institute of Science, Rehovot, Israel

Purpose/Objective: The Interferon inducible transmembrane protein family (IFITM) consists of several members, highly homologous and conserved among species. The IFITM genes are involved in multiple cellular processes: early development, immune response, inflammation, malignant transformation, cell cycle control etc. They were recently found to powerfully inhibit virus infection *in vitro* and to restrict the morbidity and mortality induced by Influenza infection *in vivo*. Members of the IFITM family are overexpressed in inflamed and malignant tissues, in mice and humans. Moreover, IFITM expression was shown to be altered during malignant transformation in the gastro-intestinal tract. We have highlighted the IFITM proteins as putative immunodominant tumor-associated antigens of colon carcinoma, since peptides derived from the IFITM2 protein induced both immunogenic and antigenic responses in humanized mice. We have previously reported that exogenous overexpression of IFITM2, induced apoptosis in various cell lines, through the intrinsic mitochondrial pathway, independently of p53. Furthermore, we have shown that overexpression of wild-type p53 (WTp53), downregulated IFITM2 steady-state protein levels.
Materials and Methods: As a part of our effort to characterize the IFITM2 gene, its functions and contribution to tumorigenesis, the presented study was designed to establish the detected downregulation in IFITM2 expression levels by WTp53 and to investigate the mechanism of suppression.
Results: Here we show that the regulation of endogenous IFITM2, at the protein level, is specifically p53-dependent and cell-independent. On the other hand, the regulation of IFITM2, at the RNA level, is cell and condition-specific. We demonstrate that the action of p53 on IFITM2 levels requires the integrity of the DNA binding and transactivation domains. Thus, it is probably mediated by a DNA-bound form of p53. This indicates on participation of another, yet unidentified, factor in this regulation. Finally, we show that IFITM2 is degraded by the lysosomal and not by the proteosomal pathway.
Conclusions: Further investigation of the precise mechanisms, by which IFITM2 is regulated, as well as its functional activity in tumor microenvironment are of great importance in attributing to our understanding of the cancer pathology.

Poster session: Veterinary Immunology

P1408

A sandwich ELISA for quantitative detection of transcription factor of porcine natural regulatory T cell

Y. Zhao,* A. Jia,† G. Wang† & C. Lu*
*College of Veterinary Medicine, NanJing Agricultural University, Nanjing, China, †Vaccine Group, Guangdong Institute of Modern Agriculture Group, Guangzhou, China

Purpose/Objective: The transcription factor forkhead box P3 (Foxp3) is not only a master regulator for the development and the function of natural regulatory T cell (nTreg), but also the most specific marker identified thus far for nTreg. To understand the role of Foxp3 in all sorts of immune responses in swine, it is necessary to determine the function and the expression level of Foxp3. A sensitive and specific indirect sandwich enzyme-linked immunosorbent assay (ELISA) for detecting porcine Foxp3 was developed.
Materials and methods: The prokaryotic expression vector pET-28a-Foxp3 transformed into host strain *E. coli* BL21. The fusion protein about 48 kDa was induced by IPTG and purified with Ni-NTA Agarose. The rabbit antiserum against porcine Foxp3 protein was obtained by immunizing a rabbit with purified fusion protein. In addition, five hybridoma cell clones (2A4, 2C4, 3F3, 4C8 and 4C11) were obtained, which can be cultured stably and secret McAb against porcine Foxp3 protein. By Protein G affinity chromatography, McAb 4C8 and the antiserum were purified and then used as coating antibody and detecting antibody, respectively.
Results: The relationship between ELISA signal and concentration of Foxp3 was linear with an R^2 of 0.9981. Minimum detectable concentration was 0.458 ng/ml. Using this ELISA, samples of 17 diseased pigs and 27 disease-free pigs were detected. Mean and standard deviation of the above two groups were 108.82, 85.77 and 167.54, 89.97, respectively. One-way ANOVA analysis showed that the difference was significant ($P < 0.05$).
Conclusions: An indirect sandwich ELISA for detection of porcine Foxp3 with McAb and PcAb was established and it will be useful to detect porcine Foxp3 and nTreg.

P1409

Adenovirus-mediated canine interferon-γ expression and its antiviral activity to canine parvovirus

F. Zhong,* K. Zhang,* H. J. Jin,* X. J. Li,† C. A. Neng,† H. H. Chen,‡ W. Y. Li‡ & J. X. Wen‡
*Veterinary Medicine, Agricultural University of Hebei, Baoding, China, †Environmental and Chemical Engineering, Yanshan University, Qinhuangdao, China, ‡Veterinary Medicine, Agricultural University of Hebei, Baoding, China

Purpose/Objective: To investigate adenovirus-mediated IFN-γ gene transductionand its antiviral activity to CPV in canine kidney cells (MDCK).
Materials and methods: The cIFN-γ gene amplified by RT-PCR was inserted into adenovirus shuttle plasmid to construct pShuttle3-cIFN-γ vector, from which the cIFN-γ expression cassette was transfered into the adenovirus genomic plasmid pAdeno-X by specific restriction sites to generate recombinant adenovirus genomic plasmid pAd-cIFN-γ. The plasmid pAd-cIFN-γ was linearized by Pac Idigestion and transfected into human embryonic kidney (HEK) 293T cells to generate the replication-defective cIFN-γ recombinant adenovirus. The cIFN-γ recombinant adenovirus was identified by PCR and the recombinant cIFN-γ expression was identified by Western blot. To analyze its anti-canine parvovirus activity, the MDCK cells were pre-infected by cIFN-γ recombinant adenovirus, and then infected by canine parvovirus. The antiviral activity of the cIFN-γ recombinant adenovirus against parvovirus was evaluated based on the parvovirus titer reduction.
Results: The results showed that the recombinant adenovirus containing cIFN-γ gene was successfully constructed by the ligation method. Western-blot analysis showed the recombinant adenovirus could mediate cIFN-γ secretory expression in MDCK cells. The cIFN-γ recombinant adenovirus could significantly inhibit canine parvovirus replication in MDCK cells pre-infected with the recombinant virus.
Conclusions: The cIFN-γ recombinant adenovirus has the potent antiviral activity to canine parvovirus.

P1410

Anti-canine parvovirus activity of recombinant canine soluble transferring receptor prepared with codon-optimized gene construct

F. Zhong,* S. M. Pan,* X. J. Li,† C. A. Neng,† K. Zhang,‡ H. H. Chen,‡ W. Y. Li‡ & J. X. Wen‡
*Veterinary Medicine, Agricultural University of Hebei, Baoding, China, †Environmental and Chemical Engineering, Yanshan University, Qinhuangdao, China, ‡Veterinary Medicine, Agricultural Uiversity of Hebei, Baoding, China

Purpose/Objective: To inhibit canine parvovirus (CPV) infection using recombinant soluble canine transferrin receptor (sTfR), the receptor of CPV.
Materials and methods: The codon-optimized sTfR gene was inserted into pcDNA3.1A-CD5 plasmid by fusing His-tag to the C-terminus and human CD5 signal peptide to the N-terminus of sTfR, respectively. The sTfR vector was then transfected into HEK 293FT cells, the expressed sTfR was purified from culture supernatants by Ni-NTA agarose affinity chromatography and identified by Western-blot. Furthermore, the binding ability of sTfR to CPV and CPV envelope protein 2 (VP2) were analyzed by ELISA., and the sTfR antiviral activity against CPV was evaluated by viral titer reduction in feline F81 cells.
Results: The results showed that codon optimization significantly enhanced (a more than twofold increase) sTfR expression compared with wild-type sTfR. Moreover, the recombinant sTfR is able to specifically bind to CPV and VP2 proteins and also capable of preventing CPV infection in the host cells.
Conclusions: The recombinant sTfRpossesses the antiviral activity to CPV, which provides the solid foundation for further investigation of sTfR anti-CPV activity with dogs *in vivo*.

P1411

CCL2 and CCL5 induce LPS-insensitive S100A8/A9-positive bovine macrophages

H. J. Schuberth, C. Frank, J. Hussen, J. Maass & A. Düvel
Institute of Immunology, University of Veterinary Medicine, Hannover, Germany

Purpose/Objective: Little is known about macrophage plasticity in the bovine system, where two mutually exclusive subpopulations can be identified in tissues. The objective was a) to analyze whether monocyte-attracting chemokines CCL2 and CCL5 skew the differentiation of macrophages into CD163+ or S100A8/A9+ cells and b) to analyze the functional phenotype of CCL2/CCL5-differentiated macrophages.
Materials and methods: MACS-separated peripheral blood monocytes (using a mouse anti-human CD172a mAb) were phenotyped for their CD14 expression. RboCCL2 or rboCCL5-induced $Ca2^+$ influx was assessed flow cytometrically with Fluo-4-loaded monocytes. Monocytes were cultivated *in vitro* for up to 7 days in the presence or absence of rboCCL2, rboCCL5. At day 4 and day 7 cells were analyzed flow cytometrically for their expression of CD163 and

S100A8/A9. Day 7 macrophages were stimulated for 3 h with LPS. Quantitative RT-PCR was performed for CXCL1, CXCL8, Arginase, iNOS, IL-10, and IL-12.

Results: Bovine monocyte subpopulations were identified as $CD172a^{+}/CD14^{high}$ (71.8%) and $CD172a^{+}/CD14^{low}$ monocytes (28.4%). CCL5-mediated Ca^{2+} influx in monocytes was significantly stronger than CCL2-mediated cell activation (with $CD14^{high}$ monocytes responding more sensitive than $CD14^{low}$ cells). The presence of CCL2 and CCL5 gave rise to macrophages (CCL2/5-MdM) with significantly up-regulated S100A8/A9 expression and significantly down-regulated CD613 expression. In CCL2/5-MdM the basal mRNA expression of CXCL1 and CXCL8 was significantly up-regulated. The mRNA expression of anti-inflammatory mediators (IL-10, Arginase) and pro-inflammatory mediators (IL-12 and iNOS) were not influenced by CCL2 and CCL5 during the differentiation and could not be enhanced by LPS stimulation.

Conclusions: The principal possibility of directing monocyte/macrophage differentiation *in vitro* has been demonstrated with rboCCL2 and rboCCL5, which skew the differentiation of monocytes into $S100A8/A9^{+}$ macrophages. Their LPS-insensitive phenotype is in contrast to the general opinion, that such macrophages *in vivo* are pro-inflammatory. Their *in vivo* role and function should be reconsidered and analyzed in more detail.

P1414

Equine arteritis virus replication in monocytic cells suppresses differentiation and function of dendritic cells

N. Moyo,* D. Westcott,* R. Simmonds† & F. Steinbach*
**Virology Department, Animal Health & Veterinary Laboratories Agency, Weybridge, UK, †Microbial & Cellular Sciences, University of Surrey, Guildford, UK*

Purpose/Objective: Equine viral arteritis (EVA) is an infectious disease of equids caused by equine arteritis virus (EAV), a single-stranded RNA virus of the family *Arteriviridae*. Dendritic cells (DC) are important modulators of the immune reaction with the ability to present antigen to naïve T cells and are crucial for the establishment of protective antiviral immunity. DC can be generated *in vitro* from monocytes (MoDC). Little is known of the effect EAV has on host immune cells, particularly DC. Understanding how the role of DC is affected during infection with EAV can provide insight into the mechanisms used by this virus to potentially exploit DC.

Materials and methods: An optimized system was established to generate equine monocyte-derived DC (eqMoDC) *in vitro*. Purified recombinant equine cytokines (GM-CSF & IL-4) were used to differentiate monocytes to immature MoDC (iMoDC) and a pro-inflammatory cocktail was used for maturation of iMoDC to mature MoDC (mMoDC). The phenotype of DC was studied, using flow cytometry and functional assays such as endocytosis/phagocytosis and mixed leukocyte reaction (MLR) were applied to characterise immature and mature MoDC. To study the interaction with EAV, MoDC were infected at multiplicity of infection of 5 with EAV strains of different genotypes and pathogenicity. Virus replication was determined through titration and real-time PCR (qPCR).

Results: Real-time qPCR and viral titrations revealed that EAV replicates in monocytes and MoDC. The replication was most efficient in mMoDC, but variable between the strains. Only the virulent strain caused a significant down-regulation of CD14 and CD163 on monocytes and of CD83 on mMoDC. The replication of the virus resulted in an apoptosis mediated cell death, which inevitably inhibited the differentiation and long-term function of DC. Functional studies carried out early after infection showed that EAV inhibited the endocytic and phagocytic capacity of Mo and mMoDC with minimal effect on iMoDC. In line with the detrimental effects and results of the virus replication, particularly infected mMoDC showed a reduced ability to stimulate T cells.

Conclusions: EAV evades the host antiviral immunity both by inhibition of antigen presentation early after infection and through killing infected DC during replication.

P1415

Expansion of combinatorial primary antibody repertoire in domestic cattle prior to the exposure of external antigens

J. Liljavirta, A. Ekman, M. Niku & A. Iivanainen
Department of Veterinary Biosciences, University of Helsinki, Helsinki, Finland

Purpose/Objective: In many domestic species fetal and neonatal gut-associated lymphoid tissue (GALT) is essential for the generation of the primary antibody repertoire. We found limited range of immunoglobulin genes in the bovine genome (Ekman *et al*. 2009, Niku *et al*. 2012) that effectively limits the degree of combinatorial diversity in cattle. In some species mechanisms such as junctional diversity may contribute significantly to the repertoire expansion. Terminal deoxynucleotidyl transferase (TdT) adds N-nucleotides between immunoglobulin gene segments primarily during heavy-chain gene rearrangement. However, in order to effectively compensate the limited recombinatorial diversity, many domestic species rely on GALT for further postrecombinatorial inflation of their primary antibody repertoire.

Somatic hypermutation (SHM) and gene conversion (GC) have been suggested to expand the limited antibody repertoire in ruminants prior to encountering external antigen. These post-recombinatorial processes are dependent on activation-induced cytidine deaminase (AID). It favours to deaminate C residues in WRCY hot spot motif (W = A/T, R = A/G, Y = C/T). This error in DNA sequence is either replicated or recognized by base excision or mismatch repair pathways. The outcome is often a mutation regardless of the mechanism.

Materials and methods: We studied the contribution of TdT and AID to the size of primary antibody repertoire in bovine fetuses. The expression levels were measured using reverse transcription-qPCR and the specific localizations were analyzed using immunohistochemistry. Several IgH cDNA libraries of different developmental stages were constructed and mutations were analyzed.

Results: Our work demonstrates TdT expression in bone marrow and a strong AID expression in ileal Peyer's patch. V-D-J junctions appeared heterogeneous in sequence, suggesting the addition of N-nucleotides by TdT. AID hotspot motif WRCY was preferentially mutated. Also, we found preferentialtargeting of complementarity-determining region (CDR) over framework region (FR) and preference of replacement over silent mutations in CDRs but not in FRs.

Conclusions: In conclusion, our results suggest that both TdT-mediated junctional diversity and AID mediated SHM contribute to the expansion of primary antibody repertoire in bovine fetuses prior to the presence exogenous antigens.

P1416

Extension of the storage time of blood in interferon gamma assays to diagnose paratuberculosis: combination of IL-7 and IL-12 stimulation

D. J. Begg, K. M. Plain, K. de Silva, A. C. Purdie & R. J. Whittington
Veterinary Science, The University of Sydney, Sydney, Australia

Purpose/Objective: Detection of specific interferon gamma (IFN-γ) responses can aid in the diagnosis and control of paratuberculosis in sheep and cattle. IFN-γ is produced as part of the cell-mediated immune response to *Mycobacterium avium* subspecies paratuberculosis

(MAP) infection. IFN-γ detection assays offer the potential to detect more infected animals at an earlier stage of the disease than antibody ELISA, providing an opportunity for control strategies aimed at the removal of young infected animals before they shed bacteria into the environment. A limitation to the widespread application of IFN-γ assays has been logistical difficulties, as the assay needs to be performed within 8 h of blood collection. Earlier research has shown that, for bovine blood samples with a delayed assay setup (24 h), addition of Interleukin (IL)-12 can rescue the Th1 cells that produce IFN-g. For some countries such as Australia, however, samples may take up to 2 days to reach a laboratory. For this reason an improved protocol, applicable across multiple species, was required to increase white blood cell survival. IL-7 is a survival factor required to maintain resting T cells in cell culture. We hypothesised that IL-7 alone or in combination with IL-12, added at stimulation, could extend blood storage time.

Materials and methods: Blood collected from MAP infected sheep was stored from 0 to 4 days at room temperature, after which time IL-12 and or IL-7 was added to the blood with MAP specific antigens. After 48 h incubation the supernatant was harvested and examined by ELISA for IFN-γ.

Results: The addition of IL-7 and IL-12 in combination had a synergistic effect, giving IFN-g responses greater than adding IL-12 alone, for sheep blood stored up to 2 days. Better recovery of IFN-g responses was achieved for animals with low grade and paucibacillary lesions compared to animals with multibacillary disease. From a cohort of naturally infected sheep it was found that the same number of animals could be identified as test positive with blood samples stored for 2 days with addition of IL-7 and IL-12 compared to the same blood samples set up within 8 h of collection without additives.

Conclusions: This practical and easily implemented potentiation protocol (IFN-γPlus assay) extends the permissible transit time of blood samples from farm to laboratory for IFN-γ testing to detect Johne's disease.

P1417

FAS and FAS-L expression and apoptosis in the CD4+ T and CD8+ T cells from PBMC and spleen in dogs with visceral leishmaniasis

V. M. F. Lima, K. L. O. Silva, L. M. Melo, J. Perosso & B. B. Oliveira
Faculdade de Medicina Veterinária, Clínica Cirurgia e Reprodução Animal, Araçatuba, Brazil

Purpose/Objective: Dogs are the main domestic reservoirs of *L. (L.) chagasi*. Once in the vertebrate host, the parasite may cause visceral leishmaniasis, which can also be transmitted to humans. Infected symptomatic dogs show a reduction in T lymphocytes in spleen and peripheral blood. To investigate whether apoptosis is involved with diminished T cell counts in peripheral blood and spleen, apoptotic CD4+ T and CD8+ T cells from the spleen and peripheral blood of dogs naturally infected with *L. (L.) chagasi* and presenting clinical manifestations were quantified and compared with healthy dogs. The receptors involved in apoptosis were also investigated to determine which receptors are involved in the process of apoptosis.

Materials and methods: Fifteen symptomatic adult dogs infected by *L. (L.) chagasi* and six healthy dogs from a nonendemic area (controls) were included in the study. Samples from spleen and peripheral blood were used to quantify apoptosis in CD4+ and CD8+ lymphocytes and the cellular receptors involved in apoptosis. The apoptosis was measured by flow cytometry using Anexin V kit. The cellular receptors in CD4+ or CD8+ lymphocytes were measured using monoclonal antibodies anti-FAS-PE-Cy5, or anti FASL-PE, or anti TRAIL-PE by flow cytometry; the results were compared using the Mann Whitney test.

Results: The percentage of total of apoptosis levels in T CD4+ and T CD8+ lymphocytes from spleen and PBMC were higher in infected dogs than in controls. It was observed a decreased expression of FAS and FAS-L on CD4+ T lymphocytes from spleen from infected dogs compared to healthy ones, and similar result was observed to FAS-L on CD8 T lymphocytes from spleen. In PBMC only FAS-L on CD4+ lymphocytes showed decrease in infected dogs. The TRAIL receptor not showed difference between two groups. The blocking of receptors using monoclonal antibodies is in progress to understanding of the mechanisms of apoptosis.

Conclusions: Taken together, these data indicate that in infected dogs, the immunosuppression associated with chronic infection and decrease of lymphocytes is related to apoptosis of CD4+ and CD8+ T The present results could contribute to improving current understanding of the immune response in dogs infected with *L. (L.) chagasi*, while additional studies can allow future therapeutic interventions in order to reduce the depletion of lymphocytes, thus increasing the capacity of the defense.

Genetic basis of resistance to viral diseases in rainbow trout

E. R. Verrier,* C. Langevin,* C. Torhy,* C. Ciobataru,† E. Quillet† & P. Boudinot*
**Institut National de la Recherche Agronomique, VIM, Jouy-en-Josas, France, †Institut National de la Recherche Agronomique, Gabi, Jouy-en-Josas, France*

Purpose/Objective: Controlling health of livestock is a key component of competitiveness and sustainability of fish breeding. Selection schemes (including marker-assisted selection) for resistance to pathogens already exist in fish farms. The aim of this project is to better understand the mechanisms of resistance to viral hemorrhagic septicemia virus (VHSV) in rainbow trout.

Materials and methods: Susceptible and resistant homozygous mitogynogenetic grand-parents were selected for their ability to support *in vitro* viral growth on fin explants, that was previously shown to correlate with resistance in order to study the genetic bases of resistance to VHSH. In parralel, cell lines were derived from a set of previously established resistant and susceptible mitogynogenetic clonal trout lines (Quillet *et al.*, 2007).

Results: A major quantitative trait loci (QTL) was identified, that controls both survival after waterborne infection and *in vitro* viral growth in fin explants. In parralel, the susceptibility of the cell lines to VHSV appeared well-correlated to the survival of the corresponding fish. The comparison of resistant versus susceptible lines demonstrated that key mechanisms are induced by the very early steps of infection, before the interferon induced response.

Conclusions: Taken together, these results strongly suggest the involvement of non-adaptive immune mechanisms in resistance to VHSV in rainbow trout.

Mechanisms and genes responsible for these phenotypes are under characterization, and will provide useful tools to develop selection schemes for future breedings.

Identification of a parasite antigen recognised by both CD4 and CD8 T cells specific for lymphoblasts infected with *Theileria parva*

A. Aguado-Martinez, N. D. MacHugh & W. I. Morrison
Infection & Immunity, The Roslin Institute, Edinburgh, UK

Purpose/Objective: Infection of cattle with the tick-borne protozoan *Theileria parva* induces strong CD4 and CD8 T cell responses specific for parasitized cells. Adoptive cell transfer experiments with purified T cell subsets have demonstrated that CD8 T cells play a key role in

immunity and a number of *T. parva* antigens recognised by CD8 T cells have been identified. The aim of this study was to identify antigens recognised by parasite-specific CD4 T cells in order to investigate and the pathways by which the antigens are processed within infected cells and their role in immunity.
Materials and methods: Parasite-specific CD4 and CD8 T cell lines specific for parasitized cells were generated from cattle of defined MHC genotypes that had been immunised with *T. parva* by infection and treatment. CD8 T cells were used to screen a *T. parva* cDNA library as described previously (Graham *et al.*, 2006, *Proc Natl Acad Sci USA* 103: 3286-91). CD4 T cell antigen recognition involved screening of antigen-presenting cells incubated with pooled overlapping peptides for a series of candidate genes. T cell clones were generated to identify epitopes and to determine the dominance within the cultures.
Results: A novel CD8 T cell antigen termed Tp9 was identified, which was presented by the N*2301 class I MHC allele. A single 10 amino acid epitope was identified within Tp9. Screening of pooled peptides for 20 *T. parva* antigens with CD4 T cells identified four antigens including Tp9, which was recognised by CD4 T cells from seven cattle. A number of animals expressing different DR alleles did not recognise this antigen. Subsequent class II MHC typing showed that six of the seven positive animals shared the 1101 class II DRB allele and that they all recognised a single common peptide in Tp9. The CD4 T cell lines were also shown to recognise CHO cells transfected with a DR $\alpha\beta$ cDNA construct expressing the 1101 DRB allele. Analysis of a set of CD4 T cell clones from an animal homozygous for DRB 1101 revealed that >40% of the clones were specific for the epitope within this peptide.
Conclusions: The results of this study indicate that, as shown previously for CD8 T cells, CD4 T cell responses to *T. parva*-infected cells in individual animals are focused on a limited number of antigens/epitopes. Further studies are underway to investigate processing of the Tp9 antigen in infected cells for CD4 T cell response.

Identification of new antigens from *Rhipicephalus microplus* ticks associated to infestation phenotypes of susceptibility or resistance in bovine hosts

G. R. Garcia,* J. M. Ribeiro,† S. R. Maruyama,* L. G. Gardinassi,* K. Nelson,‡ D. Rossi,§ B. R. Ferreira,¶ F. C. Galvao,§ C. F. Zanelli,§ S. R. Valentini,§ A. M. Maia & I. K. F. de Miranda Santos***
**Biochemistry and Immunology, Medical School of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, †National Institutes of Health-USA, National Institute of Allergy and Infectious Diseases, Rockville, MD, USA, ‡Center for the Study of Biological Complexity, Virginia Commonwealth University, Richmond, VA, USA, §School of Pharmaceutical Sciences, São Paulo State University, Araraquara, Brazil, ¶Ribeirão Preto School of Nursing, University of Sao Paulo, Ribeirão Preto, Brazil, **School of Animal Science and Food Technology, University of Sao Paulo, Pirassununga, Brazil*

Purpose/Objective: *Rhipicephalus microplus* cattle tick causes great economic losses to livestock. Current vaccines have partial and transient effects against infestations. To develop effective anti-tick vaccines, new targets must be identified. Bovines express breed-specific, heritable, contrasting phenotypes during infestation. Composition of tick saliva proteins may be affected by these different levels of host immunity and may be crucial to hematophagy, i.e., potential antigens.
Materials and methods: With DIGE, MudPIT and 454-based RNA-Seq we investigated the protein expression profile of salivary glands from nymphs (NSG), males (MSG) and females (FSG) from *R. microplus* ticks fed on resistant or susceptible bovines as well as unfed larvae (UFL) from eggs of females fed on these hosts.
Results: We identified 321 different proteins: 68 in samples derived from the ticks fed on susceptible hosts, 17 only on resistant and 236 shared by both groups. DIGE results showed 20 differentially expressed proteins in UFL, 27 in NSG and 35 in FSG. In addition, the sialotranscriptome revealed 11 676 coding sequences (CDS), with 3590 CDS for putative secreted proteins. Many differentially expressed proteins in the global analyses show similarity with proteases, nucleases, protease inhibitors, antimicrobial peptides and pathogen recognition proteins among others and are associated with the immunity raised in susceptible or resistant hosts.
Conclusions: This study represents the first attempt to identify protein profiles in developmental stages of *R. microplus* ticks that are affected by the different host immune responses developed by susceptible or resistant bovines. It offers an opportunity to identify new protective antigens for an effective anti-tick vaccine.

P1422

Ig-free colostral whey-supplemented formula: effects on adherent intestinal microflora and immune state of normal and low birth weight piglets

B. R. Tambuyzer,* L. Che,† M. De Vos,* V. Huygelen,* S. Willemen,* S. Van Cruchten,* C. Casteleyn* & C. Van Ginneken*
**Applied Veterinary Morphology, University of Antwerp, Wilrijk, Antwerp, Belgium, †Swine Nutrition Group Institute of Animal Nutrition, Sichuan Agricultural University, Sichuan, China*

Purpose/Objective: The use of hyperprolific hybrid sows in pig industry has led to increased litter sizes and consequently more low birth weight (LBW) piglets. At birth these animals are less competitive, which results in lower colostrum intake, making them more prone to infectious diseases. Pig farmers often transfer piglets to brooders where they are artificially fed with formula *ad libitum* until weaning. This research aims to elucidate the benefit of colostral whey fraction provided in conjunction with formula by its effect on the piglet's gut immune system and intestinal flora.
Materials and methods: LBW and normal birth weight (NBW) piglets, from day 3 onwards, were fed formula or formula supplemented with colostral whey fraction (Ig-free, <50 kDa, daily/7d). At 10 or 28 days of age, ileal samples were collected for analysis of the adherent microflora (LPS and Gram staining) combined with RT-PCR analysis of (innate) immune-related genes (TLR pathway, cytokines).
Results: In contrast to sow-fed animals, which had a beneficial ratio (i.e. 1.5) of $Gram^+$ to $Gram^-$ bacteria, LBW and NBW piglets reared on formula till day 10 had an adherent flora that was richer in $Gram^-$ bacteria (ratio's 0.66 and 0.33, respectively). Alternatively, formula feeding supplemented with colostral whey fraction, improved these ratio's (0.75 and 1.33, respectively). Whey fraction-supplemented piglets showed a significantly increased TLR-2 expression ($P = 0.01$) and lower expression of IL-1b ($P = 0.04$) in the gut, irrespective of birth weight. Additionally, NOD2 expression was increased specifically in LBW piglets when fed supplemented formula ($P = 0.05$). At day 28, most animals displayed a predominantly $Gram^+$ adherent microflora (ratio >1), except for NBW piglets fed supplemented formula (0.6). However, the optimal ratio of a sow-fed animal (LBW: 1.875, NBW: 2.5) was never reached. The expression of virtually all immune proteins dropped with age, except for NF-κB in animals fed supplemented formula ($P = 0.03$), which is consistent with the maturation of the immune system towards adaptive immunity.
Conclusions: In conclusion, a more beneficial microflora is preponderant in piglets fed formula with colostral whey fraction at day 10, which seems to be related to an altered immune state of the gut. However, this effect did not prevail in the long term, possibly due to supplementation restricted to the first week.

P1423

Immunoproteomics analysis of Brucella abortus antigen reveals differential antibody profiles between S19-vaccinated and naturally infected cattle

A. C. Pajuaba,* D. A. Silva,* K. C. Almeida,* J. P. Cunha-Junior,* C. P. Pirovani,† L. R. Camillo† & J. R. Mineo*

**Immunology Microbiology and Parasitology, Institute for Biomedical Sciences, Universidade Federal de Uberlândia, Uberlandia, Brazil, †Universidade Estadual de Santa Cruz, Institute of Biotechnology, Ilhéus, Brazil*

Purpose/Objective: Brucellosis is an infectious disease caused by bacteria of the genus *Brucella* and it is one of the most widespread zoonotic diseases, including infectious abortion in domestic animals and potentially debilitating infection in humans. The food-producing herds, such as cattle, sheep, goats, and pigs are highly susceptible to disease. In some areas, however, the complete control of disease is complicated by the presence of wildlife reservoirs. The diagnosis of brucellosis is mainly based on serological methods, because of the requirement for faster and more reliable diagnostic tests. The majority of the conventional serological tests use whole cell preparations, sonicated cell extracts, or lipopolysaccharide (LPS)-enriched fractions obtained from smooth (S) *B. abortus* strains, called the S-LPS antigen. Although LPS induces a strong antibody response and classical serological tests are mainly based on the detection of antibodies to LPS, there are some limitations in the use of these S-LPS antigen preparations.

This study aimed to characterize a *B. abortus* S19 antigen preparation obtained by Triton X-114 (TX-114) extraction through immunoproteomics to differentiate infected from vaccinated cattle.

Materials and methods: Three groups of bovine were studied: GI, 30 naturally infected cows; GII, 30 S19-vaccinated heifers; and GIII, 30 nonvaccinated seronegative cows. Serum samples from these animals were analyzed and one-dimensional (1D) and two-dimensional (2D) electrophoretic were obtained from the TX-114 hydrophilic phase antigen of the bacteria, followed by MS/MS analysis, after immunoblotting assays.

Results: The results revealed a broad spectrum of polypeptides, varying from 10 to 79 kDa. 1D immunoblot showed widespread seroreactivity profile in GI compared with restricted profile in GII. Three antigenic components (10, 12, 17 kDa) were recognized exclusively by GI sera, representing potential markers of infection and excluding vaccinal response. The proteomic characterization revealed 56 protein spots, 27 of which were antigenic spots showing differential seroreactivity profile between GI and GII, especially polypeptides <20 kDa that were recognized exclusively by GI. MS/MS analysis identified five *B. abortus* S19 proteins (Invasion protein B, Sod, Dps, Ndk, and Bfr), which were related with antigenicity in naturally infected cattle.

Conclusions: In conclusion, immunoproteomics of this new antigen preparation enabled the characterization of proteins that could be used as tools to develop sensitive and specific immunoassays for serodiagnosis of bovine brucellosis, with emphasis on differentiation between S19 vaccinated and infected cattle.

P1424

Immunoreactivity to salmonella infection in chicks protected with enteroccocus administration

V. Revajová,* M. Levkut,* A. Lauková,† R. Herich,* Z. Ševčíková* & M. Kolesárová*

**Department of Pathological Anatomy and Pathological Physiology, University of Veterinary Medicine and Pharmacy, Kosice, Slovakia, †Institute of Animal Physiology, Slovak Academy of Science, Kosice, Slovakia*

Purpose/Objective: The aim of study was to determinate in *Salmonella* Enteridis PT4 infected chicks, protected with 7-day *Enterococcus faecium* EK 13 administration, the influence on some immunocompetent cells in blood and immune organs (thymus, bursa of Fabricius, spleen).

Materials and methods: Sixty 2-day-old White Plymouth Rock chicks were divided into four groups * control (C), administered with *E. faecium* (EF; 1.10^{11} CFU), infected at day 7 with *S. Enteritidis* PT4 (SE; 1.10^{8} CFU), and combined EF + SE. The samples from five chicks of each group were taken on days 2, 5 and 7 after salmonella infection. Isolated lymphocytes, flow cytometry, indirect immunoflourescent method and primary mouse anti-chicken monoclonal antibodies (CD3, CD4, CD8, IgM) were used to measure relative percentage of positive-stained cells. The values of white blood cells were tested haematologically.

Results: The increase of lymphocytes, CD3+ and IgM+ cells on 7 days post salmonella infection (pi) in blood was observed in combined EF + SE group compared to SE and C groups. Relative percentage of CD3+ and CD4+ cells in EF + SE group was improved in spleen on days 2 pi. Thymus showed increase of CD3+, CD4+ and CD8+ cells on days 5 pi. No significant changes were observed in bursa of Fabricius.

Conclusions: The results showed higher values of T lymphocyte subpopulations in EF + SE group during the experiment. Their increase depicted the important of cell-mediated immune response to salmonella infection. Administration of *E. faecium* EK13 showed beneficial effect which led to earlier and more intensive T cell immune response in comparison to salmonella infection alone and may be used as probiotic additive in food.

P1425

Infection by swine, human or avian influenza virus differentially activates porcine dendritic cells cytokine profile

M. Baratelli,* T. Mussá,* M. Ballester,† E. Silva,‡ N. Busquets,§ M. Lecours,¶ J. Dominguez, L. Fraile,†† J. Hernández‡ & M. Montoya***

**Centre de Recerca en Sanitat Animal (CReSA), Endemovir, Barcelona, Spain, †Centre de Recerca en Agrigenómica, CSIC-IRTA-UAB-UB, Barcelona, Spain, ‡Laboratorio de Inmunología, Centro de Investigación en Alimentación y Desarrollo (CIAD), Hermosillo, Mexico, §Centre de Recerca en Sanitat Animal (CReSA), Exotiques, Barcelona, Spain, ¶Faculté de Médecine Vétérinaire, GREMIP-CRIP, Québec, Canada, **Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria (INIA), Biotecnología, Madrid, Spain, ††Veterinaria, Universitat de Lleida, Lleida, Spain*

Purpose/Objective: To study the porcine immune response generated by porcine bone marrow derived dendritic cells (poBMDCs) against swine, human and avian influenza viruses *in vitro*.

Materials and methods: *In vitro*, poBMDCs were infected with 10^4 $TCID_{50}$ of circulating trains of swine influenza virus (SwIV) A/Swine/Spain/SF32071//2007 (H3N2), 2009 human pandemic influenza virus A/Catalonia/63/2009 (H1N1), low pathogenic avian influenza virus (LPAIV) A/Anas plathyrhynchos/Spain/1877/2009 (H7N2) or high pathogenic avian influenza virus (HPAIV) A/Chicken/Italy/13474/99 (H7N1) for 4, 8, 16 and 24h. Supernatants were collected for IFN-α,

TNF-α, IL-12 and IL-18 detection by ELISA, while RNA was extracted from the cells to analyse the gene expression of *NF-κB*, *TGF-b*, *IL-10* and *IFN-b* by RT-qPCR. Moreover, after inhibition of NF-κB with CAPE, cells were infected with the swH3N2 influenza virus and IL-12 and IFN-α secretion was evaluated by ELISA.

Results: All viruses induced expression of *NF-κB*, *TGF-β* and *IL-10* in swine poBMDCs to different extents and in a time dependent manner suggesting a specific function in cytokine production. All viruses induced the secretion of IL-12 mostly at 24 hpi and IL-18 which was time dependent. Only swH3N2 induced IFN-α in a time dependent manner. Swine H3N2, aH7N2 and aH7N1 induced secretion of TNF-α also in a time dependent manner. Inhibition of *NF-κB* resulted in a decrease of IFN-α and IL-12 by swH3N2 infected-poBMDCs at 24 hpi, suggesting a role of this transcription factor on the synthesis of these cytokines.

ConclusionsThere is a differential response of porcine DCs against swine, avian or human influenza virus. These data pave the way for understanding the relation between influenza viruses and porcine DCs in triggering the immune response in swine through soluble mediators such as cytokines.

P1426

Influences of birth weight, age and milk composition on the developing porcine immune system

C. Casteleyn, B. R. Tambuyzer, O. Zdanchuk, H. Vergauwen, M. De Vos, V. Huygelen, S. Van Cruchten & C. Van Ginneken
Veterinary Sciences, University of Antwerp, Wilrijk, Antwerp, Belgium

Purpose/Objective: Introducing hyperprolific hybrid sows in pork production has resulted in large litters that contain up to 20% low birth weight (LBW) piglets. As these piglets are more susceptible to disease than normal birth weight (NBW) piglets, the litter is often weaned early and subsequently fed with formulated milk (formula). Although this strategy allows LBW piglets to catch up growth, their morbidity and mortality do not decrease. This could be due to the fact that formula is low in bioactive molecules (e.g. growth factors, hormones and cytokines), necessary for the development of the immune system. This study determined the influences of birth weight, age and milk composition on the development of the porcine GALT during the normal suckling period.

Materials and methods: To this purpose, LBW and NBW piglets were pre-weaned at the age of 3 days, and subsequently fed *ad libitum* for 7 or 25 days with either formula or formula supplemented with a whey fraction (FW) (Ig-free, molecular weight <50 kDa) that was daily administered via gavage until day 10. Control animals suckled the sow. After euthanasia of the animals at day 10 or 28, samples of the ileum were processed for quantitative analysis of $CD4^+$, $CD8^+$ and $CD172a^+$ cells that were immunohistochemically visualized.

Results: With increasing age, the lower $CD4^+$ and $CD8^+$ densities in sow-fed LBW piglets, compared to NBW piglets, were leveled up by both types of artificial feeding. At day 10, the densities of lymphoid cells in the formula-fed piglets resembled most those present in the control piglets when compared to piglets fed FW. This means that formula feeding results in lower immunological stress, i.e. altered numbers of lymphoid cells, caused by pre-weaning at 3 days of age. As a result, the higher immunological stress in the FW-fed piglets seems to be caused directly by the whey fraction and/or the manipulation of daily gavage. Elevated $CD4^+$ and $CD8^+$ cell densities in the lamina propria were seen in the formula-fed group at day 28 compared to day 10. In contrast, only the $CD4^+$ or $CD8^+$ cell populations increased in the FW and sow groups, respectively.

Conclusions: It is concluded that FW-fed piglets display an altered development of the GALT, as demonstrated by the inverted $CD4^+$/$CD8^+$ ratio compared to sow- and formula-fed animals. Consequently, formula feeding could be a valuable alternative for suckling the sow until conventional weaning age.

P1427

Investigation of the pathogenic effects and specificity of alloantibody in Bovine Neonatal Pancytopaenia (BNP)

C. R. Bell,* M. S. Rocchi,† M. P. Daglish,‡ E. Melzi,† M. G. Kerr,§ S. F. E. Scholes,¶ K. Willoughby & W. I. Morrison††**
**Infection and Immunity Division, The Roslin Institute and Royal (Dick) School of Veterinary Studies, Edinburgh, UK, †Immunology Division, Moredun Research Institute, Edinburgh, UK, ‡Pathology Division, Moredun Research Institute, Edinburgh, UK, §Veterinary Consulting, Scottish Agricultural College, Edinburgh, UK, ¶Pathology Division, Veterinary Laboratories Agency, Edinburgh, UK, **Virus Surveillance Unit, Moredun Research Institute, Edinburgh, UK, ††Infection and Immunity Division, Roslin Institute and Royal (Dick) School of Veterinary Studies, Edinburgh, UK*

Purpose/Objective: Bovine Neonatal Pancytopaenia (BNP) is a recently emerged haemorrhagic disease of calves characterised by leukocyte depletion and thrombocytopoenia, which has been linked epidemiologically to the use of a vaccine with a novel adjuvant. Feeding colostrum from cows that have previously produced a BNP affected calf has been shown to induce the disease in some calves, suggesting BNP is mediated by alloantibodies. Herein we report the results of an experimental study to define the haematological changes in calves fed colostrum from dams of BNP calves and present preliminary findings on the specificity of the alloantibodies present in dam serum.

Materials and methods: Two groups of five calves that received a standardised colostrum pool from known BNP dams or an equivalent colostrum pool from non-BNP dams, were subjected to detailed clinical, haematological and pathological analysis, including examination of bone marrow biopsies. The alloreactivity of BNP dam serum was tested using a panel of cell lines of defined MHC genotypes. Specificity was investigated further using tranfected lines expressing individual class I and class II MHC alleles, and mutated cell lines lacking expression of class I MHC alleles.

Results: All challenge calves showed bone marrow and haematological changes consistent with the development of BNP, supporting the hypothesis that BNP is induced by ingestion of colostrum-derived alloantibody. Haematology results coupled with serial bone marrow histopathology results indicated that alloantibody damage to different blood lineages varies. Peripheral cell depletion was confined to leukocytes and platelets, while bone marrow damage affected the primitive precursors and lineage committed cells of the thrombocyte, lymphocyte and monocyte lineages but only to more primitive precursors in the neutrophil, erythrocyte and eosinophil lineages. Serum from BNP dams was shown to have a higher titre of lymphocyte reactive antibodies than control cows and showed variable patterns of alloreactivity against a panel of MHC-defined cells.

Conclusions: BNP is caused by the ingestion of colostral alloantibody which produces variable damage to different haematopoietic lineages. Ongoing studies aim to determine the antigenic specificity of the antibodies in relation to their differential effects.

P1428

Proteome of Brucella abortus 2308 and its virB type IV secretion system mutant

M. Moreno-Lafont,* V. Paredes,* H. Lanz,† A. Tello,† J. Castillo,‡ V. Pando,† G. Hurtado,† E. Gonzalez,* R. Flores,* O. Rodriguez* & M. T. Vega*

*Inmunologia, Escuela Nacional de Ciencias Biologicas-Instituto Politecnico Nacional, Mexico City, Mexico, †Inmunologia, CISEI-INSP, Cuernavaca Morelos, Mexico, ‡Microbiologia, Escuela Nacional de Ciencias Biologicas-Instituto Politecnico Nacional, Mexico City, Mexico

Purpose/Objective: Brucellosis is a zoonotic disease caused by the genus *Brucella*, that is an alpha-2 proteobacteria with a type IV secretion system (T4SS) known as VirB. The T4SS is necessary to gain virulence by building up a replicative vacuole associated with the endoplasmic reticulum of the host cell. Since the mutant strains do not possess a T4SS, they are unable to secrete the proteins usually produced and secreted for the wild type strains. A different protein profile in the mutant strain suggests that the proteins identified may be T4SS-related and they can be used as a biomarker of the infection.
Materials and methods: A *virB* T4SS mutant of the *B. abortus* 2308 strain and its wild-type strain were grown in acid medium. The protein content of the bacteria was analyzed by 2D-PAGE and mass spectrometry. STRING program v8.3 was used for known interactions and possible predictions among proteins including direct (physical) and indirect (functional) interactions.
Results: A total of 47 overexpressed and 22 underexpressed proteins from the *virB* T4SS mutant strain were selected and sequenced. The majority of the 69 analyzed proteins have not been described before either as over or under-expressed in relation to a *virB* T4SS mutation, whereas some of them have been already described by other groups as potentially important secretory proteins in other *Brucella* species.
Conclusions: An important number of the proteins identified are outer membrane and periplasmic space protein, which makes them particularly important new T4SS-related candidate proteins. We confirm that the T4SS regulates a large number of proteins with diverse functional categories that can be used as biomarkers of the infection.

Purpose/Objective: To investigate the effects of canine interleukin-2 (cIL-2) and cIL-7 genes on enhancing the immunogenicity of canine parvovirus (CPV) VP2 DNA vaccine.
Materials and methods: The bicistronic vectors of cIL-2 and cIL-7 genes was constructed using the eukaryotic expression vector containing internal ribosome entry site (IRES). The cIL-2/clL-7 dicistronic vector plus previously constructed vectors, including CPV VP2 DNA vaccine vector, cIL-2 vector and cIL-7 vector, were used to co-immunize the mice with the different combinations, consisting of VP2 alone, VP2+cIL-2, VP2+cIL-7 and VP2+cIL-2/cIL-7. The VP2-specific antibody levels in immunized mice were measured by ELISA at different time post-immunization. The proliferation indexes and interferon-γ expression were measured by lymphocyte proliferation assay and ELISA, respectively.
Results: The results showed that the cIL-2/cIL-7 bicistronic vector was correct and could mediate cIL-2 and cIL-7 gene expression in eukaryotic cells. Immunization results revealed that the antibody titers and the neutralizing antibody levels of the mice co-immunized with VP2+cIL-7/cIL-2 vectors were significantly higher than that with either VP2+cIL-2 vectors or VP2+cIL-7 vectors ($P < 0.05$). The lymphocyte proliferation indexes of VP2+cIL-7/cIL-2 vector-immunized mice were also higher than that of other two groups although not statistically significant. However, the IFN-γexpression levels of VP2+cIL-7/cIL-2 vector-immunized mice were significantly higher than other immunized mice ($P < 0.05$).
Conclusions: cIL-2 and cIL-7 genes have the significant synergic effects on enhancing the immunogenecity of CPV VP2 DNA vaccine.

P1430

The biological characterisation of avian receptor activator of NF-κB ligand and RANK

K. Sutton, P. K. P. Kaiser & Z. W. Z. Wu

Infection and Immunity, The Roslin Institute, Edinburgh, UK

Purpose/Objective: The Th1/Th2 paradigm is well-established, both in mammals and in the chicken, as a model for the initiation of appropriate adaptive immune responses to clear infections with intracellular and extracellular pathogens respectively. Cytokines play a pivotal role in the coordination of these responses. In the chicken, detailed knowledge of the initiation, control and potentiation of the adaptive immune response is lacking compared to mammals, and the immune system is somewhat different. For example, chickens have a reduced number of genes in their MHC, lack lymph nodes and have a separate organ and mechanism for development of the B cell receptor (antibody) repertoire. The availability of the avian genome sequence has enhanced our ability to identify avian immune genes and subsequently to investigate their biological roles. Receptor activator of NF-κB ligand (RANKL) and its receptor, RANK, are members of the tumour necrosis factor superfamily which play pivotal roles in processes of immunity, differentiation and apoptosis. In mammals, RANKL and RANK are transmembrane proteins present on the surface of Th1 cells and dendritic cells (DC) respectively. Their interaction induces the binding of a number of adaptor proteins called tumour necrosis factor associated factors (TRAFs) to the intracellular domain of RANK, inducing the expression of pro-inflammatory cytokines and enhancing the life span of DC by the upregulation of anti-apoptotic molecules.
Materials and methods: Both genes have been identified in the avian genome and cloned along with TRAF 2, 3, 5 and 6. Chicken RANKL and RANK soluble fusion proteins have been generated from COS-7 cells and verified by western blot analysis and ELISA.
Results: ChRANK, which is predicted to be 655 amino acids in length, consists of four cysteine-rich domains, contains three putative TRAF-binding domains near the COOH-terminus that are conserved within mammalian RANK. However, chRANK seems to be missing a TRAF-binding motif expressed in the middle of the intracellular domain (342−349) which is one of the sites for TRAF2 binding but not essential for RANK signalling in human and mouse.
Conclusions: We were the first to successfully generate non-mammalian bone-marrow derived DC and thus now have the tools to study the biological role of avian RANKL/RANK in DC biology and Th1 responses in the chicken.

P1431

The cattle germline IGHV repertoire is very limited

M. Niku,* J. Liljavirta,* K. Durkin,† E. Schroderus* & A. Iivanainen*

*Department of Veterinary Biosciences, University of Helsinki, Helsinki, Finland, †Unit of Animal Genomics GIGA-R & Faculty of Veterinary Medicine, University of Liège, Liège, Belgium

Purpose/Objective: Ruminants are thought to have a small germline repertoire of Ig gene segments, but the *IGHV* genes have been poorly known. We have now characterized the bovine *IGHV* repertoire based

on genome sequencing data. The expression and chromosomal localization of the identified genes were investigated and the repertoire was compared to related species.

Materials and methods: Both bovine genome assemblies (Btau_4.2 and UMD_3.1) and the raw sequencing data were blasted using *IGHV* sequences from ruminants, human and mouse. RSSs obtained from the identified genes were used to search for identical motifs. The functionality of the *IGHV* genes was analyzed *in silico* and utilizing sequences from fetal ileal RNA and the EST database. Phylogenetic analyses were supplemented with clan-specific genomic PCR. Chromosomal localization of the *IGHV* genes was investigated by FISH using BAC probes.

Results: A total of 36 *IGHV* genes were identified and assigned to three subgroups. In the fetal ileal cDNA library/EST database, 99%/94% of sequences aligned to these genes with 98.4/92.3% average identity. Only 10 genes appear functional, all in subgroup IGHV1, with identical FR and CDR lengths and canonical CDR structures. The functional genes are contained in homology units consisting of a subgroup IGHV1 gene and a subgroup IGHV2 pseudogene.

The bovine *IGHV* genes belong to mammalian clans I and II. No clan III genes were found in the sequence data or by clan-specific PCR. Of related species, sheep and elk were negative for clan III, but DNA from deer, pig and dolphin was amplified by clan III primers. The functional bovine subgroup is homologous to the murine IGHV2 (Q52), but there is no clear human homolog.

Most IGHV genes were found in UMD_3.1 but missing from Btau_4.2. In UMD_3.1, they were distributed in BTA21 and BTA7. FISH analysis confirms the locus on BTA21 but suggests that the BTA7 locus is an assembly error.

Conclusions: The bovine IGHV repertoire is very limited. The single functional subgroup was likely generated by recent duplication events. Within the related Cetartiodactyla, the evolution of *IGHV* gene usage appears highly dynamic. The complex IGH locus is largely incorrectly assembled in the current cattle genome versions. We are now sequencing *IGHV* genes in several individual animals to verify the repertoire and to evaluate the allelic diversity.

P1432

The effect of florfenicol and *E. coli* lipopolysaccharide interaction on lymphocytes subset in newly-hatched chicks

K. Chrzastek, T. Piasecki & A. Wieliczko

Department of Epizootiology and Clinic of Bird and Exotic Animals, Wroclaw University of Environmental and Life Sci, Wroclaw, Poland

Purpose/Objective: Florfenicol is a broad-spectrum bacteriostatic antibiotic that is widely used in poultry production. The aim of this study was to investigate the influence of florfenicol and *E. coli* lipopolysaccharide interaction on T and B cells subsets in lymphoid organs.

Materials and methods: One-day-old broiler breeder Flex were treated orally, into the crop with a single doses of 30 mg/kg during 5 days, whereas LPS (O127:B8, Sigma) was given i.v. once at the dose of 200 μg kg -1 BW on 2nd day of experiment (d.e.). The samples were done 24 h after last treatment and at 14th d.e. The effect of florfenicol on subset of T and B cells pretreated with high doses of *E. coli* LPS and non-treated LPS was evaluated by measurement percentage of chicken lymphocytes in thymus (CD3+, CD3+ TCR $\gamma\delta^+$, CD4+, CD4+CD8+, CD8+, TCR $\gamma\delta^+$ cells), spleen (CD3+, CD4+, CD8+, TCR $\gamma\delta^+$, Bu-1+ cells), and bursa of Fabricius (Bu-1+ cells) by flow cytometry using appropriate fluorescein and phycoerythrin conjugated monoclonal antibodies.

Results: Florfenicol decreased percentage of Bu-1+ cells in bursa of Fabricius on day 7. It was also demonstrated decrease percentage of CD3+ and CD8+CD4+ thymocytes. In spleen the decrease percentage of CD3+, CD4+ on 7th d.e. and CD3+, CD4+, CD8+, TCR $\gamma\delta^+$, Bu-1+ cells on 14th d.e were observed. Additionally, it was shown decrease percentage of TCR $\gamma\delta^+$ and Bu-1+ cells in spleen on day 7 and 14 in florfenicol with LPS treated group. However, increase percentage of CD8+ cells in thymus was observed in both florfenicol and florfenicol with high doses of LPS treated group on day 7.

Conclusions: This study provides new information which indicate the influence of florfenicol on percentage of T and B cells in lymphoid organs. This is especially important on account of the fact that normal function of this organs have an influence on development and differentiation of lymphocytes in birds. The suppressive effect of florfenicol on selected cells was shown. Moreover, this effect was enhanced by *E. coli* LPS. This could indicate that florfenicol tratment might impair the immune response to bacterial endotoxin in chicks.

P1433

The importance of myeloid differentiation factor 88 on the infestation by *Rhipicephalus sanguineus* ticks

E. Anatriello,* C. J. Oliveira,† C. J. Ribeiro,‡ I. De Miranda Santos‡ & B. R. Ferreira*

**Department of Maternal-Child Nursing and Public Health, School of Nursing, University of São Paulo, Ribeirão Preto, Brazil, †Department of Parasitology Immune, Institute of Biological and Natural Sciences, Federal University of TriânguloMineiro, Uberaba, Brazil, ‡Department of Immunology, School of Medicine, University of São Paulo, Ribeirão Preto, Brazil*

Purpose/Objective: Ticks are hematophagous arthropods that parasitize vertebrate host and transmit a variety of infectious agents to domestic animals, wildlife and humans. In the tick-host interface there is an involvement of both the innate and acquired immune response of the host, which are modulated by the inoculation of tick saliva. Our group has shown that mice are susceptible to tick infestations and develop a Th2 type immune response. Additionally, we and others have shown that tick saliva can modulate the function of various immune cells, including macrophages, lymphocytes, and modulate differentiation, maturation, migration and function of dendritic cells (DCs) stimulated with ligands for Toll-like receptors (TLRs). We observed that saliva of *R. sanguineus* induced a high expression of TLR-2 on the DCs surface *in vitro*. These results suggest that tick saliva possibly can modulate the host immune response through TLRs. Knowing that the Receptor adaptor myeloid differentiation factor 88 (MyD88) signaling is critical for most TLRs signaling, we investigated if this molecule interfere in the infestation with *R. sanguineus* on mice.

Materials and methods: C57/B6 WT and MyD88-/- mice were infested with three pairs of ticks and the biological parameters of the ectoparasites were evaluated, such as number and weight of engorged females; feeding period; egg mass weight; hatching rate and reproductive index.

Results: The number of engorged female ticks on MyD88-/- mice was significantly ($P < 0.05$) enhanced when compared with C57Bl/6 WT mice. Related to reproductive parameters, we observed a large difference within animals from the C57Bl/6 WT mice group, impairing the statistical comparison. New experiments are being done in order to enhance the animal's number.

Conclusions: Our findings demonstrate the importance of the MyD88 for the success of the *R. sanguineus* infestation, suggesting that tick infestation may modulate mice immune response through the TLR-MyD88 pathway.

P1434

The T cell immunoglobulin and mucin domain (Tim) family in a non-mammalian species – a unique isoform of Tim4

T. Hu, & P. Kaiser
Infection and Immunity Department, The Roslin Institute, Edinburgh, UK

Purpose/Objective: T cell immunoglobulin and mucin domain (Tim) proteins are a family of molecules that are expressed on specific cell types (e.g. Tim4 on dendritic cells and Tim1 on CD4+ Th2 cells). Their functions include enhancement of the phagocytosis of dead cells and co-stimulation of Th2 cells through Tim1-Tim4 interactions. In the chicken, there are only two Tim family molecules, Tim1 and Tim4 (compared to three in man and eight in mouse). Uniquely, chicken Tim4 has two isoforms (long and short) formed by alternative splicing of three exons leading to an extra immunoglobulin domain in the long isoform. The chicken Tim genes have been cloned, expressed and monoclonal antibodies have been raised to Tim1 and both isoforms of Tim4.

Phosphatidylserine (PS) is an indicator of apoptotic cells. In dying cells PS translocates from the inner layer of the cell membrane to the outer layer. As receptors for PS, TIM molecules enhance the clearance of dead cells by macrophages or dendritic cells. Here I will focus on their phagocytic functions in the chicken immune system.

Materials and methods: Dot-blotting.

Solid phase ELISA.

Flow-cytometary.

Phagecytotic activity assay.

Results: Recombinant chicken Tim molecules can bind PS, but not other phospholipids. Stimulated splenocytes express more Tim4S (short isoform) ligand. If PS is blocked, Tim4S proteins exhibit decreased binding to stimulated splenocytes. NHI-3T3 cells transfected with chicken Tim molecules have increased ability to phagocytose dead cells.

Conclusions: In conclusion, this study demonstrates that chicken Tim molecules play an important role in phagocytosis through interaction with their ligand * phosphatidylserine.

P1436

TLR2 and TLR4 expression and oxidative response in PBMC from dogs with visceral leishmaniasis

V. M. F. Lima, L. M. Melo, K. L. O. Silva & J. Perosso
Faculdade de Medicina Veterinária, Clínica Cirurgia e Reprodução Animal, Araçatuba, Brazil

Purpose/Objective: Leishmaniasis visceral is an endemic disease that has spread over several continents, mainly in tropical and subtropical regions. It is caused by *Leishmania chagasi* and affects millions people worldwide. The parasite is transmitted by sandflies, which infect mammals including man and dog, which is considered the most important urban reservoir of *L. chagasi*. Dogs with visceral leishmaniasis are highly susceptible to infection and Th2 immune response in target organs facilitates the spread of the parasite in the host. Toll-like receptors 2 and 4 were involved in *Leishmania* recognition, but the role of TLRs in dog pathogenesis of canine visceral leishmaniasis and the effect of the interaction with parasite in the antimicrobial activity has not been addressed.

Materials and methods: Thirty dogs presenting clinical symptoms compatible with leishmaniasis and positive detection of antibodies anti-leishmania were used, five healthy dogs were used as control. To examine the expression of TLR 2 and TLR 4 in PBMC of infected dogs with *L. chagasi* and controls, PBMCs were double-stained with specific fluorochrome-conjugated antibodies: FITC conjugated monoclonal antibody anti-human TLR2, and PE conjugated monoclonal antibody anti-human TLR4 or control isotypes. Intracellular ROS levels were measured in PBMCs using H2DCFDA (29,79-dichlorodihydroflurescein diacetate), according to manufacturer's intructions. After the acquisition of data in EasyCyte mini® (Guava, Hayward, CA, USA), the analysis of the data was performed in the Software Guava Express® Plus. The results were compared using nonparametric tests.

Results: Comparison between the groups showed a decrease of TLR4 on PBMC from infected dogs ($P < 0.05$), the TLR2 was equally express on PBMC from infected and control dogs. The ROS production was higher in PBMC from infected dogs compared to control dogs ($P < 0.05$).

Conclusions: The data reveals that the receptor TLR4 is involved in immune response in symptomatics dogs chronic infected. The high ROS production observed in infected dogs indicates that ROS not showed antimicrobial effect and suggest that ROS could be useful by the protozoa to chronic the infection. Studies are in progress to further determine the mechanisms involved in this process.

P1438
'Enforced virus replication' as an immunological mechanism for adaptive immune activation

K. S. Lang, P. A. Lang, N. Shaabani & N. Honke
Institute for Immunology, University hospital Essen, Essen, Germany

Purpose/Objective: The innate immune system suppresses virus replication by interferon type I (IFN-I) and also induces presentation of viral antigens to adaptive immune cells. We analyzed how the innate immune system manages to inhibit virus propagation but still allows the presentation of sufficient amounts of antigen to adaptive immune cells.
Materials and methods: Mouse model of VSV infection.
Results: We found that the expression of *Usp18* in metallophilic $CD169^+$ macrophages reduces their IFN-I responsiveness, thereby allowing locally restricted replication of virus. This early virus replication was essential for the induction of sufficient antiviral immune responses and, therefore, for inhibiting the spread of virus to neuronal tissue and preventing fatal disease.
Conclusions: In conclusion, we found that 'enforced' virus replication within marginal zone macrophages is a novel immunological mechanism that ensures the production of sufficient antigen for effective adaptive immune activation.

P1439
A crucial role for the CC-chemokine receptor CCR5 in the pathogenesis of dengue virus infection in mice

R. Guabiraba,* R. E. Marques,† A. L. Queiroz,† C. T. Fagundes,‡ D. Cisalpino,‡ D. G. Souza‡ & M. M. Teixeira†
**Institute of Infection Immunity and Inflammation, III, Glasgow, UK, † Bioquimica e Imunologia, ICB/UFMG, Belo Horizonte, Brazil, ‡Microbiologia, ICB/UFMG, Belo Horizonte, Brazil*

Purpose/Objective: Dengue virus (DENV) infection is a public health problem faced by 2.5 billion people in tropical countries. Infection is characterized by a systemic inflammatory response and hematological alterations that may lead to shock and death in severe cases. Recent clinical data have shown an association between components of the chemokine network and severity of Dengue. Previous works from our group indicate that CC chemokine receptors play discrete roles in DENV infection in mice. The chemokine receptor CCR5 has been associated with severe disease following flavivirus infection. Here we investigated the role of CCR5 receptor in a mice model of DENV infection and disease.
Materials and methods: Wild-type (WT), $CCR5^{-/-}$ and WT mice treated with CCR5 antagonists were inoculated intraperitoneally with a mouse-adapted strain of DENV-2 (P23085). Samples were collected at day 5 and 7 post-infection (p.i.). Platelet count, hematocrit, cytokines (IFN-γ, TNF-α, IL-6, CXCL-1) and myeloperoxidase (MPO) activity were evaluated in spleen and liver, in addition to histopathology in the liver. Viral load was analyzed in organs, blood and in murine primary macrophages culture samples, treated or not with CCR5 antagonist Met-RANTES or Pertussis toxin (PTX).
Results: CCR5 deficiency or blockade with antagonists prevented dengue associated disease. All hematological parameters, MPO activity, tissue damage, cytokines and chemokines levels in organs largely affected by the infection were strongly reduced in $CCR5^{-/-}$ mice compared to WT at day 7 p.i. ($P < 0.01$). Viral load was reduced in blood and spleen of $CCR5^{-/-}$ mice at day 5 p.i. and completely abolished at day 7 p.i., contrary to the viral load observed in WT mice, which increased from day 5 to 7 p.i. ($P < 0.001$). $CCR5^{-/-}$ primary macrophages infected with DENV presented reduced viral load in cells compared to WT, which can be reproduced by treating WT cells with Met-RANTES or PTX.
Conclusions: The lack of CCR5 cannot prevent DENV infection *in vitro* and *in vivo* but can prevent disease. We hypothesized that the reduced viral load in mice organs leads to a reduced inflammatory response and tissue damage, allowing an effective viral clearance. We aim to investigate whether the diminished viral load in $CCR5^{-/-}$ tissues is due to impaired DENV entry into cells or impaired replication.

P1440
A novel subset of anti-viral T cells: the CD161dim $CD8^+$ population

J. R. Fergusson,* J. U. Ussher,* E. W. Newell† & P. Klenerman‡
**Nuffield Department of Medicine, University of Oxford, Oxford, UK, †Department of Microbiology and Immunology, Stanford University, Oxford, UK, ‡Department of Microbiology and Immunology, University of Oxford, Oxford, UK*

Purpose/Objective: $CD8^+$ T cells are important in the control of viral infections, and can be divided into three subsets based upon expression of the C-type lectin CD161. While the $CD161^{bright}CD8^+$ T cell population is largely comprised of anti-bacterial mucosal associated invariant T (MAIT) cells, the phenotype and function of the $CD161^{dim}$ $CD8^+$ T cell population, which can constitute up to 60% of the $CD8^+$ T cell pool, remains to be characterized. This $CD161^{dim}$ population is found in the naïve pool in cord blood, but in adult blood contains viral-specific cells, including those specific for epitopes from CMV, EBV and influenza, and is especially enriched in responses to Hepatitis B and C.
Materials and methods: We have used gene expression analysis and 'Cytometry by Time-of-Flight (CyTOF)', to probe the phenotype and function of these cells.
Results: They have a highly differentiated memory phenotype and share some features with the $CD161^{bright}$ population, including expression of the transcription factor ZBTB16 and the multi-drug efflux pump, MDR-1, albeit at lower levels. Functional expression of MDR-1 suggests that $CD161^{dim}$ $CD8^+$ T cells may be relatively resistant to cytotoxic agents and steroids. Expression of CD16 in this subset indicates additional functional capacity.
Conclusions: Overall, $CD161^{dim}$ $CD8^+$ T cells constitute a potentially important population in the context of viral infection, especially hepatic infection, with distinct phenotype and function.

P1441
Activation of TLR-2 by murine hepatitis virus (MHV) induces exacerbated inflammatory response in liver increasing hepatic damage

C. Bleau,* M. Burnette,* M. Samson† & L. Lamontagne‡
**Biological Sciences, Université du Québec à Montréal, Montreal, Canada, †Seraic, Université de Rennes 1- INSERM, Rennes, Canada, ‡Biological Sciences, Université du Québec à Montréal, Montréal, Canada*

Purpose/Objective: Viruses are generally detected by intracellular Toll-like receptors (TLRs) and helicases that sense nucleic acids and trigger signalling pathways leading to antiviral interferon (IFN) α, β production, but evidences show that surface TLRs may also participate in mounting an initial acute inflammatory response. It was recently reported that viral proteins from hepatitis viruses (HVC and HVB) could activate TLR-2 and -4-mediated signalling, however the consequences on hepatitis outcome remain unknown. We have reported that the S protein of the highly virulent mouse hepatitis virus 3 (MHV3) was able to ligate TLR-2 on macrophages, increasing inflammatory cytokine response. Using different virulent MHV viruses, we investigated the *in vivo* role of TLR-2 in viral replication, IFNs and inflammatory responses in the development of a fulminant hepatitis.

Materials and methods: Wild type and TLR2$^{-/-}$ C57BL/6 mice were infected with a high-, mild- or low-pathogenic MHV (L2-MHV3, MHV-A59 and YAC-MHV3 respectively). At various times postinfection, livers were fixed in formaldehyde or RNA and protein were extracted for qRT-PCR and/or ELISA assays to evaluate the expression of viral nucleocapsid, CEACAM1a, TLRs, IFNα, β, γ, IRFs, and inflammatory cytokines and chemokines. Blood was collected for serum determination of ASAT and ALAT levels.
Results: Results showed that extensive hepatic damage occurred sooner in L2-MHV3-infected mice and correlated with viral nucleocapsid mRNA levels. Surprisingly, TLR-2 expression levels strongly only increased in the liver of L2-MHV3-infected mice while no marked differences were noted for other TLRs nor for the viral receptor CEACAM1a. IFN-b production in the liver of L2-MHV3-infected mice was delayed when compared to MHV-A59, whereas inflammatory cytokine and chemokine levels were higher in L2-MHV3-infected mice. Most of these changes were associated to TLR-2 since hepatic lesions, viral replication, IFN-b and inflammatory cytokine and chemokine levels strongly decreased or were delayed in TLR-2$^{-/-}$ mice infected with L2-MHV3.
Conclusions: These results reveal for the first time that virulence of hepatotropic viruses may be related to their ability to activate the TLR-2 pathway resulting in an exacerbated inflammatory response increasing hepatic damages. Blocking of TLR-2 pathway may be considered as a new potential therapeutic approach in controlling viral-induced hepatitis.

P1442
Age-dependent seroprevalence to influenza A(H3N2) variant virus in 2011 – comparison to immunity to seasonal influenza A(H3N2) circulating in the mid-1990's

K. Waalen, A. Kilander, S. G. Dudman, R. Ramos-Ocao & O. Hungnes
Department of Virology, Norwegian Institute of Public Health, Oslo, Norway

Purpose/Objective: Since August 2011, 13 cases have been identified in the US of human infection with a variant of influenza A(H3N2) virus, A(H3N2)v, that is circulating in North American pigs and that descends from human seasonal H3N2 viruses circulating in the mid-1990s. Almost all cases occurred in children. In some no exposure to pigs were recognised and limited human-to-human transmission appears to have occurred. To assess the risk of further spread of the influenza A(H3N2)v virus in humans, the immunity to A(H3N2)v has been investigated and compared to seroepidemiological data from 1996 to 1998.
Materials and methods: Anonymised, age representative Norwegian sera (n = 253) collected in 2011 were tested in the haemagglutination inhibition (HI) assay. A HI titre of ≥40 is regarded as seropositive. Influenza A/Indiana/08/2011 (H3N2)v virus, provided by the U.S. Centers for Disease Control and Prevention through the GISRS system, was used as antigen. Data from 1996–1998 was obtained from the Norwegian Annual Influenza Serology Archive.
Results: The overall seroprevalence to A(H3N2)v was 40%. An age-related pattern was seen, which ranged from 0% in children born after 1998 and up to 71% in adults born between 1987 and 1993 (1). A seroprevalence of 40–50% was seen in adults born between 1967 and 1976 and those born in the mid-1950s or earlier. In contrast, low seroprevalence, 14%, was seen in adults born between 1957 and 1966. In 1998 the immunity to the current influenza A(H3N2) virus (A/Nanchang/933/95) was highest, 77%, in people born between 1987 and 1993.
Conclusions: The high overall seroprevalence seen in 2011 suggests that A(H3N2)v has a limited epidemic potential in its current form. The high seroprevalence seen in young adults is consistent with persisting immunity caused by exposure in childhood to antigenically related human viruses during the mid-1990s. This was confirmed by serology data from 1996 to 1998, as A/Nanchang/933/95, a A/Wuhan/359/95-like virus, is antigenically most similar to the A(H3N2)v virus. Children, ≤12 years, are most susceptible to A(H3N2)v, previously not exposed to H3N2 viruses of the mid-1990s. Surprisingly, adults born in 1957–1966 appear to have limited immunity to A(H3N2)v. The differences in immunity to A(H3N2)v between adults, exposed to similar H3N2 antigenic variants albeit at different stages in life, remains elusive.

P1443
Analysis of CD27/CD27L and CD30/CD30L in T lymphocytes exposed to dengue virus

H. L. Garcìa-Xolalpa, C. J. Fuentes-Miranda & M. M. B. Moreno-Altamirano
Immunology, Escuela Nacional de Ciencias Biologicas-Instituto Politecnico Nacional, Mexico City, Mexico

Purpose/Objective: To analyze if the co-stimulatory molecules CD27/CD27L and CD30/CD30L are differentially expressed in T Lymphocytes exposed to dengue virus.
Materials and methods: Peripheral blood mononuclear cells were obtained from Buffy coats from healthy donors by differential centrifugation over Fycoll-paque^{TM}PLUS. The T lymphocyte subpopulation was purified by anti-CD3-coated magnetic microbeads and these CD3^{+} T cell were assayed for the expression of CD27/CD27L and CD30/CD30L upon culture with: a) Concanavalina A, b) dengue virus, c) dengue virus plus Concanavalina A and d) medium alone. After incubation for 36 h at 37¡C in 5% CO_2, the expression of the co-stimulatory molecules was analyzed by flow cytometry.
Results: The expression of CD27 and CD30 in Concanavalina A stimulation cells was twice as much as that of un-stimulated cells. Pre-incubation with dengue virus inhibited such a response, no significant differences were observed in the expression of CD27L/CD30L on T lymphocytes cultured under the same conditions.
Conclusions: The CD27/CD27L and CD30/CD30L co-stimulatory molecules are related to the proliferation of T cells. Dengue virus seems to downregulate the expression of these co-stimulatory molecules, partially explaining the abnormal proliferation of T lymphocytes observed *in vitro* assays. Supported by SIP:20120911, and COFAA-IPN.

P1444
Analysis of the essential nature of viral proteins considered to be important target antigens against CMV in candidate vaccine strategies in the guinea pig model

A. McGregor, K. Y. Choi, M. Schleiss, C. Bouska, M. Leviton & J. Sweet
Pediatrics & Center for Translational Research, University of Minnesota, Minneapolis, MN, USA

Purpose/Objective: Development of a HCMV vaccine is a major public health priority. Species specificity precludes the direct study of HCMV in an animal model and pre-clinical study of intervention strategies requires the use of an animal CMV. The guinea pig is the only small animal model for congenital CMV. In HCMV infection, the viral glycoproteins are neutralizing antibody targets and the important protective T cell target antigens are the pp65 and IE1 proteins. Recent analysis of the guinea pig CMV (GPCMV) genome indicates that the virus encodeshomologs to important HCMV genes. We previously demonstrated that GPCMV gB glycoproteinand pp65 protein homologs are antibody and T cell targets respectively. However, little is

known about other candidate vaccine target antigens (glycoproteins and immediate early (IE) proteins). GPCMV transient gene expression and knockout mutagenesis studies were carried out to determine more specific information. Additionally, viral epithelial tropism was investigated in GPCMV to determine if a functional homolog endocytic complex similar to that in clinical strains of HCMV is also present in GPCMV.

Materials and methods: Genes encoding the presumptive HCMV glycoprotein homologs were cloned into expression epitope tagged vectors to analyze protein cellular localization. Individual genes (viral glycoproteins and IE genes) were knocked out in an infectious GPCMV BAC. Pathogenic salivary gland (SG) GPCMV and lab adapted virus were compared in their ability to infect epithelial cells.

Results: Studies indicated that GPCMV encodes functional homologs to HCMV glycoproteins: gB (GP55); gH (GP75); gL (GP115); gO (GP74); gM (GP100); and gN (GP73). Only gO (GP74 gene) was non-essential for virus replication in tissue culture but did modulate the level of gH in mature virions. The nuclear IE proteins (IE1 and IE2) are essential for virus growth. SG virus had epithelial tropism which could lost by passage of this virus on fibroblast cells. Analysis indicated that modified tropism was associated with a homolog to HCMV UL128−131 locus which was rapidly deleted. The homolog UL128 and UL131 proteins interacted with gH and gL in transient expression studies suggesting potential for a endocytic complex similar to that in HCMV (gH/gL/UL128−131).

Conclusions: Overal, l studies indicate that the encoded homolog glycoproteins and IE proteins have similar function to their HCMV counterparts. This initial characterization should aid in the development of candidate CMV vaccines in the guinea pig, including novel strategies against viral epi/endothelial viral tropism which could be potentially important in preventing transplacental infection.

CD4$^+$ T and B cell antigenic determinants are aligned in secondary dengue infections

L. Rivino,* E. Kumaran,* V. Jovanovic,* E. W. Teo,* S. W. Pang,† B. J. Hanson,† K. G. Smith,‡ A. Bertoletti,§ M. D. Kemeny* & P. A. MacAry¶

**Department of Microbiology, National University of Singapore, Singapore, Singapore, †DSO National Laboratories, Defense Medical and Environmental Research Institute, Singapore, Singapore, ‡Cambridge Institute for Medical Research, University of Cambridge School of Clinical Medicine, Cambridge, UK, §Singapore Institute for Clinical Sciences, A*STAR, Singapore, Singapore, ¶Deaprtment of Microbiology, National University of Singapore, Singapore, Singapore*

Purpose/Objective: Dengue virus (DENV) is the principal arthropod-borne viral pathogen afflicting human populations. Whilst antibody repertoires to DENV have been linked to protection or enhanced infection, the role of T lymphocytes in these processes remains poorly defined. The objective of this study is to characterize T cell responses in dengue patients, to understand if CD4$^+$ and CD8$^+$ T cell epitopes target distinct viral proteins and whether these proteins are similar to those recognized by B cells.

Materials and methods: T cell responses were assessed in a Singapore cohort of adult patients affected by dengue. T cell epitope reactivities were assesed by screening ex vivo isolated PBMCs with an overlapping peptide library spanning the entire DENV proteome. CD4$^+$ and CD8$^+$ T cell responses were further charaterized by intracellular staining. Linear B cell epitopes were assesed by ELISA with overlapping peptides spanning the entire E protein sequence.

Results: Whereas CD8$^+$ T cells preferentially target non-structural proteins (NS3 and NS5), CD4$^+$ T cell epitopes are skewed towards recognition of viral components that are also targeted by B lymphocytes (E, C and NS1). Within the E protein CD4$^+$ T and B cell epitopes display a significant degree of overlap, suggesting a direct link between antibody-antigen recognition and peptide presentation to CD4$^+$ T cells. Consistently, a large proportion of dengue-specific CD4$^+$ T cells have phenotypic characteristics of follicular helper T cells, providing evidence of their interaction with B cells *in vivo*..

Conclusions: Based on our data we propose that in secondary DENV infections, virus-specific B cells may skew the CD4$^+$ T cell repertoire by selectively supporting CD4$^+$ T cells of matched antigen specificity.

P1447

Characterisation of human natural killer cell responses to dengue-infected monocyte-derived dendritic cells

D. Lim,* N. Li,† L. H. Yeong* & S. B. J. Wong*

**Microbiology, National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore, †Singapore-MIT Alliance for Research and Technology, National University of Singapore, Singapore, Singapore*

Purpose/Objective: Natural Killer (NK) cells are required in innate responses during early viral infections. However, the factors that regulate the response of primary human NK cells to primary human cells infected with dengue virus (DV) remain poorly characterised.

Materials and methods: In this study, we demonstrate the responses of naïve human NK cells co-cultured with DV-infected monocyte-derived dendritic cells (DCs) using flow cytometry and BATDA cytotoxicity assays. Blocking/neutralizing antibodies were used to determine factors that triggered NK cell responses. ELISAs were employed to detect cytokines produced by DV-infected DCs.

Results: NK cells were found to produce IFN-γ, upregulate cell surface CD107a, and lyse DV-infected DCs. Type I interferons and TNF-α produced by the DV-infected DCs were crucial for this IFN-γ response, since blocking IFNAR combined with neutralization of TNF-α completely abolished the IFN-γ response in these co-cultures. Cytokines previously reported to play important roles in NK cell activation, e.g. IL-12, IL-15, IL-18 and IL-27, were not produced in significant amounts by DV-infected DCs. Transwell experiments suggested that membrane-bound ligands were also important for NK cell recognition of DV-infected DCs. However, we failed to detect the upregulation of ligands for NKG2D or DNAM-1 on DV-infected DCs as well as for ligands for the NK cell natural cytotoxicity receptors.

Conclusions: In summary, our results have uncovered a previously unappreciated role for the synergy between Type I interferons and TNF-α in triggering the anti-dengue defence of naïve human NK cells.

P1448

CMV infection in young individuals associates to CD8$^+$ T cells polyfunctionality

A. Pera,* C. Campos,* C. Alonso,* R. Tarazona† & R. Solana*

**Immunology, Department of Immunology, IMIBIC − Hospital Universitario Reina Sofía, University of Cordoba (Spain), Córdoba, Spain, †Immunology, Department of Physiology (Immunology Area), University of Extremadura (Spain), Córdoba, Spain*

Purpose/Objective: When naïve T cells are activated they become effector cells with different cytokine production patterns. Thus, different cytokine producer T cell subsets have been defined depending on the type and number of cytokines produced. A single T cell can produce simultaneously multiple cytokines of the same type, being then commonly referred as polyfunctional. Several publications have shown that a higher number of polyfunctional T cells is correlated with a better prognosis during HIV infection and vaccine animal's studies have shown that the quality of the response, i.e. polyfunctionality, is predictive of control of the infection following challenge. Thus, this analysis of the T cell response to vaccination and infection has demonstrated that the efficiency of the response is associated with the

capacity of responding cells to produce several cytokines ('polyfunctionality' as a marker of quality) rather than with the percentage (quantity) of specific T cells.

The aim of this work is to analyze the effect of CMV infection on the polyfunctionality -degranulation (CD107a) and/or cytokines co-production (INFg and TNFa) – of $CD8^+$ T lymphocytes, in a cohort of young healthy donors.

Materials and methods: We studied 20 young healthy donors (18–35 years old), stratified by CMV serostatus. Cells were stimulated for 5 h with SEB (*Staphylococcus enterotoxin* B) or with pp65/IE-1 CMV peptides. Following stimulation, cells were stained and analyzed on a 7 color MACSQuant instrument (Miltenyi Biotech).

Results: Our results showed that, after stimulation with SEB, $CD8^+$ T cells of CMV+ subjects are more polyfuntional (degranutation, IFNg and TNFa production) than $CD8^+$ T cells of CMV- individuals, whose $CD8^+$ T cells are predominantly monofunctional (TNFa or CD107a). We also observed an increase in $CD8^+$ $CD57^+$ T cells in CMV+ individuals when comparing with the CMV-. In addition, after stimulation with CMV peptides (pp65/IE-1), $CD8^+$ T cells exhibit the same pattern of polyfunctionality as when stimulated with SEB, but the differences between CMV+ and CMV- individuals were higher.

Conclusions: CMV infection in young individuals enhances the functionality and therefore the quality of $CD8^+$ T cells. This effect is associated to the increase of $CD8^+$ $CD57^+$ T cells in CMV+ young individuals.

P1449

Complex interferon- and immunotherapy in the treatment of immunocompromised children suffering from often and long recurring symptoms of respiratory infections

I. Nesterova,* N. Kolesnikova,† S. Kovaleva,† G. Chudilova,† L. Lomtatidze† & R. Sepiashvili*

**Allergology and Immunology, Russian University of Friendship of Peoples, Moscow, Russia, †Experimental Immunology, Kuban State Medical University, Krasnodar, Russia*

Purpose/Objective: Immunocompromised childrenwho suffer from recurrent (from 4–6 to 16–24 episodes a year) acute viral and/or bacterial respiratory tract infections are referred to as 'difficult patients', that is patients with frequent diseases. Earlier we had shown that such states develop on the background of disturbances in the function of the immune system (IS) and interferon (IFN) system (I. Nesterova *et al*., 2005).

Materials and methods: We had studied 48 immunocompromised children (both sex, age 5–9 years) who suffer from recurrent (from 4–6 to 16–24 episodes a year) acute viral and/or bacterial respiratory tract infections. An algorithm for integrated investigation of patients included clinical and anamnestic control, microbiological mucous microbiocenosis investigation, PCR, sulfur diagnostics, testing of antiviral immunity (T chain, humoral chain, neutrophlic granulocytes (NG), natural killers (NK) and IFN status.

Results: All patients had disturbance of IFN status (low levels of induced production of IFNα (100% of cases) and IFNγ (50%) and combine immunodeficiencies (91.6% of cases). A program of interferon- and immunotherapy for those patients was developed. It included basic therapy with Viferon (system and local), using differential doses of IFNα2 (from 1 up to 2 Mln IU) with further reduction of the prolonged course dose (2.5–3.5 months). In case of need, targeted immunotherapy was used. Licopid was used to correct the defects in NK system and/or NG; Isoprinosinum was applied to recover the T chain of immunity; IRS-19 was used in patients with disturbed specific humoral immunity. The use of this integratedprogram of interferon- and immunotherapy in 48 immunocompromised children allowed us to achieve a high clinicaleffects: the level of acute viral and/or bacterial respiratory tract infections was decreased in 3.5-fold, the reconstruction of immune system had more than 85% of all of patients.

Conclusions: Created program of combine interferon – and immunotherapy for immunocompromised children who suffer from recurrent acute viral and/or bacterial respiratory tract infectionshad demonstrated high clinical and immunological effects in 87.5% of cases.

P1451

Differential functional ability of T cells in patients with dengue haemorrhagic fever

G. Malavige,* L. C. Huang,† M. Salimi,† E. A. S. T. Edirisinghe,* A. Wijewicjrama,‡ S. D. Jayaratne* & G. S. Ogg†

**Microbiology, University of Sri Jayawaedenapura, Nugegoda, Sri Lanka, †NDM, University of Oxford, Oxford, UK, ‡Microbiology, Infectious Diseases Hospital, Nugegoda, Sri Lanka*

Purpose/Objective: The pathogenesis of dengue haemaorrhagic fever (DHF) is poorly understood. It has been shown that there is delayed clearance of the dengue virus (DEN) in patients with DHF. We set out to investigate if impaired DEN specific T cell responses were associated with development of DHF and dengue shock syndrome (DSS).

Materials and methods: *Ex vivo* ELISpot assays were done to determine DEN3 NS3 peptides specific T cell responses in 40 patients with DHF (10 of them had DSS). Other cytokines produced by DENV-NS3 specific T cells were determined by using multiple bead array analysis on ELISpot supernatants. CD107a expression was determined in 11 patients with DHF and in four healthy volunteers with previous asymptomatic dengue infection by intracellular cytokine assays.

Results: Although not statistically significant, IFNγ DENV3 NS3 specific responses were higher in patients who developed DSS (mean 639.3, SD ± 820.1) when compared to patients who did not develop DSS (mean 313, SD ± 513.1). We did not observe significant production of TNFa, IL-10, IL-4, IL-13, IL-17 by DEN3 NS3-specific T cells. Interestingly, PBMC incubated overnight in the absence of any further stimulation produced large amounts of TNFa, IL-10 and also TGF§ (spontaneous cytokine release). Spontaneous release of TNFα from PBMC ELISpot supernatants was significantly higher ($P = 0.009$), in patients with DSS (mean 2193, SD ± 2094 pg/ml) when compared to those who did not develop DSS (mean 721.4, SD ± 1921 pg/ml). Spontaneous release of IL-10 from PBMCs showed a significant and positive correlation with spontaneous release of TNFα from PBMCs (Spearmans $r = 0.88$, $P < 0.0001$).

CD107a expression was not seen in DEN3 NS3 specific CD8+ T cells in 5/11 DHF patients and CD4+ T cells in 8/11 patients. CD107a expression was seen in 0.25–1.2% of CD8+ T cells and 0.53–1.83% of CD4+ T cells in the 4 healthy volunteers with past asymptomatic dengue infection.

Conclusions: Our data suggest that T cells of patients with DHF and DSS produce high levels of IFNγ, which may be associated with disease pathogenesis. However, their T cells appear to have impaired capacity to degranulate in response to dengue virus proteins, which may delay virus clearance and contribute to severe dengue.

P1452

Do Crimean Congo hemorrhagic fever virus infected human monocyte-derived dendritic cells affect epithelial cell permeability?

C. Andersson,* K. E. Magnusson† & A. Mirazimi*

**Department of Microbiology Tumor and Cell Biology, Karolinska Institutet, Stockholm, Sweden, †Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden*

Purpose/Objective: Crimean Congo Hemorrhagic Fever virus (CCHFV) is an arthropod-borne pathogen that in humans causes a

severe disease, Crimean Congo hemorrhagic Fever (CCHF) characterized by hemorrhage and vascular leakage and with high case fatality rate. The mechanisms determining the pathogenicity of this virus is however largely unknown.

We have previously shown that CCHFV entry and release occur basolaterally and that infection does not affect permeability of polarized MDCK-1 cells. We have also shown that CCHFV can infect PBMCs resulting in increased release of Il-,6 Il-10 and TNF-alfa and that infection activates endothelial cells resulting in release of higher levels of IL-6 and IL-8. In this study, we have been interested to set up an *in vitro* model system to study the effect of proinflammatory factors on the tight and adherens junctions during CCHFV infection.

Materials and methods: Human epithelial cells, Caco2 cells were grown on 3.0 μm transwell membranes and resistance measurements were made to ensure confluence before infection. We also isolated human monocyte-derived dendritic cells (DCs) from buffy coats and checked for purity by CD14-positive FACS. Uninfected DCs or supernatant from uninfected DCs were added to the Caco2 model either apically or basolaterally and the resistance was measured.

Results: Our preliminary data demonstrate that Caco2 cells can be infected with CCHFV. Furthermore we found that CCHFV infection *per se* does not have an effect on the permeability of the cell layer.

Conclusions: We have succeeded to set up an *in vitro* model system for studying the role of proinflammatory factors during CCHFV infection and are currently investigating the effect that infected DCs and their supernatant could have on tight and adherens junctions.

P1453

Does hepatitis C virus regulate FcgammaRIIIa expression on NK cells?

B. Oliviero, D. Mele, S. Mantovani, S. Varchetta & M. U. Mondelli
Research Laboratories Infectious Diseases, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Purpose/Objective: FcgammaRIIIa (CD16) is an activating receptor playing an important role in NK cell function. Previous studies showed that CD16 is down-regulated in HIV-infected macrophages and on NK cells of patients with chronic hepatitis B virus infection, suggesting that it may be involved in the pathogenesis of several chronic viral infections. The aim of the present study was to evaluate CD16 expression on NK cells during chronic hepatitis C virus (HCV) to better understand the possible relationship between virus persistence and the modulation of the FcgammaR IIIa molecule.

Materials and methods: Surface CD16 expression and mRNA levels were examined in NK cells from patients with chronic HCV infection and healthy donors by flow cytometry and by quantitative real-time RT- PCR, respectively. IFNg and TNFa production was analysed by intracellular staining of NK cells after specific stimulation with anti-CD16 antibody. To determine the effect of HCV on CD16 expression, PBMC were exposed to culture-derived cell-free virus or HCV-infected target cells or recombinant HCV proteins.

Results: Expression of CD16 was significantly lower on NK cells from HCV-infected patients compared with healthy donors ($P < 0.0001$). The finding of reduced expression was also supported by lower CD16 mRNA levels in HCV+ patients versus healthy subjects ($P = 0.005$). However, cytokine production mediated by CD16 stimulation was comparable. Following exposure to cell-free HCV, NK cells from control subjects down-regulated CD16, which was confirmed when co-cultured with HCV-infected compared with uninfected Huh 7.5 target cells. Exposure of PBMC to recombinant HCV E2 envelope glycoprotein down-regulated CD16 on NK cells, whereas this effect was not observed with HCV NS3 protease or HIV gp120.

Conclusions: The data suggest that HCV modulates CD16 expression on NK cells. Since CD16 is an important NK cell activating receptor we surmise that regulation of its expression may influence innate immune responses in chronic HCV infection.

P1455

Gammaherpesviruses fail to stimulate IFN responses but induce inflammatory cytokines by a STING-independent pathway

J. P. Jorgensen, R. Gonzalez-Dosal, C. K. Holm & S. R. Paludan
Health Science, Institute of Biomedicine, Århus C, Denmark

Purpose/Objective: Herpesviruses are important human pathogenic DNA viruses divided into three subgroups: α-, β-, and γ-herpesviruses. Recent results have indicated that the innate immune response plays an important role in control of α- and β-herpesvirus infections, and that viral DNA is a potent inducer of innate immune responses. Despite the similarities in the family of herpesviruses different DNA receptors may be expected to regulate innate immune responses. Different contribution of receptors to viral recognition, leads to differential regulation of signaling components (e.g. STING a common adaptor protein involved in signaling from most DNA receptors), and therefore diverse cytokine expression. In this project we have investigated the role of DNA-receptors in the innate immune response during an infection with γ-herpesvirus.

Materials and methods: Murine γ-herpesvirus, MHV68, was used to infect cell culture systems and primary macrophages and dendritic cells from wildtype and relevant KO-mice (e.g. STING). Innate immune responses were evaluated by measuring cytokine and type I interferon using RT-PCR, IFN bioassay, and ELISA, accompanied by cellular immunohistochemical staining.

Results: After infection of dendritic cells and macrophages with α-, β-, and γ-herpesviruses we found that the a-herpesvirus herpes simplex virus type 1 and murine cytomegalovirus induced type I IFN and the IFN-stimulated gene CXCL10 and this was dependent on STING, indicating a role for cytosolic DNA sensors in this response. By contract, MHV68 failed to induce IFN responses, even at very high doses of infection. When examining for induction of inflammatory cytokines, we observed that all families of herpesviruses were able to induce such a response, although at different magnitude. Importantly, the MHV68-induced production of TNF-α and IL-6 was not dependent on STING.

Conclusions: The g-herpesvirus MHV68 fails to induce IFN responses in macrophages and dendritic cells, which is in sharp contrast to the STING-dependent induction of type I IFN by a- and b-herpesviruses. Moreover, MHV68 induces inflammatory cytokines in a STING-independent manner, suggesting a role for Toll-like receptors or a novel pathway.

P1456

Genomic and epidemiological dynamics of human metapneumovirus

L. Coupland,* P. Hunter,† M. Sillis* & C. Fanutti†
**Department of Microbiology, Norfolk and Norwich University Hospital, Norwich, UK, †Norwich Medical School, The University of East Anglia, Norwich, UK*

Purpose/Objective: Human metapneumovirus (hMPV) is a leading cause of acute respiratory tract infection in young children, with a spectrum of disease similar to that of respiratory syncytial virus (hRSV). The main objective of this study was to identify circulating hMPV lineages and associated sublineages within the local Norwich community (UK) in order to determine the geographical and temporal distribution pattern of hMPV infection within this region.

Materials and methods: The target population included children <18 years attending the Norfolk and Norwich University Hospital with

symptoms of acute respiratory tract infection between October 2005 and December 2008. Viral nucleic acid extraction from nasopharyngeal aspirate samples was performed using the COBAS AmpliPrep total nucleic acid isolation kit and analyser (Roche Diagnostics Ltd) and analysis of the highly conserved fusion (F) gene and the polymorphic glycoprotein (G) gene regions of hMPV was carried out by RT-PCR using primers specifically designed to anneal to the F and G genes. The molecular epidemiology and genetic analysis of hMPV genes was performed using the bioinformatic and molecular biology Geneious Pro™ software.

Results: The findings presented in this study suggest that hMPV exhibits local and global circulation of two distinct genetic lineages, A and B, with switching of the predominant circulating sublineage every 1–3 years. Additionally, phylogenetic data analysis of partial G gene sequences revealed a unique strain or closely related strains within sublineage A2a circulating within the locality of Norwich, which was responsible for large outbreak of infection within the paediatric cohort in 2004/2005, indicating that local factors, such as population patterns of strain-specific immunity, may influence the dynamics of hMPV circulation in different geographical populations.

Conclusions: Phylogenetic analysis of hMPV glycoprotein and fusion gene sequences revealed the frequent displacement of the predominant circulating hMPV sublineage. Additionally, a unique strain was shown to circulate within the paediatric cohort within Norwich, which indicates that local factors may influence hMPV circulation. The high degree of polymorphism observed in the glycoprotein gene has been associated with ability of hMPV to evade recognition by the immune system.

P1457
Genotype cross-reactive antibody responses to hepatitis C virus

J. E. Allan,* S. Lee,† K. X. Tan,* K. Kyuu,* J. Flexman† & M. Watson‡
**Medicine and Pharmacology, University of Western Australia, Fremantle, Australia, †Microbiology and Infectious Disease, Royal Perth Hospital, Perth, Australia, ‡Immunology and Infectious Diseases, Murdoch University, Perth, Australia*

Purpose/Objective: Hepatitis C virus (HCV) is a blood borne pathogen which is responsible for life long, chronic infection of the liver. The humoral immune response to the virus has not been as intensively studied as the cellular response, in part, due to the largely conformational nature of antibody recognition. Here cell culture passaged HCV is used to study the antibody response. The aim of this study was to assess different functions of the humoral response through cross-reactivity for genotype 2 HCV.

Materials and methods: Antigen from cell culture passaged HCV (genotype 2a, JFH-1a strain) was produced by lysis of infected human hepatoma Huh7 cells for ELISA, ELISPOT and western blot analysis. Memory B cells were quantiated following stimulation with the TLR7/8 agonist, R848, and IL-2 for 5 days. Neutralising titres were determined by microassay using HCV infection of Huh7 cells.

Results: Reactivity to JFH-1 virus was found by ELISA for 98% of approximately 100 chronic hepatitis C patients tested prior to treatment. Neutralisation assay revealed that sera from patients of all 4 genotypes inhibited JFH-1 infection strongly. Titres remained high following treatment with interferon and ribavirin. All patients, representing genotypes 1, 2, 3 and 4, tested by western blot recognised HCV core antigen and the majority also recognised the alternate reading frame of core.

Conclusions: Genotype cross-reactive antibody for HCV is common among genotype 1, 2, 3 and 4 HCV patients and core antigenis the most frequent source of cross-recognition. The JFH-1 strain of HCV passaged in human cells can be used for analysis of the specificty, memory and functions of the humoral response to HCV.

Hantavirus-infection confers resistance to cytotoxic lymphocyte-mediated apoptosis

S. Gupta,* M. Braun,† N. D. Tischler,‡ M. Stoltz,§ K. B. Sundström,* N. K. Björkström,¶ H. G. Ljunggren† & J. Klingtsröm*
**Department of Microbiology Tumor and Cell Biology, Karolinska Institutet, Stockholm, Sweden, †Department of Medicine, Center for Infectious Medicine, Karolinska Institutet, Stockholm, Sweden, ‡Fundación Ciencia & Vida, Santiago, Chile, §Department of Preparedness, Swedish Institute for Communicable Disease Control, Solna, Sweden, ¶Liver Immunology Laboratory, Division of Gastroenterology and Hepatology, Department of Medicine, Karolinska Institutet, Stockholm, Sweden*

Purpose/Objective: Hantaviruses cause hemorrhagic fever with renal syndrome (HFRS) and hantavirus cardio-pulmonary syndrome (HCPS). Endothelial cells are the main targets for hantaviruses, and increased vascular permeability is a hallmark of HFRS and HCPS. An intriguing observation in patients with HFRS and HCPS is that the virus-infection leads to strong activation of CD8 T cells and NK cells but no obvious endothelial cell destruction. Here, we provide an explanation for this dichotomy by showing that hantavirus-infected endothelial cells are protected from cytotoxic lymphocyte-mediated induction of apoptosis.

Materials and methods: HUVECs were infected or left uninfected and co-cultured with Il-2 activated NK cells. Cell death was measured with FACS (Dead cell marker) or immuno-fluorescence (TUNEL). Cleavage of viral protein was detected by western blot. Granzyme B and caspase 3 activity were measured with specific colorimetric assay.

Results: Our study show that hantavirus-infected endothelial cells are protected from cytotoxic lymphocyte-mediated induction of apoptosis. When dissecting potential mechanisms behind this phenomenon, we discovered that the hantavirus nucleocapsid protein inhibits the enzymatic activity of both granzyme B and caspase 3.

Conclusions: Thus, hantaviruses block cytotoxic granule-mediated apoptosis thereby protecting infected cells from cytotoxic lymphocytes.

P1460
Heligmosomoides polygyrus co-infection reduces lung immune cell responses to respiratory syncytial virus

A. J. McFarlane,* H. J. McSorley,† K. J. Mackenzie,* P. M. Fitch,* A. Ilchmann,* R. M. Maizels† & J. Schwarze‡
**MRC Centre for Inflammation Research, University of Edinburgh, Edinburgh, UK, †Institute of Immunology and Infection Research, University of Edinburgh, Edinburgh, UK, ‡Child Life and Health, University of Edinburgh, Edinburgh, UK*

Purpose/Objective: Respiratory syncytial virus (RSV) bronchiolitis in infancy may involve Th2 responses and is associated with an increased risk of asthma development. Helminth infection inversely correlates with atopy and allergy in developing countries and can inhibit allergic airway inflammation in animal models, suggesting that they can suppress pathological Th2 responses. Here, we investigated whether a Th2-inducing helminth infection can alter the immune responses to RSV infection.

Materials and methods: Female BALB/c mice (6–8 weeks old) were gavaged orally with 200 L3 *Heligmosomoides polygyrus* larvae or PBS 10 days prior to intranasal infection with RSV, or UV-inactivated RSV.

Results: Compared with RSV infection alone, co-infection with *H. polygyrus* significantly reduced the total lung cell numbers on day 8 post infection (p.i.). Using flow cytometry, we found that the increases in both $CD4^+$ and $CD8^+$ T cell, B cell and conventional dendritic cell (cDC) numbers, all seen in RSV infection, were significantly reduced in co-infection, as were numbers of $CD8^+$ $CD11c^+$ activated cytotoxic T cells. Cytokine analysis of lung homogenates on day 8 p.i. did not

reveal changes in the Th1 type cytokines, but did show increased Th2 type cytokine responses to RSV in co-infection, with significant differences for IL-4.

During early RSV infection (day 2 p.i.) numbers of natural killer (NK) cells increase and are thought to be important in limiting viral titres. Following co-infection we did not find any increase in lung NK cell numbers. However, on day 2 p.i. we did find elevated numbers of basophils in lungs from co-infected mice which were not detected in RSV infected controls. In addition, co-infected mice had significantly lower levels of TH1 type cytokine responses, including IFN-γ, TNF-α and IL-6, during the early stages of RSV infection.

Conclusions: Co-infection with *H. polygyrus* reduces a broad range of immune cell responses to RSV infection, but induces lung basophils and results in decreased early TH1 type cytokines responses to RSV and increased Th2 type cytokines later in infection. Thus, helminth infection can alter immune responses to RSV infection and could possibly result in reduced inflammation and disease. The mechanism behind interactions of helminths with RSV and its consequences require further investigation.

P1461
HLA-G effects on Crimean Congo hemoragic fever

B. Basturk,* E. Akinci,† H. Bodur,† M. Falay,‡ A. Aral* & Y. Uyar§
**Immunology, Gazi Universty, Ankara, Turkey, †Infection Disease, Numune Educational Hospital, Ankara, Turkey, ‡Hematology Lab., Numune Educational Hospital, Ankara, Turkey, §Virology Lab, Hifsissiha Institution, Ankara, Turkey*

Purpose/Objective: Objective: Innate immunity generates the first defencive step during viral infections. Viruses try to reduce innate immunity to enhance their virulance. Crimean-Congo Hemorrhagic Fever virus (CCHFV), a member of the genus Nairovirus, family Bunyaviridae, causes to a severe hemorrhagic fever and may be fatal in humans. Progression is very fast and after an incubation period of 1–3 days severe hemorrhagic symptoms may occur on 3th or 5th day. It has been previously shown that many diseases are releated to human leukocyte antigen (HLA) molecules important in presenting of antigens. HLA-G, a member of HLA class I molecules is different from other members of this class and named also as non-classical class Ib molecule.

Purpose: In this study we planned to investigate HLA-G effect on CCHF.

Materials and methods: We measure the plasma levels of HLA-G, serum levels of IL-6, IL-10, TGF-beta by ELISA and proportion of, $CD16^+$, $CD56^+$, $CD14^+$, $CD4^+$ 25^+ and HLA-G+ cells by flow cytometry of 60 CCHF patients and 60 healthy volunteers. Results are analysed statistically via Mann–Whitney *U*-test *ve Student's T-test*.

Results: Our resuls showed that serum IL-10 levels and HLA-G expression on monocytes, NK and Treg cells are increased in patients group. During the infection HLA-G expression on monocytes, NK and Treg cells were significantly higher than recovery patients. In mortal group, HLA-G expression on monocytes, NK and Treg cells were and serum IL-6 and IL-10 levels were increased.

Conclusions: In conclusion, CCHF virus infection induce HLA-G expression on cell surface and HLA-G plasma levels. Incresed levels of HLA-G expression and plasma levels could exhibit strong immunosupressive activities. Our data showed that, fallowed HLA-G expression on cell surface may be a prognostic and predictif factor for CCHF virus infection. The importance of these results are the fist report to demostrate clinical aspects of HLA-G expression and serum HLA-G levels in CCHF virus infection.

Our study supported by T†BITAK (Project No: 109S447).

P1462
Human oncogenic retrovirus HTLV-1 replication is suppressed by the MHC class II transcriptional activator CIITA via an inhibitory action on the viral transactivator Tax-1

G. Tosi,* G. Forlani,* V. Andresen,† M. Turci,‡ U. Bertazzoni,‡ G. Franchini§ & R. Accolla*
**General Pathology and Immunology, Surgical and Morphological Sciences, Varese, Italy, †Hematology Section, Institute of Medicine, Bergen, Norway, ‡Section of Biology and Genetics, Department of Life and Reproduction Sciences, Verona, Italy, §Animal Models and Retroviral Vaccines Section, National Cancer Institute, Bethesda, MD, USA*

Purpose/Objective: The aim of the study was to evaluate whether the master regulator of MHC class II gene transcription CIITA inhibits Tax-1-mediated activation of viral LTR promoter and thus the replication of Human T-cell Lymphotropic Virus type-1, the causative agent of an aggressive malignancy of $CD4^+$ T lymphocytes.

Materials and methods: Inhibition of Tax-1 transcriptional activity was assessed by luciferase gene reporter assay. Sub-cellular localization of proteins was analyzed by immunofluorescence and confocal microscopy analysis. Proteins interaction was assessed by coimmunoprecipitations experiments. HTLV-1 viral expression was evaluated by transfecting the HTLV-1 molecular clone in 293T and U937 cells and measuring p19 production.

Results: CIITA inhibits HTLV-1 replication by blocking the function of the viral transactivator Tax-1 both when exogenously transfected in 293T cells and when endogenously expressed by U937 promonocytic cells. Tax-1 and CIITA physically interact *in vivo* via the first 108 aminoacids of Tax-1 and two CIITA adjacent regions (1–252 and 253–410). Interestingly only CIITA 1–252 mediated Tax-1 inhibition, in agreement with the fact that CIITA residues from positions 64–124 are required to block Tax-1 transactivation. CIITA inhibitory action on Tax-1 correlates with the nuclear localization of CIITA. CIITA severely impairs the physical and functional interaction of Tax-1 with the cellular co-activators PCAF, CREB and ATF1, which are required for the optimal activation of HTLV-1 promoter. Accordingly, the overexpression of PCAF, CREB and ATF1 restore Tax-1-dependent transactivation of the viral LTR promoter inhibited by CIITA.

Conclusions: These results show that CIITA acts as a physiological restriction factor against HTLV-1 by blocking virus replication and spreading. Since CIITA exerts a similar action on HIV-1 and HTLV-2 replication, these results clearly indicate that CIITA has evolved encompassing a dual function: regulator of adaptive immunity and retrovirus restriction factor in intrinsic immunity.

P1463
Identification of an early CXCR3-dependent antiviral mechanism in the female genital tract working prior to the action of interferons

M. Iversen, S. Kratholm, C. Holm & S. R. Paludan
Health science, Institute of Biomedicine, Århus C, Denmark

Purpose/Objective: Recognition of pathogens and a subsequent immune response is important for defense against infections. This recognition is mediated by pattern recognition receptors (PRRs) which recognize conserved pathogen-associated molecular pattern. Vaginal HSV-2 infection of mice results in an immediate release of cytokines which initiate and direct the subsequent immune response. The aim of this project is to describe and characterize the early innate immune response at mucosal surfaces elicited by vaginal HSV-2 infection. To do this we investigated whether vaginal epithelial cells, which are the first cells to come in contact with HSV-2, can recognize HSV-2 and elicit an immune response by secretion of cytokines. In addition we wanted to identify the PRR responsible for the early recognition of HSV-2 in vaginal epithelial cells. Finally we wanted to examine which immune effector cells respond to the cytokines released by the epithelial cells.

Materials and methods: Mice are infected vaginally with HSV-2. The mice were examined post infection (p.i.) and scored for disease development. Viral load measurements and cytokines concentration were determined in vaginal washes day 1, 2 and 3 p.i. The presence, recruitment and activation state of immune effector cells were examined in isolated vaginas by flow and IHC. PRRs expression in the vagina is investigated by qPCR.
Results: The expression kinetics of several different cytokines in response to HSV-2 infection where investigated and the cytokines CXCL9 and 10 were the only ones induced already within 24 h p.i. This was in contrast to the interferons which were not induced until day 2 p.i. The CXCL9/10 receptor KO mice ($CXCR3^{-/-}$ mice) had elevated virus titer day 1 p.i. and exhibit pronounced signs of disease compared to WT mice. Furthermore there seemed to be a disregulated recruitment of effector cells in $CXCR3^{-/-}$ mice in response to HSV-2 infection.

In uninfected vaginas specific cytosolic DNA sensor was highly expressed.
Conclusions: Our data indicate the existence of a CXCR3 receptor dependent antiviral mechanism working prior to the induction of interferons. Epithelial cells of the vagina recognize HSV-2 and subsequently release CXCL9 and 10. The PRR expression studies indicates DAI as candidate for HSV-2 sensing in vaginal epithelial cells.

P1464
IL-21 has anti-viral effect in innate immunity against vaginal HSV-2 infection in mice

S. Kratholm, M. B. Iversen & C. K. Holm
Health Science, Institute of Biomedicine, Århus C, Denmark

Purpose/Objective: $CD4^+$ T cells produce IL-21 in response to infection with HSV-2 in mice and IL-21 has anti-viral capacities in the adaptive immune response to chronic viral infection. Little attention has been given the potential role IL-21 could play in innate immunity. This is despite the fact that cells from the innate immune system like NK cells and macrophages readily express the IL-21R and respond to IL-21 treatment with increased effector functions.
Materials and methods: In this study we investigated the role of IL-21 in innate immunity to virus infections using a murine model for vaginal HSV-2 infection in C57BL6 WT and IL-21R KO mice. Mice were infected intra vaginally with HSV-2 and scored for disease progression and death. Viral titers and type 1 IFN levels in vaginal fluids were measured on day 1–3 p.i. In separate experiments WT mice were treated with murine recombinant IL-21 (mIL-21). In other experiments vaginas were harvested on day 1–3 p.i. and RNA was extracted or cells were sorted by FACS in $CD45^+$ and $CD45^-$ fractions for RNA extraction or culturing. mIL-21 and IL21R KO mice were a kind gift from Pfizer.
Results: Here we show that IL-21R expression was increased at the site of infection on day 1–3 p.i. in WT mice. This was due to an increased IL-21R expression in leukocytes ($CD45^+$ cells). IL-21R KO mice had a higher disease score and higher viral titers in vaginal fluids compared to WT. Moreover mice treated with mIL-21 had a significantly lower disease score and showed increased survival compared to infected untreated controls. mIL-21 treated mice also had significantly lower viral titers in vaginal fluids.
Conclusions: We conclude that IL-21 plays a role in innate immunity to HSV-2 infection in the murine vagina. In conclusion our data suggest a protective role for IL-21 in innate immunity against virus.

P1465
Immunophenotyping of mice after influenza A virus infection

L. Dengler, E. Wilk & K. Schughart
Department of Infection Genetics, Helmhotz Centre for Infection Research, Braunschweig, Germany

Purpose/Objective: Different inbred mouse strains exhibit striking differences in susceptibility to influenza A virus (IAV) infections. To phenotyping of infected mice we established peripheral blood count analyses and immunophenotyping of the lungs in addition to the commonly used monitoring of weight loss and survival.
Materials and methods: Two inbred mouse strains (DBA/2J and C57BL/6J) were infected with three different influenza A virus H1N1 variants (PR8M, PR8F and hvPR8). The blood analyses were performed with a veterinary hematology system (VetScan). For a more detailed analysis we investigated infected lungs using flow cytometry to study the immune cell populations recruited to the site of infection.
Results: We found significant differences in the relative distribution of the main immune cell populations in peripheral blood already on day two post infection. Susceptible mouse strains exhibited strong lymphocyte decreases, moderate increases of monocytes and very strong augmentation of granulocytes after infection. In comparison, the hemogram of infected resistant mice changed to a much lesser extent. C57BL/6J mice displayed leukocytosis when they survived an influenza A infection and leukopenia if a lethal outcome was observed. We could notice that blood parameters measured early after infection correlate well with the clinical course and outcome of influenza A virus infection in mice. By comparing the lungs of infected DBA/2J and C57BL/6J mice, we observed a high amount of phagocytes in the susceptible mouse strain on day three post infection whereas resistant C57BL/6J mice revealed an augmentation of MHCII expressing cells within the lungs.
Conclusions: In summary we can conclude that the pathogenicity of influenza A infection, depending on genetic susceptibility or virulence of the pathogen, is well reflected in the peripheral blood count. Thus, this method represents a much more sensitive measure compared to weight loss, and it is also predictive for the outcome of the infection. The analysis of immune cell infiltrates in the lung tissue revealed clear differences between susceptible DBA2/J and resistant C57BL/6J mice. To further understand the biological significance of these findings immune cell infiltrates will have to be investigated in more detail and are subject of ongoing research.

P1466
Impact of CMV infection on human dendritic cell TLR expression and function

N. Janssen,* K. Ioannou,† O. Tsitsilonis,† G. Pawelec* & E. Derhovanessian*
**Center for Medical Research, University of Tübingen, Tübingen, Germany, †Department of Animal and Human Physiology, University of Athens, Athens, Greece*

Purpose/Objective: A latent CMV infection in humans is associated with accumulations of late-stage differentiated peripheral T-cells and poor responsiveness to influenza vaccination in the elderly. As monocytes and dendritic cells (DCs) serve as a reservoirfor latent CMV, and considering the important role of DCs in T-cell activation, we analyzed the impact of a latent CMV

infection on human dendritic cell TLR expression and function.
Materials and methods: We analyzed the impact of a latent CMV infection on the distribution of myeloid (mDC, Lineage-, HLA-DRhi, CD11c+, CD123-) and plasmacytoid (pDC, Lineage-, HLA-DRhi, CD11c-, CD123+) DCs in peripheral blood and the expression level of Toll-like receptors (TLR-2, -4 and -7, determined by mean fluores-

cence intensity) on circulating monocytes ($CD14^+$), as well as mDCs and pDCs in middle-aged healthy individuals ($n = 20$). The responsiveness of immature monocyte-derived DCs to stimulation through TLR-2/6 and TLR-4 was also analyzed in 19 middle-aged healthy donors.

Results: Our results demonstrate a significantly higher expression level ($P = 0.021$) of TLR-2 on monocytes in CMV-seropositive individuals. However, stratifying the donors according to gender revealed an impact of CMV-seropositivity only in men. We also detected a significantly higher expression level of TLR-7 on pDCs ($P = 0.048$) in men with a latent CMV infection. The distribution of different DC subsets, the mDC/pDC ratio and the expression level of TLRs on mDCs, did not differ between CMV-seropositive and *seronegative individuals. However, functional experiments with monocyte-derived DCs revealed a strong trend ($P = 0.05$) towards higher up-regulation of CD86 in CMV-seronegative individuals in response to stimulation through TLR-2/6, but not TLR-4.

Conclusions: These results suggest a potential impact of a latent CMV infection on the capacity of DCs to respond to different TLR-agonists. Thus, CMV-serostatus might have an impact on responsiveness to different adjuvanted vaccines, as well as the functional capacity of monocyte-derived DCs used in different clinical settings, such as cancer immunotherapy.

Increased pathology during infection with an atypical European porcine Arterivirus correlates with an enhanced adaptive immune response

S. B. Morgan,* S. P. Graham,* J. Salguero,† F. Steinbach* & J. P. Frossard*

**Virology, Animal Health and Veterinary Laboratories Agency, Addlestone, UK, †Histopathology, Animal Health and Veterinary Laboratories Agency, Addlestone, UK*

Purpose/Objective: The porcine reproductive and respiratory syndrome virus (PRRSV) causes one of the most economically important diseases of swine worldwide. PRRSV replicates primarily in alveolar macrophages, and outside the lung is mainly found in the lymphoid tissues. Respiratory infection of piglets with European strains normally results in subclinical disease and mild pathology. However, recent years have seen the emergence of more pathogenic strains. This study aimed to characterise the immune response to a virulent European PRRSV strain.

Materials and methods: Pigs were inoculated with the prototype European strain, a British field strain or a recently isolated strain from Belarus (SU1-bel). Lung gross pathology was scored and bronchoalveolar lavage fluid (BALF) collected at 3, 7 and 35 days post-infection (dpi). Viral loads were determined by qRT PCR. Immunophenotyping was performed using flow cytometry, and adaptive responses were analysed by IFN-γ ELISpot and PRRSV-specific Ab ELISA.

Results: Clinical signs and gross lung pathology were most severe in the SU1-bel infected pigs with inflammation particularly pronounced at 7 dpi. Viral load in the lung did not correlate with pathology, and was lowest in the SU1-bel pigs at 35 dpi. The SU1-bel pigs mounted a stronger cellular immune response with higher numbers of IFN-γ secreting cells in both the blood and lungs. The humoral response was also greater with earlier detection of PRRSV-specific Ab in the BALF and serum, although these were not neutralising. At day 7, the SU1-bel group showed the greatest influx of both myeloid and lymphoid cells into the lungs, with numbers of CD4 and CD8 T cells and neutrophils all positively correlating with pathology.

Conclusions: This study suggests that the basis of PRRSV pathogenesis is immune-led, rather than a direct effect of the virus, as has been suggested for the related SARs-CoV. Although IFN-γ is anti-viral, and may be a contributing to viral clearance, it is likely that this pro-inflammatory cytokine is exacerbating tissue damage. Work is ongoing to further characterise the cellular immune response in the lung of SU1-bel infected pigs and investigate the innate immune factors, which may contribute to this enhanced adaptive response.

P1469

Interferon- and immunotherapy in immunocompromised patients with chronic recurrent herpes simplex infection

I. Nesterova,* R. I. Sepiashvili,* S. Kovaleva† & G. Chudilova†

**Allergology and Immunology, Russian University of Friendship of Peoples, Moscow, Russia, †Clinlcal and Experimental Immunology, Kuban State Medical University, Krasnodar, Russia*

Purpose/Objective: The treatment of immunocompromised patients with chronic recurrentherpes simplex infection is very actual problem. IFN system is the major part in antiviral immunity provides fast antiviral and protective effects. By numerous authors it was shown that viruses of a herpes simplexI type are capable to undertake countermeasures and to carry out damage IFN system and antiviral mechanisms of immune system, that complicates them elimination and promotes their long persistence.

Materials and methods: Method: We investigated 95 patients at the age from 20 till 55 years, suffering with chronic recurrent herpes simplex type I infection l herpes (HSV1 or HSVII) infection with oral and facial localization. The frequency of acute episodes was 6−14/year. The state of IFN system (induced production of IFN alpha and IFN gamma and the basic mechanisms of antiviral immunity (T lymphocyte's and humoral chains, NK cells, phagocytic cells) were studied.

Results: All patients had combine defects ofIFN alphaand IFN gamma induced production, and some defects of functioning ofimmune systems. Complex program of interferon- and immunotherapy was developed. This program included: (1) carrying out basic system differentiated interferon therapy with application recombination IFNα2 in a complex with antioxidants -viferon, (2) restoration of lymphocyte chain of immune system with using of 10-day izoprinozin course (4), (3) restoration NK, humoral chain, neutrophilic granulocytesand their phagocytic activity by basic and supporting courses oflicopid − drug with multi potential properties. Features of treatment in acute period ofHSV1infection Synthetic antiviral drug famvir was used. The importance of replacement therapy by adequate doses ofviferon at the first stage of treatment was demonstrated. It was shown necessity for the further decrease in doses viferonfor realizationofinterferon correcting and modulating influences inpersons with secondary defects in IFN system. Primary innate defects of IFN system were needed in replacement basic prolonged IFN therapy by viferonduring long time and then in support viferon therapy during life.

Conclusions: Conclusion: It was demonstrated expressive clinical and immunologic efficiencies of the developed program of interferon − and immunotherapy in chronic recurrent HSV1 infection in 82.3% of patients. The frequency of acute episodes ofchronic recurrent herpes simplex type I/IIinfection with oral and facial localization haddecreasedtill2.1 ± 0.05/year ($P \leq 0.001$). IFN and immune system were restored in 82.3% of patients.

P1470

Ligation of mouse hepatitis virus type 3 (MHV3) to TLR-2 decreases interferon type I transcription and favours viral replication by a lipid raft/caveolin dependent mechanism

M. Burnette, C. Bleau, A. Jacques & L. Lamontagne

Biological sciences, Université du Québec à Montréal, Montreal, Canada

Purpose/Objective: Innate immunity is the first line of defense against viral infections and consequently many viruses have developed immune evasion mechanisms, particularly in the liver. Macrophages

possess toll-like receptors (TLRs) at their surface and in endosomes to detect viral infections leading to the induction of antiviral interferons (IFN) α, β and inflammatory cytokines. Recently, surface TLRs, notably TLR-2, have been involved in the recognition of viruses, such as hepatitis B and C, but their role in pathogenesis remains elusive. We have reported that TLR-2/heparin sulfate may act as a receptor for the highly virulent murine hepatitis virus 3 (MHV3), increasing IL-6/TNF-α production. The aim of this work is to verify whether the fixation of MHV3 onTLR-2 modulates the antiviral IFN-β response and/or viral fixation/internalization steps.

Materials and methods: The murine macrophage J774A.1 cell line, permissive to MHV replication, was infected with the highly virulent L2-MHV3 or lesser virulent MHV-A59 variants in the presence or absence of specific inhibitors of various endosomal pathways and levels of TLR-2, IFN-β, viral nucleocapsid and cytokine gene expression were determined by qRT-PCR and/or ELISA tests. The modulating effect of TLR2 in IFN-β production and viral replication was confirmed with TLR-2 and/or CEACAM1a (the MHV receptor) siRNA treated cells.

Results: Our results demonstrate that the MHV3 serotype is significantly more virulent than MHV-A59 in macrophages, as evidenced by higher nucleocapsid expression. However, TLR-2 and IFN-β mRNA levels are lower in cells infected with MHV3. TLR-2 and CEACAM1a siRNA treatments confirm that both receptors are involved in viral load and subsequent IFN-β response. Interestingly, viral load, TLR-2 and IFN-β expression are significantly dependent on the clathrin endosomal pathway for both variants. Indeed, they drastically increase in MHV3 infection when this endosomal pathway is favoured at the expense of the lipid-raft/caveolin mediated pathway.

Conclusions: Taken together, these results suggest that the ligation of MHV3 to TLR-2 enhances viral replication whilst abating the type I IFN response by a still unknown immune evasion mechanism. Furthermore, in stark contrast to MHV-A59, viral load of the MHV3 serotype is remarkably heightened when endosomal entry is shifted to the clathrin-dependent pathway.

P1471

Massive CD8$^+$ T cell activation during acute dengue: role of T cells in dengue pathology?

E. Kumaran,* C. T. Too,* S. W. Pang,† B. J. Hanson,† A. Bertoletti,‡ M. D. Kemeny,* P. A. MacAry* & L. Rivino*

**Microbiology, National University of Singapore, Singapore, Singapore, †DSO National Laboratories, Defense Medical and Environmental Research Institute, Singapore, Singapore, ‡A*STAR, Singapore Institute for Clinical Sciences, Singapore, Singapore*

Purpose/Objective: Dengue virus (DENV) infections have increased alarmingly over the last decades with an estimate of 50 million people affected per year. DENV is an arthropod-borne flavivirus that exists as four distinct serotypes (Den 1–4). Severe disease has been linked to secondary infections with heterologous serotypes suggesting an important role of pre-existing immunity in dengue pathology. In this study we sought to better understand the role of T cells in mediating protection and/or dengue immuno-pathology. T cell responses have been characterized in a Singapore cohort of adult patients affected by dengue during three time points of disease.

Materials and methods: CD8$^+$ T cells from ex-vivo isolated PBMCs were stained with antibodies against the activation and proliferation markers CD38/HLADR and Ki67/Bcl2 and analysed by flow cytometry. Dengue virus specific T cells were assessed by IFN-γ ELISPOT using a peptide library spanning the entire dengue proteome. Furthermore with the use of HLA tetramers specific for two epitopes derived from the DENV NS3 protein the frequencies, phenotypes and cytokine producing capacities of CD8$^+$ T cells specific were investigated.

Results: We observe that DENV infection induces massive activation and proliferation of CD8$^+$ T cells during the acute phase of infection with up to 70% of cells expressing activation and proliferation markers. In contrast, only up to 1% of circulating CD8$^+$ T cells are specific for DENV as assessed by IFN-γ ELISPOT. Using previously described MHC tetramers for the persistent cytomegalovirus (CMV), we showed that CD8$^+$ T cells specific for CMV also display an activated phenotype, are proliferating and produce IFN-γ during acute dengue. This implies the total activated CD8$^+$ T cells contain populations of T cells specific for unrelated antigens.

Conclusions: The discrepancy between the total CD8$^+$ T cell activation profile and the frequency of circulating DENV specific T cells as well as the activated profile of T cells specific of CMV indicates a bystander activation of unrelated T cells during acute dengue. The factors driving the proliferation of these bystander activated cells and their role in Dengue viral infection are currently under investigation.

P1472

MHC II tetramers visualising CD4$^+$ T cell responses to primary and persistent Epstein-Barr virus (EBV) infection: atypical kinetics of the EBNA1 response

H. M. Long,* O. L. Chagoury,* A. M. Leese,* E. James,† R. J. M. Abbott,* S. Sabbah,* W. Kwok† & A. B. Rickinson*

**School of Cancer Sciences, University of Birmingham, Birmingham, UK, †Tetramer Core Laboratory, Benaroya Research Institute at Virginia Mason, Seattle, WA, USA*

Purpose/Objective: CD4$^+$ T cells are key orchestrators of virus-induced immune responses, being important for the development and/or maintenance of both humoral and CD8$^+$ T cell-mediated immunity. Yet relatively little is known about the characteristics of virus-specific CD4$^+$ T cell responses at the single cell level in man. Here we use novel MHC II tetramers to carry out the first concerted analysis of the human CD4$^+$ T cell response to primary and persistent infection with the gamma-herpesvirus EBV at the single cell level.

Materials and methods: Nine MHC II: epitope peptide tetramers representing a range of EBV latent and lytic cycle proteins were used in multicolour flow cytometry, along with a panel of cell surface phenotyping antibodies, to visualise the evolution of CD4$^+$ T cell responses to EBV. Our donor cohort included 21 acute infectious mononucleosis (IM) donors undergoing primary infection, of which 11 gave further donations through to convalescence, and 10 EBV seropositive donors with no history of IM.

Results: In Acute IM, MHC II tetramer-positive CD4$^+$ T cells specific for the latent antigen EBNA2 and lytic cycle antigens were expanded to frequencies that reached 10-fold above those seen during viral persistence. The diverse range of epitopes targeted by the highly activated CD4$^+$ T cell response led to skewing of the phenotype of the overall CD4$^+$ population. During the course of IM, responses were rapidly culled to values typical of life-long virus carriage, where most tetramer-staining cells display conventional memory markers but some, unexpectedly, revert to a naïve-like phenotype. Interestingly, CD4$^+$ T cell responses to EBNA1 epitopes were delayed in primary infection, appearing in the blood 2–13 months post IM. This delay may reflect differences we have detected in the processing of the different viral antigens *in vitro*.

Conclusions: Primary EBV infection drives expansion of a broadly targeted, highly activated CD4$^+$ T cell response that quickly reverts to healthy virus carrier state. There is a delay in development of a CD4$^+$ response to EBNA1 which parallels the well-documented delay in antibody response to the same protein. We suggest, from an *in vitro* system, that this may be explained by antigen supply.

P1473

Modulation of influenza virus mediated immunopathology; the role for SOCS proteins

M. Nicol,* T. C. Yeh,* Y. Ligertwood,* A. McFarlane,† K. Bryson,* A. Nash* & B. M. Dutia*

Roslin Institute and R(D) SVS, University of Edinburgh, Midlothian, UK, †MRC Centre for Inflammation Research, University of Edinburgh, Edinburgh, UK

Purpose/Objective: Cytokine storms are aggressive host cytokine responses causing excessive inflammatory damage, characterized by high levels of TNFα and IFNγ. Activation of cytokines is normally tightly controlled to prevent excessive inflammatory damage. Important regulators of cytokines are suppressor of cytokine signaling (SOCS) proteins. We *hypothesize* that influenza virus interferes with SOCS function as a regulator of cytokines, contributing to the generation of cytokine storms.

Materials and methods: BALB/c mice were inoculated intranasally with increasing doses of of A/WSN/33 influenza A (H1N1) virus. Mice were monitored daily for weight loss and clinical signs. Lungs were harvested 2, 4, 6 and 8 days post-infection. The lungs were fixed with 10% formal saline for immunohistochemistry (IHC), or homogenized for assay of virus titres by plaque assay on Madin-Darby canine kidney (MDCK) cells.

Results: We established a model of influenza infection which resulted in different clinical outcomes; BALB/c mice inoculated with 100 plaque forming units (pfu)/mouse of A/WSN/33 influenza A showed mild pathology with no loss of weight. However, mice inoculated with 10 000 pfu/mouse showed 25% weight loss and severe pathology. SOCS1 expression determined by IHC on lung sections 4 days post-infection, when virus titers peak, was below that observed at baseline (day 2), in all infected groups. SOCS1 expression was maximal at day 8 in the 100 pfu/mouse group. In the 10 000 pfu/mouse group, SOCS1 expression remained at baseline levels throughout the time course of infection. Lung titers (4 days post-infection) showed only a twofold difference between the high and low virus dose.

Conclusions: SOCS1 expression appears to be inversely correlated with virus titers, with decreased SOCS1 expression when virus titers are highest. Expression of SOCS1 is highest at day 8 in the 100 pfu/mouse infected mice, which appear to control viral infection and show no clinical symptoms. Whereas, SOCS1 expression is lowest in 10 000 pfu/mouse infected mice, which lost most weight and had severe pathology. There was not a significant difference in the virus load between the high and low virus challenge groups, yet one appears to control inflammation better. Is the difference in the SOCS expression key?

P1474

Orthopoxvirus seroprevalence in cattle and human in rural areas of São Paulo State, Brazil

M. G. Peres,* T. S. Bacchiega,* C. M. Appolinario,* A. F. Vicente,* J. M. A. P. Antunes,* S. D. Allendorf,* E. M. Pituco,† L. H. Okuda† & J. Megid*

Higiene Veterinária e Saúde Pública, Universidade Estadual Paulista ''Julio de Mesquita Filho''(UNESP), Botucatu, Brazil, †Laboratório de Viroses de Bovideos, Instituto Biológico de São Paulo, Botucatu, Brazil

Purpose/Objective: Viruses of the genus *Orthopoxvirus* (OPV) are known to present and promote immunological cross reaction; infection or immunization with a virus of the genus confers protective response to the other. *Vaccinia virus* (VACV), a member of this genus was widely used in the production of vaccine against smallpox during the campaign of the World Health Organization (WHO). Since the end of the global program of mass vaccination, when WHO declared the eradication of smallpox in worldwide, VACV outbreaks causing a zoonotic exanthematic disease, characterized by the appearance of cutaneous lesions on udders and teats of cows and hands of milkers has been reported in Brazil, resulting in economic losses through decreased of milk production and humans infections. This study aimed to carry out a serological study in areas with and without history of VACV outbreaks affecting cattle and milkers in S'o Paulo State, Brazil.

Materials and methods: Blood samples were harvested from dairy cows and milkers of 48 farms distributed throughout the counties of Torre de Pedra, Bofete e Anhembi in S'o Paulo State. After centrifugation the serum samples was obtained and submitted to virus neutralization test. Epidemiological investigation was applied to obtain relevant information such as history of outbreaks affecting cattle and humans and age of the milkers.

Results: From 438 cows analyzed, 178 presented antibodies against OPV. Concerning to 58 milkers, 28 were reagents from which six of them have never been vaccinated against smallpox once their age ranged from 13 to 29 years. The others were vaccinated when young during the campaign of eradication to smallpox.

Conclusions: The presence of antibodies agains OPV in milkers never vaccinated against smallpox suggest their exposure to OPV circulating in environment. In fact, the results of epidemiological investigation reported history of lesions on udders and teats of cows and sometimes lesion in milker's hands. In these areas, previous studies identified VACV as zoonotic agent of outbreaks, so the sera positivity of cows and milkers may indicate environment virus maintenance. The positivity of vaccinated persons can be due to previously specific memory cell response stimulated by natural contact during the outbreaks.

P1475

Proliferation of human T lymphocytes is down-regulated by dengue virus

M. M. B. Moreno-Altamirano,* C. J. Fuentes-Miranda,* A. R. Coker,† O. Rojas-Espinosa* & M. R. Salinas-Tobòn*

Immunology, Escuela Nacional de Ciencias Biologicas-Instituto Politecnico Nacional, Mexico City, Mexico, †Center for Amyloidosis and Acute Phase Proteins, University College London, London, UK

Purpose/Objective: To analyze some mechanisms involved in the lack of activation and proliferation of T Lymphocytes exposed to dengue virus serotype-2, *in vitro*.

Materials and methods: Peripheral blood mononuclear cells (PBMC) were obtained from Buffy coats from healthy donors. The T lymphocyte subpopulation was purified by anti-CD3-coated magnetic microbeads. T cells were cultured under: (1) Concanavalin A, (2) dengue virus, (3) dengue virus plus Concanavalin A and (4) medium alone. After incubation for 4–16 h at 37¡C in 5% CO_2, T cell were Analyzed for (1) proliferation by using carboxy-fluorescein diacetate, succinimidyl ester (CFSE) and flow cytometry, (2) Expression of CD25, by flow cytometry, (3) Synthesis of IL-2, by ELISA and (4) activation and nuclear translocation of the transcription factors NFAT and NF-kB, by confocal microscopy in whole cells, and by flow cytometry of isolated and labeled nuclei.

Results: The proliferation of T lymphocytes was inhibited in Concanavalin A stimulated cells when pre-incubated with dengue virus. The synthesis of IL-2 was inhibited when these cells were incubated with DENV-2 before addition ofCon A. A reduction in IL-2Ra expression was also observed, by flow cytometry. The nuclear translocation of NF-AT and NF-kB was diminished when Con A-stimulated T cells were previously exposed to DENV-2.

Conclusions: Understanding the role of the immune system in the pathogenesis related to dengue virus will help to improve patients« treatment. Some reports indicate that patients infected with dengue

virus have a dysfunctional proliferation of T lymphocytes. However, studies *in vitro* have not been performed to analyze in more detail the DEN-2-mediated mechanism(s) of inhibition. As shown in this study, inhibition of nuclear translocation of NFAT and NFkB by DEN-2, as well as inhibition of IL-2 synthesis and IL2Ra expression could be accountable for the observed dysfunctional proliferation of T cells. The present work was supported by SIP: 20120911 & COFFA-IPN.

Respiratory syncytial virus infection augments NOD2 signalling in an IFN dependent manner in human primary cells

M. Vissers,* T. Remijn,* M. Oosting,† D. J. de Jong,‡ D. Diavatopoulos,* P. W. M. Hermans* & G. Ferwerda*
**Laboratory of Pediatric Infectious Diseases, Nijmegen Intitute for Infection Inflammation and Immunity, Nijmegen, Netherlands, †Department of Medicine, Nijmegen Intitute for Infection Inflammation and Immunity, Nijmegen, Netherlands, ‡Department of Gastroenterology and Hepatology, Nijmegen Intitute for Infection Inflammation and Immunity, Nijmegen, Netherlands*

Purpose/Objective: Respiratory syncytial virus (RSV) is a major cause of lower respiratory tract infections in infants, with high variability in disease severity. It is unknown if the presence of specific bacterial species in the nasopharynx may affect RSV pathogenesis. We investigated how bacterial components modulate the inflammatory response to RSV infection in human cells.
Materials and methods: Human PBMC from healthy volunteers and Crohn patients homozygous for the 3020insC frameshift mutation (NOD2fs) were stimulated with RSV A2, MDP and specific PRR ligands. Subsequently, cytokines were measured by ELISA and quantitative PCRs were performed.
Results: Pro-inflammatory cytokine production of human PBMC was increased after stimulation with RSV and muramyl dipeptide (MDP), which is recognized by nucleotide-binding oligomerization domain 2 (NOD2). PBMC from Crohn patients homozygous for a mutation to their NOD2 gene did not show a synergistic response to stimulation with RSV and MDP, suggesting that NOD2 is essential for the observed synergy. Further experiments, which aimed at identifying the viral ligand, indicated that viral RNA plays an essential role. Stimulation with RSV or Poly (I:C) induced IFN-β expression, which resulted in an increased expression of the viral receptors TLR3 and RIG-I, as well as an increased NOD2 expression. Our data indicate that IFN-β induction by viral RNA is an essential first step in the increased pro-inflammatory response to MDP.
Conclusions: We hypothesize that the enhanced pro-inflammatory response to bacterial ligands, such as MDP, following RSV infection may be an important factor in determining the outcome of the severity of disease. These data suggest that the composition of an individual's nasopharyngeal flora may help to determine their susceptibility to severe RSV infections.

P1477

Rhinovirus infections and immunisation induce cross-serotype reactive antibodies to VP1

G. McLean,* R. Walton,* S. Shetty,* T. Kebadzee,* L. Gogsadze,* K. Niespodziana,† R. Valenta,† N. Bartlett* & S. Johnston*
**Imperial College London, National Heart and Lung Institute, London, UK, †Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria*

Purpose/Objective: Rhinoviruses (RVs) are ubiquitous human respiratory viruses, the major cause of common colds, acute exacerbations of asthma and other respiratory diseases. The development of antibodies to RV following primary infection is not well understood and there is currently no RV vaccine available largely because over 100 serotypes of RV exist. As humans are frequently infected with RV and develop both protective and nonprotective antibody responses, we used mouse models of intranasal RV infection and immunisation to determine the induction, magnitude and specificity of antibody responses to RV.
Materials and methods: Mice were intranasally infected with RV or immunised systemically to determine the induction, magnitude and specificity of antibody responses to RV. Antibody responses to whole RV and individual capsid proteins were determined by ELISA, western blot and ELISpot assays. RV neutralisation was also assessed by *in vitro* assay using HeLa cells.
Results: Strong cross-serotype RV-specific IgG responses in serum and bronchoalveolar lavage were induced towards the RV capsid protein VP1. Both serum and mucosal IgA responses were weaker, requiring two infections to generate detectable RV-specific binding. Similarly two or more RV infections were necessary to induce neutralising antibodies. Systemic and intranasal immunisation strategies boosted homotypic as well as inducing cross-serotype neutralising IgG responses.
Conclusions: Our findings demonstrate the utility of the mouse model for investigating anti-RV humoral immunity and for determining the effect of vaccine strategies on the response to RV infection. VP1 based antigens combined with adjuvants have promise as candidate vaccines to boost serotype-specific as well as cross-serotype neutralising antibodies.

P1478

Selected parameters of innate immunity and mortality in rabbits infected with different strains of RHD virus with different biological properties

B. Hukowska-Szematowicz,* B. Tokarz-Deptula,* P. Niedzwiedzka-Rystwej,* A. Trzeciak-Ryczek,* J. Dzialo* & W. Deptula†
**Immunology, University of Szczecin, Szczecin, Poland, †Microbiology, University of Szczecin, Szczecin, Poland*

Purpose/Objective: The purpose of this study was to record the view of the innate immune responsein rabbits experimentally infected with 25 European strains of the rabbit hemorrhagic disease virus with different biological properties including haemagglutinating (HA+) and non-haemagglutinating (HA-) strains as well as antigenic variants (RHDVa).
Materials and methods: The rabbits were experimentally infected with twenty five European strains of RHDV with different biological properties, such so as HA (+) (Polish: Kr-1, SGM, KGM, MAL, PD, GSK; French: Fr-1, Fr-2; Czech: V-351, V-561, V-562, V-558; Italian: BS89; Hungarian: 1447V/94); non-haemagglutinating (HA-) strains (Polish: BLA; German: Frankfurt, Spanish: Asturias; British: Rainham) and strains with the variable HA (HA+/-) ability (German: Hagenow; Polish: ZD); as well as HA(+) and RHDVastrains (German: Triptis, Hartmansdorf; Italian: Vt97) and HA (-) and RHDVa strains (Italian: Pv-97; French: 9905). After infecting rabbits, in peripheral blood at times 4, 8, 12, 24, 36 and 48, 52, 56, 60, 72, adherence and absorption capacity were marked in such animals and capacity of NBT reduction in PMN cells, as well as stimulation index and granulocyte metabolic activity index, and the test of intracellular leucocyte killing was performer, as well as the percetage ofTc lymphocytes ($CD8^+$) was marked using flow cytometry. At that time the mortality of animals was also recorded.
Results: The study revealed that the image of innate immunity indices and mortality in rabbits studies varied depending on the biological property of the strains analysed.
Conclusions: The immunological difference in the strains analysed and various mortality of animals caused differentiation of three

immunogroupes (immuntypes) and four pathotypes among such strains of the RHD virus.

The study was funded by the research grant NN 308 289937 from National Science Centre

P1479

Specific immunoglobulin G subclass spectrum in previously vaccinated and unvaccinated measles convalescents

A. Toptygina,* T. Mamaeva,† E. Semikina‡ & V. Alioshkin*
**Cytokines Laboratoty, G.N. Gabrichevsky Institute of Epidemiology and Microbiology, Moscow, Russia, †Immuno-Chemistry Laboratory, G.N. Gabrichevsky Institute of Epidemiology and Microbiology, Moscow, Russia, ‡Clinical Diagnostical Laboratoty, Scientific Center of Children's Health RAMS, Moscow, Russia*

Purpose/Objective: Measles outbreaks continue to occur even in highly vaccinated countries. The aim of study was to investigate peculiarities of specific immune responses in vaccinated and unvaccinated measles convalescents.
Materials and methods: Ten adults with natural measles infection at 5th day (Group 1), nine adults with measles at 12th day after onset of rash (Group 2), and 10 measles patients previously vaccinated against measles (Group 3) were investigated. Twelve healthy adults had two-dose measles vaccination at 1 and 6 years old (Group 4), and 17 healthy adults had measles many years ago (Group 5) were examined as a control groups. Specific IgM, IgA, IgG antibodies in serum, and their subclasses and avidity were tested by ELISA.
Results: All unvaccinated measles patients had a high level of measles IgM antibodies (more than 3.0 OD). The patients in Group 3 had negative or slightly positive specific IgM. None of donors in groups 4 and 5 had any measles IgM. Specific IgG were 0.612 IU/ml in Group 1, and 0.957 IU/ml in Group 2. In healthy donors specific IgG were 0.907 IU/ml in Group 4 (two donors had no measles IgG), and 1.928 IU/ml in Group 5. IgG level in Group 3 differed from others, it was 42.145 IU/ml. In Group 1 the predominant subclass was IgG3. It was present in 100% of serum samples and contributed, on average, 79.2% of the total IgG anti-measles response. In Group 2 the predominant subclass was IgG2. It was 51.5% of total IgG anti-measles response. IgG1 was 19.3% and IgG3 − 26.3% of anti-measles IgG. In Group 4 IgG1 was 67.7%, IgG3 was 18.5%, and IgG2 and IgG4 were low. In group 5 the predominant subclasses were IgG2 − 43.4%, and IgG1 − 34.7% of anti-measles IgG. In Group 3 the predominant subclass was IgG1 -94.3% of anti-measles response. High levels of specific IgA antibodies were founded in all groups.
Conclusions: Differences in IgG subclass profile in vaccinated and unvaccinated measles convalescents could explain as differences in primary and secondary antibody response.

P1480

The control of a moderate dose of MCMV and downstream induction of T Cell responses are dependent on either MyD88 or Ly49H signaling pathways

C. Cocita, R. Guiton, G. Bessou, K. Crozat, Y. Alexandre & M. Dalod
CIML, Immunology, Marseille, France

Purpose/Objective: The control of Murine Cytomegalovirus (MCMV) infection is known to rely on two mechanisms of innate immunity: (1) virus recognition by dendritic cells (DCs) through their endosomal Toll Like Receptors (TLR) 7 and 9, leading to the synthesis of antiviral cytokines via a signaling cascade dependent on the adaptor molecules MyD88 and IRAK4, and (2) recognition and killing of infected cells by Natural Killer (NK) cells expressing adequate activation receptors such as Ly49H or Ly49P. However, the relative importance of these two mechanisms in the control of infection is unclear.
Materials and methods: To understand this issue, we examined resistance to MCMV infection in 4 BALB/c congenic mouse strains deficient for Ly49H, MyD88 or both.
Results: Three days post-infection (pi), only $Ly49H^+$ mice controlled viral replication in the spleen and liver. However, at day 6 pi, both $Ly49H^-$ $MyD88^+$ and $Ly49H^+MyD88^-$ mice, but not double deficient $Ly49H^-$ $MyD88^-$ animals, had also achieved MCMV control. Antibody-mediated NK cell depletion *in vivo* impaired late viral control in $Ly49H^+MyD88^-$ mice but not in $Ly49H^+MyD88^+$ mice. At moderate doses of viral inoculum, only $Ly49H^-$ $MyD88^-$ mice succumbed to MCMV infection. Hence, both MyD88 and Ly49H were required for control of MCMV early after infection. However, upon moderate dose infection, MyD88 and Ly49H were redundant for late control of MCMV replication and for the promotion of health over disease. MyD88 was instrumental for efficient activation of DCs and NK cells in $Ly49H^-$ but not in $Ly49H^+$ mice. Double deficient $Ly49H^-$ $MyD88^-$ mice failed to mount strong MCMV-specific CD8 T cell responses, which was associated with a major attrition of splenocytes and with extensive tissue damage in spleen and liver as compared to the three other mouse strains studied.
Conclusions: Thus, our results demonstrate that MyD88 is dispensable for the induction of efficient innate and adaptive immune responses against moderate dose MCMV infection in animals which NK cells are able to directly recognize and kill infected cells through the engagement of an activation receptor. This might explain in part why MyD88 and IRAK4 have been reported to be redundant for immunity against viruses in humans. This observation could thus help reconciling the conclusions drawn on antiviral immune defenses from the analysis of animal models as compared to the study of human immunity *in natura*.

P1482

The innate antiviral immunity factor Tetherin does not restrict poxviral replication

K. Sliva,* T. Resch,* B. Kraus,* C. Goffinet,† O. T. Keppler‡ & B. S. Schnierle*
**Virology, Paul-Ehrlich-Institute, Langen, Germany, †Institute for Molecular Virology, Ulm University Hospital, Ulm, Germany, ‡Institute for Medical Virolgie, Universitätsklinikum Frankfurt, Frankfurt am Main, Germany*

Purpose/Objective: Mammalian cells encode numerous restriction factors to counteract infections with pathogens and inhibit viral replication at cellular levels. In turn, viruses have evolved factors that functionally counteract these intrinsic restrictions. Upon infection, secretion of type I interferons (IFNs) from virus-infected cells is a hallmark of innate antiviral immunity and cells express almost countless interferon-stimulated antiviral genes. One of these interferon-induced cellular restriction factors is Tetherin (also known as BST-2, CD317 or HM1.24), which blocks the release of many enveloped viruses form infected cells. Vaccinia viruses (VACV) encode numerous immune modulators interfering with antiviral host responses. Therefore, it was tempting to study a potential VACV-THN interaction.
Materials and methods: A potential Tetherin (THN)-VACV interaction was analyzed using cell lines either stably expressing a HA-tagged THN and the corresponding cells without THN expression. Cells were infected with VACV and analyzed for viral spread and THN surface expression.

To identify a potential impact of VACV infection on THN cell surface levels, infected cells were stained after infection for THN expression.

To spot possible THN antagonists encoded by VACV that counteract THN by a mechanism distinct from cell surface downregulation we made use of a recombinant MVA, MVA-HERV-K_{gag}, which expresses the human endogenous retrovirus K (HERV-K) Gag/

pol protein. Infection of cells with the recombinant MVA results in the release of HERV-K virus-like particles budding from the MVA-infected cell which are inhibited in their release by THN. Consequently budding of HERV-K particles should be decreased in THN-expressing cells in comparison to THN-negative cells. Potential THN antagonists encoded by MVA should restore the budding phenotype as observed in THN negative cells.

Results: Viral titers were determined at different time points after infection from lysed cells as well as from culture supernatants and were comparable. THN expression levels at the surface of infected cells were not significantly altered. Potential antagonits encoded by VACV would be detected utilising a recombinant MVA expressing HERV-K gag. HERV-K particle release was significantly inhibited in both settings in 293HA-THN cells compared to THN-negative cells.

Conclusions: Our data indicate that poxviruses do not interfere with THN function. THN expression did not inhibit VACV release and replication. VACV infecion did not diminish THN-surface levels or impaired its function on retroviral release. This suggests that THN is unable to restict VACV infections.

P1484

The role of non-neutralizing antibodies in infection with the non-cytopathic lymphocytic choriomeningitis virus

T. Straub & H. Pircher

Immunology, Institute of Medical Microbiology and Hygiene, Freiburg, Germany

Purpose/Objective: Persistent infections with non- or minimally cytopathic viruses like HBV, HCV or HIV represent a major health problem world wide. Despite intense research there are hardly any options to treat these diseases. To improve the treatment strategies it is of great importance to gain better knowledge of the effector functions of the immune system that contribute to the elimination of non-cytopathic viruses. Infection of mice with the Lymphocytic Choriomeningitis Virus (LCMV) is a well established murine model for infection with a non-cytopathic virus. We used this model to study the contribution of non-neutralizing antibodies to the anti-LCMV immune response.

Materials and methods: To investigate the contribution of non-neutralizing antibodies to virus control we analysed the effect of passive immune-serum transfer on the anti-LCMV CD8 T cell response in LCMV-infected C57Bl/6 mice.

Results: Passive transfer of LCMV-immune sera or IgG purified from LCMV-immune sera resulted in an accelerated virus clearence in LCMV-infected C57Bl/6 mice. Interestingly, no effect on the virus titer in spleen, liver, lungs, kidney and serum was observed before day 8 post infection. This suggests an indirect effect of these antibodies on virus clearence.

Conclusions: It has been known for decades that cytotoxic CD8 T cells are key players in LCMV elimination. During the acute infection only non-neutralizing LCMV-specific antibodies are detectable whereas neutralizing antibodies against the virus appear only very late, if any at all. Our data suggest that these early non-neutralizing antibodies contribute to the mainly CD8 T cell-mediated immune response to this virus.

P1485

The role of type I interferon in persistent murine norovirus infection

B. Blacklaws, J. Chettle, A. Shortland, P. Zaccone, S. Newland, S. Gibbs, P. Tonks, S. Man, P. Tourlomousis, A. Cooke, C. Bryant & J. Heeney

Department of Veterinary Medicine, University of Cambridge, Cambridge, UK

Purpose/Objective: Persistent viruses have evolved many mechanisms to evade the host immune response including alteration of the host's ability to produce or respond to type I interferon (IFN). Certain strains of murine norovirus (MNV) are able to persist for months following infection, whereas other strains are cleared within days. However, the reasons for these differences and how the host immune system may be involved are not well understood. The importance of type I IFN in the immune response to MNV infection has been demonstrated by findings that type I (along with type II) IFNs inhibit the translation of MNV proteins during infection and that the virus encodes a protein whose functions include delaying the up-regulation of IFN-beta following infection. We have recently characterised a persistent strain of MNV, known as O7, and have investigated whether inhibition of type I IFN induction by infected cells could be a mechanism of immune evasion by persistent MNV strains.

Materials and methods: Immortalised and bone marrow derived macrophages (BMM) and bone marrow derived dendritic cells (BMDC) were infected with different strains of MNV at varying multiplicities of infection and the induction of type I IFN measured by quantitation (ELISA) of the amount of IFN beta in the supernatant at 24 and 48 h post infection. Controls included LPS and poly I:C as well as UV inactivated virus.

Results: We have demonstrated that both immortalised cell lines and primary bone marrow-derived macrophages initiate a significantly reduced type I IFN response on infection by O7 compared with MNV-1. Furthermore, a comparison of the immune response of bone marrow-derived macrophages with bone marrow-derived dendritic cells revealed different response patterns to the virus strains.

Conclusions: We are now investigating whether this difference in cytokine induction is also seen *in vivo* as our results indicate that persistent strains of MNV inhibit induction of type I IFN in certain cell types, which may contribute to the establishment of persistent infection.

Topical application of imiquimod on distant healthy skin of patients with HSV or HPV infections causes systemic immunomodulation and long-term remission

M. Rodi,* E. Pasmatzi,† A. Monastirli,† D. Tsambaos† & A. Mouzaki*

**Department of Internal Medicine, School of Medicine, University of Patras, Patras, Greece, †Department of Dermatology, School of Medicine, University of Patras, Patras, Greece*

Purpose/Objective: Imiquimod, an exogenous ligand of TLR7, can be used as an immune response modifier to generate effective antiviral immune responses to HSV. In this study we evaluated the effect of topical application of imiquimod on distant healthy skin of three patients with HSV and two with HPV infections.

Materials and methods: Three patients with HSV (recurrent herpes labialis) and two with HPV infections (condylomata) and five age and sex-matched healthy volunteers (controls) participated in this study. At the start of an HSV or HPV episode a 62.5 mg quantity of imiquimod (Rx: Aldara; 5% cream, Lavipharm S.A., Athens, Greece) was topically applied under occlusion × 1/day (at bedtime) every day for 3 weeks to a lesion-free abdominal skin area (100 cm^2) of the patient and left in

place for 8 h. The patient was advised to strictly avoid any exposure to sunlight or UV light during the treatment period. Peripheral blood samples were collected prior, during and after cessation of treatment and analyzed by flow cytometry for the estimation of all peripheral lymphocyte populations, including Tregs. Serum cytokines (IL-2, IL-4, IL-6, IL-10, TNF-α, IFN-α, IFN-γ) were measured with a cytometric bead array method.

Results: All patients entered long-term remission (>1 year) post-Rx. The controls did not experience any serious side effects during or after Rx. Rx caused proliferation and activation of CD4 and CD8 T-cells, especially the naïve populations, and B1α cells, whereas it caused reduction of CD20 B-cells. $CD4^+$ $CD25^{+/high}$ $FoxP3^+$ Treg numbers (+%) increased within the 1st week post-Rx (from 0.479 ± 0.207% Pre-Rx to 0.696 ± 0.312% 1st week post-Rx, estimated as % of total lymphocytes), and subsequently decreased (0.219 ± 0.141% by 2nd week post-Rx). By the 2nd week, serum IL-6, IFN-α and IFN-γ levels increased (to 47.03 ± 32.52, 19.9 ± 1.07 and 230.3 ± 179.5 pg/ml respectively). Post-Rx (3 months to 1 year), the patients had control levels of all cytokines, increased levels of activated CD8 and CD4 T-cells and B1α-cells, and normal levels of all other lymphocyte populations including Tregs.

Conclusions: Our results indicate that topical application of imiquimod on distant healthy skin can cause systemic immunomodulation and enhance virus specific immune responses. This type of treatment can be an effective therapeutic regimen for HSV and HPV infections.

P1487
Understanding the adaptive immune response to yellow fever vaccine

M. Bassi, A. R. T. A. R. Thomsen & J. P. C. J. P. Christensen
International Health Immunology and Microbiology, Panum Institute, Copenhagen, Denmark

Purpose/Objective: The Yellow Fever vaccine, based on a live-attenuated virus (YF-17D), is one of the most effective vaccines ever made. Neutralizing antibodies are thought to be the primary correlate of protection against infection and immunization is known to confer protection in more than 90% of vaccinees. T cells are also thought to have an important role; however, so far only a few studies have investigated primary and memory T cell responses to YF-17D.

While studies on YF-17D virus in humans are limited to the analysis of basic features of the immune response following vaccination, certain aspects of the host response can be studied in much greater detail in a mouse model system.

In this project we use a murine model to investigate the adaptive immune response to YF-17D vaccination and to characterize the role of cellular and humoral immunity in the vaccine−induced protective response.

Materials and methods: In order to investigate cell subsets and effector molecules driving the YF-17D induced immune response, we have used several strains ofknockout mice (ko) in vaccination-challenge experiments; serum transfer and adoptive transfer of splenocytes from YF-17D infected to naïve mice have been performed to study the contribution of cellular and humoral immunity.

Moreover, we have characterized the primary and secondary T-cell responses following vaccination by tetramer staining and intracellular cytokine staining for IFN-γ.

Results: We have observed that while the absence oftype I IFN signaling and of both IFN- γ and perforin have only a very modest impact on the YF-17D induced immune response, both *Rag1* ko mice and MHC class II ko mice fail to develop a protective immune response when immunized prior to challenge. Moreover, in the absence of B cells and antibodies (B cell ko), about 20% of the mice immunized prior to challenge will still develop a protective immune response and survive i.c. challenge, displaying an increased $CD8^+$ T cell response in the spleen compared to surviving wild type mice.

Also, even though transfusion of serum from immune mice to naïve recipients confers 100% protection, adoptive transfer of primed spleenocytes prior challenge also confers protection in about 70%of the animals tested.

Conclusions: Our findings suggest that althoughB cells/antibody are major players in the YF-17D induced protective response in mice, T-cells are also involved.: future experiments will address the specific contribution of$CD4^+CD8^+$ T cells in the vaccine induced protective response in mice.

P1488
Viral load and humoral responses in relation to disease severity in hantavirus infected patients

T. Lindgren,* L. Pettersson,† M. Bylund,† J. Rocklov,‡ J. Rasmuson,* J. Klingstrom,§ M. Evander† & C. Ahlm*
**Infectious Diseases, Clinical Microbiology, Umeå, Sweden, †Virology, Clinical Microbiology, Umeå, Sweden, ‡Department of Public Health and Clinical Medicine, Epidemiology and Global Health, Umeå, Sweden, §Swedish Institute for Infectious Disease Control, Umeå, Sweden*

Purpose/Objective: Hantaviruses are the causative agents of hemorrhagic fever with renal syndrome (HFRS) in Euroasia and hantavirus cardiopulmonary syndrome in the Americas. The clinical picture and severity of disease varies depending on the particular virus involved. The mechanisms behind the pathogenesis of human hantavirus infections are complex and likely involve both virus and host-mediated mechanisms. It has been suggested that immune responses, including cytokines, cytotoxic T cells and antibodies might have an important role. Thus, the aim of our study was to investigate the viral load and humoral response in HFRS patients. To study possible correlations between viremia, humoral responses and different clinical labparameters to disease severity.

Materials and methods: In total, 105 patients with verified Puumala hantavirus infection were included in this prospective study. Blood samples were collected and clinical symptoms were studied from the acute onset of disease to the convalescent phase. The kinetics of labparameters, viral load and the humoral (IgA, IgM and IgG) response was investigated.

Results: The patients had classical symptoms of acute mild HFRS and 88% of the patients had signs of renal impairment. 1/3 of the patients had low platelets and clinical signs of bleeding manifestations. Fifteen of the 105 patients were classified as having a moderate/severe illness. A correlation was observed between severe illness and low platelets ($P < 0001$), a high creatinine ($P = 0.01$) and a high white blood cell count (WBC) ($P = 0.001$). A high WBC was also associated with renal impairment (high creatinine). Viremia was detected for up to 1 week after symptom debut and the viral load was not associated with severe illness, neither with a high creatinine level. Upon humoral response analysis a low Puumala virus specific IgG response is significantly associated with severe disease ($P = 0.023$), but not when adjusted for age.

Conclusions: During HFRS, levels of viremia did not affect outcome, but the data indicate that low levels of specific IgG in patients could be linked to a more severe clinical outcome in Puumala hantavirus infected patients. A high white blood cell count is linked both to severe disease and to renal impairment. We have previously showed that a there is marked increase of activated CD8 T cells and NK-cells during the acute phase of infection, which could contribute to the severity of disease (Bj*rkstr*m *et al*., JEM 2011; Lindgren *et al*., J Virol 2011). Hence, the level of host defence including neutralizing antibodies and cellular immune responses may play important roles in the pathogenesis of the infection.

A flow cytometric assay for pharmacodynamic measurements of antibody therapeutics targeting cell surface receptors and its application to a "Site-of-Action" PK/PD model

K. Long, Y. Vugmeyster & A. Abraham
Pharmacokinetics Dynamics and Metabolism, Pfizer, Andover, MA, USA

Purpose/Objective: (1) To develop flow cytometric pharmacodynamic (PD) assays to assess target expression and coverage by an anti-receptor X therapeutic monoclonal antibody (mAb-A) in pre-clinical species; (2) to utilize these data for qualification of a mechanistic PK/PD model for mAb-A.
Materials and methods: Receptor X numbers/cell and occupancy (RO) by mAb-A or a surrogate antibody in blood and lymphoid tissues from cynomolgus monkeys or mice, respectively, were determined using the Quantibrite System from BD Biosciences and an LSR Fortessa flow cytometer. Target (receptor X) coverage was determined using a combination of antibodies to identify total and free receptor. We first assessed these PD endpoints in a mouse model to qualify predictions of a 'Site-of-Action' PK/PD model and to confirm percent coverage at selected dose levels. We next investigated receptor number and RO in blood and lymphoid cells in cynomolgus monkeys over 2 months following a single 2 mg/kg dose.
Results: In a mouse pharmacology study with surrogate antibody, total receptor X levels on B cells were constant and at the high dose 100% target coverage was achieved, consistent with predictions. Upon a single 2 mg/kg dose of mAb-A to cynomolgus monkeys, receptor X levels in blood were stable and complete RO was observed for the first 19 days, after which RO declined to zero. Loss of RO correlated with the appearance of anti-drug antibodies in these animals. In splenic B cells, significant levels of RO was observed in at study termination (56 days) and total receptor X expression was decreased compared to control animals. This study provides a general workflow for the prediction of target coverage in humans using a site-of-action PK/PD model and confirmation of such predictions from PD data generated through flow cytometric assays.
Conclusions: Flow cytometric assays were developed that characterized total and free receptors/cell from *in vivo* samples in pre-clinical species; similar methodology may be applied to human samples. RO, expression levels, and modulation of expression during disease or upon antibody administration are critical parameters for developing and qualification of the 'Site-of-Action' PK/PD models. This study demonstrates a general workflow for the incorporation of PD measurements into PK/PD models that aid in the prediction of human efficacious doses.

P1490

Abatacept is highly effective in inhibiting T cell priming but fails to induce T cell tolerance after primary antigen encounter

A. Patakas,* R. Ji,† S. E. Connolly,† S. G. Nandler,† J. M. Brewer,* I. B. McInnes* & P. Garside*
**Institute of Infection Immunity and Inflammation, University of Glasgow, Glasgow, UK, †Department of Immunology and Inflammation, Bristol Myers Squibb Co. Research and Development, Princeton, NJ, USA*

Purpose/Objective: Absence of co-stimulation in the presence of TCR-stimulation has been linked to the induction of tolerance, deletion or anergy. Abatacept is a CTLA-4-Ig molecule that binds with high affinity to CD80/86 on antigen presenting cells. It modulates CD28-mediated T cell co-stimulation and is currently used to treat rheumatoid arthritis, however it is unknown if its use leads to the development of immunological tolerance. The aim of this study is to gain a greater understanding of the mode of action of Abatacept by investigating *in vivo* its ability to induce antigen-specific immunological tolerance.
Materials and methods: We employed TcR transgenic mice, oral tolerance and adoptive transfer systems to investigate whether abatacept can induce a state of immunological tolerance during primary antigen encounter.
Results: While T cells that have been tolerised by antigen feeding were unable to produce IL-2 after *ex-vivo* restimulation, T cells primed in the presence of abatacept produced copious amounts of this cytokine and resembled naïve T cells. Furthermore, tolerised T cells exhibited a significantly higher proportion of CD25+ $FoxP3^+$ T cells and $CTLA\text{-}4^+$ cells, whereas T cells primed in the presence of abatacept were characterised by the absence of CD25+ $FoxP3^+$, more resembling naïve rather than tolerised T cells. However, abatacept treatment significantly affected T cell activation, as demonstrated by the high proportion of $CD44^{low}CD62L^+$ transgenic T cells in these mice, in contrast to untreated and tolerised T cells that had an antigen-experienced phenotype ($CD44^{high}CD62L^-$). Upon secondary *in vivo* exposure to antigen, abatacept treated T cells expanded to the same degree as naïve or primed T cells, which was significantly greater than expansion observed with tolerised T cells. Furthermore, isolated T cells from abatacept treated mice had a unique transcriptional profile, distinct from naïve, tolerant and primed T cells. These results demonstrate that abatacept treatment significantly modulates antigen specific T cell priming *in vivo*, however does not induce tolerance phenotypically, functionally or transcriptionally.
Conclusions: In this study we demonstrate that abatacept does not induce a state of immunological tolerance after primary antigen encounter, however it significantly affects T cell activation.

P1491

Auto-antibodies in SLE: is antigen microarray the future in autoimmunity diagnosis?

K. Bassilious, P. Tighe, O. Negm & A. Al-Mehairi
Immunology Department, School of Molecular Medical Sciences, Queens Medical Centre, University of Nottingham, Nottingham, UK

Purpose/Objective: The successful diagnosis of Systemic Lupus Erythematosus (SLE) is based on clinical presentation as well as multiple autoantibody serological testing; both of which are expensive and time-consuming. This study aimed to optimise and henceforth illustrate the potential use of antigen microarray to detect various autoantibodies for the purpose of screening as well as disease monitoring.
Materials and methods: The procedure was initially optimised by trialling various printing surfaces and slides as well as dilution and blocking buffers. Serum samples were obtained from SLE patients ($n = 19$) and healthy controls ($n = 7$). Followig optimisation serum was analysed by antigen microarray technology to detect 8 known SLE antigens, a Rheumatoid Arthritis (RA) antigen and several positive control antigens.
Results: Optimum results were obtained when antigens were printed in trehalose PBS-Tween onto aminosilane slides (Nexterion®). The lowest background and highest signal-to-noise ratios were obtained when serum was diluted in antibody diluent (Dako). The main finding of this study was that patients had significantly higher autoantibody presence in three of the SLE antigens tested: Nucleosome, Ribonucleoprotein and Ribosomal P ($P < 0.001$, $P < 0.001$, $P < 0.05$), in addition to the RA antigen CCP2 ($P < 0.001$). Other auto-antibodies tested for, such as Anti-dsDNA, showed a non significant higher presence in patients ($P = 0.056$) of which could be due to good control of disease by most patients. Furthermore, antibody levels from patients on treatment correlated with disease improvement.

Conclusions: These results suggest that microarray is an efficient technique to monitor and detect a wide variety of antibodies in multiple patients simultaneously, doing so at a relatively lower cost then current methods. This demonstrates the need for further development of this technology due the potential for providing a means of mass screening, early diagnosis and reliable monitoring of autoimmune disease including, but not limited to, SLE.

Autoreactive IgG antibodies activity may be suppressed by other immunoglobulins in human serum and colostrum

I. Manoylov, I. Djoumerska-Alexieva & A. Tchorbanov
Immunology, Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria

Purpose/Objective: The immune system of healthy individuals contains B cells that synthesize IgG antibodies, which recognize a great variety of self antigens. These auto antibodies, can be found in the serum and respectively in the intravenous immunoglobulin preparations, and may interact with antigens that can also be targets of some pathological autoantibodies. Natural IgG autoantibody reactivity can be induces by subjecting the immunoglobulins to extreme environmental conditions (high and low pH values when using affinity elution buffers). This activity is not observed when non-denaturating methods of purification are used.
Materials and methods: We have investigated the *in vitro* interactions between human liver antigens and human serum and colostrum from healthy individuals or pooled human IVIg. Two different methods of IgG purification were performed: immunoaffinity elution (using low pH treatment of antibodies) and soft salt precipitation (no extreme pH value buffers were used). Pure IgA and IgM were obtained from the different fractions of serum and colostral proteins (distribution based on their molecular mass).
Results: Serum or mucosal IgM and IgA isolated by immunoaffinity elution as well as the fraction containing immunoglobulin F (ab')2 fragments possess the ability to inhibit in a dose-dependent manner the interaction of eluted IgG antibodies or pooled IVIg preparation to human liver antigens. These results suggest that the inhibition was due to idiotype-antiidiotype interactions between immunoglobulin molecules before their contact with autoantigens.
Conclusions: The results show that binding of auto-reactive IgG antibodies to self-antigens can be inhibited by serum as well as mucosal IgA and IgM. Our study supports previous findings that IgM has a major role in blocking the IgG autoantibodies. We suggest that normal pooled human IgM and IgA preparations may have a positive immunomodulatory activity in patients with autoimmune diseases, as the control of the auto-reactivity is highly inefficient in those cases.

Development of a plasma cell specific antibody

F. Oden,* C. Kriegel,* J. Brand,† U. E. Höpken,* G. Müller* & M. Lipp*
**Molecular Tumor Genetics and Immunogenetics, Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany, †Structure and Membrane Interaction of G-Proteins, Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany*

Purpose/Objective: In this project we developed a chimeric antibody for the depletion of multiple myeloma (MM) and autoreactive plasma cells. Multiple myeloma is a malignancy of plasma cells and is classified as a Non-Hodgkin's lymphoma. Although it is the second most common hematological cancer there is no suitable antibody available yet. Today the treatment of choice is the proteasome inhibitor Bortezomib followed by an autologous hematopoietic stem-cell transplantation. Our antibody binds to a plasma cell specific antigen (PCspA) which is not present during other stages of B cell development.
Materials and methods: Heavy and light chain of a monoclonal antibody produced by hybridoma technology were cloned upstream of a human IgG1-heavy and kappa-light chain. The chimeric antibody has been characterized by ELISA, flow cytometry, surface plasmon resonance and *in vitro* cytotoxicity assays.
Results: After validation of the binding specificity and assessment of the K_d we performed *in vitro* cytotoxicity studies. The antibody showed a strong killing of MM cells already after 4 h. Recently, we established a xenograft model of multiple myeloma in mice in which we currently assess the efficiency of antibody-mediated tumor regression. At the same time we are working on the three dimensional structure of the Fab fragment bound to the antigen in order to facilitate the humanization process.
Conclusions: The newly developed chimeric antibody binds with high affinity to its antigen, shows promising characteristics *in vitro* and will be further developed for a possible clinical use.

P1496

Effect of anti-interleukin-2 receptor antibody on human dendritic cell maturation and activation

F. Herr,* F. Gouilleux,† R. Lemoine,* A. Ceroi,* F. Velge-Roussel,* C. Baron‡ & Y. Lebranchu‡
**EA4245 Cellules Dendritiques Immunomodulation et Greffes, Université François Rabelais, Tours, France, †UMR CNRS 6239 Génétique Immunothérapie Chimie et Cancer, Université François Rabelais, Tours, France, ‡Service de néphrologie et d'immunologie clinique, CHRU Tours, Tours, France*

Purpose/Objective: Although anti- CD25 (α chain of IL2 receptor) monoclonal antibodies are widely used in transplantation to prevent acute allograft rejection, their effects on human dendritic cells (DC) are poorly understood. A recent study (Wuest *et al.* Nature Medicine 2011) suggests that the main function of CD25 on DC was to transpresent IL2 to activate T lymphocytes. Interestingly, this study could neither found any evidence of signalling in DC by IL2 nor detect the β chain of the receptor (CD122) on the surface of DC. Therefore, we decided to further explore the effects of IL2 in DC.
Materials and methods: Human blood $CD14^+$ cells were selected differentiated into immature DC with IL4 and GM-CSF for 5 days. Maturation was induced by LPS or TNFα in presence or absence of anti-CD25 (Basiliximab, 100 μg/ml) with or without IL2 (100 U/ml) during 48 h. $CD8^+$ T lymphocytes were cultured with allogeneic DC for 5 days after extensive wash. Surface expression of molecules was analyzed by FACS and cytokine secretion was measured by ELISA and FACS. Protein phosphorylation of STAT3, STAT5 and ERK1/2 was detected by Western blot.
Results: First we showed a constitutional expression of β and γ chain of IL2R on DC, while α chain was inducible by LPS and TNFα. Then we found that IL2 induced transcription factor STAT5 phosphorylation in DC. Interestingly, IL2 increased IFNγ synthesis in DC, while anti-CD25 had opposite effects. While these agents don't have any effect on co-stimulatory or migration molecules expression. Finally we showed that IL2 increases the ability of DC to activate $CD8^+$ T cells cytotoxic functions, whereas anti-CD25 decreases these properties.
Conclusions: This study, for the first time, discloses that IL2 induces DC activation through IL2 receptor binding and subsequent intracellular STAT5 phosphorylation. Interestingly, our study suggests a direct effect of monoclonal anti-CD25 on DC that may contribute to their clinical efficacy.

Fully-human recombinant antibodies are opsonic to genetically diverse Staphylococcus aureus strains

H. Russell, A. Arruda, A. Colantonio, K. Gareau, S. W. Hicks, M. Lewis, V. Medik, E. Reczek & V. Coljee
Excelimmune Inc, Research, Woburn, MA, USA

Purpose/Objective: Anti-surface *Staphylococcus aureus* (SA) antibodies were to be identified and tested functionally for development of a human recombinant polyclonal antibody (HRPA) therapeutic to protect against all SA strains.
Materials and methods: Antibodies to SA were identified based on surface reactivity to formalin-fixed bacteria as measured by Luminex technology. Human anti-SA antibodies reacted to a diverse range of SA strains including USA300 and USA400 strains of Methicillin Resistant SA (MRSA). The antibodies were tested for opsonic activity against several SA strains using two assays * cell-line phagocytosis and whole blood killing. Cell-line assays utilized FITC-labeled SA and opsonization was measured by flow cytometry. Whole blood killing assays (analyzed by viable bacteria counts) were utilized to confirm the cell-line assay results. The use of whole blood demonstrated that our antibody contribution would enhance phagocytosis beyond any background activity from anti-SA antibodies present in human serum. Antibodies were tested both individually and as sets of antibodies.
Results: We identified a number of antibodies able to recognize and opsonize a wide range of SA strains including MW2, LAC, COL and JDK6159 * which represent a diversity of sequence types. The antibodies provided efficacy in these assays to 100 ng/ml or less final depending on antibodies used. The addition of these antibodies was also able to enhance phagocytosis above circulating antibodies found in human serum during whole blood killing assays.
Conclusions: An array of opsonic anti-SA antibodies have been identified and characterized functionally. These new antibodies to naturally antigenic SA molecules allow for strong *in vitro* activity which will contribute to an efficacious HRPA against SA including MRSA strains. By creating HRPAs for therapeutics, it is possible to protect against all SA strains. Targeting multiple epitopes of several different surface molecules will provide protection from drug-resistance common to current antibiotic-based practices.

Humanisation of DOC2 anti CCR2 antibody; a MAB with therapeutic potential for MS and other autoimmune diseases

E. Cullen, E. Bureau & S. Fox
Antibody Therapeutics, MRC Technology, London, UK

Purpose/Objective: DOC2 a murine anti-CCR2 antibody has been shown to deplete monocytes which express the CCR2 chemokine receptor in both mouse and NHP animal models. Further studies have shown a clinically significant effect in both murine and NHP experimental autoimmune encephalomyelitis (EAE) disease models. We have humanised this monoclonal antibody (MAB) creating a version which can bind both human and NHP CCR2 expressed on monocytes prepared from PBMCs harvested from both species. It has also been demonstrated that this humanised version can induce monocyte depletion in NHP after injection with repeated doses of the MAB. We propose the mechanism for this depletion is by antibody dependent cellular cytotoxicity (ADCC). The main goal of the study is to determine if this humanised MAB can show clinical improvement in the NHP EAE animal model with a view to developing a treatment for MS in humans.
Materials and methods: Humanisaton was carried out by CDR grafting using suitable human donor frameworks for both heavy and light chains of the antibody. The humanised version was tested by flow cytometry using human and NHP PBMCs to demonstrate that the original specificity for the CCR2 target was maintained. NHPs were dosed with the candidate antibody over a 3 week period and flow cytometry monitoring CD14+CD11b+ monocyte depletion was carried out on blood harvested at specific time points throughout the study period. The ADCC assay was carried out by adding the antibody to europium (Eu) labelled CHO cells expressing CCR2 in the presence of NK cells. Target cell lysis was measured by Eu release.
Results: Good binding to both human and NHP CCR2 target on PMBCs was demonstrated by flow cytometry. The antibody also showed a clear ability to induce monocyte depletion in NHPs over the study period. The ADCC assay results confirm that the likely method for monocyte depletion is mediated by this mechanism.
Conclusions: We have established that the humanised anti CCR2 antibody binds to the target and has demonstrated the capacity to induce monocyte depletion in a NHP animal model. Furthermore our ADCC assay results indicate that the monocyte depletion is likely to be mediated by this mechanism. These results indicate that the DOC2 humanised antibody is a good candidate to test in a NHP EAE model with a view to developing a treatment for MS in humans.

Identification and characterization of a peptide mimetic recognized by disease −associated antiprothrombin antibodies in antiphospholipid syndrome patients

S. Huang,* B. Tsai,* Y. Yang,† P. Chen‡ & B. Chiang†
**National Taiwan University Hospital, Graduate Institute of Clinical Medicine, Taipei, Taiwan, †Department of Pediatrics, National Taiwan University Hospital, Taipei, Taiwan, ‡Division of Rheumatology, Department of Medicine, University of California, Los Angeles, CA, USA*

Purpose/Objective: Antiphospholipid syndrome (APS) is an autoimmune disease characterized by association with recurrent thrombosis, recurrent feral loss, and thrombocytopenia. Antiphospholipid antibodies (aPL) play an important role in thrombocytosis and/or fetal loss related to APS. Prothrombin (PT) is one of the most important targets for the aPL that was considered with prothrombinase activity. To test the feasibility of applying a mimetic specific for a patient-derived monoclonal antiprothrombin [aPT] antibody to study the homologous, disease-associated aPT in APS patients.
Materials and methods: We used the IS6 monoclonal aPT to screen phage-display peptide libraries. In terms of the conserved amino acid sequence in phage peptide selected, peptide and their derivatives were synthesized and analyzed for binding affinity and for their competitive ability to prothrombin from IS6. In addition, the peptides were designed to study IS6-like IgG aPT in serum samples from patients with APS, patients with rheumatoid arthritis (RA), patients with juvenile rheumatoid arthritis (JRA), patients with systemic lupus erythematosus (SLE) but without APS, and normal healthy donors.
Results: After library screening with IS6, four peptides were designed and synthesizes. Analyses of peptides showed that peptide 9099 reacted with IS6 antibody better than the other 3 and inhibited binding of IS6 to prothrombin. The results suggested that peptide 9099 might be a peptide mimetic for the IS6 aPT. ELISA analyses with serum sample indicated that 9099-reactive IgG was present (positivity defined as the mean + 3 SD optical density of the 11 healthy controls) in 27 of 31 APS patients.
Conclusions: The results suggest that the peptide 9099 might be with the potential to develop a specific ELISA distinct disease *associated aPT.

Impaired langerhans' cell migration in psoriasis: effect of systemic therapies

R. J. Dearman,* K. T. Mellody,* F. Shaw,* S. Ogden,† I. Kimber* & C. E. M. Griffiths†
*Faculty of Life Sciences, University of Manchester, Manchester, UK, †Dermatological Sciences, University of Manchester, Manchester, UK

Purpose/Objective: Epidermal Langerhans cells (LC) act as sentinels of the immune system: they migrate from the skin to local lymph nodes to present antigen to T cells and are believed to play important roles in the initiation and regulation of immune responses. We have shown previously that *in vivo* LC migration is impaired in the uninvolved skin of patients with early-onset psoriasis (onset <40 years of age). In the current experiments the impact of systemic therapies on LC migration in these patients has been investigated.
Materials and methods: Punch biopsies (6 mm) were taken from non-sun-exposed buttock skin of healthy controls, untreated psoriasis patients or from those patients who had responded well to either T-cell targeted therapies (ciclosporin, methotrexate); anti-cytokine biologics (adalimumab, etanercept, ustekinumab), or fumaderm. Epidermal sheets were prepared, a $t = 0$ control sheet processed for counting, and the remaining sheets floated on medium for 24 h in the presence or absence ofHaCaT (human keratinocyte) cell conditioned medium. Following immunofluorescent staining for CD1a, LC frequencies were assessed.
Results: Similar levels of LC migration to those stimulated *in vivo* by cytokine or allergen (20−30% of cells) were observed in explants excised from healthy controls (mean 19.6 ± 3.1%) in the presence of culture medium alone. However, in biopsies taken from untreated psoriasis patients there was little or no migration under the same conditions (mean 0.9 ± 1.8%). Migration was impaired also in patients who had responded to T-cell targeted therapies (mean -2 ± 4.4%). In contrast in patients who had responded to anti-cytokine biologic agents and fumaderm, migration was restored to similar levels to those recorded for healthy control subjects (mean 17.7 ± 3.9%). We speculated that the lack of LC migration in samples derived from the untreated psoriasis patients was due to deficiencies in the epidermal microenvironment. We therefore cultured epidermal explants from these patients in the presence or absence of supernatants derived from the human keratinocyte cell line HaCaT. There was a significant restoration of LC migration in explants cultured in conditioned medium (mean 23.0 ± 4.7%) compared with control biopsies (mean 2.7 ± 1.3%).
Conclusions: These data indicate that therapies which target key cytokines involved in the pathogenesis of psoriasis can restore LC migration whereas T-cell targeted approaches do not. Further, the restoration of migration by HaCaT conditioned medium suggests that local, keratinocyte-derived factors may be responsible for the lack of LC migration in biopsies derived from untreated psoriasis patients.

Insertion of artificial cell surface receptors for antigen-specific labelling of hybridoma cells

M. Listek, B. Micheel & K. Heilmann
Nachwuchsgruppe Antikörper-Technologien Institut für Biochemie und Biologie der Universität Potsdam, Universität Potsdam, Golm, Germany

Purpose/Objective: M. Listek, B. Micheel, K. Heilmann Insertion of artificial cell surface receptors for antigen-specific labelling of hybridoma cells. Monoclonal antibodies are universal binding molecules and play a central role as powerful tools in biomedical research, therapy and especially in diagnostics. The generation of antibody molecules is generally done by hybridoma technology since published by Kohler and Milstein in 1975. But the identification of antigen-specific antibody-producing hybridoma cells within a heterogeneous cell population is time-consuming and laborious.

To accelerate the screening procedure in order to detect the hybridoma cell of interest we have created a knock in myeloma cell line that express an artificial cell surface receptor.
Materials and methods: To accelerate the screening procedure in order to detect the hybridoma cell of interest we have created a knock in myeloma cell line that express an artificial cell surface receptor.
Results: By bridging the antigen of interest to the artificial system we could clearly show a specific labelling of cells producing antibodies with the desired specificity. These cells were enriched by FACS and cultivated in order to use them for antibody production.
Conclusions: Compared to conventional screening procedures this new approach is able to select antibody-producing cells at an early stage and therefore improve the detection of positive cell clones after fusion.

P1503

Low expression of immunoglobulin G receptor CD16 on mouse NK cells

M. Biburger,* V. Greiner,* K. Meinhardt,† E. Ullrich† & F. Nimmerjahn*
Chair of Genetics, Biology Department, University of Erlangen-Nuremberg, Erlangen, Germany, †Chair of Hematology/Oncology, Department of Internal Medicine 5, University of Erlangen-Nuremberg, Erlangen, Germany

Purpose/Objective: Cellular Fcγ-receptors are crucial for mediating the functions of therapeutic antibodies. Antibody dependent cellular cytotoxicity (ADCC) is an important mechanism by which Fcγ-receptor expressing cells of the innate immune system including natural killer (NK) cells can kill antibody-decorated target cells. Whereas the high expression of FcγRIII (CD16) on human NK cells is well documented, data on CD16 expression of NK cell under steady state conditions are barely available. Conclusion from human NK cells are frequently taken as a basis for interpretation of results in mice. We, thus, wanted to measure whether also in mice NK cells reveal prominent expression of CD16.
Materials and methods: Expression of murine CD16 was measured on leukocytes derived from blood, spleen and bone marrow by flow cytometry. Cells were isolated from C57BL/6 and Balb/c mice for comparison. Relative expression levels on murine blood peripheral blood cells types were compared to those on their human counterparts.
Results: Surprisingly, under steady state conditions murine NK cells were among the cell populations with rather low expression levels compared e.g. to inflammatory monocytes, neutrophils and eosinophils, which showed a much more prominent expression both in Balb/c and in C57BL/6 mice. Rather low CD16 expression on NK cells was found in the tested organs/compartments with only slight variations. In general, cells from Balb/c mice revealed significantly higher expression levels than those from C57BL/6 mice. We also compared expression levels on different subpopulations of NK cells, as identified with respect to expression of CD11b and CD27. These subpopulations revealed reproducible but only rather small differences in CD16 expression.
Conclusions: Cell-mediated antibody effector functions like ADCC are often discussed with respect to NK cells as main effectors *a priori* in humans as well as in mice. Since in mice NK cells express much less CD16 than several other populations which, in addition, express a broader repertoire of Fcγ receptors, the former might be overestimated in some models and the latter should also be taken into consideration as potential effector cells.

P1506

Personalised medicine in rheumatoid arthritis: Interleukin-6-receptor polymorphisms rs12083537 and rs2228145 as predictors of responsiveness to tocilizumab

C. Enevold,* B. Baslund,* L. Linde,† N. L. Josephsen,‡ U. Tarp,‡ H. Lindegaard,§ T. M. Hansen,† S. Jacobsen* & C. H. Nielsen*
*Department of Infectious Diseases and Rheumatology, Institute for Inflammation Research, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark, †Department of Rheumatology, Gentofte Hospital, Gentofte, Denmark, ‡Department of Rheumatology, Århus University Hospital, Århus, Denmark, §Department of Rheumatology, Odense University Hospital, Odense, Denmark

Purpose/Objective: Immunomodulatory biologics have revolutionized the treatment of rheumatoid arthritis (RA) and other autoimmune diseases. A substantial proportion of patients show no or limited response to these drugs, however, and may suffer irreversible disease progression during treatment. Moreover, the expense of biologics put a tremendous pressure on public health budgets worldwide. Much attention is being paid to development of companion diagnostics that reliably predict patient responsiveness, but so far none have proved clinically useful. Tocilizumab (TCZ; Actemra®), a mAb targeting the IL-6 receptor (IL-6R), has recently been approved in several countries mainly for the treatment of RA and other autoimmune diseases.
Materials and methods: Seventy-eight patients with RA were treated with TCZ. After 3 months, changes in swollen joint count (SJC) and C-reactive protein (CRP) were used as objective measures of any relationship with genotype at the two IL-6R SNPs rs2228145 and rs12083537.
Results: TCZ induced median reductions in SJC and CRP of 76% and 85%, respectively, in 49 patients who were homozygous for the major allele of rs12083537, compared to 100% ($P = 0.06$) and 91% ($P = 0.09$) in 29 patients, who were heterozygous for the SNP. No patients were homozygous for the minor allele of rs12083537. Thirty patients who were homozygous for the major allele of rs2228145 experienced a median reduction in SJC of 66% versus 100% in the group of 37 heterozygotic patients, as well as in 11 patients who were homozygous for the minor allele of rs2228145 ($P = 0.13$). The median reductions in CRP were 85%, 88% and 92%, respectively ($P = 0.68$). Nineteen patients, who were homozygous for the major allele of both SNPs, experienced a median reduction of only 50% in SJC and 69% in CRP, compared to 100% ($P = 0.0047$) and 89% ($P = 0.10$), respectively, in the rest of the patients.
Conclusions: Genotyping of rs12083537 and rs2228145 may prove a useful tool in predicting the clinical response of RA patients to TCZ. Our data suggest that the approximate one fourth of patients who are homozygous for the wild type allele at both loci constitute a group of poor responders.

P1507

Recovery of the T cell receptor repertoire in chronic inflammatory neuropathies with intravenous immunoglobulins: a novel approach to analyze CDR3 spectratyping data

A. K. Mausberg,* M. Dorok,* M. Stettner,* M. Müller,† H. P. Hartung,* T. Dehmel,* C. Warnke,* G. M. zu Hörste* & B. C. Kieseier*
*Department of Neurology, Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany, †Faculty of Mathematics and Computer Science, Friedrich-Schiller-University Jena, Jena, Germany

Purpose/Objective: Chronic inflammatory demyelinating polyneuropathy (CIDP) is an autoimmune disorder of the peripheral nervous system (PNS) with pronounced heterogeneity of disease severity and treatment response. The pathogenic role of T cells remains controversial. Intravenous immunoglobulins (IVIg) are effective in CIDP but their effect on antigen specificity of PNS autoreactive T cells is unknown.
Materials and methods: The T cell receptor (TCR) repertoire of $CD4^+$ and $CD8^+$ T cells in the peripheral blood was analyzed using CDR3 spectratyping. CIDP patients were included without and with IVIg treatment. To simplify the spectratyping analysis, we introduced a new classification system of alterations in the TCR length distribution and correlated this with the statistical values skewness and kurtosis.
Results: While the TCR length distribution of CIDP patients was only moderately altered for most of the Vbeta elements of $CD4^+$ T cells, the $CD8^+$ population displayed extensive oligoclonal expansions in all analyzed 24 Vbeta elements. Treatment with IVIg reduced the oligoclonal expansions within both the $CD4^+$ and $CD8^+$ population. The evaluation of the simplified analysis of spectratyping data correlated with the degree of alterations.
Conclusions: Our data demonstrate that cytotoxic $CD8^+$ T cells exhibit a much broader activation than $CD4^+$ T cells indicating a potentially crucial role of $CD8^+$ T cells in the immunopathogenesis of CIDP. The profound oligoclonal response in T cell activation suggests that multiple peptides may induce and propagate this autoimmune driven disease. The observed reduction of highly activated T cells may contribute to the therapeutic effects of IVIg. The validation of the classification system integrated in a reduction the of time consuming analysis of spectratyping data.

The creation of immunosensors based on antigen-antibodies against human growth hormone interaction and the application for the analysis in real samples

N. German,* A. Kausaite-Minkstimiene,† J. Voronovic,* J. Kirlyte,† A. Ramanavicius† & A. Ramanaviciene*
*Department of Immunology, State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania, †Department of Chemistry, Vilnius University, Vilnius, Lithuania

Purpose/Objective: The immunosensors combine the selectivity of the binding interactions between immobilized biomolecules and the analyte of interest with the sensitivity and subsequent detection by appropriate detector. The quantification of antibodies in serum samples from patients is essential for evaluation of the immune response and understanding the immunological properties of these proteins. Anti-hGH antibodies at medium-high concentrations inhibited the growth response to administered hGH and seemed to suppress also the effect of endogenous growth hormone. Detection of these antibodies may be useful for the diagnosis of lymphocytic hypophysitis.

The main aim of this research was to investigate simultaneous application of surface plasmon resonance (SPR), electrochemical (EL) and electroassited chemiluminescent (ECL) techniques on the same chip detecting interactions of the specific anti-hGH antibodies with human growth hormone immobilized on a SPR-chip surface. The created immunosensor was applied for the analysis in human serum samples.
Materials and methods: Indirect immunoassay format was chosen for the registration of immune complex formation (hGH/anti-hGH immune complexes using secondary HRP labelled antibodies) using combination of three different physical phenomena and for the formation of new effective platform for immunosensing.
Results: All types of tested analytical signal detection methods (SPR, EL, ECL) showed very good sensitivity for specific anti-hGH antibodies detection. Compared with SPR and ECL methods, EL detection of anti-hGH using pulsed amperometry characterized by the lowest limit of detection (0.027 nM) and the wider linearity range (0.098 * 1.11 nM). Created immunosensor was used for the determination of antibodies against human growth hormone in human serum

samples using the detection of pulsed amperometry. It was found that the recoveries were in the range of 93 * 98%.
Conclusions: This research work demonstrates the successful exploitation of different techniques to detect the specific anti-hGH antibodies using indirect immunoassay format on the same surface. The SPR immunosensor in contract to other used anti-hGH detection methods is suitable for multiple use.

P1509
The IgM CH2 domain as covalently linked homodimerization module for the generation of fusion proteins with dual specificity

O. Seifert, A. Plappert, N. Fuß, S. Fellermeier, S. Messerschmidt & R. E. Kontermann
Biomedical Engineering, Institute of Cell Biology and Immunology, Stuttgart, Germany

Purpose/Objective: Dimeric assembly of antibody fragments and other therapeutic molecules holds great potential to increase binding and to improve bioactivity. Here, we investigated the use of the IgM heavy chain domain 2 (MHD2) as covalently linked homodimerization module. MHD2 provides the scaffold for bi- or tetravalent molecules with single or dual specificity by fusion of two different scFv fragments to the *N*- and/or *C*-terminus. In addition, the combination of targeting antibody fragments and therapeutic moieties in one molecule results in a tetravalent and bifunctional fusion protein for targeted cancer therapy.
Materials and methods: The scFv fragments directed against EGFR and HER2 were used as targeting components for the generation of both *C*- or *N*-terminally-linked bivalent and monospecific fusion proteins as well as tetravalent, bispecific molecules. Furthermore, a bifunctional construct was generated by the replacement of one of the scFv fragments by a single-chain derivative of tumor necrosis factor (scTNF). All fusion proteins were produced in HEK239T cells. The ability to bind to and mediate killing of target cells was shown in flow cytometry analysis, IL-8 release assays and cytotoxicity assays.
Results: All MHD2 fusion proteins showed selective binding to tumor cells, expressing EGFR or HER2 in FACS analysis. The bispecific scFv-MHD2 fusion proteins exhibited improved binding to cell lines expressing both markers. The antibody-scTNF MHD2 construct exhibited improved TNF activity, also mimicking the membrane-bound form of TNF, as shown by the activation of TNFR2-mediated cell killing. Furthermore, the scFv moiety allowed for an antigen-dependent delivery of TNF to EGFR-positive tumor cells and an improved TNF action on these cells.
Conclusions: Taken together, we established the MHD2 as a versatile module for the generation of bispecific and bifunctional fusion proteins.

The production of porcine anti-CSF-1R antibodies: reagents to evaluate the effects of CSF-1 on postnatal growth

D. J. Gow, V. Garceau, L. Moffat, R. Kapetanovic, D. Sester & D. A. Hume
Developmental Biology, The Roslin Institute & R (D) SVS, Edinburgh, UK

Purpose/Objective: Macrophage Colony-Stimulating Factor (CSF-1) is required for the proliferation, differentiation and survival of cells of the mononuclear phagocyte lineage and acts via the CSF-1 receptor (CSF-1R). Mice with a homozygous mutation in CSF-1 are deficient in biologically active CSF-1 (*op/op* mice). Amongst other defects, these mice have low birth weights and are growth retarded compared to litter mate controls. Injecting *op/op* mice with rh-CSF-1 or expression of a CSF-1 transgene (full length or cell surface), can partially, or fully correct the body weights associated with the *op/op* phenotype. Additionally, serum CSF-1 is elevated in mice in the postnatal period and, together with the finding that injecting newborn mice with rh-CSF-1 causes a significant increase in body weight, it appears that CSF-1 plays an important role in postnatal growth. Therefore, CSF-1 may be a useful therapy in premature human infants. Since the domestic pig has many similarities with humans, especially in terms of innate immune responses, this provides an alternative to traditional rodent models to evaluate the effect of CSF-1 and anti-CSF-1R antibodies on postnatal growth.
Materials and methods: Full length functional porcine CSF-1R (Met1 * Cys969) was expressed in the factor-dependent Ba/F3 cell line and used in conjunction with an Fc-CSF-1R protein to inoculate four adult male BALB/c mice every 28 days for a total of four injections.
Results: Hydridoma cells were generated by fusion of mouse spleen cells with immortal Sp2/0 cells and supernatant screened by indirect ELISA for the production of pig specific anti-CSF-1R antibodies. Positive hybridoma cells were subcloned and assessed by FACS for their ability to bind porcine CSF-1R both in its native state (PBMC and BMC) and on the cloned CSF-1R cell line. Additionally, MTT assays demonstrated the competitive binding properties of the anti-CSF-1R antibodies. The cross-species reactivity of these antibodies has also been investigated.
Conclusions: In conclusion, we have developed porcine anti-CSF-1R antibodies that can be used in a variety of applications and ultimately to assess the role of CSF-1 in the postnatal growth of pigs.

P1513
Versatile generation of human pMHC-specific monoclonal antibodies

L. Gautreau, M. C. Devilder, F. Legoux, M. Bonneville & X. Saulquin
INSERM U892, Centre de Recherche en Cancérologie, Nantes, France

Purpose/Objective: Monoclonal antibodies specific for peptide/major histocompatibility complex (pMHC) specifically expressed by tumors or pathogens-infected cells can be exploited for both diagnostic and immunotherapeutic purposes, in particular for the targeted delivery of toxic agents or immune potentiators. We herein describe a novel versatile approach allowing generation of fully human pMHC-specific monoclonal antibodies.
Materials and methods: We recently set up a pMHC-multimer-based strategy allowing ex vivo detection and flow cytometry sorting ofrare pMHC-specific T cells, present at frequencies as low as 1 in 10^6 from human blood sample (Legoux *et al.*, 2010). Through a similar 8-color flow cytometry approach, we could isolate B cells (CD3-, CD19+) stained by pMHC fluorescent multimers in a peptide dependent fashion. The antibody genes of purified B cells were then amplified by single cell RT-PCR, cloned into expression vectors and transfected into a human cell line. The expressed antibodies were then purified and assayed for binding specificity.
Results: Using this technique, we have been able to generate human antibodies specific for HLA-A2 molecules loaded with particular immunodominant peptides of viral or tumor origins.
Conclusions: This protocol can be performed starting from small blood samples of even non-immunized donors, and can be extended from the generation of human monoclonal antibodies directed against any peptide-MHC specificity to virtually any defined antigen. Our entire strategy used established techniques but is novel in its specificity, sensitivity and applications.

3-dimensional laser structured scaffolds improve macrophage adherence and antigen-specific response

I. Zerva,* C. Simitzi,† A. Ranella,‡ E. Stratakis,‡ C. Fotakis§ & I. Athanassakis*

**Biology Department, University of Crete, Heraklion, Greece, †Biology Department, Institute of Electronic Structure and Laser, Foundation for Research & Technology-Hellas, University of Crete, Heraklion, Greece, ‡Foundation for Research & Technology-Hellas, Institute of Electronic Structure and Laser, Heraklion, Greece, §Institute of Electronic Structure and Laser, Physics Department, Foundation for Research & Technology-Hellas, University of Crete, Heraklion, Greece*

Purpose/Objective: The aim of the present study was to investigate whether 3D micro and submicron laser textured transplantable biomaterial scaffolds with tunable morphology and chemistry could support macrophage adherence, antigen presentation and specific antibody response development.

Materials and methods: Differences of the morphological features of the candidate biomaterials were advantageously achieved by tuning the laser structuring parameters resulting in scaffolds of gradient micro- and nano-geometries and 3D porosity and hydrophilicity. Macrophages were isolated from BALB/c mice and cultured upon 3D surfaces. Macrophage-coated scaffolds were seeded with antigen (Human Serum Albumin, HSA) and subsequently T_H cells, isolated from BALB/c mice, were introduced to the culture. The absorbance and recognition of macrophages and T_H cells on the 3D surfaces was revealed by SEM and Confocal Microscopy. The system's activation was revealed by Elisa experiments, by measuring the secretion of interleukins IL-2, IL-4 and specific antibody production in cell culture supernatants.

Results: SEM microscopy experiments revealed that less rough 3D hydrophilic scaffolds surfaces were more favorable to macrophage adherence as compared to flat or high roughness scaffolds. Under these conditions cells conserved their morphology and structural properties. Cells were identified as macrophages and T_H, using specific cell markers and by confocal microscopy analysis. T cell activation was demonstrated by detection of IL-2 and IL-4 in culture supernatants, while the development of antigen specific response was proved by detection of HSA-specific antibody production.

Conclusions: The 3D scaffolds displaying the capacity to exquisitely control the size of pores, the micro/nanotopography, the surface chemistry and distribution of bioactive species, represent significant progress beyond the current state of the art enabling a multi-parametric assessment of various factors affecting cell behavior, with far-reaching implications human health.

A novel carbon monoxide-releasing molecule ALF421 attenuates the development of autoimmune diabetes in mice induced by multiple low doses of streptozotocin

S. S. Grujicic,* I. Nikolic,* I. Stojanovic,* T. Saksida* & F. Nicoletti†

**Immunology, Institute fof Biological Research "Sinisa Stankovic", University of Belgrade, Belgrade, Serbia, †Biomedical Sciences, University of Catania, Catania, Italy*

Purpose/Objective: Carbon monoxide (CO), a by-product of heme catabolism by heme oxygenase, has recently been demonstrated to have potent anti-inflammatory and anti-apoptotic effects. ALF421 is a novel compound designed to liberate controlled quantities of CO in the cellular systems. However, its biological activity in autoimmune type 1 diabetes (T1D) has not been examined so far. Therefore, present study was conducted to investigate possible therapeutic value of ALF421 in the animal model of disease and to explore potential cellular mechanisms involved.

Materials and methods: T1D was induced in C57BL/6 mice by multiple low doses of streptozotocin (5×40 mg/kg). ALF421 (2 and 4 mg/kg) was administered as continuous or 8-day treatment as either prophylactic, early, or late therapeutic regimen. Disease development was evaluated by measuring blood glucose level on a weakly basis. Splenocytes were harvested on day 8 after T1D induction from ALF421-treated or vehicle-treated mice and cytokine levels in 48 h splenocyte-derived culture supernatants were measured by ELISA. Pancreatic islets isolated from healthy C57BL/6 mice, as well as mouse (MIN) and rat (RIN) insulinoma cell lines were exposed to proinflammatory cytokines (IL-1β+IFN-γ+TNF-α, 10 ng/ml each) in the presence or absence of ALF421 (range 12.5—100 μM) and analyzed for their survival by MTT assay.

Results: Administration of ALF421 during diabetes induction, or even after the induction of the disease, suppressed the development of hyperglycemia. *In vivo* treatment with ALF421 down-regulated the *ex vivo* secretion of proinflammatory cytokines (IFN-γ, IL-2, IL-6, IL-1β, and TNF-α), while IL-10, IL-17 and IL-4 production were not affected. *In vitro* studies revealed that ALF421 in a dose-dependent way reduced cytokine-induced cell death in three beta cell types tested (mouse islets of Langerhans, as well as MIN and RIN insulinoma cells), but did not affect basal cell viability.

Conclusions: Although the molecular mechanisms involved in the drug action remain to be established, our results suggest that the observed beneficial effect of ALF421 in the disease process could be attributed at least partly to the interference of ALF421-released CO with cytokine-mediated pro-apoptotic stimuli within endocrine pancreas.

P1517

A novel platform to screen for carbohydrate-based adjuvants and immunomodulators

M. Eriksson, M. Maglinao, M. K. Schlegel, C. Anish, P. H. Seeberger & B. Lepenies

Biomolecular Systems, Max-Planck-Institute of Colloids and Interfaces, Berlin, Germany

Purpose/Objective: C-type lectin receptors (CLRs) are pattern recognition receptors mainly expressed by antigen presenting cells. CLRs specifically recognize carbohydrate structures present on pathogens, but also self-antigens. The primary interaction of a dendritic cell (DC) and a pathogen shapes the following immune response. Thus, searching for immune modulators that can either enhance or modulate an initiated immune response is of high importance. The objective of this study was to develop a glycan array-based platform to screen for carbohydrate ligands of CLRs and to evaluate their immune modulatory properties *in vitro* and *in vivo*.

Materials and methods: A carbohydrate microarray was prepared consisting of synthetic amine- and thiol-functionalized carbohydrates, including high-mannose structures, phosphatidylinositol mannosides, heparins, lipoarabinomannans, sialylated oligosaccharides, blood group antigens, and tumor antigens. The respective CLR carbohydrate-recognition domains (CRDs) were eukaryotically expressed as fusion proteins with the F_c fragment of human IgG_1 molecules. MGL1-, DCIR-, MCL-, OLR1-, MICL-, CLEC2-, CLEC9A-, and CLEC12b-hF_c were used in this glycan array to screen for carbohydrate ligands. Identified CLR ligands were covalently coupled to the model antigen ovalbumin (OVA). These OVA-carbohydrate conjugates were used in DC/T cell co-cultivation assays to stimulate transgenic T cells *in vitro*.

In addition, mice were immunized with these conjugates to identify immune modulatory CLR ligands *in vivo*.
Results: By using these CLR-Ig fusion proteins in the carbohydrate microarray, several novel glycan structures were identified as binders of CLRs. DC/T cell co-cultivation assays revealed that some of the identified carbohydrate ligands modulated T cell activation and cytokine production. These *in vitro* results were confirmed by immunization studies in C57BL/6 mice indicating that the platform presented here is indeed suitable for the identification of immune modulatory carbohydrate ligands of CLRs.
Conclusions: We here present a platform that brings together CLR ligand identification and their immunologic evaluation. This platform is a useful tool for the development of adjuvants and immune modulators.

P1518
Aedes aegypti saliva as a therapeutic option in the treatment of experimentally induced inflammatory bowel disease

H. S. Campos,* P. R. Souza,* A. Sá-Nunes† & C. R. B. Cardoso*
*Departamento de Análises Clínicas Toxicológicas e Bromatológicas, Universidade de São Paulo, Ribeirão Preto, Brazil, †Departamento de Imunologia, Universidade de São Paulo, São Paulo, Brazil

Purpose/Objective: Inflammatory Bowel Disease (IBD) is a chronic inflammatory disorder characterized by an imbalance between inflammatory and regulatory responses at the gut mucosa. Current treatments are not totally effective and novel therapies are still needed to control IBD. Since mosquito saliva is a source of immunomodulatory molecules, the aim of this study was to evaluate the impact of *Aedes aegypti* salivary gland extract (SGE) in the treatment of experimental IBD.
Materials and methods: To induce colitis C57BL/6 male mice were exposed to 3% (w/v) Dextran Sulfate Sodium (DSS) uninterruptedly in drinking water during nine consecutive days or for two cycles of 9 days with an 11-day interval before the second exposure. From 5th until the 8th day, animals were treated with 1, 3 or 5 μg of *A. aegypti* SGE in 0.1 ml of PBS. Negative control group received only PBS. Mice were daily evaluated for mortality and clinical signs of the disease such as body weight, bloody stools, hiporeactivity and piloerection. The production of cytokines (IFN-γ, TNF-α, IL-4, IL-17 and IL-10) was evaluated by ELISA on gut homogenates of DSS-exposed mice, in the presence or absence of saliva treatment.
Results: The results showed a dose-dependent improvement of the clinical score and recovery of animals treated with EGS. Reduced disease signs were observed in the presence of 3 or 5 μg treatment in the first challenge with DSS, with a lower score in the 5 μg group on days 14 and 15 after initial DSS exposure. During the second DSS-challenge mice treated with 5 μg of SGE showed later and overall reduced clinical signs when compared to the other groups, along with a better recovery at the end of this period. In addition, mortality was lower in 3 and 5 μg groups when compared to the others. Although we did not observe any difference in IL-4, IL-17 or IL-10 in the gut, the improved clinical presentation of the disease could be related to the modulation of cytokines interplay in the intestine, since the 5 μg treated group produced less Th1 or pro-inflammatory cytokines such as IFN-γ and TNF-α in the large bowel when compared to colitis non-treated mice.
Conclusions: These data suggest that *Aedes aegypti* SGE have a beneficial effect when used in the treatment of experimentally induced IBD.

P1521
C-terminal peptide of prothymosine alpha detected by SELDI-ToF-MS affinity capture technology

M. Neagu,* C. Constantin,* D. Popescu,† A. D. Iancu,‡ D. L. Radu,‡ H. Kalbacher,§ O. Tsitsiloni¶ & W. Voelter§
*Immunology, Victor Babes National Institute of Pathology, Bucharest, Romania, †Pathology, Victor Babes National Institute of Pathology, Bucharest, Romania, ‡Cellular Immunity, Cantacuzino Institute, Bucharest, Romania, §Biochemistry, University of Tuebingen, Tuebingen, Germany, ¶Animal Physiology, University of Athens, Athens, Greece

Purpose/Objective: C-terminal peptide of prothymosine alpha [ProTα (100−109)] is a possible early apoptotic marker. We have developed a highly purified polyclonal antibody against the peptide in order to investigate the earliest apoptotic events associated to bacterial infections.
Materials and methods: SELDI-ToF-MS protocols. Chips: NP20 (neat protein) Q10 (weak anion exchanger) and CM10 (weak cation exchanger); matrix CHCA and SPA; several binding buffer pHs; high and *low intensity* laser conditions and several acquisition settings.
Reagents: Antibody Anti-ProTα (100−109); ProTα (100−109); control peptide; Protein A.

Method: Pre-coating of the chips with/without protein A for antibody fixation on the chip; overnight Ab-Ag preincubation; standard chip preparation.
Results: Optimum concentrations of Ab and peptides in the pre-incubation experiments were prior tested in competitive ELISA. Pre-coating with protein A was intended for a better/oriented binding of antibodies. This treatment of chips induced similar spectra with the un-coated conditions. The best spectra were obtained using binding buffer pH = 7. Testing several chip chemistries (see methods), much to our surprise, the NP20 chip did not perform at all in our experiments. In both high/low laser intensity spectra, the antibody, wheatear in Ab-Ag complex or alone, displayed several fragments at m/z 33 666−33 477; 67 419−67−67 148 and 130 500−130 600. In contrast to the reproducible Ab peaks, protein A had a quite random peaks spectrum when comparing triplicate spots or overall duplicate experiments. We have obtained the best results on Q10 chips, ProTα (100−109) being detected as a sharp peak of m/z 1207−1209. Control peptide (scrambled peptide, with identical aminoacid composition but in a different sequence) was detected 7.5 times less that the specific one when the complex Ab-scrambled peptide was subjected to MS.
Conclusions: We have shown that SELDI-ToF-MS can be used as an affinity capture technology to detect Ab-Ag specific complexes.

Optimization of the protocol showed that weak anion exchanger chip gives the best peptide spectra.

ProTα (100−109) displayed a m/z 1207−1209 concordant to the prior published MS data and was detected in the Ab complexes, mass spectrum pulling out the relevant peptide from a specific Ab-Ag complex.

Characterisation of antidrug antibodies (ADA) against therapeutic interferon beta

K. Govindappa,* S. Sethu,* M. Wadwa,† R. Stebbings,† I. Kimber,‡ D. J. Naisbitt,* M. Pirmohamed,* B. K. Park* & J. G. Sathish*
*Translational Medicine, Molecular & Clinical Pharmacology, Liverpool, UK, †Biotherapeutics, National Institute for Biological Standards and Control, Hertfordshire, UK, ‡Toxicology, Faculty of Life Sciences, Centre for Excellence in Biopharmaceuticals, Manchester, UK

Purpose/Objective: A significant proportion of multiple sclerosis patients undergoing therapy with interferon beta develop neutralising antibodies against this drug. In this study, our objectives are to cha-

racterise antidrug antibodies to therapeutic interferon beta and to test the potential for differential neutralising capacity of the major drug-specific immunoglobulins.
Materials and methods: Plasma samples from 19 MS patients and 10 age-matched healthy controls were obtained under informed consent from The Walton Centre for Neurology and Neurosurgery, Liverpool, UK. Total and interferon beta specific IgM, IgG and IgG subclasses were quantified by ELISA. Semi-quantitative assessment of neutralising potency of drug-specific antibodies was performed by a bioassay based on the interferon beta responsive Myxovirus-A (MxA) protein. MxA protein levels were measured by immunoblotting.
Results: Interferon beta specific IgG but not IgM was detected and quantified in 8/19 clinical samples. ADA in 7/8 samples neutralised interferon beta. The major interferon beta-specific IgG subclasses were IgG1 and IgG4.
Conclusions: Our data suggests that the interferon beta-specific neutralising antibody profile is dominated by IgG1/IgG4 response in multiple sclerosis patients. Profiling the drug-specific neutralising antibody responses could provide insights into the quality and potential mechanisms that underlie emergence of antidrug antibodies to biologics.

P1523
Development and characterization of an immunosensor for the determination of oxidized low density lipoprotein (ox-LDL)

G. C. de Miranda,* M. G. F. Sales,† R. B. Queirós,† A. M. Monteiro,* F. J. Rios,* S. A. Silva,* E. H. Yamashiro-Kanashiro‡ & M. Gidlund*
**Department of Imunologia, Instituto de Ciências Biomédicas, University of São Paulo, ICB-IV USP, São Paulo, Brazil, †BioMark Sensor Research, Instituto Superior de Engenharia do Instituto Politécnico do Porto Portugal, ISEP, Porto, Portugal, ‡Instituto de Medicina Tropical, University of São Paulo, São Paulo, Brazil*

Purpose/Objective: The oxidized lipoproteins, especially the oxidized low density lipoprotein (ox-LDL) are present in the plasma of patients with atherosclerosis and have been attributed an important role in illness development. Therefore, the determination of ox-LDL in plasma is essential not only to investigate its relevance for the atherosclerotic diseases, but also to contribute to disease diagnosis.

Thus, this work aims to couple monoclonal antibody to biosensing technology, and produce an immunosensor capable of fast and accurate detection/quantification of ox-LDL in point-of-care.
Materials and methods: oxLDL was prepared and employed to produce anti-oxLDL monoclonal antibodies by hybridomas cells (previously obtained by our group), which were cultured in DMEM with fetal calf serum, glutamine and gentamicin. The monoclonal antibodies were purified by affinity chromatography using Protein G.

The immunosensor was set-up by self-assembling cysteamine (Cys) on the gold (Au) layer (4 mm diameter) of a disposable screen-printed electrode. Antibodies were let react with N-Hydroxysuccinimide and ethyl (dimethylaminopropyl) carbodiimide, and subsequently incubated in the Au/Cys. All these steps were followed by electrochemical techniques.
Results: Three monoclonal antibodies showed the ability of detecting exclusively ox-LDL antigen. All these structures are to be involved in the construction of the immunosensing platform.

Employing Cys self-assembling on gold is a successful way of binding the antibody to a physical support. One of the difficulties around this process is to avoid non-oriented binding of the antibody, which could prevent antigen access to the Fab region. So, the *COOH groups were previously activated, ensuring that mostly the Fb region is involved in connecting the antibody. After optimization of all chemical and physical variables, this sensor will be tested in patients plasma of hypercholesterolemic, with or without atherosclerosis, and normocolestolemics.
Conclusions: The use of monoclonal antibodies on a biosensing platform seems to be a very attractive approach and is expected to provide very important information, correlating the level of ox-LDL fraction with the atherosclerosis disease, in a simple, fast and cheap way. After complete optimization, this device has the potential to improve the current diagnosis of atherosclerosis.

P1524
Evidence for membrane-bound lactoferrin as a pattern recognition receptor on macrophages

H. L. Dong, H. Dai & X. M. Gao
Institute of Biology and Medical Sciences, Medical College of Soochow University, Suzhou, China

Purpose/Objective: Lactoferrin (LTF) is a soluble glycoprotein of the transferring family well known as a bacterial LPS-chelating agent in biological fluids of mammals. Although it has previously been found on the surface of neutrophils, whether cell surface LTF (scLTF) could function as a receptor for LPS or other pathogen-associated molecular patterns (PAMP) has not been investigated. The present study focuses on the role of csLTF as a pattern recognition receptor (PRR) on macrophages.
Materials and methods: THP-1 cells and peritoneal macrophages, freshly collected from C57BL/6, CD14-knockout or TLR4-knockout mice, were stained with fluorecence-labeled Abs against LTF, MYH9, CD14, or isotype controls, followed by follow cytometric analysis or confocal laser scanning microscopy. For function assays, macrophages were cultured for 48 h in wells precoated with LTF-Abs, or control Abs and then concentration of TNF-α and NO in the culture supernatant quantitated using ELISAs. Routine immunoprecipiation and siRNA inhibition protocols were followed.
Results: Flow cytometric analysis detected LTF on the surface of primary murine macrophages as well as monocytic tumor line cells. Expression of csLTF was greatly reduced in macrophages from CD14-, but not TLR4-, knockout mice. Immunoprecipitation using anti-LTF-Abs pulled down LTF together with non-muscle heavy-chain myosin-9 (MYH9) and also CD14 from the lysate of peritoneal macrophages. SiRNA inhibition of MYH9 or CD14 also led to down-regulation of csLTF expression. Confocal laser scanning microscopy revealed co-localization of LTF, CD14 and MYH-9 on the membrane surface of the cell. Immobilized LTF-Abs were able to induce TNF-α and NO production by wild type, but not $TLR4^{-/-}$ or $CD14^{-/-}$, macrophages *in vitro*. Furthermore, siRNA inhibition of LTF gene expression rendered macrophages refractory to stimulation with LPS or β-glucans.
Conclusions: LTF is anchored to macrophage surface via MYH9 as well as membrane-bound CD14, capable of tranducing activation signals through TLR4. Given that LTF can bind a variety of PAMPs such as LPS, β-glucan, α-mannan and CpG-DNA with high affinity, we propose that csLTF could play an important role as part of a putative broad-spectrum PRR complex on phagocytes.

Gold nanoparticles downregulate interleukin-1ß-induced biological responses

V. Sumbayev,* I. Yasinska,* C. P. Garcia,† D. Gilliland,† G. S. Lall,* B. F. Gibbs,* L. Varani,‡ F. Rossi† & L. Calzolai†
**Medway School of Pharmacy, University of Kent, Chatham Maritime, UK, †Institute for Health and Consumer Protection, European Comission Joint Research Centre, Ispra, Italy, ‡Institute for Research in Biomedicine, Bellinzona, Switzerland*

Purpose/Objective: Interleukin 1 beta (IL-1β)-dependent inflammatory disorders such as rheumatoid arthritis, psoriasis and many others pose a serious medical burden worldwide, where patients face a life-

time of illness and treatment. Organogold compounds have been used since the 1930s to treat rheumatic and other IL-1β-dependent diseases and, though their mechanisms of action are still unclear, there is evidence that gold interferes with the transmission of inflammatory signalling. The aim of this work was to study the effects of gold nanoparticles on cellular responses to IL-1β.

Materials and methods: THP-1 human myeloid cells were used for *in vitro* studies and C57BL/6 male mice * for *in vivo* experiments. Cellular responses were studied using Western blot analysis, ELISA, scanning electron microscopy in transmission, biochemical assays.

Results: Here, we show for the first time that citrate-stabilized gold nanoparticles specifically downregulate, in a size dependent manner, cellular responses induced by IL-1β both *in vitro* and *in vivo*. Our results indicate that the anti-inflammatory activity of gold nanoparticles is linked to extracellular interaction with IL-1β, thus opening interesting options for further therapeutic applications.

Conclusions: In summary, we have discovered the biochemical mechanisms of AuNP-dependent downregulation of IL-1β-induced inflammatory reactions. This has been addressed on the *in vitro* (cell culture) and *in vivo*. These data allow us to understand the mechanisms underlying the positive therapeutic effects of gold when treating IL-1β-dependent autoimmune disorders (for example rheumatoid arthritis). Furthermore, our study suggests possible clinical implications of AuNPs against different types of widely distributed IL-1β-dependent autoimmune disorders (rheumatoid arthritis, scleroderma, psoriasis etc.).

P1528
Immunological receptors' expression and communication on extravillous trophoblast cell surface

A. Jabeen,* P. P. Laissue,* B. Obara,† P. Jain* & N. Fernández*
**School of Biological Sciences, University of Essex, Colchester, UK,*
†Oxford e-Research Centre, Oxford Centre for Integrative Systems Biology, Oxford, UK

Purpose/Objective: Molecular and immunological significance of selectively expressed MHC on extravillous trophoblast cells (EVTs) is not well understood. EVTs invade the maternal decidua and are intimately in contact with maternal immune effector cells. The unique MHC class I expression pattern on invasive EVTs shows that classical transplantation antigens HLA-A and HLA-B expression is down-regulated; these cells however, express HLA-E, -F, -G and HLA-C. The expression of MHC class Ib products with limited polymorphism (HLA-G,-E and -F) or class Ia with limited expression (HLA-C) protect EVTs from natural killer (NK)-like large granular lymphocytes (LGL)-mediated attack. In this study, we hypothesise that surface expressed MHC class I molecules interact with each other to modulate the immune-tolerance at the feto-maternal interface.

Materials and methods: Trophoblast model cell lines JEG-3 and ACH-3P were subjected to flow cytometry, immunoblotting and confocal microscopy for expression and quantitation of MHC I antigens . Cell surface HLA-C, -E, -F and -G molecules were detected by L31, MEM-E/07, 3D11 and MEM-G/09 1° antibodies respectively, followed by anti mouse IgG conjugated with either Alexa fluor 488 or 555 2° antibodies. Images were acquired in red and green channels with Nikon confocal microscope using Nyquist resolution with optimised settings (e.g. for Alexa488/555 xy = 55 nm/pixel, z = 140 nm/pixel). This new colocalisation approach is object based, three dimensional and depends on local intensity of highly resolved receptors using sub-pixel resolution. Same algorithm has been used to investigate the level of colocalisation among all MHC I molecules.

Results: Both cell lines expressed cell surface HLA-C, -E and -G but not -F. The object based novel colocalisation analysis revealed that out of total surface HLA-E molecules ~60% of HLA-E molecules are colocalised with HLA-C (~12%) and -G (~47%). Similarly, out of total surface HLA-G molecules ~42% of HLA-G colocalised with HLA-C(~18%) and -E(~24%) and out of total surface HLA-C ~25% of HLA-C colocalised with HLA-G(~14%) and -E(~11%). We also calculated intermolecular distances of colocalised receptors from euclidean distance maps with highest resolution of 15 nm. No significant difference was found on colocalisation in response to progesterone.

Conclusions: Hence, all MHC I receptors may communicate with each other to regulate placentation and facilitate pregnancy progress.

P1529
Monoclonal antibodies from human influenza NP-specific memory B-cells

Y. Dwai, S. Reiche & C. Jassoy
Institute for Virology, University of Leipzig, Leipzig, Germany

Purpose/Objective: Human monoclonal antibodies (mAbs) have previously been derived from individual HIV glycoprotein-specific memory B-cells from infected individuals. The goal of this study was to generate human mAbs from memory B-cells against other viruses.

Materials and methods: Biotinylated recombinant Influenza nucleoprotein (NP) was used to isolate antigen-specific B-cells. ELISpot analysis was performed to determine the purity of the isolated B-cell population. Heavy and light chain variable regions were amplified from single cells and cloned into expression plasmids. MAbs were produced in 293T-cells and analysed in ELISA and Western blot.

Results: 20 mAbs were derived from the blood of three individuals. MAbs recognized linear and conformational epitopes. The paratopes were diverse suggesting that the mAbs are specific for different epitopes.

Conclusions: Purification of protein-specific memory B-cells by immunomagnetic isolation together with antibody gene amplification from single cells can be used to generate recombinant human mAbs from influenza-specific memory B-cells. The technique should be applicable to other viral proteins.

NK cell — MSC interactions can result in NK cell activation and increased MSC recruitment

C. R. Almeida,* D. P. Vasconcelos,* D. Gomes* & M. A. Barbosa†
**NEWTherapies Group, INEB — Instituto de Engenharia Biomedica, Porto, Portugal, †NEWTherapies Group, INEB — Instituto de Engenharia Biomedica and Instituto de Ciências Biomédicas Abel Salazar Universidade do Porto, Porto, Portugal*

Purpose/Objective: NK cells can have a role in regulating tissue regeneration, particularly through interactions with Mesenchymal Stem/Stromal Cells (MSCs). MSCs can differentiate in different lineages, such as osteoblasts, chondroblasts and adipocytes, secrete bioactive molecules and are immunoregulatory. Since this modulatory capacity does not depend on the donor, clinical strategies using allogeneic cells are being developed for different applications, including treatment of autoimmune diseases and Tissue Regeneration strategies. However, it has become evident that MSCs must be activated to be able to suppress an immune response. And while MSCs can inhibit cytokine-activated NK cells, some reports indicate that MSC can stimulate NK cell cytokine production. Thus, it is crucial to clearly understand the outcome of NK cell and MSC interactions in different contexts. Here, we focused on studying the outcome of bidirectional interactions between freshly isolated NK cells and unstimulated MSCs.

Materials and methods: Human bone marrow MSCs were isolated by adherence and characterized for phenotype and differentiation capacity and peripheral blood human NK cells were obtained by negative isolation (EasySep, StemCell Tech). The outcome of intercellular

interactions was analysed by flow cytometry and imaging flow cytometry. MSC recruitment was determined with Matrigel-coated transwells.

Results: NK cells were found to form conjugates with MSCs, and interestingly MSCs were able to stimulate IFN-γ production and CD107a degranulation by freshly isolated NK cells. Furthermore, MSCs lead to an increased survival of NK cells in culture in the absence of externally added cytokines. On the other hand, it was found that NK cells stimulate MSC recruitment in a chemokine receptor-dependent way, while not impacting on its differentiating capability.

Conclusions: Here, we show that MSCs are capable of activating NK cells, and on the other hand, that NK cells stimulate MSCs recruitment. We believe that taking into account the outcome of NK cell – MSC interactions in different contexts will be crucial in predicting the impact of cell therapies. (Work funded by 'COMPETE – Programa Operacional Factores de Competitividade' (FEDER component) and Foundation for Science and Technology (OE component and QREN-POPH) *PTDC/SAU-BEB/099954/2008 and SFRH/BPD/48533/2008.)

Non-viral adeno-associated virus-based platform for stable expression of polyclonal antibody mixtures and/or recombinant proteins

S. W. Hicks, G. M. Wilmes, S. R. Lutz, J. A. Stevenson, M. D. Capacian, K. L. Carey, A. D. Colantonio, H. H. Russell, E. E. Reczek & V. W. Coljee

Excelimmune Inc, Research, Woburn, MA, USA

Purpose/Objective: Recombinant polyclonal antibodies represent a promising new therapeutic approach for the treatment of disease. The polyvalent nature of this technology makes it uniquely suited for the control of diseases in which selection for the outgrowth of resistant populations is a growing problem, including antibiotic resistant infectious disease and cancer. However, their complexity also represents a distinct manufacturing challenge. The objective of this work was to develop a rapid, reliable method for the manufacture of polyclonal antibody mixtures of specific and stable composition.

Materials and methods: We have developed a recombinant protein expression platform based on Adeno-Associated Virus (AAV), which demonstrates a high rate of non-random integration and allows the rapid generation of stable antibody-expressing cell populations. HEK 293 suspension cells were cotransfected with an antibody expression plasmid and an AAV virus-derived Rep integrase plasmid, resulting in stable integrants in ~10% of cells. Cells were selected in bulk to generate stable cell populations each expressing a single antibody. Following selection, populations expressing individual antibodies were mixed to generate polyclonal cell cultures for long term expression studies. Cultures were followed over time by Luminex and HPLC for stability of expression and ratios of the component antibodies.

Results: Polyclonal cultures maintained consistent expression levels and stable ratios of component antibodies up to 100 days. Cultures showed remarkable reproducibility following cell banking and antibody ratios were maintained following batch purification. Ratios of component antibodies could be manipulated to achieve desired composition.

Conclusions: Using this method, cell populations expressing antibodies with diverse antigen reactivities can be mixed to produce a stable polyclonal cell population of any desired composition within 30 days. Therefore, this AAV-based expression platform represents a predictable, reproducible, quick and cost effective method to manufacture recombinant polyclonal antibody therapies and other recombinant protein mixtures.

Outer membrane vesicles of *Neisseria meningitidis* as a new antigen preparation for *Escherichia coli* (STEC)

E. De Gaspari, T. F. T. Ferreira & T. N. C. T. N Cunha

Immunology, Adolfo Lutz, São Paulo, Brazil

Purpose/Objective: *E. coli* (STEC) disease represents an important emerging group of food-borne pathogens. Domestic animals, particularly cattle and sheep, have been identified as natural reservoirs of STEC . Hide contamination occurs from direct or indirect faecal contamination in cattle production and lairage environments. The cause of super shedding by infected cattle, which allows certain individuals to transmit disease at a much higher rate than others, is not known . In Brazil, cases were detected. There are currently no vaccines available that can prevent STEC infection. Production of verocytotoxin or Shiga-like toxin (Stx), particularly Stx2, is the basis of haemolytic uremic syndrome (HUS. The aim of this study was to determine the value of the detoxified Shiga toxins Stx1 and Stx2 (toxoids) from *E. coli* and *N. meningitidis* outer membrane proteins (OMPs) as new antigen preparation.

Materials and methods: The meningococcal group B strain derives from an epidemic in Brazil. OMPs were extracted by treatment of bacteria with 0.5% deoxycholate in 0.1 M Tris-HCl buffer (pH 8.6) containing 10 mM EDTA and purified by differential centrifugation. *E. coli* strains obtained from clinical samples from the state of Baia, Brazil. They are designated as (C7-88) O157:H7 (Stx1) and (1189) ONT:H49 *stx2+stx2vb-hb* (Stx2). All *E. coli* bacterial strains were grown in LB broth. The toxins were detoxified . Briefly, bacteria were centrifuged at $5000 \times g$, and the supernatant was filtered through a 0.45-μm membrane. To evaluate the toxoids and the neutralising activity of anti-Stx1 and Stx2 (OMPs sera), a neutralisation assay using HeLa (CCL-2) cells was performed.

Results: The production of verocytotoxin or Shiga-like toxin (Stx), particularly Stx2, is the basis of haemolytic uremic syndrome (HUS), a frequently lethal outcome for subjects infected with Stx2-producing enterohaemorrhagic *E. coli* (STEC) strains. Our study shows that mice immunised with two doses of the toxoids together with *N. meningitidis* OMPs induced anti-Stx1 or anti-Stx2 antibodies that could neutralise the toxins *in vitro*, at a concentration of 0.75 pg/200 μl/well for Stx2 and 0.39 pg/200 μl/well for Stx1.

Conclusions: *N. meningitidis* may represent a new, nonliving bacterial antigen preparation for use in vaccine as adjuvant in a vaccine against STECtoxin . It has excellent safety properties, high immunological potential and induces production of IgG antibodies capable of neutralising *E. coli* toxins.

P1533

Overcoming multidrug resistance with inhibitor of ABC transporters bound to HPMA copolymer carrier as a novel therapeutic approach in cancer treatment

M. Kabesova,* L. Sivak,* V. Subr,† K. Ulbrich,† M. Kovar* & B. Rihova*

**Immunology and Gnotobiology, The Institute of Microbiology of the Academy of Sciences of the Czech Republic, Prague, Czech Republic, † Biomacromolecular and Bioanalogous Systems, The Institute of Macromolecular Chemistry of the Academy of Sciences of the Czech Republic, Prague, Czech Republic*

Purpose/Objective: Intrinsic or acquired multidrug resistance (MDR) of cancer cells is one of the major obstacles in chemotherapeutic treatment of tumors. Investigated inhibitors of ABC transporters act nonspecifically on the cells of the body, which may be limiting for their clinical use.

The aim of this study was to examine the potential of novel polymeric therapeutics based on *N*-(2-hydroxypropyl) methacrylamide

(HPMA) copolymers bearing either anticancer drug, inhibitor of ABC transporters or both. Binding to the polymeric carrier prolongs blood circulation of the drug and overcomes nonspecific side effects on healthy tissue due to the passive accumulation in tumor tissue (EPR effect). Here we tested the inhibitory activity of three derivatives of reversin 121, which can be bound to HPMA copolymer through a defined biodegradable bond, and we prepared reversin 121 bound to HPMA copolymer carrier.

Materials and methods: The inhibitory effect of unmodified reversin 121 and its derivatives was analyzed by the calcein efflux assay in sensitive mouse P388 cell line and its doxorubicin-resistant counterpart P388/MDR. The cytostatic activity of doxorubicin in both cell lines was tested by [^{3}H]-thymidine incorporation assay.

Results: The results showed that only the derivative of reversin 121 modified with 5-methyl-4-oxoheptanoic acid (MeOHe) increased calcein accumulation to the same extent as unmodified reversin 121 in doxorubicin resistant P388/MDR cells, while neither had any effect in sensitive cell line P388. Similarly, the cytostatic activity of doxorubicin was significantly enhanced by unmodified reversin 121 and reversin modified with MeOHe in resistant P388/MDR cells. Also, an increased cytostatic activity of doxorubicin in P388/MDR cells was seen after incubation with reversin 121 bound to HPMA copolymer. In sensitive line P388, the cytostatic activity of doxorubicin was not affected after incubation with reversin 121, derivatives of reversin 121, nor with reversin 121 bound to HPMA copolymer.

Conclusions: Here we determined that a derivative of reversin121 modified with MeOHe is suitable for binding through a biodegradable bond to HPMA copolymer. Such conjugate exhibits an inhibitory activity to ABC transporters and can be useful in the attempt to overcome the multidrug resistance in cancer.

Peripheral allergic inflammation affects hypothalamic pituitary adrenal axis function and behavior in a neuropeptide and neurotrophin dependent manner

E. Peters,* C. Liezmann,* S. Pavlovic,* A. Örsal,* B. F. Klapp* & J. Kruse†

**Department of Psychosomatic Medicine and Psychotherapy, Psycho-Neuro-Immunology, Charité Center 12 for Internal Medicine and Dermatology, University-Medicine Charité, Berlin, Germany, †Department of Psychosomatics and Psychotherapy, Justus-Liebig-University, Gießen, Germany*

Purpose/Objective: An altered reactivity of the hypothalamus pituitary adrenal axis (HPA) has been observed in various patients with chronic humoral inflammatory diseases and in chronically stressed alike. It is associated with an increased production of cytokines such as interleukin (IL) 4, IL 5 or IL 10 and was therefore considered to participate in disease development and aggravation. Allergic inflammation of the skin is one such example. However, the question remained, if the enhanced cytokine production was the cause or the result of enhanced allergic inflammation under stress. Also, additional stress mediators such as substance P (SP) or nerve growth factor (NGF) have evolved and may play a key role in the inflammatory stress response.

Materials and methods: We here employed a combined model of inflammatory and perceived stress in syngeneic C57BL/6 mice to investigate HPA function and interaction with neuropeptidergic and neurotrophin stress mediators.

Results: Atopic dermatitis-like allergic dermatitis (AlD) and control mice showed no significant difference in the total number of activated cFos+ neurons in the hypothalamus. The presence of AlD is therefore not affecting basal HPA function. However, a solitary increase of cFos+ neurons was found in the dorsomedial nucleus at bregma level 1.58 in AlD mice and could be blocked by treatment with SP-neutralizing NK-1 blocker. Exposure to 24 h of noise-stress significantly increased the number of cFos+ neurons in the hypothalamus of control mice as expected. By contrast, AlD reduced the stress-induced increase in the number of cFos+ neurons in the hypothalamus. It also reduced stress-induced peripheral corticosteroid levels alongside with an increased hypothalamic PPT1-mRNA level (endcoding Substance P). As a consequence, stressed AlD mice displayed decreased exploratory behavior in the elevated plus-maze. Increased hypothalamic Substance P mRNA in stressed AlD mice could be reversed by peripheral injection with NGF-neutralizing antibodies.

Conclusions: Taken together, peripheral inflammation derived neurotrophin alters SP expression in the hypothalamus of AlD mice with consequences for HPA function and behavior.

P1535

Phenotypisation of microparticles in heparin-induced thrombocytopenia

A. N. Kopitar,* E. Malicev,† T. Korac,* A. Ihan* & A. Blinc‡

**Immunology, Medical Faculty, Ljubljana Institute of Microbiology and Immunology, University of Ljubljana, Ljubljana, Slovenia, †Blood Transfusion, Blood Transfusion Centre of Slovenia, Ljubljana, Slovenia, ‡Department of Vascular Diseases, University Medical Center, Ljubljana, Slovenia*

Purpose/Objective: Heparin-induced thrombocytopenia (HIT) with thrombosis is a serious complication of heparin use. Microparticles (MPs) are cellular signalling vesicles released during cell activation or early apoptosis that play an important role in vascular in-flammation, atherosclerosis and thrombosis. MPs expose phosphatidylserine, a procoagulate phospholipid made accessible after membrane remodelling and tissue factor, the initiator of blood coagulation at the endothelial and leukocyte surface. They are present in low concentrations in normal plasma but increased levels are generated by PF4-heparin-antibody interaction. Increased numbers of platelet-derived MPs, which are produced in a heparin-dependent manner, could be a useful biomarker for diagnosis of HIT. The aim of our study was quantification and phenotypisation of MPs in the platelet poor plasma of HIT patients. Additionally we wanted to determine whether MPs could be useful biomarkers for diagnosis of HIT.

Materials and methods: Studies were performed using sera from fourteen patients with HIT who met the clinical criteria. In all patients the diagnosis of HIT was confirmed by using ELISA and functional assays. The results were compared to twenty-one healthy controls. MPs were isolated from plasma by differential centrifugation. Flow cytometry was used to measure the number of MPs, surface exposure of procoagulant phosphatidylserine on MPs (by Annexin V staining), the expression of platelet activation marker * P selectin (CD62P), CD42b and CD42a (glycoprotein Ib and IX) and tissue factor (TF-CD142).

Results: HIT patients displayed higher levels of circulating MP ($P = 0.018$), and higher percept of platelet delivered microparticles (PDMP) which express CD42a+ CD31+ and annexin V ($P = 0.01$), CD42b+annexin V+ ($P = 0.01$), and CD62P+ CD41+ and annexin V+ ($P < 0.01$), and CD142+ (i.e. tissue factor [TF]) and annexin V+ ($P < 0.001$).

Conclusions: Measurement of PDMP in combination with current available assays may be useful for diagnosis of HIT.

P1537

Study of the antigenic cross-reactivity between *Neisseria meningitidis* and commensal *Neisseria* species using (DDA-BF) as adjuvant

E. De Gaspari,* M. R. Fabiana,* E. B. Gaspar,† A. S. Rosetti† & N. Lincopan†

Immunology, Adolfo Lutz, São Paulo, Brazil, †Department of Microbiology, Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil

Purpose/Objective: Outer membrane vesicles (OMVs) from *N. lactamica* have emerged as an alternative to vaccination against meningococcal disease .Bilayer fragments of the cationic lipid dioctadecyldimethylammonium bromide (DDA-BF) can be obtained by dispersion of the white powder in an aqueous solution at low ionic strength after sonication at a temperature below 60°C. DDA-BF can be used as an adjuvant, and its main advantage is that DDA-BF requires a lipid concentration lower than the concentrations traditionally used in liposomal formulations .Aluminum compounds remain the only adjuvant that is licensed worldwide.

Materials and methods: Complexes of 25 μg of OMVs of *Neisseria lactamica* in 0.1 mM of DDA-BF were colloidally stable, exhibiting a mean diameter and charge optimal for antigen presentation. Immunogenicity tests for these complexes were performed in mice. In the present study, the immunogenicity of the OMVs of *N. lactamica* was tested in association with fragments of the lipid bilayer of dioctadecyldimethylammonium bromide (DDA-BF) used as adjuvant. In addition, DDA-BF was compared to alum. The evaluation of the cross reactivity of the serum of the animals was performed 45 days after the first immunization. By Dot-ELISA they were tested against different meningococcal strains 39 strains of serogroup A, 42 of serogroup C (1972−1974), 120 of serogroup B (1990−2007), 120 of serogroups B, C, W135, Y (2011−2012) and 50 commensal Neisseria species of Brazil. By Immunoblot we analysed the cross reactivity againstOMVsof *N. meningitidis* of different serogroups, serotypes, subtypes and Neisseria species. The cross reactivity of antibodies was evaluated by immunoblot, ELISA and the avidity index (AI) of IgG antibodies produced.

Results: Results demonstrate byDot ELISA for a total of 321 strainsanalyzed 91% of strains of *N. meningitidis* present reactivitywith polyclonal serum from mice immunized with OMVs of *N. lactamica* and DDA-BF compared with 15% reactivity with aluminum. The serum presented reactivity with the20−130 kDa protein of commensal Neisseria species and interestingly recognized OMVs in *N. meningitidis* of 10−85 kDa. Even after only one immunization, the animals immunized with OMV-DDA-BF produced antibodies with intermediate avidity. For OMV-alum, antibodies with intermediate avidity were only found after two rounds of immunization. However, even in animals immunized two times with OMV alone, only low avidity antibodies were ever generated.

Conclusions: To our knowledge, this is the first study showing an immune response induced by DDA-BF and *Neisseria* genera. Interestingly, DDA-BF was superior to alum as an adjuvant for subcutaneous immunization.

P1538

Therapeutic potential of Saq-NO in blood cancers

M. Mojic,* S. Mijatovic,* D. Maksimovic-Ivanic,* M. Bulatovic,* M. Radojkovic,† M. Kuzmanovic,‡ M. B. Zocca,§ Y. Al-Abed¶ & F. Nicoletti**

*Immunology, Institute for Biological Research ''Sinisa Stankovic'', Belgrade University, Belgrade, Serbia, †Hematology, Clinical Center Dr Dragisa Misovic, Medical Faculty, University of Belgrade, Belgrade, Serbia, ‡Haematooncology, Medical Faculty, Institute for Health Care of Mother and Child of Serbia Dr Vukan Cupic, University of Belgrade, Belgrade, Serbia, §Management, Onconox Aps, Copenhagen, Denmark, ¶Medicinal Chemistry, North Shore Long Island Jewish Health System, New York, NY, USA, **Biomedical Sciences, University of Catania, Catania, Italy*

Purpose/Objective: First approved HIV protease inhibitor Saquinavir (Saq) showed remarkable potential to decrease the incidence or promote regression of HIV related cancers such as Kaposi's sarcoma and Non Hodgkin lymphoma. Drug developed by the addition of NO moiety to Saq (Saq-NO) overcomes the quality of original drug, preferentially through neutralization of toxicity. Previously we reported that Saq-NO is efficient against wide array of cell lines *in vitro* as well as rodent models of solid tumors. Here we evaluated its potential against different blood cancer cell lines as well as cells isolated from corresponding pediatric and adult patients.

Materials and methods: Cell viability was estimated by acidic phosphatase test, flow cytometric analysis was done on cells stained by Propidium iodide, Annexin V-FITC/PI, Apostat, DAF-FM or CFSE dye. Mononuclear cells (MNC) from peripheral blood and/or bone marrow were isolated by density gradient centrifugation.

Results: Saq-NO strongly suppressed the viability of Jurkat, Raji, K562 and HL-60 cells *in vitro* with significantly lower IC50 value in comparison to original compound. Sensitivity of blood cancers to Saq-NO overcomes previously determined efficacy of this drug on solid tumors. Reduced cell viability was the consequence of inhibited proliferation while in p53 deficient K562 and HL-60 cells Saq-NO induced caspase dependent apoptosis. Antitumor activity of the drug is not due to the release of NO. Results obtained on cell lines were further evaluated on blood and/or bone marrow MNC of pediatric and adult patients with acute myeloid leukemia and chronic lymphoproliferative disorders. Saq-NO efficiently diminished the viability of MNC and obtained results were in correlation with their malignant potential marked by LDH serum level. Response of MNC from adult patients was stronger in comparison to pediatric patients, while the highest sensitivity to Saq-NO treatment showed MNC from patients with acute myeloid leukemia.

Conclusions: Obtained results showed that Saq-NO possesses extraordinary potential to down-regulate leukemia cell progression indicating the importance of its evaluation in this type of cancers.

This work was partly supported by the Serbian Ministry of Education and Science (Grant 173013).

Use of antibody gene library for the isolation of specific single chain antibodies by ampicillin-antigen conjugates

M. Neumann-Schaal, K. Messerschmidt, N. Grenz, B. Micheel & K. Heilmann

Department of Biochemistry and Biology, University of Potsdam, Potsdam, Germany

Purpose/Objective: Isolation of recombinant antibodies from antibody libraries are commonly performed by different molecular display formats including phage display and ribosome display or different cell-surface display formats. We describe a new plate assay method which allows the selection of *Escherichia coli* cells producing the required single chain antibody by cultivation in presence of ampicillin conjugated to the antigen of interest.

Materials and methods: The method utilises the neutralization of the conjugate by the produced single chain antibody which is secreted to the periplasm. Therefore, a new expression system based on the pET26b vector was designed and a library constructed. The method was successfully established first for the selection of *E. coli* BL21 Star (DE3) cells expressing a model single chain antibody (anti-fluorescein) by a simple plate assay.

Results: Using this plate assay, we could identify a new single-chain antibody binding biotin by growing *E. coli* BL21 Star (DE3) containing the library in presence of a biotin-ampicillin conjugate.

Conclusions: In contrast to methods as molecular or cell surface display our selection system applies the soluble single-chain antibody molecule and thereby avoids undesired effects e.g. by the phage particle or the yeast fusion protein. By selecting directly in an expression strain, production and characterization of the selected single-chain antibody is possible without any further cloning or transformation steps.

A study of a highly conserved intronic region's polymorphism of TIGIT costimulatory receptor in T1D

M. Shunina, K. Kisand, K. Kisand & R. Uibo
Institute of General and Molecular Pathology, University of Tartu, Tartu, Estonia

Purpose/Objective: TIGIT (T cell immunoglobulin and ITIM domain) is a recently discovered receptor, which share the same ligands with costimulatory receptor CD226 and is expressed on regulatory, memory and activated T cells. In this receptor pair TIGIT pathway leads to T cell inactivation while CD226 transmits activating signal. Genome-wide association study suggested strong association of CD226 locus with type I diabetes (T1D), but there are some evidences, that TIGIT can also play an important role in the development of autoimmune diseases as a negative regulator of immune responses. Currently very little is known about CD226 and TIGIT genetic polymorphisms and their significance in T1D. The aim of the study is to examine genetic polymorphisms of one of these receptors – an inhibitory receptor TIGIT in Estonian population, and look for their association with T1D.
Materials and methods: We compared human and mouse TIGIT gene sequences and found 10 highly conserved intronic regions within the human TIGIT gene. Then we screened these regions for SNP with MAF (minor allele frequency) value over 0.15 and found two SNPs suitable for further investigation. We carried out restriction analysis of one of them: rs62265703 SNP (MAF = 0.1526) located in the second conserved region.
Results: We showed that the SNP MAF is higher in Estonian population (0.254) compared to predicted frequency (0.233) for HapMap CEU population. Statistical analysis revealed no association between the rs62265703 genotype and T1D diagnosis. However in our study population we confirmed that the CD226 polymorphism rs763361 (Gly307Ser) is associated with increased T1D susceptibility.
Conclusions: A further study could assess a functional role of the CD226 polymorphism in the control of T cell activation in both healthy individuals and T1D patients and the TIGIT's impact on an impediment of auto-reactive T cell activation.

P1545

Association of +3179G/A IGF-1R polymorphism and IGF-1 serum level with colorectal cancer development

I. Karakolev,* N. Stanilov† & S. Stanilova‡
**Molecular Biology Immunology and Medical Genetics, Medical Faculty of Trakia University, Stara Zagora, Bulgaria, †Department of Surgery, Medical Faculty of Trakia University, Stara Zagora, Bulgaria, ‡Department of Molecular biology Immunology and Medical genetics, Medical Faculty of Trakia University, Stara Zagora, Bulgaria*

Purpose/Objective: The insulin-like growth factor (IGF) system plays a prominent role in cancer development. The IGF-1 receptor (IGF-1R) and its associated signalling pathway is an important growth regulatory pathway that has been implicated in tumour genesis, angiogenesis, metastasis and autoimmune diseases. Through IGF-1R, the proliferative activity of IGF-1 is mainly regulated by the MAPK signalling pathway and its antiapoptotic activity by the PI-3 kinase pathway. It has been demonstrated a significant elevated risk for colorectal cancer (CRC) in relation to increased IGF-1 serum level. Recently, single nucleotide polymorphism located in exon 16 (+3179G/A; rs2229765) of *IGF-1R* gene was found associated with serum levels of IGF-1 and human longevity.
Materials and methods: This study was designed to compare +3179G/A *IGF-1R* genotype distribution in 110 CRC patients to a group of 220 healthy controls. We also investigated serum IGF-1 levels in CRC patients and healthy controls in an association to genotype. IGF-1 serum levels were measured by ELISA and genotyping for the +3179G/A polymorphism was performed by RFLP-PCR assay.
Results: In the study population no significant differences in allele frequencies of investigated polymorphism of IGF-1R between CRC and healthy controls were observed. The higher frequency of heterozygous AG genotype (53% versus 45%; OR = 1.43, 95%CI = 0.82 ÷ 2.50) and lower frequency of GG genotype (29% versus 36%; OR = 0.88, 95%CI = 0.43 ÷ 1.83) was seen in cases versus controls. When CRC patient's group was divided into stages of disease by TNM classification we observed statistically significant increased frequency of AG genotype in III stage compared to controls: 62% versus 45%; OR = 2.81, 95%CI = 1.09 ÷ 7.57; $P = 0.019$. Moreover, AG genotype was overrepresented in advanced (III-IV) CRC compared to early (I-II) stages: 63% versus 43%; OR = 3.37, 95%CI = 1.21 ÷ 9.54; $P = 0.009$, demonstrating that the AG genotype is a risk factor for progression of the disease. According to genotype serum IGF-1 levels decreased depending on number of G allele. Patients with AA and AG genotypes had significantly increased IGF-1 level then patients with GG genotype regardless of disease stage.
Conclusions: Our results showed a relationship between the +3179G>A polymorphism of the IGF-1R and serum IGF-1 with the progression of colorectal carcinoma.

P1547

Deficiency of cyclin D3 a cell cycle gene contributes to development of type 1 diabetes in NOD mice

N. S. Avila,* U. S. Gupta,* E. S. Solé,* D. Mauricio,† J. Verdaguer,† C. Mezquita,‡ M. Roussel,§ P. Sicisnki¶ & C. Mora Giral*
**Experimental Medicine, Institut de Recerca Biomèdica de Lleida, Lleida, Spain, †Endocrinology and Nutrition Department, Arnau de Villanova University Hospital, Lleida, Spain, ‡Laboratory of Molecular Genetics, Physiology Department, University of Barcelona, Barcelona, Spain, §Tumor Cell Biology, St. Jude Research Hospital, Memphis, TN, USA, ¶Cancer Biology, Harvard University, Boston, MA, USA*

Purpose/Objective: To find a new target gene that help to develop a new treatment for type 1 diabetes.
Materials and methods: Mice: KO CcnD3 C57BL6 mice were developed in the laboratory of Peter Siscinski . The mice were then backcrossed 13 times with NOD or NOD/SCID mice to generate aKO micein a NOD background.

Immunofluorescence (IF) and immunohistochemistry (IHC).

Pancreatic sections were incubated with (GP anti mouse INS, IgG anti-Cyclin D3, DAPI) antibodies, and as secondary antibodies anti GP Cy2 and anti IgG Cy5.

Pancreatic islet studies.

Pancreas were digested by collagenase (1.5 mg ml * 1) and isolated in Hanks Buffer salt solution (HBSS). For Cyclin D3 expression, islets per condition were handpickedand digested with trypsin, intensity media of fluorescence (IMF) of Cyclin D3 in CD45-Glut2+ cells were observed by flow cytometry.

Cell culture, transient transfections.

NIT-1 cultures were grown in DMEM supplemented with 25 mM glucose and 10% fetal bovine serum. The cDNA of Cyclin D3 was subcloned under the rat insulin promoter (RIP) in a cassette derived from pBluescript SK (Stratagene, USA) named pBSK-Neo, which confers resistance to Neomycin. The NIT-1 cell line was stably transfected and the resistant clones were selected by Geneticin (G418).
Results: Using the Microarray technology we have identified genes that have downregulation in pancreatic islet endocrine cells during the autoimmune attack progression, one of which encodes for cyclin D3.

The expression of cyclin D3 is greater in a mouse that has no infiltration (NODSCID 11w) compared to a mouse that has (NOD11w). The expression of cyclin D3 is reduced when you transfer at 9 weeks with 10 million total spleen cells to NOD/SCID mouse. The greater the number of total cells of spleen and therefore greater infiltration of pancreatic beta cells decrease expression of cyclin D3. NIT-1 cells transfected with CcnD3 are less susceptible in proinflammatory niche (in medium containing IL-1beta, IFN-gamma or both) to die by apoptosis. Cyclin D3-deficient mice generated faster and with a higher incidence of disease and metabolize glucose more slowly compared to wild type littermates. Human islets express Cyclin D3.
Conclusions: Deficiency of cyclin D3 a cell cycle gene contributes to development of type 1 diabetes in NOD mice. Cyclin D3 is also expressed in human beta pancreatic islets, then, it can maybe help us to develop a new treatment of type 1 diabetes.

P1549
Effect of HLA genotype on the development of neutralizing antibodies to interferon beta in patients with multiple sclerosis

M. Lundkvist, J. Link, K. Fink, C. Hermanrud, B. Brynedal, A. Fogdell-Hahn, I. Kockum & J. Hillert
Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden

Purpose/Objective: Development of anti-drug antibodies is a clinical problem associated with the use of different biological therapeutics. A significant proportion of multiple sclerosis (MS) patients treated with interferon beta (IFNβ) develop neutralizing antibodies (NAbs) that can reduce or completely block the therapeutic effect of the drug. Since only a subset of treated patients develops NAbs it is likely that other factors, such as HLA genotype can influence the risk of becoming NAb positive. This study investigates the association of certain human leukocyte antigen (HLA) class I and II alleles with NAb development in a Swedish cohort of IFNβ-treated MS patients and whether or not an association with clinically relevant NAb titers exists.
Materials and methods: Two hundred and thirty NAb-positive and 189 NAb-negative patients with known HLA status were included. NAb titers were measured with RT-PCR (MxA expression). Titers equal or above 150 10-fold reduction units/ml were considered clinically relevant, i.e. reducing the therapeutic efficacy.
Results: HLA-DRB1*15 was associated with clinically relevant titers, especially when correcting for treatment (OR = 2.90, $P = 0.00069$). However, no allele group affected risk of NAbs or clinically relevant titers as much as the treatment formulations. However, The A higher risk was observed in Rebif or Betaferon users compared to Avonex users and HLA genotype was found to influence NAb development differently between users of the different preparations. In Rebif users carriage of *DRB1*15* was associated with development of NAbs and clinically relevant titers. In Betaferon users carriage of *HLA-A*02* was associated with development of NAbs and clinically relevant titers.
Conclusions: The development of NAbs mainly depends on the type of IFNβ preparation used, but is in some part also influenced by HLA class I and II genotype.

P1550
Gene polymorphisms of leptin and leptin receptor are associated with BIM and WHR in obese Mexican woman

M. Fafutis-Morris,* C. Monraz-Gomez,* V. Delgado-Rizo,* S. D. T. Arreola,* A. A. Navarro* & J. Segura-Ortega†
**Immunology, Universidad de Guadalajara, Guadalajara, Mexico, † Gastroenterology, Hospital Civil de Guadalajara, Guadalajara, Mexico*

Purpose/Objective: The Leptin, a pro-immflamatory adipokine, is significantly involved in the activation and development of both regional inflammatory responses in adipose tissue and peripheral. The aim of this work, was to determinate the relationship between the polymorphisms G-2548A of *LEP* gen and gln223arg of the *LEPR* gene with the BMI, the body fat distribution, the serum Leptin and the sLR.
Materials and methods: To determinate BMI we used the basic anthropometric parameters, weight and height, for the body fat distribution we used the waist-hip ratio (WHR), as well as the waist circumference of risk for the obese. The polymorphisms were analyzed through its amplification (PCR) and after by restriction enzyme digestion (RFLP s), we used polyacrylamide gels in the electrophoresis to determine the genotypes. The serum concentration of leptin and sLR were measures by ELISA through (R&D) commercial kits.

Statistical analysis: for the description variable we used means and standard deviations, such as frequencies and percentrages. For the inferential analysis we used χ^2 test, *t*-student test, the one way ANOVA (Bonferroni s *post-hoc* test) as well as the Pearson s correlation coefficient.
Results: The obesity group presented high Leptin levels than the normal weight group ($P = 0.018$), as well as lower sLR levels ($P = 0.035$ one tailed). We got significative positive correlation between the BMI and the Leptin concentration ($P = 0.000$, $r = 0.661$) and negative to sRL ($P = 0.018$, $r = -0.331$), also between the sLR and WHR ($P = 0.041$, $r = -0.325$). Respect to the polymorphism, that the individual we found for the *LEP G-2548A* polymorphism, that the individuals with the polymorphic genotype (A/A) presented a higher BMI, into the Obesity group ($P = 0.027$), while for the *LEPR* gln223arg polymorphism, we found in the Normal Weight group that presented the arg/arg genotype had lower sLR concentrations ($P = 0.034$).
Conclusions: The polymorphisms *LEP* G-2548A and *LEPR* gln223arg, are related with the Leptin and sLR levels, as well as with the BMI in the case of *LEP* G-2548A but not with HWE or the cardiovascular risk waist circumference, in women from western of Mexico.

P1551
Genetic risk variants in multiple sclerosis and gene expression in stimulated peripheral blood mononuclear cells

M. Linden, M. Khademi, S. K. Bedri, M. Jagodic, I. Kockum & T. Olsson
Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden

Purpose/Objective: Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system. Most of the genetic risk loci identified to date are located near genes involved in immune signaling. The objective of the study was to investigate if carriage of MS risk alleles influences the magnitude of expression of immune activation markers upon *in vitro* stimulation of peripheral blood mononuclear cells (PBMCs).
Materials and methods: PBMCs from patients with MS ($n = 34$), clinically isolated syndrome ($n = 7$), other neurological diseases ($n = 27$) and other neurological diseases with inflammation ($n = 26$), were stimulated with LPS and ConA. Relativeexpression of IFN-g, TNF, VAV1, CD74 and TIM1 was measured using Q-PCR with GAPDH as housekeeping gene. The fold change of target gene expression was calculated as the ratio between the expression in stimulated samples and the unstimulated controls. 64 MS-associated SNPs were genotyped using TaqMan OpenArray, while typing of *HLA* genes was done with the Olerup SSP low resolution kit. Differences in fold change of expression stratified by MS risk genotypes were analyzed using the Mann-Whitney test. Benjamini-Hochberg corrections were used to adjust for multiple testing.
Results: The MS risk allele of rs17066096 (*IL22RA2*) was associated with higher fold change of TIM-1 (raw $P = 1.3 \times 10^{-3}$) and IFN-g (raw $P = 4.9 \times 10^{-3}$) expression upon stimulation with LPS. TIM-1 expression was also influenced by presence of rs6062314-TT (*TNFRSF6B*), (raw $P = 2.8 \times 10^{-3}$). The risk allele of rs11129295 (*EOMES*) was

associated with higher fold change of VAV1 (raw $P = 5.5 \times 10^{-3}$) and IFN-g ($P = 9.0 \times 10^{-4}$) expression upon ConA stimulation. None of the associations survived correction for multiple testing at $\alpha < 0.05$. However, there was a trend towards association between rs6062314-TT (*TNFRSF6B*) and TIM-1 (adj $P = 0.091$), rs17066096 (*IL22RA2*) and TIM-1 (adj $P = 0.085$) and rs11129295 (*EOMES*) and IFN-g (adj $P = 0.057$).

Conclusions: We observed a suggestive association between presence of the MS-risk alleles of rs17066096 (*IL22RA2*), rs6062314 (*TNFRSF6B*) and increased fold change of TIM1 expression, as well as increased fold change of IFN-g expression when the risk allele of rs11129295 (*EOMES*) was present. These results warrant replication in a larger, independent material, as well as further investigation of potential functional relationships.

Immunodetection of human carbonic anhydrase XII as a new potential biomarker of tumor cells

D. Dekaminaviciute,* R. Lasickiene,* M. Zilnyte,* V. Michailoviene,† V. Jogaite,† S. Parkkila,‡ D. Matulis† & A. Zvirbliene*

**Department of Immunology and Cell Biology, Vilnius University Institute of Biotechnology, Vilnius, Lithuania, †Department of Biothermodynamics and Drug Design, Vilnius University Institute of Biotechnology, Vilnius, Lithuania, ‡Department of Anatomy, University of Tampere Institute of Biomedical Technology, Tampere, Finland*

Purpose/Objective: Carbonic anhydrases (CAs, EC 4.2.1.1) are zinc enzymes that catalyse the reversible hydration of carbon dioxide to bicarbonate. CAs have important physiological and pathological functions in human organism. Some human CAs, such as CA IX are well-recognized tumor markers. Recently, the association of CA XII with human cancers has been demonstrated. The CA XII is a transmembrane protein with an extracellular catalytic domain. It is involved in tumor progression by acidification of the extracellular milieu and regulation of intracellular pH. Recent studies indicate that CA XII is aberrantly overexpressed in breast, cervix, brain cancers, renal carcinomas. Therefore, CA XII might be considered as a useful biomarker of tumor cells and a promising target for specific therapies. The aim of the current study was to develop new monoclonal antibodies (MAbs) against human recombinant CA XII and evaluate their diagnostic potential.

Materials and methods: The extracellular domain of human CA XII was expressed in *E. coli* and used as an immunogen. The MAbs were generated by hybridoma technology. MAb specificity was analysed by ELISA, IHC and flow cytometry.

Results: Seven stable hybridoma cell lines producing IgG antibodies against human CA XII were generated. The MAbs were highly specific to CA XII and did not cross-react with human recombinant CA I, II, III, VII and XIII. In order to demonstrate the diagnostic value of the MAbs, they were employed for the IHC staining of CA XII in human tumor tissue specimens. The MAbs demonstrated a strong and specific reaction with colon and renal carcinoma specimens and did not show any unspecific background staining of the respective normal tissues. Flow cytometry analysis revealed a specific immunostaining of CA XII in human tumor cell lines.

Conclusions: The newly developed MAbs represent a promising diagnostic tool for the immunodetection of CA XII-expressing tumor cells.

Interleukin-2 gene polymorphism in Turkish patients with Behçet's disease and its association with ocular involvement

A. Yücel,* K. Dilek,† D. Saba,‡ A. A. Özçimen,§ H. Saricaoglu,¶ M. A. Yurtkuran† & H. B. Oral**

**Opthalmology, Faculty of Medicine, Uludag University, Bursa, Turkey, † Nephrology & Rheumatology, Faculty of Medicine, Uludag University, Bursa, Turkey, ‡Cardiovascular Surgery, Faculty of Medicine, Uludag University, Bursa, Turkey, §Biology, Faculty of Science & Art, Mersin University, Mersin, Turkey, ¶Dermatology, Faculty of Medicine, Uludag University, Bursa, Turkey, **Immunology, Faculty of Medicine, Uludag University, Bursa, Turkey*

Purpose/Objective: Behcet's disease (BD) is a chronic immune-mediated systemic disease, characterised by oral and genital lesions and ocular inflammation. Several cytokine genes may play crucial roles in host susceptibility to BD, because the cytokine production capacity varies among individuals and depends on the cytokine gene polymorphisms. The association of the interleukin (IL)-2 gene polymorphisms with the susceptibility to BD was investigated in this study.

Materials and methods: DNA samples were obtained from a Turkish population of 97 patients with BD and 76 healthy control subjects. Polymorphisms of IL-2 gene at position -330 and +166 were determined by using the polymerase chain reaction with sequence-specific primers.

Results: In the patients with BD, there was a significantly increased frequency of IL-2 -330 TG genotype. Meanwhile, a significant decrease in the frequency of IL-2 -330 TT genotype was detected in the patient group in comparison to healthy controls. Interestingly, the frequencies of IL-2 -330 TG and IL-2+166 GG was increased in BD patients with ocular involvement, whilst IL-2 -330 TT genotype was significantly decreased.

Conclusions: These results reveal that IL-2 -330 TG genotype may be a susceptibility factor for BD, whereasIL-2 -330 TT genotype seems to display a protective association with BD. Additionally, IL-2 gene polymorphisms might be associated with ocular involvement in BD.

P1556

Isolation of CD4+ T lymphocytes for the unbiased analysis of their gene expression profiles

K. Westendorf,* A. Okhrimenko,* J. Gruen,† H. Chang,* J. Dong* & A. Radbruch*

**Cell Biology, German Rheumatism Research Center, Berlin, Germany, †Bioinformatics, German Rheumatism Research Center, Berlin, Germany*

Purpose/Objective: Biomarkers are important tools for diagnosis of immune-mediated diseases, their prognosis and the prediction of response to therapy. Cells of the peripheral blood are expected to reflect systemic and local pathogenesis, in terms of their gene expression profile. Microarray analysis of cell-type specific transcriptomes, however, requires isolation of defined cells to high purity, without affecting their gene expression. Here, we analyze the influence of cell sorting procedures on the gene expression profile of human peripheral CD4+ T lymphocytes.

Materials and methods: CD3+CD4+CD45RO+ T cells were isolated from the peripheral blood of healthy volunteers, comparing seven different procedures, including erythrocyte lysis at 4°C and 20°C, ficoll gradient centrifugation, direct and indirect enrichment by magnetic bead assay as well as the use of the transcriptional blocker ActinomycinD. For control, T cells were intentionally activated with phorbol myristate acetate (PMA) and ionomycin. Total RNA was extracted from the cells, and microarray analysis of the transcriptomes was performed using Affymetrix Human Genome U133 Plus arrays.

Results: The transcriptom analysis revealed but minor differences between the isolation procedures. Nevertheless, erythrocyte lysis at

20°C induced more changes of the transcriptome than ficoll gradient centrifugation with an equally long handling step at 20°C and direct enrichment by magnetic bead assay performed best in regard to time and yield. Independent of the isolation procedure, the gene expression pattern of CD4+CD45RO+ T helper cells was however severely impacted by duration and conditions of storage of the samples between venipuncture and cell isolation.
Conclusions: When cells were isolated from fresh blood, their gene expression pattern could be maintained through the isolation procedures tested, as long as the isolation was performed fast and under predominantly cold conditions.

P1557

Restricted immunoglobulin repertoire and evolutionary mechanism of PDGFR-autoreactive memory B cells in systemic sclerosis

G. Moroncini,* C. Paolini,* A. Grieco,* G. Nacci,† C. Tonnini,* S. Svegliati,* K. Pozniak,* E. Avvedimento,‡ A. Funaro† & A. Gabrielli*
**Dipartimento di Scienze Cliniche e Molecolari, Università Politecnica Marche, Ancona, Italy, †Department of Genetics Biology and Biochemistry, University of Torino, Torino, Italy, ‡Dipartimento di Biologia e Patologia Molecolare e Cellulare, Università Federico II, Napoli, Italy*

Purpose/Objective: Systemic sclerosis or scleroderma (SSc) is a clinically heterogeneous disease of the connective tissue characterized by vascular, immune/inflammatory and fibrotic manifestations. We have provided evidence that the serum of SSc patients contains stimulatory auto-antibodies (auto-abs) directed to the PDGF receptor (PDGFR) that elicit reactive oxygen species (ROS) and collagen production in human fibroblasts (Baroni SS, NEJM 2006). This study was aimed at analyzing the native immune repertoire of two distinct SSc patients.
Materials and methods: Memory B cells of two SSc patients were immortalized and screened for PDGFR-autoreactive clones. RNA was extracted from each PDGFR-autoreactive B cell line, reverse-transcribed, and amplified with a set of primers designed to analyze the human immunoglobulin (Ig) gene repertoire. Ig variable (V) regions identified in these clones were expressed as human IgG monoclonal abs and characterized through binding and functional assays.
Results: PCR analysis of rearranged Ig genes suggested the presence of a large panel of V heavy (H) and light (L) chain subgroups. However, subsequent sequencing showed a small panel of VH and VL chains in each B cell line: the same variable Ig sequences were recovered repeatedly from independent PCR amplifications of different VH and VL subgroups, and displayed a high frequency of somatic mutations in the complementarity determining regions (CDRs). Ab engineering revealed that four different VL chains identified in one SSc patient conferred diverse biological properties to the unique VH chain identified in the same patient: loss of high affinity binding; PDGFR binding without signaling; PDGFR binding with ROS induction; PDGFR binding with ROS and collagen gene induction.
Conclusions: The repertoire of PDGFR-autoreactive SSc B cells is restricted and somatically mutated. This suggests the hypothesis of a polarization of the immune response towards the autologous PDGFR under the influence of a strong antigenic drive, the nature of which awaits identification. Stimulatory and non-stimulatory anti-PDGFR auto-abs coexist in the same SSc patient, they share a common VH chain and have, therefore, a common origin. The CDRs of the shared VH framework might represent a common trait of SSc patients Ig, and be used as novel biomarkers of this disease.

P1559

The effect of insulin-like growth factor 1 on IL-12p40 and IL-10 production depending on polymorphisms associated with the induced cytokine production

I. Karakolev, Z. Dobreva & S. Stanilova
Molecular Biology Immunology and Medical Genetics, Medical Faculty, Trakia University, Stara Zagora, Bulgaria

Purpose/Objective: Relatively recently insulin-like growth factor 1 (IGF-1) and IGF-1 receptor (IGF-1R) is considered to have a role in the regulation of immune function. It may represent an important switch governing the quality and amplitude of immune responses. IGF-1/IGF-1R signalling may also participate in the pathogenesis of autoimmune diseases, although its relationship with these processes seems complex and relatively unexplored. Interleukin (IL)-12 and IL-10 are immunoregulatory cytokines with an antagonistic effect of the T-helper (Th)1/Th2 cytokine balance and provide a functional link between innate and adaptive immune responses. The aim of the present study was to investigate the effect of IGF-1 on induced cytokine production of IL-12p40 and IL-10 by stimulated peripheral blood mononuclear cells (PBMC) isolated from healthy donors. We also investigated the association of cytokine production and single nucleotide polymorphisms (SNPs) that have been reported to show associations with the production of IL-12p40 and IL-10.
Materials and methods: Peripheral blood mononuclear cells (PBMC) from 11 healthy donors were isolated by Histopaque-1077 density gradient centrifugation. After 20 h of resting the cells were stimulated with 100 ng/ml recombinant human IGF-1 with or absent of LPS (1 μg/ml). Supernatants separated after the 6 and 24 h from the stimulation were quantity determinate by ELISA method for IL-12p40 and IL-10. Genotype and allele frequencies were defined by PCR-AFLP.
Results: Our results showed a light down regulation by IGF-1 of induced IL-12p40 production in the presence of LPS (LPS − 360 ± 292 versus LPS/IGF-1 − 313 ± 256 pg/ml). Preliminary data from qRT-PCR showed the same results for the mRNA levels. Donors with *1.2/2.2* genotype for the *IL-12p40pro* polymorphism located in the promoter of the gene have four times high production of IL-12p40 ($P < 0.05$). We observed absence in the induced cytokine production for IL-10 according to IGF-1.
Conclusions: Based on the results we can conclude that IGF-1/IGF-1R signalling pathway is not directly involved in the induced cytokine production of IL-12p40 and IL-10. These results will be supplemented by additional studies on mRNA expression of the target cytokines in PBMCs cultures.

P1560

The role of the TNF -308G/A polymorphism in disease development of pulmonary sarcoidosis in Czech patients

P. Schneiderova,* E. Kriegova,† F. Mrazek,† M. Zurkova,‡ V. Kolek‡ & M. Petrek†
**Institute of Molecular and Translational Medicine, Palacky University, Olomouc, Czech Republic, †Laboratory of Immunogenomics and Immunoproteomics, Palacky University, Olomouc, Czech Republic, ‡Department of Respiratory Medicine, Faculty Hospital, Olomouc, Czech Republic*

Purpose/Objective: Pulmonary sarcoidosis is an inflammatory immune-mediated disorder characterized by the presence of granulomas in the lung. Previous studies reported association of tumour necrosis factor (TNF) -308*A allele (rs1800629) with L*fgren's syndrome (an acute form of sarcoidosis, LS) and favourable prognosis in the Dutch population. We, therefore, aimed to determine the distribution of TNF -308G/A polymorphism in Czech sarcoidosis patients and its clinical phenotypes.

Materials and methods: TNF -308 G/A polymorphism was genotyped using MassArray technology (PCR with MALDI-TOF MS detection, Sequenom) in 122 Czech patients with pulmonary sarcoidosis. Patients were further subdivided according to the presence/absence of LS, chest X-ray stage (CXR) and disease development after 2 years (remission/progression). High-sensitivity ELISA was applied to detect TNF-alpha serum levels in order to assess the functional impact of rs1800629.
Results: The TNF -308*A allele frequency in sarcoidosis patients (22%) were similar to those published in healthy Czech population (21%). No association between TNF -308 polymorphism and sarcoidosis as a whole or with subgroups according the CXR-stage was found ($P \geq 0.05$). The TNF -308*A allele was more frequent in patients presenting LS (33%) compared to those without LS (19%, $P = 0.03$). No significant difference in allele frequency was observed between patients subdivided according to the disease development ($P \geq 0.05$). The study of association between rs1800629 and serum levels of TNF-alpha is under evaluation.
Conclusions: We confirmed overrepresentation of TNF -308*A allele in Czech sarcoidosis patients with L*fgren's syndrome. However, we didn't confirm association of the TNF -308*A allele with good prognosis in our patients with sarcoidosis. Further studies on the usefulness of TNF -308G/A genotyping for the prediction of the prognosis in an extended patient cohort are ongoing.

P1561

The search for candidate genes that characterise susceptibility or resistance to pathogenic mycobacteria

B. Dobson, R. O'Brien & J. F. T. Griffin
Department of Microbiology and Immunology, University of Otago, Dunedin, New Zealand

Purpose/Objective: Resistance and susceptibility to infectious diseases is well-documented in a variety of host species and while many factors contribute to resistance/susceptibility dynamics, a major component is the genotype of the host. *Mycobacterium avium* subspecies *paratuberculosis* can cause a chronic granulomatous enteritis, Johne's disease, in ruminant animals such as sheep, cattle and deer. Over the years the Disease Research Laboratory has observed a pattern of resistance and susceptibility to Johne's disease in some breeds of red deer (*Cervus elaphus*) but the immunological basis of this phenomenon is unknown. The macrophage is an immune cell which is central to all mycobacterial infections and therefore the gene expression response of this cell has been assayed in red deer from a resistant or susceptible genetic background.
Materials and methods: Macrophage cultures were derived from the blood monocytes of 10 resistant and 10 susceptible animals, infected with MAP *in vitro* and the expression of candidate genes assessed by qPCR. Analysis of the transcriptome of macrophages from two resistant and two susceptible animals by the Illumina HiSeq 2000 sequencing system was also undertaken.
Results: The resulting profiles indicate that susceptible animals have a much higher upregulation of inflammatory genes and pathways (such as iNOS, IL-1α, TNFα and IL-23p19) than the resistant animals. This may in fact be over-expression in the susceptible animals leading to an exacerbation of disease symptoms and inefficient clearing of the mycobacterial organism compared to the more controlled upregulation of inflammatory pathways in macrophages from resistant animals.
Conclusions: Work of this kind has never been performed before and has produced data to advance the understanding, both of the biology of JohneÕs disease and of mycobacterial disease in general.

Poster Session: Biomarkers & Disease Profiling 2: Immune-Monitoring

P1563

Adaptive and innate immunity in patients with intracranial infectious and inflammatory diseases

M. Sautin,* T. Bodrova,† N. Cherepakhina‡ & S. Suchkov‡
*Faculty of Medicine, Peoples' Friendship University of Russia, Moscow, Russia, †Higher School of Economy, School of Economy, Moscow, Russia, ‡Department of Patology, I.M. Sechenov First Moscow State Medical University, Moscow, Russia

Purpose/Objective: To study features of the immune responsiveness of patients with different clinical forms of intracranial infectious and inflammatory processes (ICIIP), to assess the clinical relevance of the data obtained and to create a model of the ICIIP immunopathogenesis and some of the typical forms of ICIIP associated with clinical and immune-mediated postinfectious syndrome (CIPIS) in the pathogenesis of ICIIP.
Materials and methods: 88 serum samples of patients with ICIIP confirmed by imaging tests (CT, MRI) or during the surgery (brain abscesses – 55; dural empyema – 25; meningoencephalitis – 8) and 29 clinically healthy donors have been studied. Cytometry was used for immunophenotyping of blood cell subsets; screening of cytokines, for anti-tissue, anti-organ and antimicrobial antibodies (Abs) as well as for B7-H1 biomarker by ELISA and cytometry; identification of infectious pathogens was done by culture and PCR.
Results: Two major forms of ICIIP-associated CIPIS have been identified and confirmed, namely, (1) postinfectious secondary immunodeficiency syndrome (PISIS) – 92% of the total number of patients (including aggressive subtypes: 38% and moderate ones: 54%); (2) PISIS associated with autoimmune syndrome (PISIDAS) * around 10% of patients. Specific features of either of two syndromes have been established, namely, for: (I) *innate* immunity and (II) *effector* link of *adaptive* immunity and *regulatory* mechanisms of the immunity as a whole.
Conclusions: Information obtained from the studies has given a way to define two new classes of criteria to be implemented into clinical and preclinical practice. The first class would include microbiome-based criteria to monitor spectrum and the localization of the microbial gene pool and serologic profile anti-microbial Abs. The second one would include immune-based criteria to predict risks of transformation (*predictive* factor) of acute forms of ICIIP into the chronic ones and development of complications.

P1564

Adiponectin, leptin, resistin – players in driving the rheumatoid arthritis activity

M. Copotoiu,* L. Georgescu,* B. Dorcioman,† A. Hutanu† & R. Copotoiu‡
*Department of Rheumatology, University of Medicine and Pharmacy of Targu Mures, Targu Mures, Romania, †The Immunology Laboratory, The Emergency County Hospital of Targu Mures, Targu Mures, Romania, ‡Department of Anaesthesia and Intensive Care, University of Medicine and Pharmacy of Targu Mures, Targu Mures, Romania

Purpose/Objective: The adipose tissue by its hormones * adipokines (adiponectin, leptin and resistin) proved to be not only a fat depot but an active player in driving the inflammatory and the immune process. The main aim of the study was to evaluate the impact of the adipose tissue in the assessment of the RA activity.
Materials and methods: A longitudinal, observational, prospective study was performed in the University Clinic of Targu Mures, Romania. 64 patients (pts.) diagnosed with rheumatoid arthritis with medium-high activity (DAS > 3.2) and no cardiovascular or metabolic conditions recorded were included in the study. They were divided into three groups according with their body mass index (BMI). The classical inflammatory biomarkers * erythrocyte sedimentation rate (ESR), C-reactive protein (CRP); the synovial activity measured by a quantitative Color Doppler ultrasound score * Color Fraction (CF); anthropometric measurements such as: body mass index (BMI), the Hoffa fat pad and the adipokines were assessed. The Graph Pad Prism5 statistical software was used to assess the data.
Results: Overall, a positive correlation between the levels of leptin and the BMI was observed ($P = 0.015$, $r = 0.313$) and a negative correlation between Hoffa fat pad and leptin ($P = 0.007$, $r = -0.050$). In the overweight (OW) patient group the synovial activity expressed by the CF was correlated with the levels of adiponectin ($P = 0.006$, $r = 0.639$). The levels of both leptin and adiponectin correlated positively with the Hoffa fat pad in the OW group ($P = 0.001$, $r = 0.723$; $P = 0.041$, $r = 0.500$). The levels of resistin were positive correlated with the CRP ($P = 0.017$, $r = 0.626$). In the obese group a positive correlation was observed between the leptin's levels and the CF ($P = 0.044$, $r = 0.466$) and a negative one with the Hoffa fat pad ($P = 0.020$, $r = -0.574$). In the normal weight patients group a positive correlation was observed between resistin and CF ($P = 0.011$, $r = 0.521$), the ESR and adiponectin ($P = 0.034$, $r = 0.465$), a positive one between Hoffa fat pad and leptin ($P = 0.021$, $r = 0.479$) and negative with adiponectin ($P = 0.006$, $r = -0.551$).
Conclusions: Leptin exerted a pro-inflammatory role in the obese RA patients. Adiponectin and resistin, adipokines rated in previous studies as anti-inflammatory showed an inflammatory behavior in the OW RA patients.

P1565

Aminoglutethimide-induced immune changes: implications for idiosyncratic drug reactions

W. Ng & J. Uetrecht
Pharmaceutical Sciences, University of Toronto, Toronto, Canada

Purpose/Objective: As with most aromatic amine drugs, the aromatase inhibitor aminoglutethimide (AMG) is associated with a variety of idiosyncratic drug reactions (IDRs) ranging from skin rashes to serious haematological toxicities. Currently, the mechanisms of IDRs are poorly understood and their rare and unpredictable natures are major issues for drug development that may lead to serious consequences upon market release. AMG-induced IDRs are typically delayed in onset and evidence suggests they are immune-mediated; therefore, the objective was to characterize the changes to the immune system induced by AMG in rodents to gain better insight on the mechanisms of IDRs.
Materials and methods: Male Brown Norway rats were dosed with 125 mg AMG/kg/day by oral gavage for 14 days and various immune changes were monitored in the blood, bone marrow, and spleen.
Results: Neutrophilia was observed as early as 24 h in AMG-treated rats, and this was sustained over the course of treatment despite no changes to the total WBC count because of lymphopenia. This corresponded to increased release of newly formed neutrophils from the bone marrow as determined with BrdU labeling and a significant increase in the M:E ratio. In addition, serum cytokines such as TNF-α, Cxcl-1, and G-CSF were up-regulated in the AMG-treated. In the spleen, increased $CD3^+CD4^+Ki\text{-}67^+$ staining was observed in the white pulp at day 14 of AMG treatment, which suggests lymphocyte proliferation.
Conclusions: These AMG-induced changes are consistent with activation of both the innate and adaptive immune response, and may be typical of other drugs that can induce IDRs. Furthermore, investigation of the balance between immune activation and immune tolerance may be crucial to understanding why most people do not have IDRs when

treated with a drug. This research was funded by grants from the Canadian Institutes for Health Research.

P1566

An analysis of regulatory B and T cells in the peripheral blood of patients with rheumatoid arthritis – using bioconductor packages for flow cytometric analyses

R. Engelmann,* N. Wang,* C. Kneitz† & B. Mueller-Hilke*
*Institute of Immunology, University of Rostock, Rostock, Germany, †Department of Rheumatology, Hospital South Rostock, Rostock, Germany

Purpose/Objective: Bioconductor offers packages for R supporting the complete work-flow to analyse large-scale flow cytometry data. We evaluated the usability of this software and compare the variability between manual and automated analysis using a large data set obtained from the analysis of regulatory B- and T-cells from patients with rheumatoid arthritis (RA).

Materials and methods: PBMCs from 61 patients suffering from RA were isolated and stained for regulatory T and B cells using two panels containing eight markers each. Additionally, isotype controls were included for two non-lineage markers. Data were acquired using a FACS Aria II flow cytometer.

Manual analysis was performed by two independent evaluators using the FACS Diva software (v6.1.2). For automated analysis, R (v2.15.0) and Bioconductor packages (v2.10) were used. Correlation analyses of the percentages of ten cell populations present in the stained and the non-lineage isotype controls were carried out to determine gating robustness.

Results: Manual analysis took 25 working hours before a table was completed that contained ten variables for subsequent statistical analyses. In contrast, the automated data analysis took 15 h only. Manual analysis resulted in median correlation coefficients for the percentages of the various cell populations in the stained and non-lineage isotype control samples of 0.88 and 0.91 for an unexperienced and an experienced evaluator, respectively. Likewise, the automated analysis resulted in a median correlation coefficient of 0.84 without any significant differences between the three analysis groups. So far, we did not find any correlation between the percentages of $CD4^+foxp3^+CD25^+CD127^{+/-}helios^{+/-}$ cells and the percentages of naïve, memory, transitional and regulatory B cells and their expression of CD80 and CD86.

Conclusions: The freely available statistical software R in combination with Bioconductor's flow cytometry packages is well suited to perform high quality flow cytometry analyses and is comparable with manual analysis in terms of gating precision yet is less time consuming for large-scale studies.

P1567

Analysis of serum S100A8/A9 in patients with anti-neutrophil cytoplasm autoantibodies -associated vasculitis

K. Djenouhat,* O. Ibsaine,† I. Bedioune,* A. A. Kaci,* L. Benyahia,‡ A. Tarzaali,‡ D. K. Berrimi* & M. C. Abbadi*
*Immunology, Institut Pasteur of Algeria, Algiers, Algeria, †Pediatric, Hôpital Parnet, Algiers, Algeria, ‡Biogroupe, Immunology, Algiers, Algeria

Purpose/Objective: S100A8/A9, also called Calprotectin is a calcium and zincum binding protein, belonging to S100 protein family, that is mainly released during neutrophil or monocyte activation. It's an important proinflammatory mediator firstly reported to be determinant biomarker to differentiate Inflammatory bowel disease (IBD) from non inflammatory intestinal symptoms. To date, there have been few reports focusing on the clinical importance of S100A8/A9 in anti-neutrophil cytoplasm autoantibodies (ANCA) associated vasculitis. The aim of this study is to determine levels of this protein in sera of patients with this disease and then to analyze their relationship with disease activity.

Materials and methods: The serum concentration of S100A8/A9 was measured, using an enzyme immunoassay, in 27 patients with ANCA-associated vasculitis and in 26 healthy control subjects. Our patients were selected such a way that 16 of them were in full disease flare with high levels of ANCA, while the serology was negative in the remaining 11 patients in remission.

Results: Serum S100A8/A9 wasnot significantly higher in ANCA-associated vasculitis patients than in control group (246 mg/l versus 251, $P = 0.183$). The breakdown of our population into two groups-according to disease activity and ANCA levels, 16 in disease flare and11 patients in remission showed thatincreased levels of Serum S100A8/A9 was notassociated with severity of ANCA-associated vasculitis ($P > 0.05$).

Conclusions: Unlike what has been recently reported that increases in serum levels of S100A8/A9 correlated well with some clinical forms of a few inflammatory diseases such as rheumatoid arthritis, our findings demonstrated the lack of correlation between this serum biomarker and the activity of ANCA-associated vasculitis, pathology in which polynuclear neutrophils are known to be involved in mechanism injury.

P1569

Automated imaging system for the analysis of antinuclear antibodies by indirect immunofluorescence

V. P. Rodriguez,* C. G. Rodríguez,* A. F. Hermida,† D. B. Roldán,* I. R. Losquiño* & F. F. Romero*
*Clinical Biochemistry, Virgen Macarena University Hospital, Sevilla, Spain, †Menarini Diagnostics, Sevilla, Spain

Purpose/Objective: Antinuclear antibodies (ANA) are essential biomarkers in the diagnosis of several autoimmune diseases. Although immunoassays in solid phase as ELISA are economic and easier to standardize, they are not able to describe ANA patterns and have less sensitivity than indirect immunofluorescence (IIF) in human epithelial cells HEP2, for this reason the American School of Rheumatology recommends IIF in HEP2 as the technique of reference for the determination of ANA. Following this tendency, technologies for the reading of ANA by IIF are being developed in order to avoid the main disadvantage of the IIF; the variability of results based on the experience of the analyst.

G-Sight Zenit is an automated system of Menarini Diagnostics for the capture of images and the interpretation of IIF tests that allows a semiquantitative analysis and the recognition of ANA patterns in HEP2. The use of these systems could help reduce the great variability in the determination of these autoantibodies.

Objective: Analyze the degree of agreement between the results obtained with the automated system (Zenith G-Sight, Menarini Diagnostics) and the microscope observation for the analysis of the ANA by IIF.

Materials and methods: We analyzed 107 serums from patients being followed by specialized consults. The samples were analyzed in parallel with the automated system Zenith G-Sight from Menarini Diagnostics (Florence, Italy) and with a fluorescence microscope Olympus BX41 (Tokyo, Japan). We used as substrate, slides of HEP2 cells, Immuno-Concepts. (Sacramento, USA) We determined the degree of agreement for pattern and titer of ANA between the images obtained by the G-Sight and the microscopic analysis, by the calculation of Kappa indices using the statistical program SPSSv19.

Results: In the study of the patterns we obtained a kappa index of 0.78, indicating a good degree of agreement between both techniques. In the study of the titer we obtained a kappa index of 0.53, thus the agreement between both techniques was moderate.

Of the 48 samples interpreted as negative/doubtful by the G-Sight, 32 were reported as positive and 16 as negative aftermicroscope observation.

Conclusions: Both methods show a good degree of agreement as far as pattern and titer. Nevertheless, it would be necessary to adjust the rank of negatives/doubtful given by the G-Sight to use this equipment in ANA screening.

P1572

Comparative study between ELISA and chemiluminescence methods for the analysis of specific ENA

V. P. Rodriguez,* B. F. Pérez,* C. G. Rodríguez,* J. M. M. Bada,† E. M. Madrid,* R. F. Seda* & F. F. Romero*

**Clinical Biochemistry, Virgen Macarena University Hospital, Sevilla, Spain, †Menarini Diagnostics, Sevilla, Spain*

Purpose/Objective: The autoimmunity laboratory plays an essential role in the diagnosis, classification, prognosis and follow up of autoimmune diseases through the detection of serum autoantibodies.

Autoantibodies to extractable nuclear antigens (ENA) anti-Ro/SSA, anti-La/SSB, anti-Sm, anti-RNP/U1RNP, anti-Scl-70/topoisomerase I and anti-Jo-1/histidyl-tRNA synthetase are clinically important in patients with autoimmune diseases such as Sjögren's syndrome, systemic lupus erythematosus (SLE), scleroderma, dermatomyositis and polymyositis among others.

Their analysis is made preferably by enzyme linked immunosorbent assay (ELISA). This method has very good sensitivity and can detect small concentrations of antibodies. Nevertheless, in the last years the development of new chemiluminescent immunoassays is changing the methodology of the autoimmunity laboratories.

Objective: Analyze the degree of agreement between chemiluminescence Zenith-RA method from Menarini Diagnostics (Florence, Italy) and the habitual ELISA from Inova Diagnostics (San Diego, USA) for the analysis of specific anti-ENA, anti-Ro/SSA, anti-La/SSB, anti-Sm, anti-RNP/U1RNP, anti-Scl-70 and anti-Jo-1.

Materials and methods: We analized 85 samples from rheumatology patients using both instruments Zenit-SP+ (ELISA, Inova Diagnostics) and Zenit-RA (chemiluminescence immunoassay, Menarini Diagnostics). Once we obtained the results of the specific anti-ENA we classified our patients in positive or negative according to the cut-off values recommended by the manufacturer and we determine the degree of agreement using the statistical program SPSSv19.

Results: The Kappa indices show a good degree of agreement foranti-Sm, anti-Scl70 and anti-Ro/SSA and moderate degree of agreement for anti-La/SSB, anti-RNP/U1RNP and anti- Jo-1.

Conclusions: Both methods show good degree of agreement in the analysis of specific anti-ENA. Given the advantages of CLIA techniques in front of ELISA (master curve for each lot of calibrators and controls, linearity and continuous access of samples) it could be a valid option for the analysis of specific anti-ENA in the clinical laboratory.

P1574

Development of a conformation-dependent immunoassay for the diagnosis of systemic sclerosis

K. Pozniak,* G. Nacci,† A. Grieco,* C. Paolini,* S. Mori,* C. Tonnini,* M. Cuccioloni,‡ M. Mozzicafreddo,‡ M. Angeletti,‡ A. Funaro,† A. Gabrielli* & G. Moroncini*

**Clinica Medica, Dipartimento di Science Cliniche e Molecolari, Ancona, Italy, †Lab of Immunogenetics, Department of Genetics Biology and Biochemistry, Torino, Italy, ‡Biochemistry, Dipartimento di Biologia Molecolare Cellulare e Animale, Camerino, Italy*

Purpose/Objective: The presence of conformational, stimulatory auto-antibodies (abs) against the PDGF receptor (PDGFR) in patients affected by systemic sclerosis (SSc) has been questioned. IgG purification procedures and technical problems in cell-based biological assays and in solid phase binding assays can disrupt agonistic conformational abs and generate artifacts. To solve these issues and to validate the presence of anti-PDGFR abs in SSc patients, we aimed at developing a conformation-dependent immunoassay to detect agonistic anti-PDGFR abs in serum samples.

Materials and methods: (1) Human monoclonal anti-PDGFR autoabs were cloned from memory B cells of SSc patients; (2) different recombinant PDGFR conformers were tested to set up a capture ELISA able to detect serum anti-PDGFR auto-abs; (3) competitive binding assays using anti-PDGFR monoclonal auto-abs and recombinant human PDGF were performed to define the PDGFR epitopes bound by these different ligands; (4) a conformational peptide library spanning PDGFR extracellular domains was generated to validate epitope mapping data; (5) peptides bound by monoclonal auto-abs were synthesized and pre-incubated with agonistic auto-abs to inhibit antibody biological activity.

Results: (1) Monoclonal anti-PDGFR auto-abs generated from SSc B cell repertoire exhibited different PDGFR binding and agonistic properties; (2) a map of extracellular PDGFR functional domains was obtained: PDGFR epitopes bound by stimulatory auto-abs differed from those of non-biologically active auto-abs; (3) pre-incubation of agonistic auto-abs with peptides corresponding to their epitopes inhibited collagen stimulation in fibroblasts; (4) a competitive ELISA based on the inhibitory peptides was established to detect conformational PDGFR auto-abs in serum: this assay allowed discrimination between SSc and control sera with remarkable specificity and sensitivity.

Conclusions: The identification of the epitopes of the stimulatory, SSc-specific, anti-PDGFR auto-antibodies was crucial to develop a conformation-dependent immunoassay discriminating between SSc and control sera. The solid phase binding assay based on these epitopes might be used as a novel tool for diagnosis of SSc and classification of the clinical subsets of disease and related conditions such as Raynaud's Phenomenon.

P1577

Diagnostic value of serum high mobility group box protein 1 (HMGB1) and soluble CD163 (sCD163) levels in brucellosis

A. O. Ayarci,* E. Yilmaz,* D. Sigirli,† F. Budak,‡ G. Göral‡ & H. B. Oral‡

**Infectious Diseases & Clinical Microbiology, Faculty of Medicine, Uudag University, Bursa, Turkey, †Biostatistics, Faculty of Medicine, Uudag University, Bursa, Turkey, ‡Immunology, Faculty of Medicine, Uudag University, Bursa, Turkey*

Purpose/Objective: Both $CD4^+$ and $CD8^+$ T lymphocytes play critical roles in immunity to *Brucella*, in part because they secrete IFN-γ and activate the bactericidal functions in macrophages. Therefore, use of markers which can evaluate macrophage activation may have diagnostic and prognostic importance.

High mobility group-box 1 protein (HMGB1) is a late-onset proinflammatory cytokine secreted from activated macrophages. Soluble hemoglobin scavenger receptor (sCD163) is a specific marker of anti-inflammatory macrophages.

The aim of this study was to test potential associations of serum levels of HMGB1 and sCD163 with Brucellosis and its acute, subacute and chronic forms.

Materials and methods: Serum HMGB1 and sCD163 levels in 49 Brucellosis patients (23 acute, 15 subacute, 11 chronic) were compared with 52 healthy control subjects. Brucellosis was diagnosed by a positive blood culture and/or increased *Brucella* antibodies in serological tests in addition to compatible clinical symptoms. Con-

centrations of serum HMFB1 and sCD163 were determined by ELISA according to the protocol of manufacturer.
Results: Both serum HMGB1 and sCD163 levels were significantly higher in Brucellosis patients compared with healthy controls. The median serum HMGB1 level was 77.09 (0.00−182.84) ng/ml in healthy controls, whereas it was 170.65 (13.19−188.23) ng/ml in Brucellosis patients ($P < 0.001$). The median serum sCD163 level was 0.57 (0.21−1.52) mg/l in healthy controls, whereas it was 1.27 (0.37−2.13) mg/l in brucellosis patients ($P < 0.001$). There was no statistically significant difference in serum levels of HMGB1 and sCD163 among acute, subacute and chronic cases with Brucellosis. Additionally, serum HMGB1 levels were positively correlated with sCD163 levels, whilst neither HMGB1 nor sCD163 levels were correlated with CRP, WBC and sedimentation values.
Conclusions: Our study demonstrated that the levels of HMGB1 and sCD163 may be diagnostic markers for Brucellosis, but none of them can be used for differentiating three different forms of disease (acute, subacute, chronic). On the other hand, studies with larger series of patient populations are necessary to confirm the biological significance of our results. Also, further studies are needed to assess the alteration of these mediators in response to treatment.

P1578
Effector and regulatory T cell subsets in hereditary hemorrhagic telangiectasia

M. De Carvalho,* M. Vaucelle,* S. Mohamed,† S. Amdouni,* C. Kohler,* M. C. Bene,* P. Kaminsky† & G. C. Faure*
**Laboratory of Immunology, Faculty of Medicine, Vandoeuvre-les-Nancy, France, †Department Internal Medicine, Universitary Hospital of Nancy, Vandoeuvre-les-Nancy, France*

Purpose/Objective: Hereditary hemorrhagic telangiectasia (HHT) is a disorder characterized by recurrent epistaxis, cutaneous telangiectasia, and visceral arteriovenous malformations caused by mutations in the TGF-β receptor complex. Most cases are due to mutations in the *ENG* (endoglin) or *ACRLV1* genes. HHT patients have higher rates of severe extracellular bacterial infections, yet few studies have evaluated their immune functions. TGF-β plasmatic levels have been described as either increased or decreased in HHT patients and one study found a deficit on IFN-γ, TNF-α and IL-2 Th1 cytokines. As TGF-β has an important role on either regulatory T cells (Treg) and Th17 development, we investigated the levels of these two CD4 T subsets as well as Th1-polarized T cells in the peripheral blood of HHT patients.
Materials and methods: Sixteen HHT patients and 15 healthy donors (HD) were included. Treg on whole blood were identified by flow cytometry on a lymphocyte gate as CD3+CD4+CD25+CD127$^{low/neg}$ cells. Th1 and Th17-polarized T cells were identified after overnight culture of PBMC in serum-free AIM-V medium in the presence of PMA, Ionomycin and Brefeldine-A. Unstimulated cells were used as negative control. Cells were labeled with a viability amine-reactive dye, with antibodies to CD3, CD4 (surface) and to IFN-γ, TNF-α, IL-2 and IL-17 (after permeabilisation) to identify cytokine-producing T cells. Data was acquired on a Beckman Coulter flow-cytometer.
Results: Median numbers of Treg in HHT patients (9.1% of CD3+CD4+ cells, 5.3−13.7) were similar to Treg numbers in HD (7.9% of CD3+CD4+ cells, 6.7−10.9, $P = ns$). Also, no statistical differences were found for IL-17+ CD3 producing cells between HHT patients (0.65% of lymphocytes, 0.17−2.5) and HD (0.8% of lymphocytes, 0.2−3, $P = ns$). Also, there was no difference between HHT patients and controls concerning IFN-γ+ or TNF-α+: IFN-γ+CD3+ (HHT 23% of lymphocytes, 8−58 versus HD 15% of lymphocytes, 8−42, $P = ns$); TNF-α+ CD3+ (HHT 43% of lymphocytes, 20−73 versus HD 44% of lymphocytes, 29−58, $P = ns$). However, HHT patients had a significantly lower number of IL2+ CD3+ cells (35% of lymphocytes, 12−51) compared to HD (46% of lymphocytes, 18−54, $P < 0.05$, *t*-test).
Conclusions;Our results suggest that there are no major changes on effector or regulatory CD4 T cell subsets in HHT patients. Deficits on innate immunity (phagocytes) could explain increased rates of bacterial infections in this condition. Further studies with a greater number of patients could potentially favor the identification of eventual subtle changes on T cell function as well as segregation of data according to genetic mutations.

P1579
ELISpot but not ELISA detects human IL-21 secreted by antigen-stimulated human PBMC

J. Huang, T. Bengtsson & N. Ahlborg
R&D Department, Mabtech AB, Stockholm, Sweden

Purpose/Objective: IL-21 is primarily secreted by activated T cells, in particular CD4+ follicular and Th17 T cells, and regulates the development of T cells, B cells, NK cells and dendritic cells. Dysregulation of IL-21 has been reported to contribute to diseases such as SLE and RA. The fundamental relevance of IL-21 as well as its involvement in inflammatory and autoimmune diseases highlights the need for development and evaluation of suitable immunoassays facilitating analysis of IL-21.
Materials and methods: Monoclonal antibodies to human IL-21 were generated and used to develop sensitive capture ELISA and ELISpot assays. The assays were used to analyze IL-21 secretion by peripheral blood mononuclear cells (PBMC) after polyclonal (PHA) or specific stimulation (Tetanus toxoid; Candida albicans extract).
Results: Polyclonal activation of PBMC induced IL-21 production detectable by ELISpot and ELISA. Increasing PBMC concentrations and pro-longed incubation times increased the number of IL-21-secreting cells found by ELISPOT. IL-21 levels in supernatants, analyzed by ELISA, showed a reversed relationship with increasing cell concentrations and incubation times associated with a decrease in levels.

In PBMC activated with specific stimuli, IL-21-producing cells could be detected by ELISpot whereas IL-21 levels in supernatants were not measurable by ELISA. Similar results were obtained when analyzing IL-4 by ELISpot and ELISA, in parallel. IL-17 production after specific stimuli, on the other hand, was detectable both by ELISpot and ELISA.
Conclusions: Our data show that ELISpot can detect IL-21-producing PBMC under conditions where IL-21 levels in PBMC supernatants are not measurable by ELISA. Similar results were obtained with IL-4, a cytokine known to be difficult to detect by ELISA in supernatants from specifically activated PBMC due to consumption by cellular receptors. Difficulties to measure IL-21 by ELISA could thus depend on a low IL-21 secretion level per cell and/or receptor consumption. Further investigations of this aspect are ongoing. The results emphasize the importance of using suitable methods for analysis of IL-21.

Key words: human IL21; human IL17; human IL4; ELISpot; ELISA

Factors associated with parietal cell autoantibodies in the general population

A. Cabrera,* D. Almeida,† A. Arencibia,‡ A. González,§ M. Carretero,† M. C. Rodríguez,§ V. Gil¶ & B. Brito§
*Research Unit, Nuestra Señora de la Candelaria University Hospital, University of La Laguna, Santa Cruz de Tenerife, Spain, †Immunology Unit, Nuestra Señora de la Candelaria University Hospital, Santa Cruz de Tenerife, Spain, ‡Digestive Diseases Department, Nuestra Señora de la Candelaria University Hospital, Santa Cruz de Tenerife, Spain, §Research Unit, Nuestra Señora de la Candelaria University Hospital, Santa Cruz de Tenerife, Spain, ¶Research Unit, Miguel Hernández University, Alicante, Spain

Purpose/Objective: The presence in serum of parietal cell autoantibodies (PCA) is a characteristic of autoimmune gastritis. We determined the prevalence of PCA in the general population and investigate their association with type 2 diabetes, insulin resistance and lifestyle factors related with autoimmune gastritis.
Materials and methods: A cross-sectional study was performed, involving 429 individuals enrolled in a cohort study of the general population of the Canary Islands. All participants underwent physical examination, provided a blood sample and responded to a questionnaire regarding health and lifestyle factors. Serum concentrations of PCA, soluble CD40 ligand (sCD40L), C-peptide and glucose (to determine insulin resistance) were measured. The association of PCA with the other factors was determined with bivariate analysis, and losgistic regression models were used to adjust the associations for age and sex.
Results: The prevalence of PCA was 7.8% (95% CI = 10.3−5.3). The factors associated with PCA were female sex ($P = 0.032$), insulin resistance ($P = 0.016$), menopause ($P = 0.029$) and sCD40L ($P = 0.019$). Alcohol consumption ($P = 0.006$) and smoking ($P = 0.005$) were associated with low prevalences of PCA. After adjustment for age and sex, the association with PCA was confirmed for smoking [OR = 0.1 (0.0−0.9)], alcohol consumption [OR = 0.3 (0.1−0.9)], insulin resistance [OR = 2.4 (1.1−4.9)], female sex [OR = 2.4 (1.1−5.3)], sCD40L [OR = 3.7 (1.2−11.4)] and menopause [OR = 5.3 (1.2−23.3)].
Conclusions: Smoking and alcohol consumption acted as protective factors against the appearance of PCA in the general population, whereas female sex, menopause, insulin resistance and elevated serum sCD40L were risk markers for PCA. In patients who smoke or drink alcohol, clinicians should be cautious when using PCA to rule out autoimmune gastritis.

P1581

Hematogonal cell populations in routine multiparametric flow cytometry analysis

E. Caranfil,* I. Funingana,* C. Barzu,* G. Grigore† & M. Zlei†
*Medicine, University of Medicine and Pharmacy "Grigore T. Popa" − Iasi, Iasi, Romania, †Laboratory of Molecular Biology, Regional Institute of Oncology − Iasi, Iasi, Romania

Purpose/Objective: Context: Multiparametric flow cytometry is a critical method in diagnosis and monitoring the evolution of neoplastic haematological processes, allowing quantitative classification, based on key molecular expression, of the cellular population structure in patient samples. Marker list selection and staining combinations are both crucial in defining normal and malignant proliferation, developmental and lineage cell identity, and may be useful to evaluate the minimal residual disease (MRD) and the postchemotherapy regenerating bone marrow.

Objective: To determine the feasability of using retrospective (repetitive) flow cytometry multiparametric data in documenting the MRD evolution and describing the regenerating haematological compartments.
Materials and methods: Repetitive bone marrow aspiration cell samples (six samples), covering a 6 year interval (2006−2011) of a B-acute lymphoblastic leukemia studied case (first diagnosed at age 15) were analysed using up to six color flowcytometry (FACS Calibur-CellQuest; FACS Canto II-FACS Diva). Staining protocol targeted with monoclonal antibodies the following molecules: CD45, CD19, CD22, CD20, CD10, CD34, CD38, TdT.
Results: Retrospective analysis of the six iterative bone marrow sample cell populations documents the complete therapeutical response of the tumor cell line (which was a phenotypically-homogenous B-cell precursor expressing CD19, CD10, CD34, CD22, intracellular CD79a and TdT), and, lately, the expansion of a B-cell precursor compartment that was heterogenous − and thus not evocative for relapse occurence (below 10%, CD45+ low CD19+ CD10+ CD34-/+, 0.6% CD22+ low CD20 s-/+, 3% CD38+ high).
Conclusions: Multiparametric flow cytometry can discriminate between regenerative postchemotherapeutical nature of cell expansions versus MRD or relapse.

P1583

Immune system genes expression in athletes with allergies

M. Boldyreva,* S. Tsarev,* M. Chulkina,† A. Savilova,† O. Burmenskaya,† D. Trofimov,† N. Shartanova‡ & N. Ilyina‡
*Immunogenetics, SSC Institute of Immunology FMBA of Russia, Moscow, Russia, †R&D, JSC "DNA Technology", Moscow, Russia, ‡Clinical, SSC Institute of Immunology FMBA of Russia, Moscow, Russia

Purpose/Objective: The aim of this study is to identify biomarkers for monitoring the functional state of the immune system in elite athletes.
Materials and methods: The expression of genes (mRNA) IL-1β, TNF-α, IL-8, IL18; TLR2, TLR4, TLR9, IFN-α, IFNγ, IL28, IL29, CD45, CD68, CD56, GATA3, TBX21, RORS2, Foxp3, TGF-β1 has been investigated. Quantitative mRNA was investigated by real-time PCR with reverse transcription and with normalization with respect to gene GUSB, HPRT1 B2M. We examined 22 athletes from the youth team of Russia on weightlifting. All the athletes were divided into three groups. Group 1 ($n = 10$) consisted of healthy athletes. Group 2 ($n = 7$) consisted of athletes who had chronic infection in anamnesis (frequent respiratory viral infection, chronic tonsillitis, herpes virus infection). Group 3 ($n = 5$) included athletes who had any manifestations of allergy in anamnesis and/or having a positive skin test and/or have elevated levels of total IgE in serum, but no allergy symptoms at the time of clinical examination. Epithelial cells scraping of the nasopharynx and peripheral blood mononuclear cells were used as a samples for the study of gene expression.
Results: The performed investigation demonstrated increased expression of genes involved in the inflammatory IL1, IL8 and innate immune receptors TLR2, TLR4, and reducing the expression of the transcription factor RORC2, providing feedback regulation of inflammation only in the scraping of the epithelial cells and only in athletes with allergies without exacerbation.
Conclusions: These results indicate that changes in immune function only in athletes with allergies (without exacerbation) in place of the primary immune cells contact with inhaled air, which may contain pathogens of respiratory infections and/or allergens.

P1584

Immunological features of IgA nephropathy development

M. Yurkevich,* V. Pilotovich,† K. Komisarov,† H. Ivanchik* & M. Zafranskaya*

*Department of Immunology, Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus, †Department of Nephrology, Minsk City Hospital N 1, Minsk, Belarus

Purpose/Objective: IgA nephropathy (IgAN) is a major cause of end-stage kidney disease but at this moment there are no reliable prognostic criteria for the assessment of IgAN severity and none of the factors initiating this disease has been identified. Defects in systemic and mucosal immunity and immune complex clearance by mesangial cells (MCs) may be of importance in IgAN initiation.

The aim of this study was to estimate the contribution of immune cells and IgA clearance *via* IgA-binding receptors to IgAN development.

Materials and methods: MCs were isolated from nephrobiopsies of patients with IgAN ($n = 6$) and non-IgA-mesangioproliferative glomerulonephritis ($n = 4$) by incubation with 1 mg/ml collagenase I type and were characterized by vimentin$^+$ CD90$^+$44$^+$31$^-$14$^-$45$^-$ phenotype. Peripheral blood lymphocytes from patients with IgAN (34 ± 5 years, $n = 28$) and other glomerulopathies (31 ± 4 years, $n = 15$) were analyzed using CD3/CD5-PC7, CD4/CD8-PC5, CD19-PE, HLA DR/CD25-PE, Vγ2 TCR-Fitc, CD45RO-ECD monoclonal antibodies by means of flow cytometry FC500 (Beckman Coulter, USA). The level of serum immunoglobulins was determined by ELISA (VecktorBest, Russia).

Results: We have observed increased level of serum IgA only in 62% patients with IgAN, while the presence of IgA in the kidney mesangium was the basic diagnostic criterion of this disease. High level of IgA receptor – CD71 (81.2% (74.6% ÷ 85.4%) expression was detected in all MCs cultures. Other IgA-binding receptors (CD89, ASCRR) were not determined in MCs.

At the same time IgAN patients are characterized by significantly decreased percentage of $\gamma\delta$ T cells in peripheral blood compared with non-IgAN patients (1.8% (1.1% ÷ 2.7%) and 3.7% (1.8% ÷ 6.4%), respectively). Compared to patients with normal frequencies of CD8$^+$ T cells (30.3% (27.0% ÷ 33.9%); IgAN patients with CD8$^+$ T cells number exceeding 38% (40.2% (38.3% ÷ 41.4%) had decreased whole blood protein concentration, increased serum creatinine andsevere proteinuria (up to 2 g/day) ($P < 0.05$).

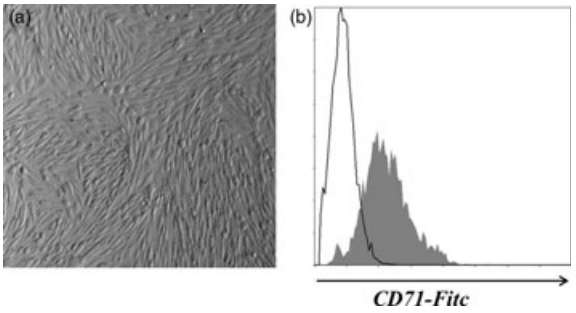

Figure 1. Morphology (A) and phenotype (B) of MCs culture.

Conclusions: The high level of CD71 expression on MCs of patients with various glomerulopathies is an evidence of the prevalence of immune system's abnormalities over kidney clearance in IgAN. We suggest that CD8$^+$ and $\gamma\delta$ T cells involve in IgAN development and progression and may be used as possible criteria for the assessment of this disease severity.

P1586

In vivo quantitative fluorescence imaging of matrix metalloproteinases activity in the CAIA mouse model of rheumatoid arthritis

Z. Stencel, S. Allden, M. Catley & S. Shaw

UCB, Pharmacology, Slough, United Kingdom

Purpose/Objective Matrix metalloproteinases including MMP-9 are known to be involved in diseases including inflammatory arthritis and contribute to pathological processes such as joint destruction. In RA patients MMP-9 is localized to sites of inflammation in synovium and is elevated in synovial fluid, serum and plasma (Ahrens *et al.*, 1996, Gruber *et al.*, 1996). Similarly in the collagen antibody induced arthritis (CAIA) mouse model MMP-9 mRNA levels are also elevated in the footpad (Chia *et al.*, 2008). The aim of this study was to determine *in vivo* MMPs activity at the site of inflammation at the acute and chronic stages of mouse CAIA using a fluorescence imaging techniques. In addition MMP-9 levels were measured in the serum.

Materials and methods: CAIA was induced in male Balb/c mice by an i.p. injection of 4 mg of monoclonal antibody cocktail to collagen II followed by 25 μg LPS 24 h later. 1 h prior to antibody cocktail administration mice were treated with 30 mg/kg Enbrel s.c. q.a.d.

The MMPSense 680, a fluorescent imaging agent, was used to detect *in vivo* activity of MMP-2, -3, -9 and -13 in hind paws at the peak of disease (d5) and in chronic stage (d12). Directly post imaging, serum samples were collected and MMP-9 concentration was measured using a mouse total MMP-9 immunoassay.

Results: Control mice showed first clinical signs of swelling 48 h post LPS challenge that peaked 72 h post challenge. The anti-TNF treatment showed significant inhibition on disease throughout the experiment.

The quantitative *in vivo* imaging showed significantly higher levels of MMP activity in inflamed paws compared to the negative control at acute and chronic stage. Positive control serum MMP-9 concentration was elevated compared to naïve serum in both, acute and chronic stages. The Enbrel treated mice showed a similar level of MMP activity as naïve mice at acute stage, however at the chronic stage MMP activity was significantly higher than naïve mice. This correlated with serum MMP-9 levels that were comparable to naïve levels at d5 and were significantly elevated in the chronic stage of disease. In addition the measured MMPs fluorescence correlated with clinical score in the chronic stage.

Conclusions: Activity of MMPs was significantly increased *in vivo* at site of inflammation during acute and chronic stage in the CAIA model. The localised MMP activity correlated with measured MMP-9 concentration in serum from all treatment groups. Moreover the MMP activity could be inhibited by anti-TNF treatment in this model. This indicates that MMP-9 is a valuable biomarker for disease progression in CAIA model and could be used as an addition to clinical score.

LC/DAD analysis of serum biogenic amines in patients with diabetes mellitus, chronic urticaria and Hashimoto's thyroiditis

J. Trifunovic,* M. Jadranin,† A. Damjanovic,‡ S. Raskovic,§ M. N. Djurovic,¶ D. Draskovic,¶ G. Pudar,** V. Tesevic,†† I. Juranic‡‡ & Z. Juranic‡

*Organic Chemistry, Faculty of Chemistry, Innovative Center, University of Belgrade, Belgrade, Serbia, †Center for Chemistry, Institute for Chemistry Technology and Metallurgy, University of Belgrade, Belgrade, Serbia, ‡Experimental Oncology, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia, §Immunology and Allergology, Institute of Immunology and Allergology Clinical Center of Serbia, Belgrade, Serbia, ¶Endocrinology, Institute of Endocrinology Clinical Center of Serbia, Belgrade, Serbia, **Endocrinology Diabetes and Metabolism Diseases, University Clinical Center "Zvezdara", Belgrade, Serbia, ††Organic Chemistry, Faculty of Chemistry University of Belgrade, Belgrade, Serbia, ‡‡Organic Chemistry, Institute for Chemistry Technology and Metallurgy, University of Belgrade, Belgrade, Serbia

Purpose/Objective: The biogenic amines putrescine (Put), histamine (His), spermidine (Spd), *N*-acetyl putrescine (NAP), *N*-acetyl spermidine (NAS), dopamine (Dop), epinephrine (Epi), norepinephrine (NE) and spermine (Spm) are a group of naturally occurring compounds exerting a large number of biological effects.

This study was commenced to elucidate the role of biogenic amines as possible diagnostic markers for three autoimmune diseases: *Diabetes mellitus*, *Chronic urticaria*, and *Hashimoto's thyroiditis*.

Materials and methods: This study involved 20 patients with *Diabetes mellitus*, 20 patients with *Chronic urticaria*, eight patients with Hashimoto's thyroiditis, and 20 healthy volunteers. We precipitated serum proteins using 0.4 M $HClO_4$. At pH 8.0 we performed derivatization with dansyl-chloride. 50 μl of prepared serum samples were injected into LC/DAD, in conditions of gradient elution, on C18 column. Commercially available Put, His, Spd, NAP, NAS, Dop, Epi, NE, and Spm were dissolved in different concentrations in ultra pure water; treated in the same way as serum samples and injected into LC. Calibration curves were made by plotting peak area values against the respective concentrations of standards. The qualitative analysis was done using the method of retention time, and quantitative analysis using external calibration. The recovery study was carried out using real serum sample from healthy control, by spiking techniques.

Results: Retention times were 6.6 min for NAS, 8.8 min for NAP, 9.1 min for Put, 10.1 min for His, 13.2 min for Spd, 13.9 min for NE, 14.7 min for Epi, 14.9 min for Dop, and 15.4 min for Spm, respectively. Obtained data showed excellent linearity of calibration curves for Put, His, Spd, NAP, NAS, Dop, Epi, NE, and Spm. Compared to controls, His levels in *Diabetes mellitus* patients were statistically higher; in *Chronic urticaria* patients levels of Put and His were lower; Spd, NE and Epi levels were enhanced; Put was statistically lower and Spd higher in *Hashimoto's thyroiditis* patients. *Chronic urticaria* patients were the only in whose serum NE was found. NAP, NAS, Dop, and Spm were under limits of detection.

Conclusions: Preliminary results from this study showed diverse distribution of investigated biogenic amines indicating different activation of metabolic pathways controlling biogenic amine biosynthesis and degradations in analyzed autoimmune diseases.

P1589

Levels of inflammatory mediators in gingival crevicular fluid from patients with periodontal disease before and after treatment

P. M. Alberga,* A. Romero,† M. Correnti† & L. Escalona†

*Postgrado en Ciencias Fisiológicas, Instituto de Medicina Experimental, Caracas, Venezuela, †Facultad de Odontología, Instituto de Investigacion Odontologica, Caracas, Venezuela

Purpose/Objective: The purpose of the present research was to determine the levels of IL-1α, IL-1β, TNF-α, MMP-3 and MMP-8 in gingival crevicular fluid (GCF) of subjects with chronic periodontitis before and after non surgical treatment.

Materials and methods: Clinical measurements were carried out in 11 patients diagnosed with chronic periodontitis and 11 periodontally healthy controls. The clinical indexes evaluated were: gingival index (GI), plaque index (PI), bleeding on probing (BOP), probing depth (PD) and attachment loss (AL). The measurements were taken at six sites per tooth in all teeth in each subject. GCF samples were taken from one tooth per quadrant, and the levels of these mediators were measured using an ELISA test.

Results: A statistically significant difference ($P < 0.05$) was observed in all the clinical parameters between patients and control group before and after periodontal treatment. Correlations between levels of mediators with the clinical parameters were not observed. Statistically significant differences were found between patients and control group in relation with levels of inflammatory mediators ($P < 0.05$) before and after treatment. The levels of IL-1α, IL1-β, TNF-α, MMP-3 and MMP-8 decreased in 44.2%, 48.35%, 53.28%, 62.16% y 34.03% respectively.

Conclusions: Periodontal therapy reduced the levels of the inflammatory mediators evaluated in this study, which were significantly associated with the severity of periodontal disease. This research was supported by CDCH PG: 10-00-7070-2007.

P1590

Measuring autoantibodies against IL-17F and IL-22 in autoimmune polyedocrine sydnrome type I

B. E. V. Oftedal,* A. Meager,† E. S. Husebye‡ & A. S. B. Wolff*

*Endocrinology, Institute of Medicine, Bergen, Norway, †Biotherapeutics, The National Institute for Biological Standards and Control, South Mimms, UK, ‡Endocrinology, Institute of Medicine, Haukeland University Hospital, Bergen, Norway

Purpose/Objective: Patients with autoimmune polyendocrine syndrome type I (APS I) have at least two of the three disease components adrenal insufficiency, hypoparathyroidism and chronic mucocutaneous candidiasis. Various other organ-specific autoimmune manifestations are common, as well as a number of ectodermal symptoms. The underlying cause of APS I is mutations in the gene encoding the autoimmune regulator protein AIRE. Deficiency of this protein leads to loss of immunologic tolerance and release of autoreactive T-cells from thymus into the periphery.

Patients frequently develop high titers of autoantibodies against molecular targets in their affected organs. The pathological role of these antibodies is unknown, but they have become important markers for APS I and other autoimmune conditions. Autoantibodies against interleukin (IL) -17A, IL-17F and IL-22 have recently been described in patients with APS I, and their presence is reported to be highly correlated to chronic mucocutaneous candidiasis (CMC). The aim of this study was to develop a robust high-throughput radioligand binding assays (RLBA) measuring IL-17F and IL-22 antibodies, and to compare them with current enzyme-linked immunosorbent assays (ELISA) of IL-17F and IL-22; moreover to correlate the presence of these antibodies to the presence of CMC.

Materials and methods: A total of five RLBAs were developed based on IL-17F and IL-22 monomers and homo- or hetero dimers. As these

interleukins are small molecules, hence difficult to express *in vitro*, they were fused as dimers, which proved to increase the efficiency of expression. Sera from 25 APS-I patients were analysed by the different RLBAs and ELISA.
Results: Analysing the presence of these autoantibodies in 25 Norwegian APS I-patients revealed that the different RLBAs detected anti-IL-17F and anti-IL-22 with high specificity, using both homo- and heterodimers. The RLBAs based on dimer proteins are highly reproducible with low inter- and intra-variation.
Conclusions: The RLBAs have the advantages of high throughput and easily standardisation compared to ELISA, thus proving excellent choices for the screening of IL-17F and IL-22 autoantibodies.

P1594
Preanalytical and analytical factors affecting assessment of extracellular vesicles as biomarkers

E. Buzás, B. György, T. G. Szabó, K. Szabó-taylor, K. Pálóczi, A. Kittel, G. Y. Nagy & A. Falus
Department of Genetics Cell- and Immunobiology, Semmelweis University, Budapest, Hungary

Purpose/Objective: Current research in the field of extracellular vesicles (including exosomes, microvesicles and apoptotic bodies) is undergoing a revolutionary development. Extracellular vesicles are considered both as disease-specific biomarkers and therapeutic vehicles. Our goal was to identify preanalytical and analytical factors that may have an impact on the detection of cell-derived extracellular vesicles.
Materials and methods: We tested the effect of different anticoagulant tubes, shaking, storage at different temperatures, centrifugation forces and times and the effect of size filtration on the number and structure of blood plasma derived extracellular vesicles assessed by flow cytometry, transmission electron microscopy, atomic force microscopy, dynamic light scattering and qNANO techniques.
Results: Our data indicate that the number of platelet derived microvesicles is strongly influenced by the type of anticoagulation. Shaking and storage of blood plasma samples at 37°C proved to be strong inducers of platelet derived microvesicles. Forced filtration caused fragmentation of extracellular vesicles. Furthermore, we found that protein aggregates (such as immune complexes, biotin-avidin complexes) shared biophysical parameters with microvesicles and resulted in microvesicle-mimicking signals during flow cytometry. We developed a differential detergent lysis method to differentiate microvesicles from protein aggregates. Here we show that by using our improved method of microvesicle assessment, important new insights are gained into the pathomechanism of diseases such as rheumatoid arthritis.
Conclusions: Correct assessment of extracellular vesicles in biological fluids requires standardization of both preanalytical and analytical parameters.

P1595
Preoperative serum levels of CA 242 in colorectal carcinoma

M. Al-Kaabe,* S. Al-Fatlawi,† J. Al-Musawi,‡ Q. Al-terrahi§ & M. Alsaidi¶
**Pathology and Foriensic Medicine, Medical College, Al Kut, Iraq, †Al Sadar Teaching Hospital, Kidney Transplantation Center, Al Najaf, Iraq, ‡Medical Microbiology, Medical College, Al Najaf, Iraq, §Pathology and Foriensic Medicine, Medical College, Al Najaf, Iraq, ¶Microbiology & Immunology, Medical College, Al Kut, Iraq*

Purpose/Objective: Biochemical markers for colorectal carcinoma (CRC) are potentially useful in screening for early disease, aid in diagnosis, determining prognosis, surveillance of patients undergoing curative resection and monitoring the treatment of advanced disease.
Materials and methods: Preoperative serum levels of CA242was determined using ELISA technique for 35 patients with colorectal carcinoma, 25 patients with benign colorectal diseases (ulcerative colitis) and 10 volunteers as control group.
Results: CA242 showed to be high distributed in patients with colorectal carcinoma which represented 37.1% as compared to patients with ulcerative colitis and control group which represented (16% and 0%) respectively ($P = 0.026$). The overall sensitivity of the CA242 test was 37.1% and the corresponding specificity was88.6%, using cut-off level 20 U/ml for CA 242. In regard to effect of age on the level of CA242 in study groups, it was showed to be high distributed in young age from (36 to 65) years which represented 17.1% ($P = 0.088$). Regarding to gender, CA242 showed to be high distributed in females which represented 61.5% as compared to males which represented 38.5% ($P = 0.149$). In regard to effect of grade (degree of differentiation) on the level of CA242, it showed to be high distributed in poorly differentiated colorectal adenocarcinoma which represented 38.5%, while in well and moderately differentiated colorectal adenocarcinoma which represented (30.7% and 15.4%) respectively ($P = 0.588$). When the stage of disease takes in a consideration CA 242 was 7.7%, 7.7%, 15.4% and 38.5% in stage (I, IIA, IIB, IIIB and IV) respectively ($P = 0.218$).
Conclusions: In conclusion these findings suggest that CA242 elevated level and high sensitive in patients with colorectal carcinoma and may be used as an indicator of disease activity and may be considered as prognostic factor for patients with colorectal carcinoma. CA242 high distribution in young age may be attributed to incidence of colorectal carcinoma in Iraq occur in young age, but the cause of why was CA242 in females higher than males remain unclear. In patients with ulcerative colitis, CA242 may be used as predicting factor for malignant transformation.

P1596
Serum ghrelin and adiponectin levels are increased in underweight COPD patients, but leptin and proinflammatory cytokines are not changed

A. K. Uzum,* M. M. Aydin,† Y. Tutuncu,* E. Kiyan,† B. Omer,‡ N. C. Ozbey* & F. Alagol*
**Internal Medicine Endocrinology & Metabolism, Faculty of Medicine, Istanbul University, Istanbul, Turkey, †Pulmonary Diseases, Faculty of Medicine, Istanbul University, Istanbul, Turkey, ‡Clinical Biochemistry, Faculty of Medicine, Istanbul University, Istanbul, Turkey*

Purpose/Objective: Weight loss, muscle wasting, and tissue depletion are common features reported in COPD patients and they are all related with systemic inflammation. We investigated the relations between pulmonary functions, circulating levels of inflammatory mediators and metabolic parameters in underweight COPD patients.
Materials and methods: Biochemical, hormonal, and anthropometric parameters, serum levels of adiponectin (ApN), ghrelin, leptin, hsCRP, IL-6, IL-1b, IL-8, TNF-α and pulmonary functions were evaluated. COPD patients were grouped according to Global Initiative for Chronic Obstructive Lung Disease criterion. Patients and control subjects were all male. Group 1: Mild-moderate COPD patients ($n = 18$; with a mean age of 66.4 ± 9.2 years; range 45–79 years and body mass index (BMI): 19.7 ± 1.5 kg/m^2), group 2: Severe-very severe COPD patients ($n = 32$; with a mean age of 65.9 ± 10.0 years; range 45–80 years; BMI: 19.3 ± 1.6 kg/m^2), group 3: Control group was composed of healthy subjects with normal BMI and pulmonary function tests ($n = 17$; with a mean age of 50.2 ± 8.4 years; BMI: 21.85 ± 1.5 kg/m^2). The mean duration of COPD was 7.1 ± 6.4 years for group 1 and 7.3 ± 5.1 years for group 2. All patients were clinically

stable for at least 3 months and were not smoking for at least 6 months.

Results: ApN concentration was higher in group 1 (43.3 ± 28.6 ng/ml; $P < 0.05$) and group 2 (59.9 ± 31.8 ng/ml; $P < 0.001$) when compared with control group (23.5 ± 13.6 ng/ml). Ghrelin concentrations were higher in both COPD groups (1281.0 ± 1173.7 and 1840.0 ± 403.6 pg/ml; $P < 0.05$) than the controls (554.0 ± 281.9 pg/ml). No significant increase for leptin, IL-1b, TNF-α, IL-8 was found between groups. IL-6, hsCRP levels were higher in group 1 than control group. ApN was negatively correlated with BMI and FEV1. Skinfold thickness were decreased in COPD patients when compared with control group.

In the whole group, FEV1 was positively correlated with BMI, skinfold thicknesses of biceps, triceps and abdomen, insulin, tryglyceride whereas was negatively correlated with age, pack/years, HDL-Chol and ApN. We detected increased SHBG level with decreased insulin and HOMA-IR which mayindicate increased insulin sensitivity.

Conclusions: We can conclude that antiinflammatory effect of ApN and ghrelin had been more evidentin severe-very severe COPD patients.

This work was supported by Scientific Research Projects Coordination Unit of Istanbul University. Project number: 2245.

Significance of T helper 17 immunity in hepatitis C virus recurrence in orthotopic liver transplantation

F. B. G. F. B. Giner,* G. S. G. Salgado,* M. B. M. Brunet,† O. M. O. Millán,† M. L. H. M. López-Hoyos,‡ D. V. H. D. Valero-Hervas,§ A. M. A. Minguela,* M. M. M. Miras,¶ R. A. R. Álvarez* & M. M. M. Muro*

**Immunology Service, Hospital Universitario Virgen de la Arrixaca, Murcia, Spain, †Pharmacy Service, Hospital Clinic, Barcelona, Spain, ‡Immunology Service, Hospital Marqués de Valdecilla, Santander, Spain, §Immunology Service, Hospital 12 de Octubre, Madrid, Spain, ¶Digestive Medicine Service, Hospital Universitario Virgen de la Arrixaca, Murcia, Spain*

Purpose/Objective: Hepatitis C virus (HCV) recurrence is universal following orthotopic liver transplantation (OLT) with an accelerated rate of fibrosis in the allograft compared to that in the native liver in chronic HCV. CD4+ T cells play an important role in HCV immunity and T-helper type 17 (Th17) cells have also been implicated in inflammatory proccesses associated with liver fibrosis. Our aim was to determinate the role of CD4+ Th17 cells in HCV recurrence in liver allograft transplantation.

Materials and methods: Thirty OLTr and eighty four healthy donors (HD) from Murcia Region, Spain was included in this study. To quantify the frequency of CD4+ Th17 cells, the OLTr and HD bloods was cultured during 4 h in humidified 5% CO_2 at 37°C and used for an intracytoplasmatic flow cytometry assay. To measure IL-17 cytokine levels, we used a specific ELISA test (Quantikine® Human IL-17 Immunoassay R&D System) after cultured the OLTr and HD bloods with Concanavaline A (ConA-Sigma®). Statistical analysis was performed by using SPSS vs15.0 for Windows (SPSS, Chicago, IL). Mann-Whitney test was used to determinate significant differences in the frecuency of CD4+ Th17 cells or IL-17 cytokine levels between three groups (AR = Acute Rejection, NAR = Non-Acute Rejection and Control). Two-sided level of significance was set at $P < 0.05$.

Results: We analyzed the frequency of CD4+ Th17 cells in non-HCV recurrence group, HCV recurrence and controls. The frequency of CD4+ Th17 cells in patients with HCV-recurrence increase since the beginning of orthotopic liver transplantation in comparison to NHCV group. Moreover IL-17 cytokine levels were higher in patiens with HCV-recurrence than in NHCV in basal situation.

Conclusions: This data suggest that the CD4+ Th17 cells plays an important role in HCV immunity.

P1598

Skin immunity in complex regional pain syndrome: epidermal langerhans cell density is significantly different between CRPS and non-CRPS affected limbs

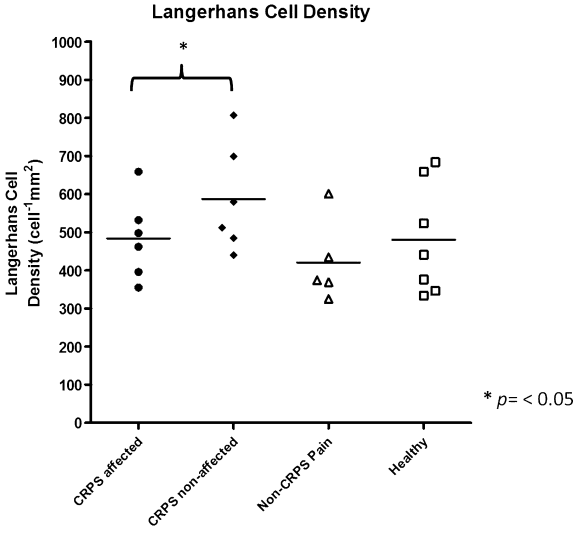
S. Osborne,* S. W. Edwards,* A. Goebel† & R. Moots‡

**Integrative Biology, University of Liverpool, Liverpool, UK, †Pain Research Institute, University of Liverpool, Liverpool, UK, ‡Institute of Aging and Chronic Disease, University of Liverpool, Liverpool, UK*

Purpose/Objective: We are investigating the role of the immune system within Complex Regional Pain Syndrome (CRPS) affected tissues in order to elucidate any possible role for immune cells in the generation or maintenance of chronic pain. Currently we are focused on cutaneous immunity and in particular on epidermal dendritic cells known as Langerhans cells (LCs). We hope that by characterizing any differences in immune cell infiltrate, phenotype, and function within CRPS limbs we can further understand the pathophysiology of the disease and discover new diagnostic indicators or avenues for therapeutic intervention.

Materials and methods: Two 6mm skin punch biopsies were taken from CRPS patients ($n = 6$), one from a CRPS affected limb and another from a non-CRPS affected contra-lateral control limb. Biopsies were then incubated in 2 mM EDTA for a minimum of 2 h before separating the dermis and epidermis. Epidermal sheets were then stained for LCs in a two step procedure using the cell specific antibody CD1a. Co-staining with HLA-DR and appropriate controls were also performed. Epidermal sheets were imaged using 3 dimensional confocal microscopy and LC densities calculated as cells/mm^2 of epidermis.

Results: LC density in CRPS affected limbs was 484 ± 44 cells/m^2 and in CRPS non-affected limbs was 587 ± 57 cells/mm^2. These values were found to be significantly different using a paired T-test analysis ($P = <0.05$). There was no significant difference between healthy control limbs and CRPS affected or non-affected limbs owing to significant donor variation.



Conclusions: Altered LC density further implicates the immune system in the pathogenesis and maintenance of CRPS. LCs are also regulated by sympathetic nerves and so can act as a synapse between the nervous and immune systems, a position which has obvious relevance in CRPS. It is not known at this stage if altered LC density

plays a functional role in CRPS or is a reliable indicator of disease. Research is ongoing in this area to fully elucidate the significance of this finding.

Soluble molecule profiling and network analysis of primary Sjögren's syndrome patient serum

J. Tarn,* A. Natasari,* S. Mitchell,* D. Lendrem,* C. Downie,* H. Foggo,* D. Young,* W. Ng* & S. Bowman†
**Musculoskeletal Research Group, Newcastle University, Newcastle upon Tyne, UK, †Rheumatology, University Hospital Birmingham, Newcastle upon Tyne, UK*

Purpose/Objective: In this study, we examine the serum samples of a large cohort of clinically well-characterised PSS patients and healthy controls in order to determine whether serum cytokines and chemokines may be used to differentiate PSS patients from healthy controls, and if so, the relationship between these serum abnormalities and clinical phenotypes.
Materials and methods: Serum levels of 24 different cytokines, chemokines and adhesion molecules for 150 pSS patients and 30 healthy controls were measured using Cytometric Bead Array (BD Biosciences). PSS patients were further classified into the following subsets: (1) Lymphoma/paraprotein positive; (2) High systemic disease activity; (3) Low residual glandular function; (4) High Fatigue. The relationship between the levels of each analyte and clinical and laboratory parameters of PSS was examined using multivariate analysis and Mann-Whitney *U* testing. Complex network analysis was performed using Cytoscape, where interactions can be integrated with and validated using published data.
Results: There were marked differences in the levels of many cytokines and chemokines between PSS patients and healthy controls, with a P value < 0.001, statistically significant after Bonforroni's correction for multiple comparisons. Serum IL4 and IL17 were found to be significantly higher in patients versus controls. Chemokines such as MIG (CXCL9), MIP1a (CCL3) and MIP1b (CCL4), IP10 (CXCL10), were also measured at higher levels in patient serum. IFNa, LTA and TNFa serum levels differ significantly between patients and controls. Network analysis has helped provide extra insight into the complex interactions between the studied serum analytes.
Conclusions: Differences in blood cytokine and chemokine levels between primary Sjogren's patients and controls can be detected in serum through the use of Cytometric Bead Arrays. Serum MIG (CXCL9), MIP1a (CCL3) and MIP1b (CCL4), IP10 (CXCL10) IFNa, LTA and TNFa levels differ significantly between patients and controls. Our observations raise the possibility that these analytes may be important in disease pathogenesis.

P1603

The role of T helper 17 cells in acute allograft rejection development in liver transplantation

F. J. B. G. F. J. B. Giner,* G. S. G. Salgado,* M. B. M. Brunet,† O. M. O. Millán,† M. L. H. M. López-Hoyos,‡ M. J. C. M. J. Castro,§ A. M. A. Minguela,* M. M. M. Miras,¶ R. A. R. Álvarez* & M. M. M. Muro*
**Immunology Service, Hospital Universitario Virgen de la Arrixaca, Murcia, Spain, †Pharmacy Service, Hospital Clinic, Barcelona, Spain, ‡Immunology Service, Hospital Marqués de Valdecilla, Santander, Spain, §Immunology Service, Hospital 12 de Octubre, Madrid, Spain, ¶Digestive Medicine Service, Hospital Universitario Virgen de la Arrixaca, Murcia, Spain*

Purpose/Objective: Orthotopic Liver Transplantation (OLT) is currently accepted as a viable therapeutic option for various end-stage liver disease and the incidence of acute rejection after OLT was still more than 30% where CD4+ T lymphocytes have been implicated in playing critical roles in allograft rejection. Recently, several groups have reported that under allograft rejection conditions OLT recipients (OLTr) showed a higher levels of IL-17 cytokine with a higher frequency of CD4+ Th17 cells. The aim of our study was determinate the role of CD4+ T helper 17 cells in OLTr either with and without acute rejection.
Materials and methods: Thirty OLTr and eighty four healthy donors (HD) from Murcia Region, Spain was included in this study. To quantify the frequency of CD4+ Th17 cells, the OLTr and HD bloods was cultured during 4 h in humidified 5% CO_2 at 37°C and used for an intracytoplasmatic flow cytometry assay. To measure IL-17 cytokine levels, we used a specific ELISA test (Quantikine® Human IL-17 Immunoassay R&D System) after cultured the OLTr and HD bloods with Concanavaline A (ConA-Sigma®). Statistical analysis was performed by using SPSS vs15.0 for Windows (SPSS, Chicago, IL, USA). Mann-Whitney test was used to determinate significant differences in the frecuency of CD4+ Th17 cells or IL-17 cytokine levels between three groups (AR, Acute Rejection; NAR, Non-Acute Rejection and Control). Two-sided level of significance was set at $P < 0.05$.
Results: We analyzed CD4+ T helper 17 cells frequency between AR, NAR and CONTROL groups and we have seen that the frequency of CD4+ T helper 17 cells in AR group before OLT was higher than CONTROL group, furthermore IL-17 interleukine cell culture supernates levels was higher in AR group in the firsts fifteen days after transplantation in comparition to NAR. In this study, we have found an inter-relationship between CD4+ Th17 cells frequency and IL-17 cytokine levels with acute rejection development in a OLTr cohort.
Conclusions: More researchers have been reported that serum levels of IL-17 were increased in patients with acute hepatic rejection which is consistent with our results in liver transplantation. In this study, we provide evidence that Th17 cells participates in the allogeneic liver rejection following liver transplantation, however the mechanism by which Th17 cells promotes allograft rejection in the liver remains to be determinated.

Tissue bank for inflammatory diseases Heidelberg/Gewebebank für entzündliche Erkrankungen Heidelberg (GEZEH): an innovative platform for translational immunology

F. Lasitschka,* E. V. A. Hadaschik,† P. Schirmacher* & A. Enk†
**Pathologisches Institut, Universitätsklinikum Heidelberg, Heidelberg, Germany, †Universitätsklinikum Heidelberg, Hautklinik, Heidelberg, Germany*

Purpose/Objective: The tissue bank for inflammatory diseases (GEZEH) in Heidelberg, Germany, was founded in 2011 by the Institute of Pathology and the Department of Dermatology as a section of the Sonderforschungsbereich 938. It is a nonprofit organization with a completely evaluated legal and ethical framework and is embedded in the Biomaterial Bank Heidelberg (BMBH) concept. Its main aim is the acquisition and characterization of fresh-frozen and paraffin-embedded non-neoplastic human tissues according to the standards of good scientific practice and the promotion of interdisciplinary translational immunology research of the Sonderforschungsbereich and its cooperating partners.
Materials and methods: It also offers expert project assistance: a project leader can submit a short proposal, and the tissue collecting/preparing process will be performed in cooperation with a specialised pathologist and, if applicable, an experienced clinical researcher.
Results: The tissue bank, in cooperation with the tissue bank of the National Centre for Tumour Diseases (NCT) in Heidelberg is also a central platform for further developing of innovative technologies for tissue handling, e.g. multi-tissue-array and virtual microscopy, with links to digital image analysis and bioinformatics.

Conclusions: Thus, the GEZEH tissue bank represents a model for innovative biobanking and for institutions with active interdisciplinary translational immunology research.

Use of biomarkers in milk for monitoring the systemic health status in Holstein dairy cows

K. Zoldan,* T. Möllmer,† C. Füldner,* J. Knauer,* S. Pache‡ & J. Lehmann*

**Cell Engineering/GLP, Fraunhofer Institute for Cell Therapy and Immunology, Leipzig, Germany, †Sächsisches Landesamt für Landwirtschaft Umwelt und Geologie, Referat 91/Tierzucht, Köllitsch, Germany, ‡Sächsisches Landesamt für Landwirtschaft Umwelt und Geologie, Referat 92/Tierhaltung Fütterung, Köllitsch, Germany*

Purpose/Objective: During peripartum immunosuppression and early lactation, dairy cows show increased susceptibility for local and systemic infections. These infections impair animal health and the economic efficiency of dairy farms. Thus, long-term maintenance of health is a basic requirement for successful herd management. The objective of this study is to detect immunological markers in milk which are indicative of the overall health status and to develop an immunoassay for marker analysis in milk. Ultimately, we aim to provide an on-farm testing technology for the monitoring of herd health and estimation of the breeding value.
Materials and methods: Blood and milk samples of Holstein cows in various health conditions (healthy/no apparent infection, mastitis, extra-mammary disorder) were collected in co-operation with local dairy farms. Blood leukocyte and milk somatic cell (MSC) populations were analyzed by flow cytometry. RNA from MSC of cows with clinical mastitis (CNS, $n = 2$; *S. uberis*, $n = 4$), endometritis (score 1: $n = 4$; score 2: $n = 2$) and matched healthy controls (2*4 years, 1st or 2nd lactation, 10*100 d pp) was applied to a bovine genome Array (Affymetrix®) for transcriptome analysis. Results were validated by analyzing selected differentially expressed genes by quantitative RT-PCR and corresponding proteins by ELISA.
Results: Cows with infectious diseases had higher percentages of $CD11b^+$ granulocytes in blood and mammary gland secretions, whereas in milk from healthy cows, lymphocytes, especially $CD8^+$ T lymphocytes and epithelial cells, were the predominant cell populations. In both milk and blood, a $CD25^+/CD11b^+$ cell population was present during infections and disorders. Transcriptome analysis revealed activation of innate immune functions (i.e. TLR pathways, chemokine signalling) and differential expression of acute-phase genes (i.e. Lactoferrin, Pentraxin 3, Haptoglobin) particularly during mastitis. Furthermore, IL2RA was up-regulated during infection, confirming results from flow cytometric analysis (CD25). In particular, acute-phase proteins in milk showed discriminatory ability for mastitis and extra-mammary infections or disorders when analyzed by ELISA.
Conclusions: Our results suggest a panel of immunological markers in milk that can be used to evaluate the systemic health status of dairy herds and will be validated in further studies.

P1606

Which anti-coagulant should I use?

R. A. Smith, J. C. Bishop, G. Morgan & C. A. Thornton
Swansea University, ILS College of Medicine, Swansea, UK

Purpose/Objective: Blood for research purposes is often collected into an anticoagulant. Different anticoagulants are available and they typically interrupt the coagulation cascade by chelating calcium or inhibiting thrombin. Each anticoagulant might differentially affect cells within blood so the appropriate anticoagulant must be chosen. This study aimed to determine the effect of four anticoagulants on cell types within adult peripheral blood.
Materials and methods: Blood was taken into heparin, sodium citrate (SC), acid citrate dextrose (ACD), or ethylenediaminetetraacetic acid (EDTA). Full haematology counts and differentials were taken. Whole blood cultures were stimulated with LPS (10 ng/ml) and PHA (5 μg/ml) for 24 and 48 h, respectively. Mononuclear cells (MNC) were prepared by density gradient centrifugation and cultured under the same conditions. Cytokine levels (IL-6, IL-1β and IL-17A) in the culture supernatants were analysed.
Results: There was no significant difference between total and differential cell counts for each of the four anticoagulants although a correction for dilution by anticoagulant must be used for ACD and SC. For whole blood cultures, LPS and PHA-induced cytokine production was significantly lower in blood collected into ACD (IL-6 $P = 0.002$; IL-1β $P = 0.019$; IL-17A $P = 0.047$), SC (IL-6 $P = 0.008$; IL-1β $P = 0.015$) and EDTA (IL-6 $P = 0.002$; IL-1β $P = 0.021$; IL-17A $P = 0.044$) compared with blood collected into heparin. The choice of anticoagulant had no significant effect on cytokine levels in MNC cultures.
Conclusions: The choice of anticoagulant is an important component of experiment design; if cellular analyses are to be on whole blood then an anti-coagulant that does not chelate calcium should be chosen. As the anticoagulant is likely washed away during preparation of MNCs the choice of anticoagulant is less critical. Further investigation is needed to understand the influence of anticoagulants on cell activation.

4-1BB engineered human T-cells demonstrate enhanced function and mediate regression of established melanoma tumors

C. J. Cohen,* M. Horovitz-Fried,* R. A. Morgan,† R. Goldstein* & I. Daniel-Meshulam*
*Faculty of Life Sciences, Bar Ilan University, Ramat Gan, Israel, †NCI, Surgery Branch, Bethesda, USA

Purpose/Objective: Gene modification of T-cells for cancer immunotherapy has been shown to mediate the regression of large solid tumors in cancer patients. However, inadequate T-cell persistence and reduced reactivity may represent major factors that would limit the clinical response to those treatments. Co-stimulation can actively shape the lymphocyte response. 4-1BB (CD137) is a co-stimulatory molecule expressed on T cell surface following TCR engagement, while its ligand 4-1BBL can be found on professional antigen presenting cells, but more importantly, also on the surface of tumor cells. The role of 4-1BB/4-1BBL pathway has emerged as central in cytotoxic CD8+ responses and survival, and consequently, it is possible that its manipulation could provide us with a way to change current anti-tumor cellular therapies.
Materials and methods: Herein, we generated a producer-cell clone which retroviral supernatant yielded high levels of transduction and constitutive expression of 4-1BB in human lymphocytes and tested the anti-tumor function of 4-1BB modified T-cells.
Results: 4-1BB-transduced T-cells produced from healthy donors or from vaccinated-melanoma patients exhibited enhanced cytokine secretion and upregulation of activation markers upon co-culture with melanoma tumor lines. In addition, these cells were able to expand and proliferate at a higher rate and expressed higher levels of the anti-apoptotic molecule Bcl-xL, compared to control cells. These cells were also rather insensitive to immunosuppression mediated by TGFβ. Finally, we tested the function of these cells in a CAM-based model of human melanoma tumors and we showed that 4-1BB-engineered human T-cells can mediate regression of established tumors.
Conclusions: Overall, we conclude that the modification of human T-cells with 4-1BB yields improved anti-tumor function which may apply to the genetic modification of cancer patient lymphocytes.

Abrogation with AB serum of TCR-independent streptamer and pentamer binding interactions: improving the identification of virus-specific CD8+ cells by multimer technology

L. Beloki,* N. Ramirez,* M. Ciaurriz* & E. Olavarria†
*Onco-Haematology, Biomedical Research Center (CIB), Pamplona, Spain, †Haematology, Complejo Hospitalario de Navarra Biomedical Research Center (CIB), Pamplona, Spain

Purpose/Objective: Multimeric MHC class I-peptide complex-based methodologies have shown promising results in the identification and selection of antigen-specific cytotoxic ($CD8^+$) T-lymphocytes.

Non-specific interaction of multimers to $CD8^-$ cells has been observed by several authors, overestimating specific-T cell quantification and contaminating the selected therapeutic cellular product by un-desired cellular lineages.

The aim of this study was to assess the use of human AB (HAB) serum as a method for blocking the non-specific binding of Pentamer (PM) and Streptamer (ST) multimers.
Materials and methods: *FcR blockade with human AB serum*: Peripheral blood mononuclear cells (PBMC) were isolated from peripheral blood of 20 HLA-A*0201 healthy donors seropositive for CMV. 1×10^6 cells were incubated with HAB serum for 10 min at room temperature (RT).

Multimer and monoclonal antibody (mAb) staining: 0.75 mg PE-labelled Strep-Tactin and 0.5 mg HLA-A*0201/STpp65$_{495-503}$ were mixed. 0.2 mg ST complex and 5 ml of HLA-A*0201/PMpp65$_{495-503}$ were incubated with PBMC for 45 min at 4°C and 10 min at RT, respectively. After multimeric staining, anti-human pan-T, CD8, CD14 and CD19 mAb were added. 500000 cells were acquired in a FACSCanto II equipment. Wilcoxon signed-rank and Mann-Whitney tests were used for statistical analysis.
Results: Multimer-positive cells are likely to represent cross-contamination by cells lacking a pp65-specific TCR, as the detected median frequency of total PM/ST-positive cells is higher than the frequency of CMV-specific $CD8^+$ cells. The cells that bind non-specifically to multimers have been identified as $CD19^+$ and $CD14^+$.

After the blockade with HAB serum, we have observed that the frequency of CMV-specific $CD8^+$ cells remains stable, while the overall frequency of multimer-positive cells was reduced significantly ($P = 0.035$ for PM and $P = 0.004$ for ST). A significant reduction of the frequency of multimer-positive $CD8^-$ cells ($P = 0.045$ for PM and $P < 0.01$ for ST) was also observed. Thus, the ability of HAB to significantly reduce non-specific binding to PM is similar to that of ST ($Z = -0.89$, $P = 0.371$).
Conclusions: TCR-independent unwanted binding between multimeric complexes and non $CD8^+$ cells can be efficiently suppressed by the incubation of the PBMCs with HAB serum.

P1610

Adoptive transfer of immature dendritic cells prevents progression of established atherosclerosis in LDLr KO mice

K. L. L. Habets,* V. Frodermann,* G. H. M. van Puijvelde,* Y. Zhao,* P. A. M. Habets,† M. ter Borg,* M. Van Eck* & J. Kuiper*
*Biopharmaceutics, Leiden Amsterdam Center for Drug Research, Leiden University, Leiden, Netherlands, †Department of Psychiatry and Psychology, School for Mental Health and Neuroscience, European Graduate School of Neuroscience, Maastricht University Medical Centre, Maastricht, Netherlands

Purpose/Objective: Dendritic cells (DCs) have the unique capacity to both initiate and regulate the immune response. Due to these properties, DCs have been used as immunotherapy in many different models for autoimmune diseases. In the present study we explored the possibility to use immature DCs (ImDCs) as a therapy in a mouse model for established atherosclerosis.
Materials and methods: Male LDL receptor knockout mice were put on a Western-type diet (WTD) for 20 weeks to induce established atherosclerosis. At this time point the baseline group was sacrificed. Remaining mice received 3 i.v. injections ImDCs or PBS (1.5×10^6 cells in 100 μl PBS) and were kept on WTD for an additional 10 weeks. After a total of 30 weeks on diet, mice were sacrificed.
Results: Plaque area analysis showed that treatment with ImDCs prevented lesion progression at major sites throughout the vasculature. We hypothesized that high cholesterol levels present in the circulation of LDL receptor knockout mice could alter the status of the DCs into a tolerogenic phenotype. Indeed, a tolerogenic semi-mature phenotype was observed *in vitro* after cholesterol loading of ImDCs in the presence of hypercholesterolemic mouse serum and lipoproteins isolated from hypercholesteremic serum. More importantly, loading of ImDCs with lipoproteins reduced the capacity to induce antigen-specific proliferation. Also *in vivo*, a semi-mature tolerogenic phenotype was observed after the adoptive transfer of GFP^+ ImDCs into hypercholestermic LDL receptor knockout mice. Furthermore, treatment with ImDCs increased Foxp3 and TGF-β mRNA expression in

lymph nodes and increased the number of atheroprotective regulatory T cells in blood and lymph nodes. Finally, treatment lowered the lesional inflammatory status as indicated by decreased $CD3^+$ T cell infiltration and reduced necrotic core size.
Conclusions: Cholesterol loading of ImDCs induces a semi-mature tolerogenic phenotype both *in vitro* and *in vivo* with reduced capacity to induce specific T cell responses. These tolerogenic DCs exert atheroprotective functions leading to prevention of plaque progression in a model for established atherosclerosis.

P1611
Amelioration of ulcerative colitis and colorectal cancer by adoptive transfer of antigen-redirected regulatory T-cells

D. Blat, T. Waks & Z. Eshhar
Immunology, The Weizmann Institute of Science, Rehovot, Israel

Purpose/Objective: The goal of this study was to examine whether antigen-redirected regulatory T-cells (Tregs) can be engineered to suppress ulcerative colitis and its associated colorectal tumors. To this end we combined the advantages of the T-body approach, which endows T-cells with antibody-type specificity, with the immunosuppressive activity of Tregs. Based on the elevated carcinoembryonic antigen (CEA) levels in the epithelia of colitis patients, we employed a model system of CEA transgenic mice and demonstrated the therapeutic potential of CEA-specific Treg T-bodies.
Materials and methods: A CEA-specific chimeric antigen receptor (CAR) was introduced *ex vivo* into isolated naïve Tregs by retroviral transduction. The CEA-specific Treg T-bodies were then adoptively-transferred into CEA transgenic mice inflicted with colitis. Two disease models were employed: the azoxymethane-dextran sodium sulfate (AOM-DSS) model for colitis and colorectal cancer, as well as T-cell induced colitis model. Colitis severity and tumor progression were monitored by endoscopic examination in live animals.
Results: Mice treated with CEA-specific Treg T-bodies showed a marked reduction in colitis severity, this in comparison to mice treated with control Treg T-bodies of irrelevant specificity. Moreover, in the AOM-DSS model CEA-specific Treg T-bodies significantly decreased the subsequent colorectal tumor burden.
Conclusions: CEA-specific Treg T-bodies showed a promising potential in ameliorating ulcerative colitis and in hindering tumor development in mice.

P1612
Analysis of Ly6ChighCD11b+ monocytes generated *in vitro* in inflammatory animal models

E. Barboza, C. Rincón, I. Hirako, L. F. Santamaria-Babi & A. Celada
Molecular Medicine, Biomedical Research Institute (IRB), Universitat de Barcelona, Barcelona, Spain

Purpose/Objective: Circulating monocytes provide defense against infections and also contribute to autoimmune diseases. Two types of blood monocytes were recently identified in mice. Ly-$6C^{low}CD11b^+$ phenotype migrate to uninjured tissues and differentiate into resident macrophages and dendritic cells (DCs). In contrast, a distinct inflamed monocyte subset with a Ly-$6C^{high}CD11b^+$ phenotype infiltrates infected tissue and contributes to the development of inflammation. Ly-$6C^{hi}$ monocytes, the aim of our work, represent 2–5% of whole monocytes presents in the bloodstream of mice. Since the Ly-$6C^{high}CD11b^+$ monocytes, are difficult to obtain, from mouse blood and the amount obtained is very low, our group developed a novel system to generate them *in vitro* from mice bone marrow.

Our goal in this study is to determine the function *in vivo* of Ly-$6C^{high}CD11b^+$ monocytes, in two animal models of inflammation.

Materials and methods: Cells were sorted in order to obtain Ly-$6C^{high}CD11b^+$ monocytes that display the phenotype as described in cells obtained from the blood flow, Ly-$6C^+$, $CD62L^+$, $CCR2^+$, $CD11b^+$, $F4/80^+$. These cells could be activated *in vitro* producing M1 or M2 cytokines when activated with IFN-γ or IL-4, respectively.

The following step was to inject these sorted cells intra venous (i.v) in both animal models. To analyze the migration capacity, we used two different animal models to induce local inflammation in non-sensitizied, immunocompetent Balb/c mice. In the first model, 1-fluoro-2,4-dinitrobenzene (DNFB) was applied topically on the mouse right ear to create skin-homing conditions (DNFB skin model), in the second model, an injection of Notexin was applied into the anterior tibialis (AT) on the mouse right leg to induce myoinjury (Notexin model). This toxin can lead to myoinjury and muscle necrosis.
Results: In both models local inflammation increased depending on the number of injected Ly-$6C^{high}CD11b^+$ cells. Cell migration was analyzed by *in vivo* imaging, where fluorescent Ly-$6C^{high}CD11b^+$ cells were present only in inflamed tissue. Haematoxylin & Eosin analysis demonstrate a tissue improvement of animals treated with Ly6-$C^{high}CD11b^+$ monocytes.
Conclusions: In conclusion, our data demonstrate that we generate high amounts of Ly$6C^{high}CD11b^+$ monocytes *in vitro* with phenotypical plasticity, able to migrate to inflamed tissues *in vivo*.

P1615
Comparison of different protocols for the generation of monocytes-derived tolerogenic dendritic cells for immunotherapy

R. Volchenkov, M. Karlsen, R. Jonsson & S. Appel
Broegelmann Research Laboratory, The Gade Institute, Bergen, Norway

Purpose/Objective: Therapeutic vaccination with tolerogenic dendritic cells (tolDC) has been shown to be a promising treatment in experimental models of autoimmune diseases. In this study we compared three different protocols for the generation of tolDC.
Materials and methods: We analyzed and compared the effects of PPAR-gamma agonist troglitazone (TGZ-DC), NF-kappaB inhibitor BAY11-7082 (BAY-DC) and a combination of dexamethasone and 1alpha,25-dihydroxyvitamin D3 (DexVD3-DC) during the generation of monocyte-derived DC regarding their phenotype, cytokine secretion and T cell stimulatory capacity.
Results: TGZ-DC and BAY-DC had a phenotype comparable to immature DC, while DexVD3-DC were more macrophage-like. Upon LPS stimulation, all DC populations had increased surface expression of MHC class II molecules and, except DexVD3-DC, also the co-stimulatory molecules CD86 and CD40. DexVD3-DC showed the highest expression of PD-L2 and co-stimulatory molecule CD80. Analysis of cytokine production using cell culture supernatants from all DC populations revealed that DexVD3-DC were the only cells not producing IL-12p70 upon LPS stimulation. IL-10 was produced by all unstimulated DC populations at a similar level. After LPS stimulation, DexVD3-DC produced the highest amounts of IL-10. To analyze the T cell stimulatory capacity of the different DC populations, the cells were co-cultured with autologous T cells using purified protein derivative (PPD) tuberculin as recall antigen. T cells co-cultured with DexVD3-DC proliferated the least.
Conclusions: DexVD3-DC have the best potential to be used in a tolerogenic dendritic cell-based immunotherapy for autoimmune diseases.

Dendritic cells in multiple sclerosis: key players in the immune pathogenesis, key players for new cellular immunotherapies

N. Cools,* A. H. Nuyts,* W. P. Lee,* N. Deckx,* P. Cras,† B. Willekens,† G. Nagels,‡ M. B. D'hooghe‡ & Z. N. Berneman*
Lab of Experimental Hematology, Antwerp University Hospital, Antwerp, Belgium, †Division of Neurology, Antwerp University Hospital, Antwerp, Belgium, ‡Division of Neurology, National Center for Multiple Sclerosis, Antwerp, Belgium

Purpose/Objective: Much has been done to understand the pathogenesis of multiple sclerosis (MS). Whereas several studies have focused on the role of the adaptive immune system in the disease pathogenesis of MS, recent data suggest that dendritic cells (DC), which are innate immune cells, also contribute to the pathogenesis of MS. Due to their specialized antigen-presenting capacity, DC play an important role in polarizing the T cell response, thereby regulating the balance between immunity and tolerance.
Materials and methods: DC were generated *in vitro* from circulating monocytes of MS patients and healthy controls. Subsequently, phenotype, cytokine profile and T cell stimulatory capacity were investigated. Additionally, DC were exposed to pro-inflammatory signals to address their maturation-resistant phenotype.
Results: Our recent observations indicate that both circulating as well as *in vitro* generated DC of MS patients display an altered phenotype and function as compared to age- and gender-matched healthy controls, thereby influencing the effector function of T cells. Of interest, we also demonstrate that migratory patterns of DC in MS are altered, as evidenced by aberrant expression of migratory molecules, i.e. CD62L, CCR5 and CCR7, by DC of MS patients as compared to healthy controls. Furthermore, current immune-modulating therapies affect DC phenotype and function, hence underscoring their pivotal role in MS pathogenesis. In light of these observations, we subsequently aimed to modulate DC function in order to restore the immunological imbalance in MS. We demonstrated that treatment of DC with immunomodulatory cytokines (such as IL-10) results in a more stable tolerogenic DC phenotype. Indeed, modulation of DC by IL-10 treatment arrests DC in a semi-mature state and prevents the up-regulation of costimulatory molecules as well as the secretion of pro-inflammatory cytokines. Moreover, we deliver proof-of-principle that tolerogenic DC generated from MS patients are capable of suppressing myelin-specific T cell responses.
Conclusions: From the results of this study, it can be envisaged that we have provided the first step in the development of a new form of immunotherapy for the treatment of MS.

P1617

Functional modulation of human CD_4^+ T cells by polyclonal stimulation with a CD28 superagonist *in vitro*

N. Beyersdorf,* T. Bedke,† S. Wener,* N. Wolf,* M. Dümig,‡ S. Krappmann,‡ M. Topp,† T. Hünig* & T. Kerkau*
Chair for Immunology, Institute for Virology and Immunobiology, Würzburg, Germany, †II Division of Hematology, Department of Internal Medicine, University Hospital Würzburg, Würzburg, Germany, ‡Junior Research Group, Research Center for Infectious Diseases, Würzburg, Germany

Purpose/Objective: Adoptive transfer of $CD4^+$ T cells plays a central role in many cell-based immunotherapies of which allogeneic bone marrow transplantations are probably the most successful. While the infusion of mature T cells offers the only chance of cure for many hematological malignancies it is also associated with Graft-versus-Host-Disease (GvHD) * a potentially lethal side effect. The pre-conditioning of the transplant recipients, however, also predisposes them to opportunistic infections like invasive aspergillosis. Therefore, novel therapeutic approaches for GvHD should prevent immunopathology while maintaining anti-infectious activity of the transferred T cells.
Materials and methods: Building on our own data generated in a pre-clinical mouse model of acute GvHD in which polyclonal stimulation of allogeneic T cells with a superagonistic anti-CD28 mAb *in vitro* prior to transplantation into allogeneic hosts *in vivo* protected from GvHD we now polyclonally stimulated human peripheral blood mononuclear cells (PBMC) either by anti-CD3 and anti-CD28 mAb-mediated co-stimulation or with a CD28-SA – both in the presence of recombinant human interleukin-2 (IL-2).
Results: While co-stimulation expanded $CD4^+$ and $CD8^+$ T cells, CD28-SA stimulation only drove proliferation of $CD4^+$ T cells. Both protocols, however, did not expand all $CD4^+$ T cell subsets equally but preferentially stimulated $CD45RA^-$ $CD25^-$ and $CD45RA^-$ $CD25^{low}$ memory cells as well as $CD45RA^+$ $CD25^{low}$ resting T_{reg} cells over $CD45RA^+$ $CD25^-$ naïve conventional T cells and $CD45RA^-$ $CD25^{high}$ effector T_{reg} cells. CD28-SA-expanded $CD4^+$ T cells differed from co-stimulated $CD4^+$ T cells as CD28-SA pre-stimulation was superior to co-stimulation in reducing allo-responsiveness of the $CD4^+$ T cells. Proliferation of memory $CD4^+$ T cells to recall antigens, including antigens of *Aspergillus fumigatus*, was, however, less affected by CD28-SA-mediated pre-activation. Cytokine skewing from IFNg towards IL-17 production further suggests induction of enhanced innate responses against *A. fumigatus* by CD28-SA-stimulated $CD4^+$ T cells.
Conclusions: Therefore, polyclonal stimulation of human $CD4^+$ T cells with a CD28-SA *in vitro* might reduce the risk of developing GvHD while maintaining the anti-infectious activity of the transferred T cells *in vivo*. This study was supported by BayImmuNet and by TheraMAB GmbH.

Generating human stem cell like central memory type EBV-specific $CD8^+$ T lymphocytes for effective and sustained cellular adoptive immunotherapy

Y. Xu, A. Mades, S. A. Khan, M. Theobald & U. F. Hartwig
III Department of Medicine – Hematology Intenistic Oncology & Pneumology, University Medical Center of the Johannes Gutenberg University of Mainz, Mainz, Germany

Purpose/Objective: Adoptive transfer of *in vitro* generated tumor- and virus-reactive T cells has evolved as a promising strategy in cellular immunotherapy to treat cancer and virus-associated malignancies such as Epstein-Barr Virus (EBV)-mediated post-transplantat lymphoproliferative disease observed after allogeneic hematopoietic stem cell transplantation. However, terminally differentiated, high avidity effector T cells (T_{EM}) exhibit limited homing and self-renewal capacity to establish sustained memory. In this study we thus explored the modulation of the canonical Wnt-signaling pathway previously shown to affect T cell differentiation to generate stem-cell like central memory-type (T_{SCM}), HLA-A*0201 restricted EBV-specific T cells.
Materials and methods: Naive $CD8^+$ T cells isolated from PBMC of HLA-A*0201 positive healthy donors using the *Naive CD8$^+$ T-Cell Isolation Kit* (Miltenyi Biotec) were repetitively stimulated with EBV-peptides (LMP2, BRLF1, BMLF1) presented first by autologous dendritic cells followed by $HLA\text{-}A2^+$ T2 cells or autologous EBV-transformed B cells (B-LCL) in the presence of the interleukins (IL)-2, -7, -15, -21 and the glycogen synthase kinase-3β (Gsk-3β) inhibitor TWS119 for 4 weeks. Phenotypic and functional analysis were performed by flow cytometry and IFN-γ ELISpot assay, respectively, at different time points of culture.
Results: Upon repetitive stimulation we obtained strong expansion of EBV-specific cytotoxic T lymphocytes (CTL) after 21–28 days of culture. These T cells expressed a recently described $CD8^+CD45RA^+CD45RO^-CD95^+CD27^+CD28^+CD62L^+$ $CCR7^+$ T_{SCM} phenotype when compared to CTL stimulated without inhibitor. First molecular studies

revealed elevated §-catenin levels suggesting a Tcf-7 mediated transcriptional effect on T cell differentiation. Interestingly, both TWS119 treated and control CTL populations elicited comparable reactivity against B-LCL *in vitro* as shown by IFN-γ secretion. Upon adoptive transfer in immunodeficient and IL-15 supplemented NSG mice EBV-reactive T_{SCM} showed prolonged engraftment. Further *in vivo* analyses on the cytolytic activity of the T_{SCM} EBV-CTL are in progress using NSG mice inoculated with B-LCL prior to adoptive T cell transfer.

Conclusions: In conclusion, this study demonstrates that T_{SCM} EBV-reactive CTLs with increased homing and self-renewal capacity can be generated from naïve T cells by modulating Wnt-signaling for improved immunotherapy.

P1621

Human adipose-derived stem cells exhibit a low susceptibility to NK cell-mediated lysis and inhibit their function

O. D. Rosa,* B. Sanchez-Correa,† S. S. Mateos,† S. Morgado,† C. Ramirez,* B. D. Rio,* R. Menta,* E. Lombardo,* R. Tarazona† & J. G. Casado‡

**Research and Development, Tigenix S.A. Tres Cantos, Madrid, Spain, †Immunology Unit, University of Extremadura, Caceres, Spain, ‡Stem Cell Therapy Unit, Minimally Invasive Surgery Centre, Caceres, Spain*

Purpose/Objective: Mesenchymal stem cells (MSCs) have potent immunomodulatory capacities representing an interesting tool for cellular therapy. Although their interactions with Natural Killer (NK) cells have been previously studied in bone marrow-derived (BM)-MSCs, little information is available regarding adipose-derived MSCs (ASCs). To better understand hASCs-host interactions, we have studied the phenotype of hASCs and their capacity to regulate NK cell function.

Materials and methods: The hASCs were isolated from human lipoaspirates obtained after informed consent under the auspices of the appropriate Research and Ethics Committees. BM-MSCs were used as an MSC reference cell source. Phenotypic analysis of MSCs was done by flow cytometry. Purified NK cells were assayed for degranulation and IFN-γ assays or tested in co-culture experiments. Indoleamine 2,3-dioxygenase (IDO) activity was measured by determining both tryptophan and Kynurenine concentrations in supernatants from co-cultures of NK cells with hASCs.

Results: The hASCs displayed a lower susceptibility to NK cell-mediated lysis and a lower expression of ligands for DNAM-1 when compared with hBM-MSCs. NK cells produce IFN-γ in response to hASCs and hBM-MSCs. We demonstrated that hASCs and hBM-MSCs decrease NK cell degranulation against the susceptible target cells K562 through the action of soluble factors such as IDO.

Conclusions: Our *in vitro* results demonstrate that hASCs may display optimal characteristics for adoptive cell therapy in an allogeneic setting. We suggest that hASCs induction of NK cell tolerance can be mediated by soluble factors. Thus, the IFN-γ secreted by NK cells during NK/MSCs crosstalk may induce IDO expression that may exert effect in the immunosuppressive activity. These results suggest that for an adoptive cell therapy using allogeneic hASCs, the NK-hASCs crosstalk will not result in an immediate elimination of the transferred cells. Thus, hASCs may remain in the tissue long enough to balance the immune response before being cleared.

P1622

Human MSC support activated CD19+ B cell expansion: identifying cell contact dependent mechanisms

M. Healy & B. P. Mahon

Biology, National University of Ireland Maynooth, Kildare, Ireland

Purpose/Objective: In order to develop, improve and license successful Mesenchymal stromal cell (MSC) therapy, it is essential to understand how transplanted MSC will interact with the host immune system. The immune-suppressive nature of MSC has been extensively characterised on human T cells and dendritic cells but the interaction between B cells and MSC remains controversial. This study characterised the effect of human bone marrow derived MSC on the activation and proliferation on allogeneic B cells isolated from healthy adult human donors.

Materials and methods: CD19+ B cells were isolated from PBMC using MACS beads. CD19+ B cells were activated with rhCD40L and CpG in the presence of pro-B cell cytokines IL-2, IL-21 and IL-10, for co-culture with human MSC. B cell activation was measured using flow cytometry (surface expression of activation markers) and real time PCR. B cell proliferation was determined using CFSE analysis.

Results: In the presence of MSC, the expression of CD69 and other markers by B cells was increased. MSC also significantly increased the expansion of CD19+ B cells, as illustrated by CFSE. MSC significantly increased the numbers of B cells entering first cell division, as well as the numbers undergoing extensive divisions (>5). This effect was dependent on direct MSC * B cell contact as shown using trans-well systems in co-culture assays. Preliminary data on candidate contact signals will be presented.

Conclusions: These results suggest that allogeneic human bone marrow derived MSC enhanced the activation and proliferation of CD19+ B cell populations *in vitro* through a contact dependent mechanism, and may limit the utility of MSC therapy for autoimmune or idiopathic conditions with a major B cell contribution to pathology such as SLE.

P1623

Induction of allo-specific IL-10-producing T cells by lentiviral vector-mediated IL-10 gene transfer

G. Locafaro, G. Andolfi, M. G. Roncarolo & S. Gregori

Department of Regenerative Medicine Stem Cells and Gene Therapy, San Raffaele Telethon Institute for Gene Therapy, Milano, Italy

Purpose/Objective: Type 1 regulatory T (Tr1) cells are a subset of $CD4^+$ regulatory T cells (Tregs) induced in the periphery characterized by high levels of IL-10 production and regulatory activity. During the last decade, Tregs cell-based therapy has become an attractive non-pharmacological therapeutic option for immunomodulation in different pathological settings. Although, several protocols to generate human Tr1 cells have been developed *in vitro*, the resulting population includes a significant fraction of contaminating non-Tr1 cells, representing a major drawback for clinical application of Tr1 cell therapy. To overcome this limitation we developed a lentiviral vector (LV) encoding for human IL-10 (LV-IL-10) and we demonstrated that enforced LV-IL-10-mediated expression confers Tr1 phenotype and function to human polyclonal $CD4^+$ T cells. In the present study we applied the LV-IL-10 platform for generating antigen-specific human Tr1 cells suitable for cell therapy.

Materials and methods: Human $CD4^+$ T cells were stimulated with allogeneic *in vitro* differentiated DC and activated T cells have been isolated based on the co-expression of early T cell activation markers. FACS-sorted T cells were expanded *in vitro* with IL-2 and transduced with LV co-encoding IL-10 and the marker gene, DNGFR. Resulting IL-10 engineered T cells were functionally characterized.

Results: The co-expression of early T cell activation markers allowed the selection of allo-specific T cells upon *in vitro* re-activation. FACS-sorted T cells can be easily transduced with LV-IL-10 and selected $DNGFR^+$ IL-10-transduced $CD4^+$ T cells expressed, upon allo-specific stimulation, high levels of IL-10, and are anergic. We are currently investigating whether IL-10 engineered T cells acquired suppressive activity.

Conclusions: We develop a suitable method to generate allo-specific IL-10 engineered T cells. These results represent the first step for the

development of antigen-specific IL-10-producing T cells and will contribute to increase the success of Tr1-based immunotherapy, inducing tolerance to selected antigens, while minimizing general immune suppression.

P1624

Lack of long pentraxin 3 (PTX3) in bone marrow-derived mesenchymal stem cells impairs wound healing in mouse

C. Cappuzzello,* A. Doni,† E. Dander,* F. Pasqualini,† M. Nebuloni,‡ B. Bottazzi,† A. Mantovani,† A. Biondi,§ C. Garlanda† & G. D'Amico*

**Research Center "M. Tettamanti", Università Milano-Bicocca, Monza, MB, Italy, †Istituto Clinico Humanitas, Istituto di Ricovero e Cura a Carattere Scientifico, Rozzano, MI, Italy, ‡Pathology Unit L. Sacco, Department of Clinical Sciences, L. Sacco Hospital Università degli Studi di Milano, Milan, MI, Italy, §Research Center "M. Tettamanti", Clinica Pediatrica Università Milano-Bicocca Ospedale San Gerardo, Monza, MB, Italy*

Purpose/Objective: Although several studies have shown the capacity of mesenchymal stem cells (MSCs) to repair and regenerate different tissues, the mechanisms underlying these processes are not understood. In the present study we analyzed the role of the long pentraxin 3 (PTX3) in enhancing the wound closure. PTX3 is a multifunctional protein produced by MSCs after activation with inflammatory cytokines, which is involved in innate immunity, inflammation and extracellular matrix deposition.

Materials and methods: PTX3-deficient MSCs ($PTX3^{-/-}$MSCs) were collected from bone marrow of PTX3 knockout mice. After 3–5 culture passages, cells were tested for the expression of specific surface markers, their ability to differentiate into mesengenic lineages and their capacity to abrogate T cell proliferation. Finally, equal number of both $PTX3^{-/-}$ and WT MSCs were implanted into excisional wounds created by a biopsy punch on the back of allogenic WT and $PTX3^{-/-}$ mice. Wound area was measured up to 14 day and calculated using an image analysis program. The wound specimens were collected at 2, 7 and 14 days and processed for histology.

Results: By analyzing MSCs obtained from bone marrow of PTX3 knockout mice we demonstrated that, similarly to WT MSCs, $PTX3^{-/-}$MSCs displayed typical fibroblastoid morphology, were consistently devoid of contaminating hematopoietic cells and expressed common MSC markers. In addition, these cells were able to differentiate into adipocytes and osteoblasts, and drastically decreased the mitogen-induced proliferation of PBMCs, in a dose dependent manner. Importantly, in a mouse model of wound healing, $PTX3^{-/-}$MSCs showed an highly significant defect in wound closure compared to WT MSCs at each time point. Histologic evaluation of skin samples from mice treated with $PTX3^{-/-}$MSCs showed a reduction in the granulation tissue at day 7, a significant increase of polymorphonuclear cells in the wound bed and an enhancement of the fibrin deposition at the 2nd day after injury. Accordingly, $PTX3^{-/-}$MSCs also failed the ulcers closure in PTX3 knockout mice.

Conclusions: We demonstrated that PTX3 deficiency does not alter the phenotype or the capacity of MSCs to differentiate into mesengenic lineages; of relevance, the production of PTX3 represents an essential requirement for MSC ability of enhancing tissue repair.

P1625

Lentivirus-induced dendritic cells co-expressing GM-CSF, IFN-a and pp65 for boosting immunity against cytomegalovirus

A. Daenthanasanmak,* G. Salguero,* A. Schneider,* S. Borchers,* C. Figueiredo,† B. Eiz-Vesper,† A. Ganser* & R. Stripecke*

**Department of Hematology Hemostasis Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany, †Transfusion Medicine, Hannover Medical School, Hannover, Germany*

Purpose/Objective: Off the shelf vaccines such as proteins, peptides, and DNA for reducing the risks of cytomegalovirus (CMV) reactivation after hematopoietic stem cell transplantation have so far not shown major efficacy in clinical trials. One possible explanation is the underlying immune suppressed or immune dysfunctional status of the host, which might be partly alleviated with Donor Lymphocte Infusions (DLI). We are seeking to harness the effects of DLI, by providing the lymphocytes with improved homeostatic and antigenic stimulation provided by engineered induced dendritic cells (iDCs).

Materials and methods: We evaluated integrase-defective lentiviral vector (IDLV) co-expressing the differentiated cytokines GM-CSF/IFN-α in combination with CMV antigen, pp65. Overnight transduction of human monocytes with IDLV generated highly viable (>21 days) and immunophenotypically stable DCs, called Self-differentiated Myeloid derived Lentivirus-induced DC (SmyleDC).

Results: *In vitro* cultured SmyleDCs demonstrated stable secretion of GM-CSF/IFN-α and several endogenously produced inflammatory cytokines (IFN-γ, IL-2, -5, -6, -8). Expansion of multi-antigenic CMV-reactive effector and memory CTLs were obtained after a single *in vitro* re-stimulation with SmyleDCs co-expressing pp65 as evaluated by tetramer analyses and IFN-γ ELISPOT. In order to evaluate the effects of anti-CMV CTLs expansion *in vivo*, immune deficient NOD.$Rag1^{-/-}$.$IL2r\gamma^{-/-}$ (NRG) mice were immunized with SmyleDC/pp65 and, 7 days later, mice were infused with autologous $CD8^+$ T cells from a CMV seropositive donor. SmyleDCs enhanced T cell engraftment and rapid expansion of multi-antigenic pp65 reactive CTLs in peripheral blood and spleen.

Conclusions: Due to their capacity to precondition the host with a suitable homeostatic and antigenic environment prior to lymphocytes infusion, SmyleDC/pp65 is a promising immune regenerative cell product for the post-transplantation setting. Development of tricistronic lentiviral vectors and evaluation of potency and safety in humanized mouse models transplanted with human hematopoietic stem cells are ongoing for further clinical development.

P1627

Mesenchymal stromal cells isolated from bone marrow from multiple sclerosis patients reveals immunosuppressive properties

G. L. V. de Oliveira,* K. C. R. Malmegrim,* A. M. Colombini,* P. B. Palma,* D. T. Covas† & E. A. Donadi‡

**Department of Immunology, National Institute of Science and Technology in Stem Cells and Cell Therapy, University of São Paulo, Ribeirão Preto, Brazil, †Department of Clinical Medicine, National Institute of Science and Technology in Stem Cells and Cell Therapy, University of São Paulo, Ribeirão Preto, Brazil, ‡Department of Clinical Medicine, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil*

Purpose/Objective: Introduction/objective: Mesenchymal stromal cells (MSCs) have shown immunosuppressive and immunoregulatory functions. These properties of MSCs suggest their potential role in tolerance induction in autoimmune diseases. We evaluated the anti-proliferative capacity of MSCs derived from multiple sclerosis (MS) patients, their ability to induce regulatory T cells and secrete IL-10 and TGF-β *in vitro*.

Materials and methods: MSCs were derived from bone marrow aspirates from MS patients ($N = 10$) and healthy controls ($N = 10$) and isolated by plastic adherence. For the inhibition assays, peripheral blood mononuclear cells (PBMCs) were labeled with CFSE and cocultivated (1:2, 1:5 and 1:10 ratios) with patients' and controls' MSCs MSCs in the presence of PHA at 37°C in a 5% CO_2 for 5 days. For the immune-regulation assays, non-labeled PBMCs were cocultivated with patients' and controls' MSCs. After 5 days of coculture, T-cell proliferation was assessed by CFSE method and the percentage of $CD4^+CD25^{hi}Foxp3^+$ was assessed by flow cytometry. IL-10 and TGF-β was measured in coculture supernatants by CBA flex kit. The results were analyzed by Mann-Whitney *t* test. This study was approved by the local ethics committee.

Results: We observed significant differences ($P = 0.002$) in proliferation mean percentage when comparing PBMCs plus PHA (71.3 ± 12.9%) with patients' MSCs plus PBMCs at 1:2 (33.3 ± 13.4%), 1:5 (39.1 ± 21.9%) and 1:10 ratios (46.6 ± 20.1%). There were no differences ($P > 0.05$) in percentages of $CD4^+CD25^{hi}Foxp3^+$ regulatory T cells recovered after 5 days of coculture with patientsÕ MSCs compared to controls. IL-10 and TGF-β secretion were significantly decreased ($P < 0.05$) in supernatants derived from cocultures with patients' MSC (IL-10: 53.8 ± 49.4 pg/ml; TGF-β: 59.4 ± 24.6 pg/ml) compared to controls (IL-10: 109.9 ± 64.6 pg/ml; TGF-β: 226.6 ± 153.2 pg/ml).

Conclusions: Although the MSCs isolated from MS patients were able to suppress T-cell proliferation, they showed lower secretion of IL-10 and TGF-β cytokines. These data suggest that MSCs from MS patients have immunosuppressive capacity *in vitro*, however more studies should be conducted before their use in autologous clinical applications.

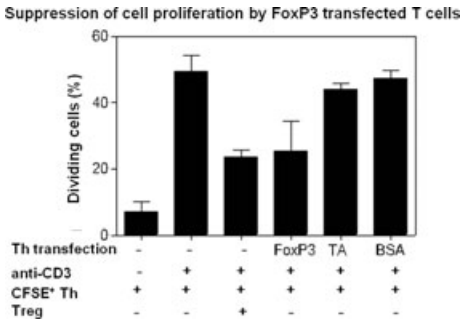
P1628

Modulation of helper T cell responses using recombinant FoxP3 transfection

A. Virksaite, S. Zigmantas & L. Zaliauskiene
Fermentas UAB, R&D, Vilnius, Lithuania

Purpose/Objective: Cationic polymer based transfection reagents are widely used as non-viral gene delivery vectors. The goal was to investigate if cationic polymers could be adapted for protein transport as well. Recombinant FoxP3 was chosen as a model protein for transfection into $CD4^+CD25^-$ T cells and potential induction of regulatory T cell phenotype and function.

Materials and methods: Full length FoxP3 gene was amplified by RT-PCR from cDNA of Balb/C mouse $CD4^+CD25^+$ cells. Protein was expressed in *E. coli* ER2566 strain and purified by affinity chromatography under denaturing conditions; activity was confirmed by EMSA. Mouse $CD4^+CD25^-$ T cells were transfected with recombinant FoxP3 using cationic polymer as transfection reagent. Protein localization after transfection was assessed by Western blot. T cell suppression was evaluated based on CFSE stained $CD4^+CD25^-$ T cell proliferation 72 h after activation with anti-CD3, ELISA assay was performed to monitor IL-2 levels in the culture medium.



Results: Recombinant FoxP3 was found in the nucleus 3 h after transfection. Transfected $CD4^+CD25^-$ T cells were able to suppress CFSE labeled $CD4^+CD25^-$ T cell proliferation to a similar extent as natural regulatory T cells (Fig). IL-2 secretion was blocked as well; however, this effect was highly dependent on FoxP3 transfection efficiency.

Conclusions: Cationic polymer can deliver functional FoxP3 protein and exert regulatory T cell phenotype to $CD4^+CD25^-$ T cells.

P1629

Optimization for contact time dependent effect of human mesenchymal stem cells on the CD_4 effector memory T cells

M. Kim,* H. Jeong,† W. Wee* & W. Lee‡
**Department of Ophthalmology, Seoul National University College of Medicine, Seoul, Korea, †Laboratory of Corneal Regenerative Medicine and Ocular Immunology, Seoul Artificial Eye Center, Seoul National University Hospital Clinical Research Institute, Seoul, Korea, ‡Department of Microbiology and Immunology, Seoul National University College of Medicine, Seoul, Korea*

Purpose/Objective: Mesenchymal stem cells (MSCs) have been known to have anti-inflammatory properties in various inflammatory diseases. However, the reported effects of MSCs on inflammation highly vary, which is partly attributed to the lack of standardized analysis. This study was aimed at analyzing contact time-dependent effects of human mesenchymal stem cells (hMSCs) on IL-17 and IFN-γ secretion by CD4+ effector memory T cells for the optimization.

Materials and methods: Bone marrow-derived hMSCs were co-cultured with human CD4+ T cells at a MSC:T cell ratio of 1:10. The suppressive effects of MSCs were evaluated by assessing their effects on the proliferation of CD4+ T cells by carboxyfluorescein diacetate succinimidyl ester (CFSE) stainingand the secretion of IFN-γ and IL-17A by CD 4+ memory T cells at different time points of contact and culture duration. The levels of IL-17 and IFN-g were determined in supernatants from the co-culture using commercial kits for enzyme-linked immunosorbent assay (ELISA).

Results: An earlier contact point between hMSCs and CD4+ T cells resulted in a greater suppressive effect on proliferation andboth IFN-γ and IL-17A secretionin an indoleamine 2,3-dioxygenase (IDO)-independent manner. While, a later contact point time of hMSCs to activated T cells after 3 days or longer and duration more than 4 days dropped most suppressive effect of hMSCs down on effector memory CD4 T cells.

Conclusions: Our study demonstrated that an earlier initial contact time, prior to the fully activated state of T cells, enhances the suppressive effects of hMSCs on effector memory CD4+ T cells. It also suggests that identifying an appropriate therapeutic window time would be critical in clinical trials with hMSC therapy for inflammatory disease.

Phenotypical/functional characterization of *in vitro*-expanded multipotent mesenchymal stromal cells from patients with type 1 diabetes

J. N. U. Yaochite,* K. C. R. Malmegrim,† K. A. Lima,* K. L. Prata,† R. M. F. Bolzoni,† P. V. B. Palma,† D. T. Covas† & J. C. Voltarelli†
**Basic and Applied Immunology, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, †Regional Hemotherapy Center, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil*

Purpose/Objective: Mesenchymal stromal cells (MSCs) are progenitor cells with capacity to modulate the immune response, migrate to injury

site and promote tissue repair, thus representing a potential treatment for autoimmune/inflammatory diseases. However, it is not established whether MSCs have functional impairments in type 1 diabetes (T1D) setting. The objective of this study was to evaluate and compare phenotypical and functional characteristics from T1D-MSCs with control-MSCs for future clinical applications.

Materials and methods: MSCs cultures were derived from bone marrow aspirates of healthy controls (control-MSCs) and newly diagnosed T1D-patients (T1D-MSCs). T1D-MSCs were characterized using the following characteristics: morphology, circularity average (ViCell-XR® analyzer), expression of cell surface antigens (flow cytometry), adipogenic differentiation capacity (*in vitro* assay), gene expression profile by microarray analyses (Agilent Technologies) and migration capacity (*in vitro* assay). Results were compared with those of control-MSCs.

Results: MSC derived from T1D patients showed typical spindle-shaped morphology. The presence of surface markers (CD45, CD90, CD105, CD73, HLA-II) and cell circularity average (16.41 ± 0.69 μm T1D-MSCs × 15.91 ± 0.59 μm control-MSCs) did not differ from control-MSCs. T1D-MSCs exhibited the same differentiation potential towards the adipogenic lineage when compared to control-MSCs. Gene expression analyses reveled about 2978 differentially expressed genes ($P < 0.05$, fold change: 2). We observed an up-regulation of chemokine receptors genes (CCR3, CXCR5) and down-regulation of genes related with focal adhesion in T1D-MSCs. According to these results, MSCs from T1D-patients exhibit higher capacity to migrate through an 8μm membrane pore using 50% FBS as chemoattraent (786.1 ± 106.8 cells T1D-MSCs × 385.8 ± 61.02 cells control-MSCs, $P = 0.006$).

Conclusions: MSCs from T1D-patients exhibit the same morphological, immunophenotype properties and adipogenic differentiation potential as their healthy counterparts. On the other hand, T1D-MSCs exhibited differences in the gene expression profile and also a higher ability to migrate than control-MSCs. Further studies are needed to investigate the immunomodulatory/regenerative features of T1D-MSCs prior to their potential use in clinical trials.

P1631

Role of interferon-gamma in the activation of mesenchymal stem cells: analysis in a model of acute kidney injury

P. B. Costa,* M. B. Silva,* P. Semedo,* M. A. Reis,† A. P. Silva‡ & N. O. S. Camara§

**Medicine, Federal University of Sao Paulo, São Paulo, Brazil,* †*Pathology, Federal University of Triangulo Mineiro, Uberada, Brazil,* ‡*Education and Research Institute, Albert Einstein Hospital, São Paulo, Brazil,* §*Immunology, University of São Paulo, São Paulo, Brazil*

Purpose/Objective: The stem cell therapy is flourishingas an alternative to acute kidney injury (AKI). It is known that in the lesion environment, pro-inflammatory cytokines, such as TNFα and IFNγ, activate the therapeutic role of MSCs. However little is known about this mechanism. This study assesses the role of IFNγ in the activation of MSC regenerative properties in acute renal models.

Materials and methods: MSC from IFNγ receptor knockout animals (IFNγR KO) and from wild type animals (WT C57/Bl6) were isolated from adipose tissue. After isolation and its culture, both cells were administrated in renal ischemia-reperfusion (IR) model. C57/Bl6 mice were subjected to bilateral IR by clamping both renal pedicles for 45 min. Four hour after reperfusion, 2.10^5 MSCs from IFNγR KO or from WT were intraperitoneally administered to each animal. After 24 h of IR, animals were sacrificed.

Results: Both treatments with MSC showed significant reduction of serum urea and creatinine, but the treatment with IFNγR KO MSC was less effective. Acute tubular necrosis (ATN) analyses corroborate with functional assays. Both cells treatments havereduced IL-6 mRNA expression when compared to untreated animals. However, IL-6 mRNA expression was greater in animals treated with IFNγR KO MSC when compared to treatment with WT MSCs. The IL-10 mRNA expression was higher in animals treated with WT MSC when compared to untreated and KO MSC group. PCNA analysis by immunohistochemistry was increased in treated animals with WT MSCs than animals treated with IFNγR KO MSC. At Tunel assays, it was observed that the group treated with IFNγR KO MSC had more apoptosis than others. In addition, *In vitro* studies have shown that IFNγR KO MSC have a lower proliferative rate than WT MSC. However, when WT MSC were incubated with recombinant IFNγ (20 ng/ml) the proliferative rate is increased.

Conclusions: The presence of IFNγ receptor at MSC is not essential for tissue repair, since functional parameters and ATN are not different in both cells treated animals. On the other hand, immunomodulation response differs. MSC response to IFNγ may play role on it, since proliferative rate and apoptosis are altered in the animals treated IFNγR KO MSC. More research is needed to better understand the role of IFNγ in activation and response of MSCs and their implication in cell therapy. Support: FAPESP, CNPq.

Salvage T cell therapy for resistant viral diseases after stem cell transplantation

M. Uhlin, J. Gertow, S. Berglund, M. Okas, M. Uzunel, E. Watz, P. Ljungman, M. Maeurer & J. Mattsson

Deaprtment of Laboratory Medicine, Karolinska Institute, Stockholm, Sweden

Purpose/Objective: Epstein-Barr virus (EBV), cytomegalovirus (CMV) and adenoviral reactivations are frequent complications after allogeneic SCT because of a lack of T cell control due to extensive immunosuppression. Cytotoxic T lymphocytes (CTLs) that recognize viral antigens are the most important immune effector mechanism controlling the persistent viral infections.

First-line treatment for viral reactivation is dose reduction of the immunosuppressive drugs and/or anti-viral therapy. For PTLD this is followed by rituximab (anti-CD20 monoclonal antibody). Despite these multiple treatment strategies, the l mortality from drug-resistant viremia after SCT is still considerable. Another treatment approach is adoptive transfer of virus specific CTLs from the donor. The standard method of adoptive T cell immunotherapy is laborious and time-consuming and is often too late to be administrated to the patient.

Materials and methods: We have developed a clinical separation protocol for virus specific CTLs based on labeling with multimeric complexes containing recombinant HLA molecules together with virus derived peptides. By combining this labeling technique with a secondary magnetic sorting we have managed to get a high purity of specific CTLs. This high purity diminish the risk of creating GVHD in the recipient even if the adoptive transfer of cells is done in an allogeneic or haplo-identical setting.

Results: We first used this protocol in an 18 year old patient with life-threatening PTLD. The patient developed an EBV associated lymphoma involving lungs, liver and both kidneys and also showed extremely high EBV titers in blood. It was decided to give her EBV specific CTLs from her mother. 2 months after the given EBV specific CTL infusion the EBV associated lymphoma was in complete regression. After this we have further successfully treated seven patients with life threatening viral disease (Adeno, CMV and EBV) with good efficacy. We could see a clinical and immunological response in six out of eigth patients. In five out of six of these responding patients we have been able to identify infused T cells using chimerism analysis and SNP markers specific for the CTL donor.

Conclusions: This method opens up the possibility to rapidly treat patients which are in acute need of T cell therapy and cannot wait for

prolonged expansion techniques or cannot tolerate standard treatment regiment.

T cells engineered to express high but not lower affinity T cell receptors recognize human tumor antigen cross-presented by the stroma and eradicate large tumors

M. Leisegang,* T. Kammertöns,† T. Blankenstein† & W. Uckert*
**Molecular Cell Biology and Gene Therapy, Max-Delbrück-Center for Molecular Medicine, Berlin, Germany, †Institute of Immunology, Charité, Berlin, Germany*

Purpose/Objective: Engineering of T cells with tumor-reactive T cell receptors (TCR) – TCR gene therapy – provides a powerful approach for adoptive therapy of cancer. The anti-tumor effect of TCR-engineered T cells is largely determined by the transgenic TCR that recognizes tumor cell-derived peptides presented on the patient's tumor tissue. However, current therapeutic approaches are impeded because although function of selected TCR can be analyzed *in vitro*, parameters that predict *in vivo* efficacy are not known. We developed a mouse model to evaluate the therapeutic effect of TCR gene therapy on established cancer.
Materials and methods: In order to establish a versatile, syngeneic model system for TCR gene therapy, we generated human MHC-transgenic mice that accept cancer cells modified to express human tumor antigens of choice. T cells were engineered with human tyrosinase-specific TCR of high or lower affinity. The anti-tumor effect of the T cells was analyzed *in vitro* and by adoptive transfer into mice bearing established, tyrosinase-positive cancer. Therapeutic efficacy was assessed by monitoring tumor growth. Cross-presentation of antigen by tumor stroma was analyzed in parallel by functional assays and by *in situ* confocal microscopy.
Results: Adoptive transfer of T cells engineered with high affinity tyrosinase-specific TCR resulted in complete rejection of cancer, whereas lower TCR affinity selected for escape variants and relapse. The tumor-derived human tyrosinase was cross-presented by tumor stroma cells. Although T cells engineered with both the high or lower affinity TCR showed identical tumor cell killing *in vitro*, only T cells expressing the high affinity TCR recognized cross-presented antigen on the tumor stroma.
Conclusions: This *in vivo* model provides a versatile, pre-clinical test system of adoptive T cell therapy of cancer to predict whether TCR-engineered T cells eradicate large tumors or select escape variants. Our results indicate that only TCR gene therapy with high affinity TCR prevents relapse, as opposed to use of lower affinity TCR which are typically isolated from the tolerant human repertoire against tumor-associated antigens. We suggest that the high affinity of the TCR enables the T cells to recognize and perhaps eliminate tumor stroma cells cross-presenting the melanoma antigen tyrosinase, resulting in bystander elimination of escape variants.

A good manufacturing practice procedure to generate therapeutic numbers of highly pure anti-leukemic virus-specific T-cells

M. M. van Loenen,* R. de Boer,* P. A. G. van Liempt,* R. S. Hagedoorn,* P. Meij,† J. H. F. Falkenburg* & M. H. M. Heemskerk*

*Hematology, Leiden University Medical Center, Leiden, Netherlands, †KFT, Leiden University Medical Center, Leiden, Netherlands

Purpose/Objective: Second half of 2012, we aim to start a clinical trial to treat patients with hihg risk acute leukemia with a donor-derived HA-1-TCR transduced (td) virus-specific T-cell product as early as 8 weeks after allogeneic stem cell transplantation. This T-cell product is selected based on well-defined specificities predicted to result in selective Graft versus Leukemia effect without Graft versus Host Disease.

Materials and methods: To obtain therapeutic cell numbers, one of the inclusion criteria is presence in donor peripheral blood of ≥1 virus-specific T-cell population with a frequency of ≥0.05% of T-cells. MHC-Streptamers will be used to isolate minimally one and maximally two virus-specific T-cell populations from donor leukocytes. MHC-Streptamer incubation will allow magnetic bead based cell selction of virus-specific T-cells of interest. Subsequently, these T-cells will be transduced with the HA-1-TCR. The process of isolation of pure populations of virus-specific T-cells and transduction with good manufacturing practice (GMP)-grade retroviral supernatant encoding the HA-1-TCR has been validated with three test procedures at large scale in the cleanroom.

Results: To pass the in process (IP) testing, T-cells needed to be ≥50% pure for the respective virus-specific tetramer after MHC-Streptamer isolation. In addition, release criteria for the cell product after transduction and subsequent culturing were positive staining for CD3/TCR$\alpha\beta$ ≥95% of the cells and ≥60% antigen-specific, as measured with virus- and HA-1-tetramers. Moreover, transduction efficiency of ≥5% as measured with HA-1-tetramers is a prerequisite.

Conclusions: All HA-1-TCR td virus-specific T-cell products met the criteria for IP testing and quality control testing, and were highly reactive against HA-1-positive leukemic cells. Here, we present a GMP-grade procedure, to generate therapeutically relevant numbers of defined antigen-specific T-cells.

Downregulation of CTLA4 by vector-mediated RNAi in human leukaemia T cells

R. Vassileva,* J. Curtin* & J. Kelly†

*Dublin Institute of Technology, School of Biology, Dublin, Ireland, †National Children's Research Centre, Our Lady's Children's Hospital, Dublin, Ireland

Purpose/Objective: In this study a gene therapy delivery system to overexpress small interfering RNA (siRNA) was designed and used to silence the expression of human CTLA4. We generated a stable T cell line expressing the CTLA4-specific siRNA that can be used as a tool for analysis of the role of CTLA4 in T cell down-regulatory pathways.

Materials and methods: A small hairpin RNA (shRNA) duplex designed to target the human CTLA4 mRNA transcript (siCTLA4) was cloned under the control of a U6 promoter in a previously described pBSU6neo vector. As a negative control a scrambled version of that sequence (scrCTLA4) was used. The efficacy of each plasmid was estimated by transient co-transfections in HeLa cells with a plasmid encoding CTLA4 expression, which was detected using Western blot and real-time PCR. Three stable T cell lines that have separately integrated pBSU6neo siCTLA4, pBSU6neo scrCTLA4 and pBSU6neo into the cellular genome have been developed and silencing efficacy was estimated by RT-PCR analysis. A stem loop RT-PCR method followed by real-time quantification was optimized to detect the expression of the mature siRNA in the new cell lines.

Results: We generated successfully a novel shRNA expressing vector pBSU6neo siCTLA4 encoding a sequence designed to silence CTLA4 expression. The ability of this vector to downregulate over 80% of induced CTLA4 expression compared to negative controls was confirmed in co-transfection experiments. Further stable T cell lines that incorporate the new plasmids were developed as a model to investigate the role of CTLA4 in functional assays. It was confirmed that the endogenous CTLA4 expression induced upon stimulation with phorbol 12-myristate 13-acetate (PMA) and ionomycin is silenced in the T cell line which constitutively expresses the CTLA4-specific siRNA.

Conclusions: In this study we demonstrated the successful downregulation of human CTLA4 expression using RNA interference. We suggest that the new developed T cell line with silenced CTLA4 expression could be used as a new model for the investigation of the role of CTLA4 as a suppressor of T cell activation.

Enhancing the potency of plasmid DNA vaccine via the incorporation of CpG motifs

C. H. Huang,* E. X. L. Loo,* G. H. Soh,* L. H. Chua,* H. M. Wen,* X. Fan,† Z. Li,† K. Y. Chua,* I. C. Kuo*

*Paediatrics, National University of Singapore, Singapore, Singapore, †Shanghai Public Health Clinical Centre, Fundan Universisty, Shanghai, China

Purpose/Objective: Plasmid DNA immunization is a potential approach against allergy, infectious diseases or tumors as it conferred many advantages over other vaccine approaches. In contrast to rodent models, most DNA vaccines exhibited low immunogenicity in non-human primates and humans. This study aimed at enhancing the immunogenicity of plasmid DNA vaccines by incorporating additional CpG motifs into the pVAX1 backbone.

Materials and methods: The D and K type CpG motifs were inserted into the pVAXBlot5 construct. The resulted plasmid, pVAXBlot5-DTKT, encoded a major allergen from the dust mite *Blomia tropicalis* for monitoring the antigen specific immune responses. The stimulatory properties of pVAXBlot5, pVAXBlot5-DTKT or DTKT oligonucleotides were evaluated by measuring the mediators released from the co-culture with human peripheral blood mononuclear cells (PBMCs). The prophylactic effects of the modified construct on Th2 immune responses were evaluated in a Blo t 5 induced murine allergy model. The immunogenicity of modified and unmodified constructs was also assessed in rhesus macaques by measuring Blo t 5 specific IgE and IgG as well as Blot 5 specific IFN-γ and IL-4 producing cells by ELISPOT assays.

Results: Co-culture of PBMCs with pVAXBlot5-DTKT elicited higher levels of pro-inflammatory cytokines/chemokines such as IL-6, TNF-α, MIP-1α and MIP-1β as compared to pVAXBlot5 or DTKT oligonucleotides stimulation at 5 and 24 h. *In vivo* evaluation in mice revealed that both pVAXBlot5-DTKT and pVAXBlot5 attenuated Blot 5 specific IgE. The modified pVAXBlot5-DTKT induced higher levels of Blot 5 specific IgG2c and IFN-γ when compared to pVAXBlot5. Monkeys immunized with both pVAXBlot5 and pVAXBlot5-DTKT and challenged with the Blot 5 protein showed lower Blot 5 specific IgE as compared to monkeys immunized with the pVAX1. The pVAXBlot5-DTKT immunized group also produced higher levels and fast kinetics of Blot 5 specific IgG when compared to those immunized with pVAXBlot5. Furthermore, the numbers of Blot 5 and Blot 5 peptides specific IFN-γ producing cells were higher from pVAXBlot5-DTKT immunized monkeys.

Conclusions: The optimal use of CpG motifs as the molecular adjuvant to enhance the priming of immune responses induced by DNA vaccine is still a feasible approach.

P1640

Entire requirement of endogenous type I interferon for the efficacious cancer treatment with viral vector-encoded interleukin-12

S. Hervas-Stubbs,* J. I. Quetglas,* J. R. Rodriguez-Madoz,* U. Mancheño,* E. Casales,* J. I. Riezu-Boj,* M. C. Ochoa,* M. Sanmamed,* N. Thieblemont,† C. Smerdou* & I. Melero*
**CIMA, Gene Therapy and Hepatology, Pamplona, Spain, †Université Paris Descartes, Hôpital Necker, Paris, France*

Purpose/Objective: To date little is known about how the innate IFNα/β response affects the efficacy of cancer treatments based in viral vector delivery of therapeutic genes. Using Semliki Forest virus encoding IL-12 (SFV/IL-12), a promising RNA viral vector for tumor treatment, we have explored this.
Materials and methods: SFV/IL-12 was administered intratumorally to MC38 tumor-bearing mice and tumor growth, IFNα/β production and/or anti-tumoral CTL response were monitored. The IFNα/β production elicited by SFV/IL-12 was compared in WT, IPS1$^{-/-}$ and TRIF$^{-/-}$ mice. The role of macrophages, pDCs and conventional DCs (cDCs) in the IFNα/β response was analyzed by depleting these populations with clodronate or anti-mPDCA-1 mAb administration to WT mice or by treated CD11c/DTRGFP mice with Diphtheria toxin, respectively. Finally, the requirement of IFNα/β for the anti-tumoral efficacy of SFV/IL-12 was tested in mice deficient for the IFNα/β receptor (IFNAR) and in mice treated with a neutralizing IFNAR mAb.
Results: Intratumoral injection of SFV/IL-12 induces IFNα/β production which is impaired in IPS1$^{-/-}$ and, to some extent, in TRIF$^{-/-}$ mice. Using bone-marrow (BM) chimeric mice we show that both hematopoietic and stromal cells are involved in the IFNα/β response. Macrophages, pDCs and cDCs are all implicated in the IFNα/β production. The therapeutic activity of SFV/IL-12 against MC38 tumor is absolutely lost in IFNAR$^{-/-}$ mice and when IFNAR signaling is blocked *in vivo* with anti-IFNAR mAb. This is also true with other tumor model efficiently cured by SFV/IL-12, such as TC1. The lack of efficacy is not related to an impaired expression of the transgene because IFNAR$^{-/-}$ mice even express higher levels of IL-12 and other reporter SFV-encoding genes, such as Luciferase. Using BM chimeric mice were only hematopoietic or stromal cells were IFNAR$^{-/-}$, we show that the IFNAR absolute requirement is operational at hematopoietic-derived cells. In accordance with the described mechanism of action of SFV/IL-12, tumor-specific CTLs are outstandingly expanded upon SFV/IL-12 intratumoral injection. However, this does not happen when tumor-bearing mice are IFNAR$^{-/-}$, or have been treated with anti-IFNAR mAb, or if they are deficient for IPS1.
Conclusions: All in all, our data show that the efficacy of tumor immunotherapy with viral vector-encoded IL-12 is totally dependent on type I IFNs, unrevealing an unexpected mechanism of action of a therapy that is being translated to patients.

P1641

Exploiting CD8 co-receptor to improve the function of genetically modified CD4 T cells for cancer immunotherapy

I. Chua,* M. Ahmadi,* S. Xue,* A. Holler,* R. Zamoyska,† H. J. Stauss* & E. C. Morris*
**UCL, Immunology and molecular pathology, London, United Kingdom, †School of Biological Sciences, University of Edinburgh, Edinburgh, UK*

Purpose/Objective: TCR gene transfer can generate tumour antigen-specific T cells for adoptive immunotherapy. Many TCR genes isolated for tumour immunotherapy are MHC class-I restricted TCR and when transduced into CD8 T cells endow potent anti-tumour protection effects in-vivo. Attempts to engage the CD4 T cell using the MHC-I restricted TCR often resulted in suboptimal antigen specific responses. In this study, we show that the anti-tumour function of genetically modified CD4 T cells can be enhanced by introducing the CD8 co-receptor.
Materials and methods: The MHC-I restricted F5 TCR recognized influenza-A nucleoprotein (NP) presented by Db. Retroviral constructs containing the F5-TCR or the CD8 co-receptor were used to transduce murine CD4 T cells for in-vitro functional studies or in-vivo tumour protection studies. Irradiated mice were injected subcutaneously with tumour cells expressing NP and luciferase. These mice were subsequently injected with genetically modified CD4 T cells and the tumour growth was monitored. Surviving mice were re-challenged with irradiated tumour cells.
Results: The in-vitro function of CD4 T cells transduced with F5-TCR shows that IL-2 and IFN-γ production is enhanced with CD8 co-receptor. In addition, introducing a L58R mutation in the CD8 co-receptor can further increase this effect. In-vivo studies shows that introducing the TCR alone did not endow CD4 T cells with significant tumour protection. However adding CD8 co-receptor to the CD4 T cells enhances tumour protection. The genetically modified CD4 T cells persist for >3 months in surviving mice and when re-challenged with antigen the CD4 T cells with both F5-TCR and CD8 co-receptor have greater proliferative capacity and have more central memory phenotype cells.
Conclusions: The CD8 co-receptor enhances the in-vitro and in-vivo function of genetically modified CD4 T cells transduced with MHC-I restricted TCR. These genetically modified CD4 T cells can provide tumour protection, persist indefinitely and proliferate on re-challenge. The effects of the CD8 co-receptor can be further enhanced by introducing the L58R mutation.

Generation of human islet antigen-specific regulatory T cells for treatment of type 1 diabetes

C. M. Hull, T. Tree, M. Peakman, J. Maher & M. Estorninho
Immunology Infection and Inflammatory Disease, King's College London, London, UK

Purpose/Objective: Type 1 diabetes (T1D) is an autoimmune disease characterised by the destruction of insulin producing beta cells in the pancreas. Research has shown that the ability of natural regulatory T cells (nTregs − CD4+, CD25hi, FoxP3+) to suppress effector T cells in T1D is defective leading to the proposal of adoptive cell therapy, in which nTregs isolated from patients are enhanced for their regulatory capacity and re-infused, as a possible therapy. Support for this comes from the NOD mouse model of T1D where it has been shown that infusion of polyclonal nTregs can suppress disease with more effective suppression seen if the infused nTregs are specific for an antigen involved in disease. Therefore this research focuses on the development of methods for lentiviral transduction of T cell receptors (TCRs) into human nTregs, allowing for redirection of a patient's polyclonal pool towards antigens involved in disease.
Materials and methods: T cells with a known specificity were clonotyped in order to identify the allele usage of the V, (D) and J regions of the TCR chains and the sequence of the V region. To sequence TCR chains cDNA was produced from RNA via 5' RACE which was then used to produce TCR alpha and beta chains using constant region primers. Each cDNA product was then sequenced and re-amplified to add restriction sites for sub-cloning in to an expression vector for future production of lentivirus . This will involve the transfection of 293T cells with the viral backbone (product of sub-cloning), viral envelope and encapsidation plasmid using polyethylenimine.

Results: Clonotyping data has identified the sequences and allele usage of three TCRs specific for peptides of: the tyrosine phosphatase IA-2, insulin and haemagglutinin (HA). From these results V region primers were designed allowing for the alpha and beta chains of each of the TCRs to be re-amplified in order to add restriction sites to the cDNA products for subcloning in to the expression vector.
Conclusions: In conclusion, previous work has shown that addition of antigen specific nTregs can suppress the development of diabetes. Therefore the redirection of a patient's nTregs towards an antigen involved in disease may represent a powerful therapeutic tool. This ectopic expression of a TCR can be induced using lentiviral transduction and therefore the alpha and beta chains of three TCRs specific for antigens involved in T1D have been cloned to produce lentiviral vectors.

Immune responses to transgene and retroviral vector in patients treated with *ex vivo* engineered T-cells

C. Lamers,* P. Elzakker van,* S. Steenbergen van,* J. Oosterwijk,† S. Sleijfer,* R. Debets* & J. Gratama*
**Medical Oncology, Erasmus MC – University Medical Centre, Rotterdam, Netherlands, †Experimental Urology, Radbout University Medical Centre, Nijmegen, Netherlands*

Purpose/Objective;Adoptive transfer of autologous T-cells that are gene-engineered to express antigen-specific receptors represents a promising experimental therapy to provide tumor-specific immunity to cancer patients. We studied safety and proof of concept of therapy with T-cells gene-engineered with a Chimeric Antigen Receptor (CAR) in patients with metastatic Renal Cell Carcinoma (RCC).
Materials and methods: In 12 patients with metastatic renal cell carcinoma (RCC), we performed a study with autologous T-cells genetically retargeted with a chimeric antibody receptor (CAR) directed towards carbonic anhydrase IX (CAIX), an antigen highly expressed in RCC. As we observed a limited (<30 days) peripheral persistence of the transferred gene-modified T cells we investigated the immunogenicity of these cells. Both humoral and cellular anti-CAIX-CAR immune responses were assessed followed by epitope mapping in case of detectable cellular responses.
Results: In the majority of patients we observed distinct humoral and/or cellular anti-CAIX-CAR T-cell immune responses. Humoral immune responses were anti-idiotypic in nature and neutralized CAIX-CAR-mediated T-cell function. Cellular anti-CAIX-CAR immune responses were directed to the complementarity-determining and framework regions of the CAR variable domains. In addition, two patients developed immunity directed against retroviral vector epitopes expressed by the therapeutic cells.
Conclusions: These observations may constitute a critical concern for clinical *ex vivo* g-retroviral gene transduction in general and CAR-retargeted T-cell therapy in particular, and underscore the need to attenuate the immunogenicity of both transgene and vector.

In vivo preclinical studies for the development of a gene therapy for IPEX patient

E. R. Mel, L. Passerini, G. Fousteri, C. Sartirana, F. Russo, M. Roncarolo & R. Bacchetta
Gene Therapy, San Raffaele Telethon Institute, Milano, Italy

Purpose/Objective: Immune dysregulation, Polyendocrinopathy, Enteropathy, X-linked (IPEX) syndrome is a lifethreatening disease due to mutations of the gene *Forkhead boxP3 (FOXP3). FOXP3* mutations cause the dysfunction of regulatory T cells (Tregs) that maintain tolerance to self-antigens. We previously showed efficient *in vitro* conversion of polyclonal T cells into polyclonal Tregs. Our goal is to validate, by *in vitro* and *in vivo* preclinical studies, the efficacy of these Tregs generated by lentiviral-vector- (LV)-mediated gene transfer of wild type FOXP3 in $CD4^+$ T cells ($CD4^{FOXP3}$) in view of a possible future therapy of IPEX syndrome.
Materials and methods: Conventional human $CD4^+$ T cells were transduced with a bidirectional LV, constitutively expressing FOXP3 under the control of the EF1a promoter and ΔNGFR as marker gene. Resulting $CD4^{FOXP3}$ were tested in a model of xenogeneic Graft-versus-host-disease (GvHD), induced by injection of $CD4^+$ T (Teff) cells into immunodeficient hosts: both NOD-SCID and NSG mice were used.
Results: Compared with NOD/SCID, NSG mice have been proven to be a more suitable model to test suppressive activity of $CD4^{FOXP3}$ cells, since they allow the induction of a xenoGvHD reaction with a lower number of Teff cells and gave more consistent results. At a ratio [Teff: $CD4^{FOXP3}$] of [1:1], $CD4^{FOXP3}$ cells efficiently blocked the development of xenoGvHD. $CD4^{FOXP3}$ have been proven to be efficient in arresting ongoing disease, even when injected in mice in which a xenoGvHD has been already established. Importantly, $CD4^{FOXP3}$ cells generated from IPEX patients were superimposable to $CD4^{FOXP3}$ cells derived from normal donors in controlling Xeno GvHD.
Conclusions: Our results showed that this protocol is efficient for the generation of $CD4^{FOXP3}$ cells suppressive *in vivo* both from normal donor and IPEX patients, and support the possibility of their future application for the therapy of IPEX and other autoimmune diseases.

Inducible TCR expression permits insights into functional properties of dual TCR T cells

S. Reuß,* Z. Sebestyén,† N. Heinz,‡ R. Loew,§ C. Baum,‡ R. Debets¶ & W. Uckert**
**Molecular Immunotherapy, Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany, †Experimental Hematology and Immunotherapy, University Medical Center Utrecht, Utrecht, Netherlands, ‡Experimental Hematology, Hannover Medical School, Hannover, Germany, §Eufets GmbH, BioNTech AG, Idar-Oberstein, Germany, ¶Experimental Tumor Immunology, Erasmus MC, Rotterdam, Netherlands, **Molecular Cell Biology and Gene Therapy, Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany*

Purpose/Objective: T cell receptor (TCR) gene therapy is an option to treat cancer. However, due to the transfer of TCR genes into T cells, mixed TCR dimers composed of endogenous and transgenic (tg) TCR chains are formed. These mixed TCR possess unknown antigen specificity and severe transfer-induced graft-versus-host-disease was reported in a mouse model. We generated dual TCR T cells with regulable expression of one TCR and analyzed the mutual influence of both TCR with regard to cell surface expression, function, and pairing.
Materials and methods: We used LCMV- (P14) and ovalbumin-specific (OT-I) TCR and generated dual TCR T cells using mouse 58 T cells which do not harbor endogenous TCR. One TCR was constitutively expressed (mimicking the endogenous TCR). The expression of the second TCR was regulable (mimicking the tg TCR) using a tet-on retroviral vector. Depending on the expression level of the tg TCR we analyzed cell surface expression and functionality of both TCR and determined the occurrence of mixed TCR dimers by fluorescence resonance energy transfer (FRET). In addition, we analyzed the influence of TCR modifications (cysteineization (introduction of a second cysteine bridge), codon optimization) on TCR functionality and formation of mixed TCR dimers.
Results: In dual TCR T cells expression of the endogenous TCR was hardly decreased by expression of the tg TCR. However, functionality was strongly reduced or completely lost. FRET analysis revealed formation of correctly paired endogenous and tg TCR but also occurrence of considerable amounts of mixed TCR dimers which most

probably contribute to the loss of functionality. This result was independent of the expression level of the tg TCR. Cysteineization did not improve functionality or correct pairing of TCR in dual TCR T cells. However, in polyclonal T cells, optimized TCR formats showed an improvement in correct pairing and improved functionality in the presence of low amounts of cognate peptide.
Conclusions: Modifications of the tg TCR improved correct pairing of TCR chains. However, the level of mispairing depends very much on the selection of the endogenous and tg TCR. Increased levels of tg TCR did not avoid the formation of mispaired TCR. Thus, in TCR gene therapy, other strategies are needed to circumvent severe off-target side effects induced by mixed TCR dimers.

P1646
Matricellular protein CYR61 drives thymic stroma expansion and thymic output

Y. Emre,* M. Irla,* I. Dunand-Sauthier,* C. Vesin,† W. Reith* & B. A. Imhof*
**Pathology and Immunology, University of Geneva, Geneva, Switzerland,*
†*Physiology and Metabolism, University of Geneva, Geneva, Switzerland*

Purpose/Objective: T-cell development relies on functional microenvironments generated by thymic epithelial cells (TEC). These cells provide functional microenvironments to support the migration and proliferation of developing thymocytes and participate to their education. Decreased TEC numbers and impaired stromal architecture accompany age-associated thymic involution. Consequent decrease of T-cell production results in loss of repertoire diversity. Similarly, thymic structure and function are also severely damaged by infection, chemotherapy or radiation.

Therefore, modulating thymic stroma is of prime importance for the development of therapies to improve T-cell based immunity. In this context, we investigated whether matricellular protein CYR61 (CYsteine-Rich protein 61), previously implicated in cell proliferation, could improve thymus functions.
Materials and methods: Impact of CYR61 on TEC and T-cell production was evaluated *in vitro* and *in vivo* using thymocyte-depleted Fetal Thymic Organ Cultures (FTOC) and engraftment of CYR61 overexpressing thymic lobes CYR61 into athymic nude mice.
Results: Expression of CYR61 was strong in TEC and decreased over age. Secreted CYR61 constituted niches for specific subsets of thymocytes, enhancing their interaction with TEC. Treatment of thymic lobes with recombinant CYR61 expanded thymic stromal compartment by inducing thymocyte-independent TEC proliferation. Engraftment of CYR61-overexpressing thymic lobes into mice drastically increased thymic output by increasing the hosting capacity of expanded lobes for circulating progenitors.
Conclusions: CYR61 drives the development of thymic stroma, thus enhancing T-cell release to the periphery.

Multicistronic vector encoding optimized safety switch for adoptive therapy with TCR-modified T-cells

M. M. van Loenen, R. de Boer, R. S. Hagedoorn, V. Jankipersadsing, J. H. F. Falkenburg & M. H. M. Heemskerk
Hematology, Leiden University Medical Center, Leiden, Netherlands

Purpose/Objective: Adoptive immunotherapy with T-cells transferred with T-cell receptors (TCRs) with anti-tumor reactivity is a promising treatment for malignancies. TCR gene transfer poses different safety issues that might warrant the inclusion of a suicide switch. Improved affinity of TCRs resulted in unwanted on-target toxicity, and off-target reactivity directed against healthy tissue was observed due to mixed dimers. For our clinical study we want to use a high affinity TCR that displayed high reactivity against multiple different tumor cell lines. However, some low on-target reactivity was observed against mature dendritic cells and proximal tubular epithelial cells. Therefore, for clinical purposes this PRAME-TCR might warrant inclusion of a suicide gene as safety switch.
Materials and methods: Human CD20 has been proposed as a non-immunogenic suicide gene targeted by the widely used clinical-grade antibody rituximab and can additionally function as a selection marker. Previously, we have demonstrated that expression of CD20 and the TCR in two separated constructs resulted in profound expression of both molecules. However, transduction of two constructs leads to reduced transduction efficiency, and requires an extra selection step *in vitro* of the $CD20^+$ T-cells to avoid the infusion of T-cells that express the TCR but do not express CD20. To increase efficiency and assure solid co-expression of both the introduced TCR and CD20, the TCR α and β chains and CD20 gene sequences were linked with self-cleaving 2A sequences in a single multi-cistronic vector. However, we observed that transduction of cells with this multi-cistronic vector resulted in impaired expression of particularly CD20. To overcome this low co-expression, both the introduced TCR as well as CD20 were codon optimized.
Results: We demonstrate that transduction with a multi-cistronic vector encoding for both the codon optimized PRAME-TCR as well as codon optimized CD20 (PRAME-TCR_{CO}-$CD20_{CO}$) results in pronounced, concordant cell surface expression of both the TCR and CD20, whereas no antigen-reactive single TCR positive cells were detected. Our data demonstrate that rituximab efficiently eliminated the transduced T cells, resulting in the absence of PRAME-specific reactivity of PRAME-TCR_{CO}-$CD20_{CO}$ transduced T-cells after rituximab treatment.
Conclusions: Codon optimization of both the PRAME-TCR and CD20 was shown to result in profound co-expression of both molecules. This concordant expression allows the use of CD20 as a selective and efficient suicide switch.

Short-Interfering RNA evaluation in experimental mice rabies virus infection caused by variant 2 and variant 3

C. M. Appolinario, S. D. Allendorf, M. G. Peres, A. F. Vicente, J. M. A. P. Antunes, J. C. F. Pantoja & J. Megid
Higiene Veterinária e Saúde Pública, Universidade Estadual Paulista "Julio de Mesquita Filho"(UNESP), Botucatu, Brazil

Purpose/Objective: Rabies is an ancient disease and until now no effective treatment is available. Treatment using short-interfering RNA (siRNA) to inhibit rabies virus (RABV) replication showed promising results *in vitro*. Our purpose was to evaluate the efficacy of siRNA in treating mice experimentally infected with different street RABV strains.
Materials and methods: Three groups of 20 C57/BL6 mice, SPF, 4−6 weeks-old were inoculated in gastrocnemius muscle with three different RABV strains. A variant two isolated from a dog [dv2 (LD50 10−3.39/0.03 ml)], a variant two isolated from a human [hv2 (LD50 10−6.66/0.03 ml)] and a variant three isolated from a human [hv3 (LD50 10−6.66/0.03 ml)]. For each group, 10 mice remained untreated and 10 mice were treated with a mix of three different siRNA sequences (3.3 μM each) associated with lipofectamine (Brand'o *et al.* 2007) based on rabies virus N gene as a target. Animals received a single dose of siRNA mixture, via intraperitoneal route, 24 h post RABV inoculation (p.i) and were observed during 30 days. Cox Proportional Hazards models were used to estimate lethality rates and Hazard Ratios (HR) between groups.
Results: For dv2, lethality was 37.5% in the inoculated group and 50% in the siRNA group ($P = 0.71$; HR= 0.75); for hv2, lethality was 100% in the inoculated group and 70% in the treated group ($P = 0.27$;

HR = 0.57); For hv3, lethality was 60% in the inoculated group and 80% in the treated group ($P = 0.21$; HR = 1.97).

Conclusions: Efficacy of siRNA seems to be associated to the RABV strain once theresults of survival was variable in the groups submitted to siRNA and infected with different RABV strain. The siRNAs used were designed based on Pasteur virus N gene sequence, a fixed strain while in our study street RABV strains were used. Even considered as a conserved gene, studies showed significant genetic variability. A nearly perfect complementary sequence between siRNA molecule and the viral RNA target is necessary for mRNA cleavage. Our RABV N gene sequences showed 85.7−95.2% of homology between v3 and siRNAs sequences and 95.2−100% to v2, confirming this natural variability. In this study, a non-biological delivery system was used and an important point is the difficulty of siRNA delivery within CNS being this a major problem in practical therapeutic.

Turning mTOR down in TCR gene therapy: the path to long-term protection?

P. Velica,* M. Zech,† H. Stauss† & R. Chakraverty*

**Haematology, UCL Cancer Institute, London, UK,* †*UCL, Immunology, London, United Kingdom*

Purpose/Objective: Gene transfer of TCRs recognising tumour antigens offer the possibility to produce large numbers of tumour-reactive T cells that can be used in immunotherapy. However, despite initial tumour killing, TCR-transduced T cells have impaired formation of a memory population resulting in tumour re-growth and lack of long-term protection.

Recently, the mTOR kinase has been implicated in memory differentiation of $CD8^+$ cytotoxic T cells. Antigen stimulation of naïve T cells activates mTOR that in turn orchestrates the change from oxidative to glycolytic metabolism and the activation of protein translation in order to cope with the proliferative burst necessary to generate an effector population. Nevertheless, attenuation of mTOR activity with low dose of rapamycin during viral infection increased memory cell differentiation. Memory fate seemed to rely on T cell-intrinsic mTOR activity, making it an appealing target for manipulation in TCR gene therapy.

In this study we aim to attenuate mTOR activity in TCR-transduced T cells to promote memory formation and long-term tumour protection.

Materials and methods: We use a TCR gene therapy model where mice are injected with EL4 lymphoma expressing the NP flu peptide and allowed to grow for varying days before adoptive transfer of T cells transduced with F5 TCR (recognising NP).

mTOR activity in T cells was reduced by either co-transduction with shRNAs against mTOR or Raptor or by *ex vivo* treatment with rapamycin (rapa).

Results: We observed that transient high dose rapa treatment during *ex vivo* T cell activation caused only a slight reduction on transduction efficiency. Rapa-treated F5 cells showed impaired interferon-gamma (IFNg) production when stimulated *in vitro* with EL4-NP and failed to protect *in vivo* from large 5-day old tumours. Paradoxically, rapa-treated F5 cells more efficiently rejected tumour in mice bearing 1-day old tumours.

Permanent mTOR inhibition using shRNA silencing against mTOR or Raptor severely limited the expansion of F5 cells in tumour-bearing mice.

Conclusions: These results suggest that mTOR inhibition during activation impairs the capacity of F5 T cells to eradicate large tumours due to reduced effector functions but this conditioning is advantageous when facing smaller tumours. On the other hand, permanent inhibition seems to be highly deleterious for T cell function.

P1653
Antigen-specific TCR-modified Treg for treatment of EAE

E. Kieback,* P. Shen,† U. Stervbo,† S. Fillatreau† & W. Uckert*
**Cell Biology and Gene Therapy, Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany, †Immune Regulation, Deutsches Rheumaforschungszentrum, Berlin, Germany*

Purpose/Objective: Adoptive transfer of regulatory T cells (Tregs) can be applied to treat autoimmune disorders, but several studies have demonstrated that treatment efficacy depends on their antigen-specificity as determined by the T cell receptor (TCR). However, the isolation of sufficient numbers of antigen-specific Tregs from the endogenous repertoire is technically difficult and most likely not feasible for most tissue-specific antigens. Therefore, we applied a novel method to overcome these difficulties and evaluated the capability of a gene therapy approach to generate high numbers of antigen-specific Tregs by TCR gene transfer into polyclonal Tregs.
Materials and methods: Using a retroviral vector, we transferred the genes for a TCR directed against myelin oligodendrocyte glycoprotein (MOG) peptide 35−55 into Tregs isolated from C57BL/6 mice and analyzed their capacity to inhibit MOG-induced experimental autoimmune encephalitis (EAE).
Results: Flow cytometry analysis revealed that the TCR was expressed in a high percentage of cells. Further, TCR-modified Tregs could suppress proliferation of effector cells *in vitro* in a MOG peptide-dependent fashion. Most importantly, adoptive transfer of very low numbers of TCR-modified Tregs * but not polyclonal Tregs * inhibited development of MOG-induced EAE in mice. By use of a marker gene we were able to detect the adoptively transferred Tregs in draining lymphoid organs and in the CNS and could show that their presence coincided with a reduction of MOG-specific IFN-γ- and IL-17-producing effector cells.
Conclusions: We have shown that TCR transfer is a suitable method to generate antigen-specific Tregs for therapy and that TCR-modified Tregs are superior to polyclonal Tregs in their capacity to prevent EAE.

P1655
Burn and/or sepsis-injury related immunosuppression is accompanied by disturbances in CD4+ T cell activation/responses.

N. Fazal, A. Shelip, H. Wang & L. Hishmeh
Pharmaceutical Sciences, Chicago State University, Chicago, IL, USA

Purpose/Objective: Burn injury caused hypo-responsiveness of T cells has been shown via evaluations of proliferative and IL-2 production responses ex vivo, and their antigen specific stimulation *in vivo*. Down-regulation of expression and functions of MHC-II and costimulatory molecules on APCs (antigen presenting cells)/DCs (dendritic cells), CD80/86, and CD40, can adversely affect their interactions with complementary costimulatory molecules on T cells, CD28, CTLA-4, CD40L, and lead to impaired T cell priming/activation and responses. Such derangements in APC/DC and T cell interactions may contribute to burn-related hypo-responsiveness of CD4+ T cells. We hypothesized that immature DCs fail to adequately prime/activate naïve CD4+ T cell in the lymph nodes. Burn/sepsis injury leads to insufficient maturation of DCs during their migration from peripheral tissue sites to lymph nodes. Changes in DC functionality with injury probably occur in a DC subset that is responsible for activation and differentiation into Th1 type T cells through DC expression of IL-12. Insufficiently mature DCs exhibit down regulation of surface expression of MHC-II and CD80/CD86/CD40 molecules.
Materials and methods: Adult male rats were subjected to a 30% TBSA full-thickness skin burn (95°C, 8 s) (B), or skin exposure to 37°C (S); Sham (S) and burned rats (B) killed 74−78 h later, their mesenteric lymph nodes (MLNs) isolated and processed to purify DCs using a positive selection procedure with MACS microbeads. CD4+ T cells were isolated from MLN using IMMULAN beads.
Results: We found potential disturbances in interactions between T cells and APCs, specifically DCs costimulatory receptors/ligands contributing to CD4+ T cell deficits in burn and/or sepsis injured animals. The latter effects of DCs are suggestive of the effects of immature DCs with insufficient expressions of MHC II, and costimulatory molecules, CD80/86, CD40, and ICOSL. Burn injured rat MLN DCs had decreased surface expressions of MHC-II, CD40, and CD80/86. Moreover, burn-injured rat MLN DCs had impaired ability to prime naïve CD4+ T cells.
Conclusions: Overall, the results suggest burn and/or sepsis-injury causes disturbances in interactions between CD4+ T cells and DCs through primary and secondary costimulatory receptor/ligand molecules, contributing to CD4+ T cell deficits in burn and/or sepsis injured animals.

Characterization of the role of MALT1 in the development of multiple sclerosis

R. Beyaert, C. McGuire, L. Elton & G. van Loo
Molecular Biomedical Research, Ghent University − VIB, Ghent, Belgium

Purpose/Objective: The paracaspase MALT1 is a cytosolic signaling molecule that plays a major role in lymphocyte activation and proliferation. MALT1 mediates antigen-induced signaling to the transcription factor NF-κB by functioning as a scaffold protein. NF-kB controls the expression of many target genes, which in turn mediate distinct events in the inflammatory response to host injury and which are frequently excessively activated in immune-mediated diseases and neoplasia. We previously found that MALT1 not only functions as a scaffold protein, but also holds proteolytic activity, which fine-tunes antigen receptor signaling. More specifically, MALT1 was shown to proteolytically inactivate the de-ubiquitinating enzymes A20 and CYLD, which function as a cellular 'brake' on immune signaling. We now further investigated the effect of MALT1 inhibition on the development of autoimmunity.
Materials and methods: The role of MALT1 was studied in experimental autoimmune encephalomyelitis (EAE), a mouse model of multiple sclerosis. Immune responses and pathology were compared in MALT1 deficient mice and wild type mice. In addition, we investigated the effect of MALT1 protease inhibitors.
Results: Data obtained with MALT1 knockout mice as well as newly developed MALT1 specific protease inhibitors will be presented, illustrating a crucial role for MALT1 in T cell activation and in the early priming phase of EAE.
Conclusions: Our results illustrate the therapeutic promise of MALT1 inhibition in the treatment of multiple sclerosis and other immune-mediated diseases.

P1657
Chloroquine treatment reduces the severity of experimental autoimmune encephalomyelitis

R. Thomé,* C. Francelin,* R. di Gangi,* T. A. da Costa,* A. S. Farias,† F. T. M. Costa† & L. Verinaud*
**Department of Structural and Functional Biology/Unicamp, Biology Institute, Campinas, Brazil, †Department of Genetics Evolution and Bioagents/Unicamp, Biology Institute, Campinas, Brazil*

Purpose/Objective: We aimed to assess whether treatment with chloroquine (CQ), an antimalarial drug, is capable of reducing the clinical signs of EAE.

Materials and methods: Mice were treated with CQ (3 mg/kg) for 5 consecutive days prior to EAE induction. Clinical signs were analyzed daily for 30 days. Ten days after the antigen administration half of the animals were killed and Ag-specific cellular proliferation was analyzed in cultures of splenic leukocytes stimulated with MOG_{35-55}. At the end of the experiment, mice were killed and brains and sera were collect for analysis of inflammatory cells of the CNS and anti-MOG IgG, respectively.
Results: We observed a significant reduction in EAE clinical score and it was accompanied with a decrease in T cell proliferative response against MOG as well as a significant reduction of infiltration of inflammatory cells in the CNS and in serum anti-MOG antibody levels.
Conclusions: The data presented here corroborates with previous findings showing that chloroquine may have an immune-modulatory function, and we show for the first time that chloroquine treatment suppressed the clinical signs of EAE.

Ethical approval: All experiments were approved by the internal ethical committee (CEUA #2687-1).

Financial support: Funda*'o de Amparo^ Pesquisa do Estado de S'o Paulo * FAPESP (#2011/17965).

Danish innovation consortium: TREG – Center. Regulatory T — cells as a new treatment paradigm for immune disorders

M. Gad, K. Holmstrøm, J. E. Wern, F. Jørgensen & S. S. Jensen
Immune Targeting, Bioneer A/S, Hoersholm, Denmark

Purpose/Objective: International scientific groups and companies have shown an increasing interest in the use of Treg cells for clinical applications. The Treg-Center innovation consortium wish to establish the first technology platform worldwide, which offers the industry access to screening facilities which will allow them to develop novel therapeutics focused on the cure of immune disorders by re-establishing the immune balance. A major challenge for development and use of Treg cells for clinical applications is the lack of biological markers. The Treg-Center will additionally try to identify novel markers for Treg identification and isolation or for diagnostic and therapeutic applications.
Materials and methods: The consortium activities are structured around two work packages (WP). The aims of WPI is to develop screening platforms for Human Treg cell stimulating drugs exploring activity, induction, expansion and homing of Treg cells. Methods include: FACS sorting and phenotypic characterisation, BD fastimmune human regulatory T cell function assay, standard Treg inhibition assay (PKH26 proliferation); Homing assay (transwell system), Tr1 cell generation. The aims in WPII are identification and validation of novel markers in Treg cells. The types of markers explored will be proteins of membrane associated and intracellular origin as well as microRNAs. All activities are based on material from healthy donors or patients with Rheumatoid Arthritis.
Results: Selected data from WPI are presented illustrating nTreg sorting procedure, nTreg expansion and phenotypic characterization. The function of nTreg cells is illustrated by using the regulatory T cell function assay, BD fastimmune, which measures the expression of the activation markers CD154 and CD69 on effector T-cells.
Conclusions: The Treg-Center consortium wish to develop predictive screening platforms for *in vitro* analysis of Treg modulating drugs acting at various levels on Treg cells; (1) activity, (2) expansion, (3) de novo generation and (4) homing. Additionally, the Treg-Center wishes to identify novel Treg cell-specific markers of secreted, membrane-associated as well as intracellular origin with the purpose of identification, isolation and diagnosis of Treg cells.

P1659

Deficiency in ST2 receptor results in a more severe adriamycin-nephropathy

V. Reis, J. Silva & A. Keller
Microbiology Immunologia and Parasitology, UNIFESP, São Paulo, Brazil

Purpose/Objective: Adriamycin (ADM)-Nephropathy is an experimental model used to mimetic the clinical manifestations of human focal and segmental glomerulosclerosis (FSGS), a leading cause of chronic kidney disease. Different work associated FSGS with Th2 immune responses, suggesting a possible implication of the IL-33/ST2 axis in disease pathogenesis. The IL-33 is a member of the IL-1-like family of cytokines, described both as an alarmin and a differentiation factor for Th2 lymphocytes. Because the T1/ST2 receptor mediates IL-33 signaling, we decided to determine the influence of ST2 deficiency in AN pathogenesis.
Materials and methods: BALB/c WT and $ST2^{-/-}$ mice received, by a single tail vein injection with 10 mg (ADM)/Kg. The renal function was determined by the proteinuria/creatininuria ratio.
Results: Proteinuria and albuminuria are evident at day 4 post-ADM and progressed in a time-dependent manner. In the $ST2^{-/-}$ mice, the proteinuria ratio was twofold increased in comparison to wild-type group, indicating a more severe disease. The western blotting analysis of the renal tissue revealed a significant increase in the levels of phosphoAKT, JNK-1 and IkBalpha in $ST2^{-/-}$ mice in comparison to WT BALB/c, indicating a higher proinflammatory signaling.
Conclusions: Taken together our data show that the severity of AN increases in the absence of ST2 receptor, suggesting a regulatory role for IL-33 cytokine during FSGS pathogenesis.

P1660

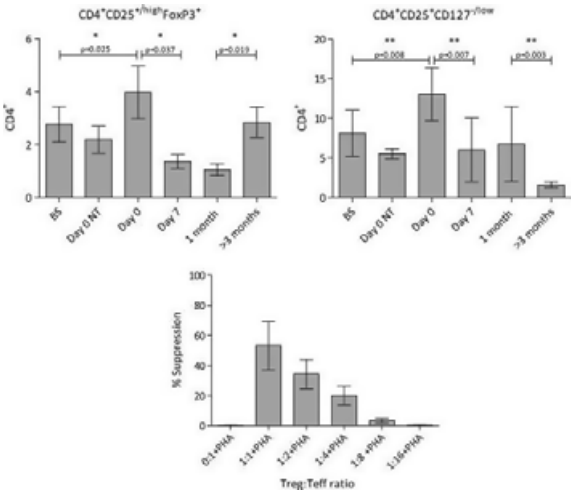
Effect of allogeneic blood transfusion on peripheral blood Tregs and cytokine levels of patients that underwent joint replacement surgery

P. Spadidea,* M. Rodi,* A. Chatziantoniou,† E. Panagiotopoulos† & A. Mouzaki*
**Department of Internal Medicine, University of Patras, Patras, Greece, †Orthopedics Clinic, Medical School and University Hospital University of Patras, Patras, Greece*

Purpose/Objective: Clinical and experimental studies have established that allogeneic blood transfusion (ABT) can cause immunosuppression. To identify immune parameters that contribute to this effect, we determined the effect of ABT on peripheral blood (PB) cytokine profiles and Treg numbers and function in a cohort of patients with no underlying pathologies.
Materials and methods: Heparinized PB samples were collected from 46 patients (7 M/39 F, 28–88 yo) that underwent joint replacement surgery. The samples were collected immediately before surgery (BS), and after surgery (AS) on days 0, 7, 1, and 3 months to 1 year. Thirty six patients received ABT and 10 did not. PBMC were isolated, and the numbers and % of $CD4^+CD25^+Foxp3^+$ Tregs and $CD4^+CD25^{high/+}CD127^{low/-}$ Tregs were determined by FACS. Tregs and T effectors (Teff) were isolated from patients on days 0–7 and Treg functional assays were performed by culturing Tregs with PHA-stimulated Teff at different ratios for 72 h with CFSE, and analyzed by FACS for proliferation. Cytokine levels were determined in plasma by a cytometric bead array assay for IL-2, IL-4, IL-5, IL-6, IL-10, TNF-α, IFN-γ, and ELISA for TNF-α, TNF-RI (p55/p60) and II (p75/p80), TGF-β1 and β2.
Results: Both, $CD4^+CD25^+Foxp3^+$ and $CD4^+CD25^{high/+}CD127^{low/-}$ Treg populations increased significantly on d0 AS and decreased on d7 AS to below BS levels, to achieve homeostasis >3 months in transfused patients. In contrast, Treg levels remained the same between BS and AS

in non-transfused patients. Functional assays showed that Tregs were functional post-ABT and could suppress Teff proliferation efficiently.

In culture, isolated Tregs secreted TGF-β1. All cytokines and TNF-RI and II plasma levels increased on d0 AS (IL-6, TNF-RI and II significantly), in transfused patients immediately AS, and decreased by d7 AS. In contrast, TGF-β1 levels decreased on d0 AS and increased by d7. No differences in cytokine or receptor levels were observed in non-transfused patients AS.



Conclusions: ABT induces the immediate production of plasma cytokines, especially pro-inflammatory IL-6 and TNF-RI and II that decreases by d7. In parallel, ABT induces the proliferation of Tregs. These Tregs are functional, and secrete TGF-β1 that reaches BS plasma levels by d7. The Tregs seem to be Th3 inducible Tregs. Homeostasis is reached by 3 months post-ABT.

P1661

Exosomal T cell suppressor factor inhibits the generation of reactive oxygen intermediates in murine peritoneal macrophages

K. Nazimek, B. Nowak, W. Ptak & K. Bryniarski
Immunology, Jagiellonian University College of Medicine, Kraków, Poland

Purpose/Objective: Contact sensitivity (CS) reaction in mice is regulated by antigen specific T CD8$^+$ suppressor lymphocytes that produce biologically active exosomes carrying T cell suppressor factor (TsF). Macrophages (MF) as effector cells of classical CS reaction mediated by Th1 lymphocytes and as antigen presenting cells may be the target cells for TsF. The aim of our experiments was to define if exosomal TsF with different hapten specificity affect macrophages in the production of reactive oxygen intermediates (ROIs).
Materials and methods: Production of TsF (tolerogenesis) is induced by intravenous application of a high dose of hapten-labelled syngeneic erythrocytes 7 days before epicutaneous immunization with the same hapten (trinitrophenol or oxazolone). Peritoneal MF are induced by mineral oil i.p. injection in naïve or tolerized donors. The ability of MF to generate ROIs was measured as luminol-dependent chemiluminescence after *in vitro* activation of macrophages by zymosan (in case of naïve MF in the presence of hapten-specific T cell suppressor factors).
Results: MF from *in vivo* tolerized donors expressed the increased ROIs production in comparison to appropriate control. On the other hand the significant inhibition of generation of ROIs by MF was observed in the *in vitro* presence of either trinitrophenol- or oxazolone- specific TsF in comparison to untreated MF.
Conclusions: Experiments indicate the influence of TsF exosomes on MF dependent on the dose and mechanisms of exosomal stimulation. Low dose of TsF *in vivo* stimulation seems to activate natural cytotoxicity of MF which in turn may lead to elimination of CS T effector lymphocytes. The effect of *in vitro* higher dose stimulation with TsF suppresses MF activity. Present study was the first step to define the exact regulatory mechanisms induced by the interaction between TsFs and macrophages.

P1662

Generation of human antigen-specific regulatory T cells by MHC-class I restricted T cell receptor gene transfer

L. E. Nickolay,* A. Skowera,* J. S. Bridgeman,† A. K. Sewell,† M. Peakman* & T. I. M. Tree*
**Department of Immunology Infection and Inflammatory Disease, Kings College London, London, UK, †Institute of Infection and Immunity, Cardiff University School of Medicine, Cardiff, UK*

Purpose/Objective: The adoptive transfer of regulatory T cells (Tregs) as a therapy in autoimmune diseases has been well demonstrated in mouse models of disease. In the case of Type 1 diabetes, this therapy could potentially prevent or dampen down the auto-reactive immune response to the islets of the pancreas, a process in which CD8+ T cells play a pivotal role. However, this therapy is limited by the number of antigen-specific Tregs that can be isolated and expanded from patients. To overcome this hurdle, lentiviral gene transfer technology can be utilised to engineer populations of Tregs to express any T cell receptor (TCR) of choice, re-directing their antigen specificity. Furthermore, by generating Tregs whose TCR is MHC class I restricted and islet antigen specific, these cells can be targeted directly to the site of the inflammation and similarly against the CD8$^+$ T cells that elicit a large proportion of islet cell damage.
Materials and methods: An HLA-A2 restricted CD8+ T cell clone specific for a peptide in the preproinsulin signal peptide region has previously been isolated from a type 1 diabetic patient and designated the 1E6 clone. In order to produce lentivirus, the packaging cell line HEK 293Ts are transfected with plasmids containing the 1E6 TCR, lentiviral packaging and integrating genes. Supernatant from these cells containing lentivirus is then used to transduce the TCRβ deficient Jurkat cell line JRT3 T-3.5.
Results: We have created a stably transduced Jurkat cell line expressing the 1E6 TCR, which led to the reassembly of the full CD3 complex on the cell surface. However MHC tetramers+ the 1E6 cognate peptide fail to stain these cells, suggesting that in the absence of the CD8 co-receptor, MHC and peptide cannot bind to cell surface of the 1E6+ cells. Furthermore, peptide specific activation of these cells shows that they cannot be activated by APCs expressing cognate peptide by both CD69 up-regulation and IL-2 secretion.
Conclusions: In conclusion we have demonstrated that we can generate stably transduced cells expressing a HLA-A2 restricted preproinsulin-specific TCR. However, our data has revealed a dependency on the presence of CD8 for this TCR to function. Thus, in order to transduce Tregs with an MHC class I restricted islet antigen specific TCR, a CD8 independent TCR will need to be identified to be used in this system.

P1664

Human dendritic cell based *in vitro* screening models mimicking Th1, Th2, Th17 and Treg responses

J. E. Wern, M. Gad & S. S. Jensen
Immune Targeting, Bioneer A/S, Hoersholm, Denmark

Purpose/Objective: Dendritic cells (DCs) play a central role in regulating the immune system both under normal conditions, but also

under pathogenic conditions like autoimmunity, allergy and infection. This function of DCs makes them attractive target cells for therapeutic intervention in inflammatory diseases. We have designed human monocyte derived DC-based *in vitro* screening models for identification of anti-inflammatory compounds for use in Th1 or Th17 mediated autoimmunity or Th2 mediated allergic reactions. Further, we have setup a Treg platform, with tolerogenic DCs differentiating $CD4^+$ T cells into IL-10 secreting Tr1 cells, in order to evaluate Treg promoting compounds.

Materials and methods: Monocyte derived DCs were incubated with pro- or anti-inflammatory DC cocktails with or without prior addition of immune suppressive reagents. The DC cocktails were evaluated by FACS phenotypic analysis, ELISA cytokine measurement and T cell proliferation [mixed lymphocyte reaction (MLR)]. Generation of Treg cells was further evaluated by classical T cell suppression assay (PKH26 proliferation).

Results: Nine different Th1 cocktails consisting of TLR agonists, cytokines and lipids were designed based on their ability to induce secretion of IL12p70 and TNFa from DCs. All cocktails induced DC expression of HLA-DR, CD40, 80, 83 and 86, indicating development of the immature DCs into mature DCs. Furthermore, DCs were able to induce a Th1 response defined by high IFN-g secretion in a MLR. The model was validated with anti-inflammatory drugs at both DC and T cell level using dexamethasone (Dex) and rapamycin.

Two different Th17 cocktails were used to induce an inflammatory Th17 response. DCs stimulated with the Th17 cocktails secreted IL23 and differentiate CD4+ T cells towards an IL17A secreting Th17 phenotype in a MLR. Dex or the small molecule inhibitor STA5326 was used to validate the model.

A single Th2 cocktail was developed modulating DCs to promote a IL5 and IL13 secreting Th2 phenotype. The model was validated with Dex which was able to suppress the Th2 response.

Finally, a Treg platform was setup with tolerogenic DCs differentiating $CD4^+$ T cells into IL-10 secreting Tr1 cells.

Conclusions: We have designed human *in vitro* DC-based screening models for identification of immune-modulatory drugs for treatment of inflammatory or allergic diseases.

P1666
IL-2 and rapamycin alone or combined, friend or foe for type 1 diabetes?

A. Baeyens, L. Perol, H. Sadeck, G. Foucarde & E. Piaggio
Therapy and Autoimmunity, UMR7211, Paris, France

Purpose/Objective: Regulatory T cells (Treg) play a major role in controlling the pathogenic autoimmune process in type 1 diabetes (T1D). We have recently shown that a short course of low-dose IL-2 administration cures new onset T1D in non obese diabetic (NOD) mice, by specifically activating pancreas infiltrating Treg and reducing interferon-gammaproduction by pancreas infiltrating T cells. However, only 60% of mice afford remission and only half of them remain normoglycemic for lifelong. Here we attempted to improve the rate of T1D remission in NOD mice.

Materials and methods: For that we tested different high doses of IL-2 and the combination of low dose IL-2 and rapamycin (RAPA) in T1D.

Results: First, we tested the capacity of different IL-2 doses to prevent T1D. Surprisingly, only with a ten times increasing ofthe curative IL-2 dose, T1D development was accelerated and higher IL-2 dosis were toxic to the mice. Of note, NOD mice of different sex and ages showed a significantly different susceptibility to high-dose IL-2 diabetes acceleration or toxicity. Second, we tested the combination of IL-2 with (RAPA), which is an immunossupressor used in human transplantation and which can selectively eliminate effector T cells (Teff) while sustaining an increase of Treg *in vitro*. It has already been described that long-term RAPA treatment can prevent diabetes, so we directly tested the RAPA+ IL-2 combination in a curative schedulle in new onset diabetic NOD mice. Of note, RAPA+ IL-2 could not induce T1D remission, associated with an absence of control of the production of IFN-gamma by pancreas infiltrating T cells. Moreover, in IL-2- cured mice, RAPA annulated the T1D remission in a reversible way. We are now studying the underlying mechanism.

Conclusions: Our results have an impact on IL-2 and RAPA treatment on human T1D, as new clinical trials are ongoing or are been implemented using these drugs in patients.

P1667
Immunomodulatory effects of different hASC clonogenic populations on human PBMNc

P. Martínez-Peinado,* M. I. A.-G. de León,† E. Roche-Collado,† M. García-Irles,* F. M. M. De la Calle* & J. M. Sempere-Ortells*
**Biotechnology, University of Alicante, San Vicente del Raspeig, Spain, †Bioengineering, University Miguel Hernández, Elche, Spain*

Purpose/Objective: Previous studies have shown that mesenchymal stem cells (MSC) are able to modulate the immune response of different leukocyte populations, i.e. Tregs, through mechanisms yet to be elucidated. Most of these studies have used heterogenic cell populations. However in the present study we analyze the immunomodulatory effect of five different MSC clones obtained from human lipoaspirates (hASCs).

Objectives: (1) To identify the membrane phenotype and Th1/Th2 cytokine production profile of each clone.

(2) To assess the modulating effect of clones on the proliferation of PBMNc in cocultures at different ratios (MSC:PBMC; 1:10 and 1:5)

(3) To establish differences between the behavior of the different clones, especially according to their specific immunomodulatory ability.

Materials and methods: Flow cytometry (FC: EPICS XL, Coulter, FACSCalibur, BD) anddirect immunofluorescence for membrane phenotype. Cytokines by FC, CBA techniques (BD) and Flow-cytomix (eBioscience). Proliferation through FC and CFSE technics (Sigma).

Results: All of the clones showed different intensities of autofluorescence (FITC emission spectrum) and different expression of CD90, CD105, CD73 and CD44 being negative for CD34 and CD45. All the clones secreted high to very high levels of IL-6 and IL-8 and mild to moderate levels of IL-1§ and TNF-α, both spontaneously and after LPS-stimulation. Two out of them also showed a slight secretion of IL-12 and INF-γ, and two more clones a slight secretion of IL-10 and/or IL-4. Cocultures carried out under different stimuli (LPS, PHA and anti-CD3/anti-CD28) showed different degrees of decrease in lymphocyte proliferation for all of the clones, reaching this immunosuppressant effect maximum values for one of these clones (two times more).

Conclusions: The Th1/Th2 profile as well as the membrane phenotype of each clone can influence in their ability to modulate various leukocyte populations. This different immunomodulating effects obtained by using clonogenic ASCs populations instead of heterogenic whole populations could be of interest for being applied with clinical purposes in the field of cell therapy.

P1668
Immunosuppression of ICR mouse strain with 5-FU administration

T. Lutsenko
Department of Cell Regulatory Mechanisms, Institute of Molecular Biology and Genetics National Academy of Sciences of Ukra, Kiev, Ukraine

Purpose/Objective: It has been already reported the experience with a variety of dosage schedules therefore an intravenous administration of

5-Fluorouracil (5-FU) is recommended, undiluted given by rapid injection of 15 mg/kg/day × 5 followed by 7.5 mg/kg on alternate days to the point of slight toxicity and so on. Our aim was to develop a half-lethal dose of 5-FU for ICR mouse strain, to determine the effect on the myeloid and lymphoid cells, to detect white blood cell abnormality.
Materials and methods: We've chosen virgin ICR female mouse strains, 2−2.5 months age. Each mouse had a 25 g weight. Intravenous administrations of 5-FU were in the following doses: 16, 32, 40, 48-mg/kg/day during four times in volume 100 μl for each time. Intravenous administrations of saline drip were used as a control. 5-FU was administered daily for 4 days, and every second day for 8 days. Blood sampling was performed before the introduction of 5-FU, and after the first administration on 5th, 7th, 12th and 30th days. Gorjaev's count chamber was used for measuring the number of white blood cells. For performing differential white blood cell counts May-Grunwald and Romanowsky stain and microscopy were applied.
Results: ICR mouse strain contains 10−15 million leukocyte cells per ml in a blood. After course of administration of 5-FU 48 mg/kg/day for during four times * the lethal dose was established. With the introduction of 40 mg/kg/day during 4 days, on the 5th day after the first injection of 5-FU, the total leukocyte count was from 3 to 4 millions cells/ml, which is three times less than normal. Also neutropenia was detected. The total number of leukocytes was restored to half rate, increased number of neutrophils detected. Doses of 32 and 16 mg/kg/day during four times and during every second day administration for 8 days didn't showed such significant results.
Conclusions: To determine the half lethal dose of 5- FU we used the following concentrations: 16, 32, 40, 48-mg/kg/day during four times in volume of 100 μl for each time. 40-mg/kg/day during four times reduced the total number of leukocytes to the minimum 3−4 million/ml. All animals were survived after this dose and restored their hematopoiesis in 30 days after first administration of 5- FU. Such kind of suppression may be used for further studies in the allogeneic transplantation and be helpful for engraftment of donor cells in the body of the recipient.

P1669
Investigating the role of splice variant CTLA-4 in cellular immunity

A. Gazali,* F. Kaiser,* F. Ward† & S. Thompson*
**Academic Rheumatology, Kings College London, London, UK, †School of Medicine, University of Aberdeen, London, UK*

Purpose/Objective: Cytotoxic T Lymphocyte Antigen 4 (CTLA-4, CD152) is a costimulatory molecule expressed on T helper cells which can bind to CD80 or CD86 molecules on antigen presenting cells and transmits an inhibitory signal to T cells. Various forms of CTLA-4 have been described in the literature. Our focus is mainly on a novel splice variant of CTLA-4 (svCTLA-4) produced by alternative mRNA splicing and importantly not by proteolytic digestion or shedding of membrane-bound CTLA-4. This transcript was first described by Magistrelli *et al.* in 1999 and it was demonstrated that unactivated human peripheral blood T lymphocytes could produce svCTLA-4. In contrast to membrane-bound CTLA-4, this protein lacks transmembrane and intracellular regions. Little is known about the immune regulatory functions of this protein.
Materials and methods: Aliquots of 2.5 × 10(5) PBMC were diluted in 1000 μl RPMI1640 supplemented with 2 mM L-glutamine, sodium pyruvate, HEPES, Penicillin & Streptomycin and 10% FCS. PBMC were incubated in medium alone or with PMA & ionomycin at a concentration of 10 ng/ml and 1 μg/ml at 37°C in a humidified atmosphere with 5% CO2. Cell supernatants were harvested every 24 h *in vitro* culture for further study of svCTLA-4 levels.

Ninety-six wells plates (Nunc Maxisorp, Thermo Fisher Scientific, Roskilde, Denmark) were used for svCTLA-4 ELISA. The coating antibody (Anti-human pan CTLA-4 antibody, BNI3 clone, BD Pharmingen) was added into each well & incubated at 37°C for 90 min. Plates were blocked with 3% BSA in PBS for 1 h at 37°C. Four replicates of samples were aliquoted into each well & incubated at 37°C overnight. A pool of high titre plasma was used as the standard & was diluted in 0.2% BSA-PBS.

After that, the detection antibody (Anti-soluble CTLA-4 biotinylated antibody, JMW-3B3 clone (specific for the splice variant form), obtained from Dr Frank Ward from University of Aberdeen) was added & incubated at RT in the dark for 2 h. Next, enzyme [Extravidin-alkaline phosphatase (Sigma-Aldrich)] was added and incubated for 90 min at RT in dark. Then, phosphatase substrate (Sigma Aldrich) was added into each well. Plates were read at 410 nm absorbance after 1 h of development.
Results: Our data demonstrates that this protein can be secreted by PBMC in *in vitro* culture. Upon stimulation of PBMC by PMA & ionomycin initially levels of svCTLA-4 were downregulated (until 48 h) in culture. SvCTLA-4 secretion was increased from 72 h in culture suggesting a possible role in controlling immune activation.
Conclusions: CTLA-4 is known to play an important role in mediating the function of regulatory T cells. Therefore, we would like to further investigate the effect of svCTLA-4 on T regulatory cell function.

P1670
Investigating the role of the aryl hydrocarbon receptor (AHR) in thymic-derived regulatory T cells (Tregs) *in vivo*

D. M. Richards,* F. Cvetkovski,* M. Platten† & M. Feuerer*
**Immune Tolerance, German Cancer Research Center, Heidelberg, Germany, †Department of Neurooncology, University Hospital of Heidelberg, Heidelberg, Germany*

Purpose/Objective: Recently, CD4+ Foxp3+ Tregs have emerged as key elements within the immune system, controlling the establishment and maintenance of immunologic tolerance and immune homeostasis. Many cells in the immune system express AHR and its activation has been shown to suppress a number of T cell responses *in vivo*. Interestingly, evidence suggests that activation of AHR induces Tregs that are suppressive in multiple *in vivo* models of autoimmune disease. Kynurenine (Kyn), a tryptophan catabolite constitutively produced by human tumor cells, was recently identified as an endogenous ligand of AHR. In this context, Kyn was shown to suppress the anti-tumor immune response and promote tumor survival. It was demonstrated that addition of exogenous Kyn to *in vitro* cultures led to an AHR-dependent increase in Treg induction. The purpose of this study was to determine if expression of AHR and interactions with endogenous ligands is important for generation, maintenance and function of thymic-derived Tregs *in vivo*.
Materials and methods: To test the importance of AHR expression on Tregs *in vivo*, bone marrow chimeras were produced using an equal mixture of AHR-deficient and Foxp3-DTR bone marrow to reconstitute lethally irradiated Foxp3-DTR recipients. Foxp3-DTR mice express the human diphtheria toxin receptor (DTR) under the control of the Foxp3 promoter. Injection of DT leads to ∼98% depletion of Foxp3-expressing cells. Upon depletion of AHR-sufficient Treg cells, all remaining Tregs would lack AHR while all other hematopoietic cell populations would include at least 50% wildtype cells.
Results: Congenic markers (CD90 and CD45) were used to identify the origin of each cell population and we found that both donors were represented in equal proportions in the CD4+ and CD8+ T cell populations. Both donors were equally present in the Foxp3+ CD4+ population of PBS treated mice suggesting that AHR-deficient Tregs had no competitive disadvantage in the steady state compared to wildtype Tregs. In addition, within 2 weeks following Treg depletion, the Foxp3+ CD4+ population returned to control levels and was nearly entirely comprised of cells originating from AHR-deficient donor. This

suggests that AHR-deficient Tregs were able to successfully respond to homeostatic pressure and fill the space left following Treg depletion.
Conclusions: Our results suggest that expression of AHR on Tregs is not required for the development and expansion of the Treg compartment *in vivo*. However, we have some evidence suggesting that expression of AHR might play a role in the function of these Tregs.

L-plastin phosphorylation: a novel target for the immunosuppressive drug dexamethasone in primary human T cells

B. Schulte, G. H. Wabnitz, H. Kirchgessner, B. Jahraus, C. Stober, D. J. H. van den Boomen, F. Michalke & Y. Samstag
Immunology, Universitätsklinikum Heidelberg, Heidelberg, Germany

Purpose/Objective: Activation of naïve T cells requires costimulation via TCR/CD3 plus accessory receptors, which enables the dynamic rearrangement of the actin cytoskeleton and immune synapse maturation. Signaling events induced following costimulation may thus be valuable targets for therapeutic immunosuppression. Phosphorylation of the actin-bundling protein L-plastin represents such a costimulatory signal in primary human T cells. Phosphorylated L-plastin has a higher affinity toward F-actin. However, the importance of the L-plastin phosphorylation for actin cytoskeleton regulation upon antigen recognition remained unclear. Here, we aim to analyze whether phosphorylation of L-plastin is important for immune synapse formation and/or maturation and whether the immunosuppressive glucocorticoid dexamethasone plays a role in L-plastin phosphorylation and synapse formation.
Materials and methods: Human peripheral T cell isolation.
Primary T cell transfection.
Immune synapse via multispectral imaging flow cytometry.
Gel electrophoresis and Western blotting.
Cell cycle analysis and flow cytometry.
Cell viability assay.
Results: We demonstrate that phosphorylation of L-plastin is important for immune synapse maturation. Thus, expression of nonphosphorylatable L-plastin in untransformed human peripheral blood T cells leads to reduced accumulation of LFA-1 in the immune synapse and to a diminished F-actin increase upon T-cell activation. Interestingly, L-plastin phosphorylation is inhibited by the glucocorticoid dexamethasone. In line with this finding, dexamethasone treatment leads to a reduced F-actin content in stimulated T cells and prevents maturation of the immune synapse. This inhibitory effect of dexamethasone could be reverted by expression of a phospho-mimicking L-plastin mutant.
Conclusions: Our data introduce costimulation-induced L-plastin phosphorylation as an important event for immune synapse formation and its inhibition by dexamethasone as a novel mode of function of this immunosuppressive glucocorticoid.

P1673

Lipopolysaccharide-induced M2 to M1 macrophage transformation for IL-12p70 production is blocked by Candida albicans mediated up-regulation of EBI3 expression

X. Q. Wei, X. F. Zheng, Y. X. Hong, H. Rogers, B. Song, M. A. O. Lewis & D. Willliams
Tissue Engineering and Reparative Dentistry, Dental School, Cardiff, UK

Purpose/Objective: The response of M1 and M2 macrophages to *C. albicans* in the presence of LPS stimulation has not previously been reported. In this study, we examined plasticity of macrophages transforming from M2 to M1 in the presence of LPS and the impact *C. albicans* has on this transformation.
Materials and methods: Bone marrow cells extracted from C57/black mice femur bones were cultured with either 10 ng/ml rmGM-CSF or 10 ng/ml of mlM-CSF/IL-4 for 7 days before seeding the cells into 24 well plates for LPS stimulation, with or without Heat-Kill *Candida* (HKC). Released cytokines were subsequently measured by ELISA and gene expression determined by real-time RT-PCR. In some experiments, cytokine proteins were examined by Western blot. To confirm intracellular EBi3/p40/35 protein interaction, IL-12p70 biscistronic expression vector and EBI3 expression vector were constructed in pcDNA3.1A. CHO cells were transfected with expression vectors before detection of the protein by ELISA, Western blot (WB) and/or Immuno-precipitation WB.
Results: M1 cells stimulated by *Candida albicans* produced much higher TNFα compared with M2 cells. LPS converted M2 macrophages to the M1 phenotype with higher IL-12p70 production. *Candida albicans* stimulated a higher Epstein-Barr Virus induced protein 3 (EBI3) which can couple with IL-12p35 to form IL-35, a heterodimer soluble protein (EBI3/p35) with an immune suppressing activity. M2 cells stimulated with *C. albicans* suppressed IL-12p70 production (induced by LPS) in a dose dependent manner. This suppression resulted from competition between EBI3 and IL-12p40 for IL-12p35 binding. EBI3 expression was higher in M2 compared with M1 cells. *Candida albicans* also induced higher levels of EBI3 expression than LPS in M2. However, LPS and *C. albicans* stimulated similar levels of IL-12p35 in M2 cells. This suggests EBI3 induced by *C. albicans* competes with IL-12p40 for p35, leading to suppression of LPS induced IL-12p70. To confirm this hypothesis, an IL-12p70 expression CHO cell line was cloned by transfection with a biscistronic IL-12p40 and p35. The over expressed EBI3 largely suppressed IL-12p70 secretion in all cell clones. This reduction of IL-12p70 production was associated with EBI3/p35 heterodimer detection in the cell culture medium.
Conclusions: This result demonstrated that *Candida* de-sensitises tissue M2 macrophages to transform to M1 phenotype in the presence of LPS, by suppressing IL-12p70 production. This may lead to the avoidance of an unnecessary Th1 response during the resolving phase of infection.

P1674

Low dose of cyclophosphamide alleviates the suppression of contact sensitivity response mediated by macrophages

K. Nazimek, E. Sikora, B. Nowak, M. Ptak, W. Ptak & K. Bryniarski
Immunology, Jagiellonian University Medical College, Krakow, Poland

Purpose/Objective: Intravenous transfer of hapten-conjugated macrophages (Mf) to naïve recipients results in the suppression of contact sensitivity reaction (CS) as an effect of IL-10 secretion by donors' Mf and recipients regulatory T cells. A single administration of low dose of cyclophosphamide (CY) inhibits the suppression of CS response. The aim of our study was to test in the *in vivo* experiment how CY treatment influences both populations * donors macrophages and regulatory T cells in recipients and leads to the alleviation of suppression of CS reaction.
Materials and methods: To estimate CS oil-induced peritoneal Mf harvested from naïve or CY low dose (50 mg/kg) treated donors were labeled with TNP and transferred *i.v.* to naïve or CY treated recipients or recipients injected *i.v.* with anti-IL-10 and/or anti-TGF-b mAbs. Some grop7 days later ear thickness was measured just before the PCL challenge and 24 h later ear swelling responses were measured.
Results: Treatment with CY of Mf donors and/or recipients as well as recipients with anti-IL-10 mAb significantly inhibits the suppression while anti-TGF-β mAb therapy is inactive.
Conclusions: A single administration of low dose of CY into either donors or recipients restores the ability of Mf to induce significant CS reaction as a result of elimination of suppressive properties of Mf and/or depletion of population of regulatory T cells in recipients or

elimination of their suppressive activities. Observed inhibition was probably a consequence of decreased secretion of IL-10 by both populations of cells as a result of CY low dose treatment.

P1675

Macrophages present a regulatory phenotype after chronic cold stress in mice: correlation with increased 11ß-hydroxysteroid dehydrogenase expression

R. Sesti-Costa, M. D. C. Ignacchiti, S. Chedraoui-Silva, L. F. Marchi & B. Mantovani
Biochemistry and Immunology, Faculdade de Medicina de Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil

Purpose/Objective: Susceptibility to infections, autoimmune disorders and tumor progression are strongly influenced by activity of endocrine and nervous system in response to a stressful stimulus. When this adaptive system is switched on and off efficiently, the body is able to recover from the stress imposed. However, when this system is activated repeatedly or sustained, as during chronic or excessive stress, an allostatic load is generated, which can lead to disease over long periods of time. Chronic stress has immunosuppressive effects as illustrated by increase in severity and duration of infectious diseases and by the impairment of immune response to vaccines. However, the cells and the mechanisms involved in this immunossupression are not completely known. We investigated the effects of chronic stress on main functions of macrophages.
Materials and methods: Balb/c mice were chronically stressed by 4°C/4 h during 7 days and macrophages were evaluated for their ability to phagocytosis, superoxide and cytokines production and stimulate T cells.
Results: We found that chronic cold stress in mice regulates macrophages functions to a regulatory pattern. This regulation is shown by diminished phagocytosis, lower TNF-α and IL-6 and higher IL-10 production. Besides, resting macrophages are able to stimulate T cells with a regulatory cytokines profile after chronic stress. Furthermore, macrophages of stressed mice have increased expression of 11β-hydroxysteroid dehydrogenase, an enzyme that converts inactive glucocorticoid into its active form, and have lower capacity to control *Trypanosoma cruzi* infection *in vivo*.
Conclusions: As stress is a common aspect of modern life and takes part in the etiology of many diseases, the results of this study are important to improve the knowledge about the neuro-immune-endocrine interactions occurring during stress and show the role of macrophages in immunosuppression induced by chronic stress.
Support: CNPq, CAPES, FAPESP and FAEPA.

P1676

Mast cells are a target of tick saliva

H. Langhansova,* M. Klein,† E. Schmitt† & J. Kopecky‡
**Laboratory of Parasite Immunology, Institute of Parasitology Biology centre of the AS CR, Ceske Budejovice, Czech Republic, †Institute for Immunology, University Medical Centre of the Johannes Gutenberg-University Mainz, Mainz, Germany, ‡Department of Medical Biology, Faculty of Science, University of South Bohemia, Ceske Budejovice, Czech Republic*

Purpose/Objective: Mast cells concentrated beneath the epithelial surface of the skin play an important role during feeding of blood-sucking arthropods including ticks. Since tick feeding period can exceed 10 days, active modulation of the host immune response by tick saliva is required for the tick to complete its blood meal. However, whether the tick saliva affects also mast cell physiology and functions was not known.
Materials and methods: We tested the effect of *Ixodes ricinus* tick saliva on the degranulation and cytokine production by ionomycin- and/or IgE receptor-activated bone marrow-derived murine mast cells.
Results: The most affected mast cell cytokine was interleukin 9; its production after 48 h upon saliva treatment was decreased by approx. 80% compared with the IL-9 production in control untreated cells. Interleukin-4 and IL-13 were also significantly inhibited by the saliva, whereas IL-6 levels were only moderately reduced. In contrast, production of TNF-α after 4-h co-culture with tick saliva was not affected. Saliva had also no direct impact on the level of mast cell degranulation.
Conclusions: We demonstrated the direct effect of tick saliva on the production of cytokines in mast cells; these effects can change the cytokine balance in the tick feeding site and contribute to the modulation of host immune responses.

Notch family signalling between MSC and immune cells

E. Cahill & L. M. Tobin
Biology, National University of Ireland Maynooth, Kildare, Ireland

Purpose/Objective: Mesenchymal Stem or Stromal Cells (MSC) are immunomodulatory cells derived from bone marrow. MSC mediated immune modulation involves the induction of regulatory T cell populations and inhibition of dendritic cell maturation. This study sought to (1) determine the contact dependent signalling pathways between MSC and dendritic cells that block DC maturation; (2) identify the parallel signal between MSC and naïve CD4+ T cells leading to Treg induction; (3) determine the induction of tolerogenic DC by MSC.
Materials and methods: MSC and either DC or CD4+ T cells were used. An eGFP*FOXP3 reporter system was used to measure Treg induction. Notch signalling was blocked using Gamma Secretase Inhibitor (GSI) on either T cells or dendritic cells and expression of GFP-FoxP3 and maturation markers were examined by FACS. Immature DC co-cultured with MSC were pulled back after 48 h and co-cultured with CD4+ T cells from DO11.10 mice in the presence or absence of cognate antigen. After 72 h, proliferation was examined and Treg determined.
Results: Use of GSI prevented the MSC mediatedinduction/expansion of CD4+ FoxP3+ T cellsto controllevels. When GSI was used with DC and MSC, the immature DC characteristics sustained by MSC were lost. These DC induced regulatory T cells and inhibited antigen driven T cell proliferation in a Notch dependent manner.
Conclusions: These data demonstrate that the Notch-Notch ligand pathway is involved in MSC mediated induction of Treg. Inhibition of the Notch pathway abrogates MSC modulation of DC function but the exact receptors/ligand interaction here have yet to be determined. Using lentiviral transduction, a stable lines of silenced MSC were created. Using these cells the specific ligand involved in MSC immunomodulation can be determined.

P1678

Rapamycin inhibits innate and adaptive immune functions of human plasmacytoid dendritic cells

P. Boor,* S. Mancham,* L. J. W. van der Laan,† H. J. Metselaar* & J. Kwekkeboom*
**Gastroenterology and Hepatology, Erasmus MC – University Medical Centre, Rotterdam, Netherlands, †Surgery, Erasmus MC – University Medical Centre, Rotterdam, Netherlands*

Purpose/Objective: Rapamycin is an immunosuppressive drug used to prevent organ transplant rejection and cancer. Plasmacytoid

dendritric cells (PDC) are important in innate immunity as they are the principal producers of IFN-α, and in adaptive immunity by presentation of antigens to T cells. PDC are critically involved in immunity to viral infections and in the pathogenesis of auto-immune disorders like Systemic Lupus Erythematosus (SLE). Here we report that innate and adaptive immune functions of human PDC are differentially regulated by Toll-Like Receptors (TLR) and CD40, and that rapamycin inhibits both innate and adaptive immune functions of PDC.

Materials and methods: Human PDC were isolated from blood of healthy volunteers and stimulated with loxoribin, CpG or CD40L in the presence or absence of rapamycin and tested for their cytokine production and T-cell stimulatory capacity.

Results: Human PDC activated by TLR-7 or TLR-9 ligands produced high amounts of IFN-α, but exhibited a weak T cell stimulatory capacity. Conversely, PDC activated by CD40-ligation failed to produce IFN-α, but induced robust allogeneic T cell proliferation and effector functions, among which production of pro-inflammatory cytokines IFN-gamma, TNF-alpha and IL-17. A clinically relevant concentration of rapamycin (20 ng/ml) inhibited the phosphorylation of S6 and the production of IFN-α by PDC, and suppressed the capacity of PDC to stimulate allogeneic T cell effector functions. Reduction of T-cell stimulatory capacity was most pronounced when rapamycin was added during activation of PDC via CD40, and was associated with inhibition of CD40 expression on PDC.

Conclusions: Activation of human PDC via TLR stimulates their innate immune functions, while activation via CD40 stimulates their adaptive immune functions. Rapamycin inhibits both innate and adaptive immune functions of human PDC, and may therefore constitute a novel treatment option for SLE, but increase susceptibility to viral infections.

P1680
Soluble MHC class II antigens as potent regulators of the immune response

K. Bakela & I. Athanassakis
Biology, University of Crete, Heraklion, Greece

Purpose/Objective: Soluble MHC-II (sMHCII) molecules are present in body fluids of healthy individuals and are considered to be involved in the maintenance of self tolerance, while they have also been related to various diseases. Their concentration has been shown to increase during *in vivo* antigen-specific tolerogenic stimulation. At the cellular level, sMHCII proteins compete with membrane MHCII for TCR binding and induce Src kinases activation. The aim of the present study was to define the physical and chemical properties of sMHCII and examine their ability to affect responsiveness and cytokine secretion profile of total spleen cells, total T-cells or CD4+ cells.

Materials and methods: Soluble MHC-II proteins were isolated from serum of mice tolerized with human serum albumin (HSA). Purity was verified through ELISA, SDS-PAGE, Western blot analysis and specific biosensor assays. Protein concentration was calculated using the Lowry method. Total spleen cells or T-cells were isolated from control or immunized BALB/c male mice, while CD4+ T-cells were purified using Flow Cytometry Sorter. The effect of sMHCII on the different cell populations tested as to cell proliferation and marker expression was evaluated using incorporation assays and Flow Cytometry analysis respectively. Cytokine production was tested by ELISA.

Results: The obtained results showed that the sMHCII proteins were capable to suppress an antigen-specific immune response by reducing the number of active cells. Thus, sMHCII induced control CD25+ and CTLA+ T-cell populations, while reducing CD28+ T-cells. Furthermore, it was shown that sMHCII induced secretion of the cytokine IL-10, while stimulating the proliferation of suppressive CTLA-4+ cells, through the negative regulation of CD4+ and CD28+ cells.

Conclusions: The results presented here showed that sMHCII can negatively regulate an antigen-specific immune response *in vivo* as well as *in vitro* by inducing immunosuppressive cell populations and mediators. It is proposed that sMHCII molecules could play a very important role in immune homeostasis, as they could mediate antigen-specific tolerance.

P1681
Structure and function of oxazolone specific T suppressor factor in contact sensitivity response

E. Sikora,* B. Nowak,* K. Nazimek,* M. Ptak,* P. W. Askenase,† W. Ptak‡ & K. Bryniarski‡
**Immunology, Jagiellonian University Medical College, Krakow, Poland, †Internal Medicine, Yale University School of Medicine, New Haven, CT, USA, ‡Immunology, Jagiellonian University College of Medicine, Kraków, Poland*

Purpose/Objective: Contact hypersensitivity (CHS) in mice is mediated and regulated by different subpopulations of T-cells. High antigen dose induced-suppressor T (Ts) lymphocytes inhibit CHS reaction through release of soluble suppressor factor (TsF). The aim of our study was to establish the nature of OX-TsF, factor specific for CHS elicited by oxazolone (OX).

Materials and methods: OX-TsF production is induced in mice by i.v. immunization with OX, followed by skin sensitization with the same hapten. OX-TsF is obtained as a culture supernatant of Ts and may be purified by phenol-chloroform extraction into a mixture of nucleic acids (PCE) and then DNA (QDNA) and RNA (QRNA) fractions may be separated on chromatography columns. Alternatively, suppressive exosomes may be isolated from culture supernatant of Ts by ultracentrifugation. Biological activity of OX-TsF and its preparations was determined *in vivo* in CHS model.

Results: OX-TsF displays the ability to inhibit both the elicitation of CHS in naïve recipients of T effector cells (Tef) and ongoing allergy in actively sensitized mice. The function of OX-TsF was observed in both PCE and QRNA, but not QDNA, fractions of the tested factor and was characterized by a dose-response effect. RNA nature of OX-TsF was confirmed by its sensitivity to RNase A treatment. Additionally, electrophoresis on agarose gel proved that the RNA fraction of TsF comprises particles of the size of 10–90 nucleotides.

TsF performs its function in antigen-specific manner, which is observed in both supernatants and exosomes obtained from cultures of Ts induced by different haptens.

The mechanism of action of OX-TsF may tentatively involve apoptosis of the Tef.

Conclusions: It seems likely that the observed suppressive effect, mediated *in vivo* by short RNAs transported antigen-specifically in exosomes in the future may be used as a therapeutic approach to the diseases which result from the impaired function of effector T cells.

P1682
Study of the effect of CAMPATH on cord blood and peripheral blood cells

F. Y. Lee, A. Madrigal & B. Shaw
Cancer Research, Anthony Nolan Trust- UCL, London, UK

Purpose/Objective: CAMPATH is an anti-CD52 monoclonal antibody used as an immunosuppressive drug that effectively depletes T cells in the pre-transplant conditioning regimen.

Materials and methods: CD52 expression of the resting and activated immune cells were checked. Both resting and activated samples were treated with CAMPATH and compared the the non-treated samples.

Results: CD52 expression on resting and activated peripheral blood (PB) and cord blood (CB) cells was studied. For resting CB cells, the

level of CD52 expression on B cells and T cells was very comparable (~569.2 ± 44.19), natural killer (NK) cells expressed the lowest level of CD52 (278.4 ± 31.64), and CD52 was not expressed on resting CB stem cells. For resting PB, B cells expressed the highest CD52 expression (540.8 ± 68.5), followed by T cells (433.1 ± 67.15), NKT cells (349 ± 74.67), and NK cells (301.4 ± 59.5). CD52 density was shown to be significantly higher in CB T cell subsets than PB T cell subsets except for Treg cells where CD52 expression was comparable in both CB and PB (~451.2 ± 53). In contrast, CD52 expression in activated cells was slightly higher in PB than CB, with T cell subsets expressing the highest level (~657.3 ± 27.70 and ~496.8 ± 4.872 respectively) followed by NK cells (~415.0 ± 16.15). However, both PB and CB activated Treg expressed similar level of CD52 density (~396.4 ± 9.948).

A viability study was designed to study the potency of CAMPATH in inducing PB and CB immune cell death. Although different concentrations were used, CAMPATH induced apoptosis and necrosis in a comparable manner, having the same effects on both CB/PB T and B cells. No difference was shown for both CB/PB NK cells. A maximum response towards CAMPATH treatment was observed approximately 24-h post administration for all cell types.

Conclusions: A better understanding of the impact of CAMPATH on immune cells would be useful to contribute to the future clinical application of the drug in order to achieve optimal efficacy.

P1683

T cell-selective mutated interleukin-2 AIC284 efficiently protects Lewis rats from experimental autoimmune encephalomyelitis

N. Beyersdorf,* A. Weishaupt,† S. Werner,* N. Wolf,* G. Köllner,† D. Paulsen,‡ T. Hünig* & T. Kerkau*

**Chair for Immunology, Institute for Virology and Immunobiology, Würzburg, Germany, †Department for Neurology, University Hospital Würzburg, Würzburg, Germany, ‡AiCuris GmbH & Co. KG, Wuppertal, Germany*

Purpose/Objective: The cytokine interleukin-2 (IL-2) critically influences the survival and function of $Foxp3^+$ regulatory T cells (T_{reg} cells) *in vivo*. Therefore, targeting T_{reg} cells via the high affinity IL-2 receptor, CD25, constitutes a novel therapeutic approach for autoimmunity. As anti-cancer therapy with IL-2 has revealed substantial toxicities due to activation of conventional memory T cells and NK cells expressing intermediate affinity IL-2 receptors, a mutated human IL-2 molecule, termed AIC284, has been developed to reduce these side effects.

Materials and methods: AIC284 shows similar binding to the human high affinity IL-2 receptor as wild-type (wt) IL-2 but about 10^4-fold less binding capacity to the intermediate affinity IL-2 receptor. In search for an appropriate rodent animal model to analyze the therapeutic potential of AIC284 in autoimmunity we observed that AIC284 only bound less well (100-fold) than wt IL-2 to intermediate affinity IL-2 receptors of the rat but not to those of the mouse. Therefore, we treated rats immunized with guinea pig myelin basic protein (gpMBP) to develop experimental autoimmune encephalomyelitis (EAE) for the first 4 days after the immunization with daily doses of 100 mg AIC284 or wt human IL-2 or 250 ml phosphate-buffered saline s.c.

Results: Treatment with AIC284 or wt IL-2 protected the rats similarly well from EAE, both, clinically and histologically. Further analyses revealed that application of AIC284 and wt IL-2 inhibited the generation of gpMBP-specific pathogenic, i.e. IFNg-producing, $CD4^+$ T cells and strongly reduced the infiltration of leukocytes into the spinal cord (SC). As expected, protection from EAE was associated with increased frequencies and absolute numbers of $Foxp3^+$ T_{reg} cells among $CD4^+$ T cells.

Conclusions: As far as the precise therapeutic mechanism is concerned, wt IL-2 and AIC284 appear to differ as wt IL-2 strongly expanded T_{reg} cells expressing the activation marker CD8 within secondary lymphoid organs (SLO) while AIC284 induced only a slight increase in $CD8^+$ T_{reg} cell numbers in SLO but instead favored their accumulation in the SC. Experiments directly addressing the contribution of CD8-expressing T_{reg} cells in AIC284-mediated protection from EAE are ongoing. This study was supported by a grant from AiCuris GmbH & Co. KG, Germany.

The compartment of human natural $CD4^+CD25^{++}CD127^-$ regulatory T cells is filled with cells reactive to various antigens

N. Litjens, K. Boer, C. C. Baan & M. G. H. Betjes

Internal Medicine Nephrology and Transplantation, Erasmus Medical Center, Rotterdam, Netherlands

Purpose/Objective: The population of regulatory $CD4^+CD25^{++}CD127^-FOXP3^+$ T cells (Tregs) is composed of thymus-derived (natural, nTregs) or Tregs induced in the periphery (iTregs). nTregs have a highly demethylated TSDR *FOXP3* and are believed to be important for control of autoreactive T cells. Tregs are important to control alloreactive T cells and could be used for cell therapy to induce tolerance to an allograft. Recognition of natural alloantigen-specific Tregs could facilitate a targeted approach for such a therapy. Expression of CD40L (CD154) can be used to detect antigen-specific $CD4^+$ T cells. In this study, we used specific expression of CD154 to study the presence of antigen-specific Tregs.

Materials and methods: Highly enriched fractions of Tregs and $CD4^+$ effector T cells ($CD4^+$Teff) were sorted and stimulated with various antigens in the presence of aCD40 to maintain CD154 on the cell surface. Subsequently, these CD154-expressing Tregs were sorted and tested either immediately for their suppressive capacity or following polyclonal (using CD3/CD28 beads) or antigen-specific expansion, respectively. The demethylation of TSDR *FOXP3* was determined for the different Treg-fractions. In addition, in depth phenotypic analyses were performed on the different Treg-fractions.

Results: Using different viral, vaccination as well as alloantigens, we detected similar frequencies of antigen-specific $CD154^+$T cells in both fractions with great specificity and sensitivity. Ag-specific $CD154^+$Tregs had a memory phenotype, no cytokine production after polyclonal stimulation, stable FOXP3 expression and a highly demethylated TSDR *FOXP3*. Sorted $CD154^+$ Tregs were superior in suppressing Ag-specific responses when compared to $CD154^-$Tregs. $CD154^+$ Tregs could be efficiently expanded in an Ag-specific manner, which enhanced their suppressor activity. After booster vaccination, the ratio of Ag-specific $CD4^+$ Teff:Treg temporarily increased substantially due to an increase in $CD154^+CD4^+$ Teff but not Tregs.

Conclusions: These data show for the first time that the compartment of circulating human nTregs is filled with Ag-specific T cells for a variety of antigens. Isolation and expansion of Ag-specific nTregs may be of potential benefit for Treg-therapy to induce tolerance in the setting of kidney transplantation.

P1685

The effect of all-trans retinoic acid on histocompatibility receptor distribution at the foeto-maternal interface

P. Jain, A. Blanch, A. Jabeen, S. Hakam, P. Laissue & N. Fernandez

Department of Biological Sciences, University of Essex, Colchester, UK

Purpose/Objective: The field of reproductive immunology was created for understanding the tolerance strategies by which the semiallogenic foetus evades the maternal immune system. Multiple mechanisms underlie the tolerance shown by the maternal immune system. A chief role is played by the Human Leukocyte Antigen -G (HLA-G), a member of the non-classical Major Histocompatibility

Complex (MHC) class I molecule. HLA G has a unique pattern of expression; low polymorphism and tissue distribution that enable it to aid the process of fetal implantation by preventing it from being recognized as 'foreign'. In early work[1] it was shown that the MHC receptors (HLA-G and HLA-E) and that their distribution is linked to the cytoskeleton. Certain retro-retinoids are known to induce growth arrest and death by apoptosis in cell lines. It was demonstrated[2] that F-actin is a functional target for Retro-Retinoid Action. Hence, F- actin reorganization is an early event in RA induced apoptosis. Lack of MHC class I a and the expression of these non classical antigens has long been hypothesized to be a major factor in immune tolerance. This study is mainly focused on investigating the expression of HLA class I b, and assessing whether Retinoic Acid plays a role in the regulation of the functional expression of HLA-G.

Materials and methods: The techniques used in order to establish this study are flow cytometry, protein analysis and microscopic analysis.

Results: Our results revealed that Retinoic Acid up regulates surface HLA-G expression significantly in a dose and time dependant manner. Proliferation and Cytotoxicity assays further confirmed this effect and results were supported by the fact that the effects of ATRA could be inhibited by various concentrations of 9-cis RA, the isomer and antagonist of ATRA. Image analysis with Nikon Viewer software identified changes in morphology in HLA-G expression after ATRA induction, includingminor changes in the cytoskeleton.

Conclusions: All trans Retinoic Acid acts as a stimulator at certain concentration for HLA-G, and can induce apoptosis beyond 50 μM. The regulation of the functional expression of HLA-G by Retinoic Acid could induce a physiological role such as apoptosis. This study is also, a novel approach for studying ATRA mediated (using cytoskeleton as a functional target) apoptosis in embryonic cell lines. As the results were consistent in both cell lines, we can also propose ACH-3P as a model cell line for trophoblast investigation.

The influence of opioids treatment on the immune response in mice: the role of macrophages

I. Filipczak-Bryniarska,* B. Nowak,† E. Sikora,† K. Nazimek,† M. Ptak,† J. Woron,* J. Wordliczek,* W. Ptak† & K. Bryniarski†
**Pain Treatment and Paliative Care, Jagiellonian University Medical College, Krakow, Poland, †Immunology, Jagiellonian University Medical College, Krakow, Poland*

Purpose/Objective: Immune responses mediated by lymphocytes and macrophages could be modulated by opioids (OPs) via their cell surface receptors. The aim of our study was to establish the role of opioid (morphine, fentanyl or methadone) treated murine macrophages (MF) in the regulation of humoral and cell-mediated responses in CBA/J mice.

Materials and methods: For this purpose macrophages obtained from opioid treated mice were either fed with sheep erythrocytes (SRBC) or labeled with TNP hapten and transferred i.v. into naïve recipients. Humoral response was estimated by plaque forming assay (PFA) and direct haemagglutination assay (HA) determining sera titres of anti-SRBC IgM and IgG antibodies. Contact hypersensitivity reaction (CHS) was tested by ear swelling measurement after challenge withTNP/PCL hapten. Macrophage properties *in vitro* were assessed in FACS analysis of surface markers expression, ELISA for cytokine secretion and chemiluminescence assay for oxygen intermediates (ROIs) production.

Results: The induction of humoral response by opioid treated Mf was strongly inhibited. Numbers of PFC were lower by 30% (morphine or fentanyl treatment) to 57% (methadone) as compared with control animals. This same holds true for Ab titers. CHS reaction was differentially affected by OPs. While all tested OPs increased the early phase of reaction, the late phase is increased only in morphine therapy and affected by fentanyl and methadone. The impairment of MF antigen-presentation ability was also observed as decreased expression of CD80, CD86 and MHC class II in FACS analysis. The secretion of proinflammatory cytokines by MF obtained from donors treated with OPs was inhibited andmorphine or methadone but not fentanyl therapy caused an enhancement of IL-10 as well as ROIs production by MF.

Conclusions: MF are the target cells for opioid activity in modulation of immunity. The inhibitory action of OPs on humoral and cellular responses seems to be an effect of impaired ability of MF to present antigen.

P1687
The role of Dickkopf-3 in immune responses

J. Ludwig, M. Papatriantafyllou, M. Meister, G. Moldenhauer, H. J. Gröne, C. Niehrs, G. Hämmerling, T. Oelert & B. Arnold
Molecular Immunology, German Cancer Research Center, Heidelberg, Germany

Purpose/Objective: It is so far unknown to which extend tissue cells influence the type and strength of a local immune response. Recently, we demonstrated that Dickkopf-3 (Dkk3) is essential to maintain peripheral CD8 T cell tolerance in a TCR-transgenic mouse model (Papatriantafyllou, M; Proc Natl Acad Sci U S A, 2012, 109:1631–1636). Since Dkk3 is highly expressed by tissue cells of immune-privileged sites, as e.g. the brain and the eye, it is of interest whether the local production of Dkk3 contributes to immuno-suppression.

Materials and methods: *In vitro* T and B cells were stimulated and proliferation and secreted cytokines were analyzed. For these experiments either Dkk3$^{-/-}$ versus wt cells or addition of exogenous Dkk3 versus control were compared.

In vivo EAE was induced in Dkk3$^{-/-}$ and wt mice. T cells were purified from the brain at the peak of disease or during the recovery phase and analyzed. To investigate B cell responses Dkk3$^{-/-}$ and wt mice were immunized and antibody titers were determined at different time points.

Results: In order to investigate whether Dkk3 has an impact on immune responses in the brain, experimental autoimmune encephalitis (EAE) was compared in Dkk3$^{-/-}$ and wt mice. Animals lacking Dkk3 exhibited a prolonged disease compared to Dkk3 sufficient animals. This was associated with changes in T cell subset composition and the local cytokine milieu.

Comparing immune responses in organs lacking Dkk3 expression as the spleen by *in vivo* cytotoxicity assay no general state of hyperresponsiveness in Dkk3 deficient T cells was observed. *In vitro* we found a decrease in proliferation, expression of CD25 and secretion of IL-2 upon stimulation of T cells in the presence of exogenous Dkk3.

B cell responses were also affected by Dkk3. Mice deficient for Dkk3 showed altered antibody responses after immunization with TNP-BSA or TNP-Ficoll in comparison to wt mice. Furthermore, B cells from Dkk3$^{-/-}$ mice showed changes in cytokine expression *in vitro*.

Conclusions: Based on these data we conclude that Dkk3 is modulating T cell responses and antibody production.

P1688

Tolerization of diabetogenic CD4+ T cells by intranasal treatment with CTA1R7K-DD containing specific peptide through the induction of FoxP3$^+$ Treg cells

S. Cardell, L. Fahlén-Yrlid, L. Mark, L. Löfbom & N. Lycke
Department of Microbiology and Immunology, University of Gothenburg, Gothenburg, Sweden

Purpose/Objective: Type I diabetes (T1D) results from immune destruction of insulin producing β-cells in the pancreas islets. Diabetogenic CD4$^+$ T cells are key cells in the autoimmune process. To achieve tolerization of diabetogenic CD4$^+$ T cells would therefore be an important advancement in the development of treatment of T1D. We previously described that a mutated (R7K), enzyme killed, form of the cholera toxin A1 subunit based adjuvant CTA1R7K-DD induces specific tolerance rather than enhancement of immunity. Intranasal (i n) treatment with CTA1R7K-DD containing a type II collagen peptide reduced *in vitro* recall responses to the peptide, and moreover, ameliorated collagen induced arthritis in mice. Here, we use CTA1R7K-DD to investigate tolerization of diabetogenic CD4$^+$ T cells of the non-obese diabetic (NOD) mouse, exploring diabetogenic TCR transgenic BDC2.5 CD4$^+$ T cells.
Materials and methods: NOD or TCR transgenic BDC2.5 NOD mice were treated i n with CTA1R7K-*peptide*-DD fusion proteins, where the inserted peptide was Ins9-23 or PS3 (a strong agonist peptide for the BDC2.5 TCR), respectively.
Results: I n treatment of BDC2.5 NOD mice with CTA1R7K-PS3-DD reduced proliferation and IFN-γ production to *in vitro* PS3 peptide stimulation. Transfer of CD4$^+$ BDC2.5 T cells to NOD.*scid* mice results in T1D development in 80–100% of recipient mice. In contrast, 95% of recipients of cells from BDC2.5 NOD mice treated with the CTA1R7K-DD peptide construct remained healthy. The i n treatment resulted in systemic increase in the frequency of CD4$^+$ BDC2.5 transgenic T cells expressing FoxP3, most enhanced in draining mediastinal lymph nodes.
Conclusions: We demonstrate that i n treatment with CTA1R7K-pept-DD induced tolerance in peptide specific diabetogenic CD4$^+$ T cells, and resulted in an increased frequency of Treg cells. The data suggest that CTA1R7K-peptide-DD may prevent T1D development by the induction of peptide specific CD4$^+$ Treg cells.

P1689

Treg differentiation induces by the immunosuppressive enzyme IL4I1

C. Cousin, F. Castellano & V. Frenkel
INSERM U955, Créteil, France

Purpose/Objective: IL4I1 is an L-phenylalanine oxidase which inhibits the TCRζ chain expression and the proliferation of T lymphocytes *in vitro* [Boulland ML *et al.* (2007) *Blood* 110(1):220–227]. IL4I1 is highly expressed by macrophages infiltrating tumors and tumor cells of some cancers, particularly different B-cell lymphomas [Carbonnelle-Puscian A *et al.* (2009) *Leukemia* 23(5):952–60]. We recently showed in a mouse model that IL4I1 inhibits the cytotoxic antitumor T-cell response [Lasoudris F *et al.* (2011) *European Journal of Immunology* 41:1629–38].
Materials and methods: To evaluate the hypothesis that IL4I1 could contribute to the enrichment of regulatory T cells (Treg) in tumors, we used a recombinant monocytic cell line expressing IL4I1 [Marquet J *et al.* (2010) *European Journal of Immunology* 40(9):2557–68] to stimulate naïve CD4+ T cells and studied the effect on T helper cell differentiation in the presence or absence of polarizing stimuli.
Results: The phenotypic analysis of the population obtained showed an enrichment in CD25^{high} FoxP3$^+$ Treg endowed with *in vitro* suppressive activity. The mechanisms involved and the phenotypic characteristics of these cells are currently under investigation.
Conclusions: Thus, IL4I1 may participate to tumor escape both via inhibition of effector T cell proliferation and functions and Treg enrichment in the tumor microenvironment.

P1690

Use of the quantitative DNA methylation assay to measure Treg frequencies in the ovarian cancer patients

I. Vancurova,* L. Sojka,† A. Fialová* & R. Spisek†
**Department of Immunology, 2nd Faculty of Medicine Charles University and University Hospital Motol, Prague, Czech Republic, †Research Department, Sotio a.s., Prague, Czech Republic*

Purpose/Objective: The type of immune cells that are present within the tumor microenvironment can play a crucial role in the prognosis of patients. However, little is known about the dynamics of the tumor-infiltrating immune cells during disease progression. We studied the immune cells infiltrating the tumor tissues of ovarian cancer patients at different stages of disease.
Materials and methods: We used the flow cytometry for detection Th17 cells and a dominant population of FoxP3$^+$ Helios$^+$ activated regulatory T cells (Tregs) in disseminated tumors (stage III-IV).

So far, the most specific marker for human naturally occurring Treg cells is the demethylation in the TSDR region of the transcription factor FoxP3. To measure nTreg frequencies we used methyl sensitive real time PCR assay (MS-qPCR) that is strictly specific for nTreg cells.
Results: The early stages of development of ovarian carcinomas were characterized by a strong Th17 immune response. A population of naturally occuring Treg cells was measured. We found that the frequency of nTregs significantly increases during the progression of the ovarian cancer.
Conclusions: Our findings demonstrate for the first time an alteration in the tumor-infiltrating immune cell pattern during ovarian cancer development and cleary show a dynamic shift from an active anti-tumor immune response represented by the presence of effector T cells, which prevail over Tregs in the early stages of EOC, to a significant immune suppression in the advanced stages of disease.

Poster Session: Immuno-Reset

A synthetic peptide that restores the inhibitory CD31 signaling as first-in class multifunctional anti-inflammatory drug

G. Caligiuri, M. Clement, G. Fornasa, K. Guedj, M. Morvan, J. Khallou-Laschet, A. T. Gaston & A. T. Nicoletti
Immunopathology and Immunomodulation of Cardiovascular Diseases, Inserm U698, Paris, France

Purpose/Objective: In addition to adaptive immune cells, platelets and endothelial activation contributes to dissemination of chronic inflammatory diseases, such as multiple sclerosis. CD31, a homophilic ITIM receptor exerts a global regulatory function on leukocytes, endothelial cells and platelets, but it is rapidly lost by cleavage upon cell activation. The aim of this study was to evaluate the inhibitory potential of a 8aa retro-inverso CD31-agonist synthetic peptide (P8RI) on cell activation *in vitro* and on the clinical course of Experimental Autoimmune Encephalomyelitis (EAE) *in vivo*.
Materials and methods: The *in vitro* effect of the peptide (5–100 μM) was evaluated on the activation of Human T cells by cytometric analysis of calcium mobilization in fluo 3-AM labelled Jurkat T cells stimulated with anti-CD3 antibodies and F(ab')2 anti-Ig fragments. The effect of P8RI on expression of VCAM-1 in response to IFNγ/TNF$\gamma\alpha$ stimulation by endothelial cells (HMEC/D3 cells) by immunofluorescence microscopy and cytometry. Finally, the anti-inflammatory effect of P8RI on platelets was tested on the release of soluble P-selectin (sCD62P) and IL-1β in response to tissue factor. Curative potential of P8RI was assessed on C57Bl6 mice (female, 8 week-old) subjected to MOG-induced EAE and clinically examined daily. When the clinical score reached a value ≥ 1, mice were randomized to receive either P8RI (2.5 mg/kg/day, sc) or prednisone (5 mg/kg/day, sc), or the vehicle alone (PBS, vol/injection = 50 μl).
Results: P8RI significantly reduced calcium mobilization in TCR-stimulated Jurkat T cells. In addition, it reduced the expression of VCAM-1 on stimulated endothelial cells as well as the release of sCD62P and IL-1b by tissue factor-stimulated platelets. In the curative EAE model, body weight and blood cell count were not affected by either the P8RI ($n = 14$) or prednisone ($n = 14$) as compared to control mice ($n = 13$). The time course of the clinical score was significantly bent by P8RI ($P < 0.01$ versus PBS, MANOVA). Of note, the extent of protection was even greater that that observed with prednisone ($P < 0.05$) up to 12 days of follow-up.
Conclusions: P8RI could be the first-in-class immune-regulatory drug that acts by rescuing a physiologic regulatory mechanism that is common to key cells involved in chronic inflammatory diseases.

Due to the fact that it does suppress/deplete resting blood cells, nor blocks a given immune pathway, its use may carry significantly fewer side effects as compared to other biologicals such as lymphocyte and cytokine neutralizing antibodies or soluble receptors.

A high throughput phenotypic screen for Cbl-b antagonists on primary human T-cells

I. Sternberger, G. Schmiedel, I. Winzenborg, B. Magsig & M. Slack
Evotec AG, Cellular Assays, Hamburg, Germany

Purpose/Objective: Cbl-b is a well validated target for anti-tumor immune therapy. It functions in controlling T cell anergy and thereby contributes to tumor growth and metastasis. Cbl-b is a member of the E3 ubiquitin ligase family and mediates ubiquitin attachment to key signaling molecules in immune cells. The Cbl-b protein consists of several conserved domains that mediate the interaction with a high number of proteins. This, together with the large size of Cbl-b protein, poses a challenge for a robust biochemical screen. Cbl-b causes numerous unique effects in T and NK cells and thus allows a number of specific cellular functional assays for inhibition of Cbl-b. Therefore, Cbl-b is a prototypic target for a cellular, phenotypic screen. In order to identify Cbl-b antagonists, a set of approximately 80 000 compounds was screened. To this end, human PBMCs have been employed in a phenotypic assay measuring IL2 secretion.
Materials and methods: Human PBMCs were isolated from pre-characterized donors, stimulated with CD3- and CD28-antibodies and used to screen 80 000 lead like compounds of Evotec's small molecule library at a concentration of 10 μM, phorbol ester stimulation was employed as a positive control. After overnight incubation, tissue culture supernatants were harvested and used to determine IL2 content by HTRF.
Results: Primary human PBMCs were obtained from pre-characterized volunteer donors. In order to identify Cbl-b antagonists, a phenotypic read-out was employed: Cells were stimulated with CD3/CD28 antibodies and Interleukin 2 content was measured after overnight incubation. Compounds that increased IL2 secretion in stimulated cells were selected. Counter screening was performed in the absence of cells, in order to rule out HTRF-related artifacts, and with naïve, non stimulated cells, to rule out pathway-unrelated stimulation of IL2 secretion. Screening of 80 000 substances revealed 39 confirmed, specific hits. The hit substances were clustered and revealed three different compound series in addition to numerous singleton hits. Hit expansion was performed by 2D based nearest neighbour searches and ca. One-sixty compounds together with the original hits were selected to be tested in 11 point concentration titration experiments on purified CD4+ T-cells.
Conclusions: Disease relevant, primary human T cells have successfully been employed in HTS using phenotypic, non-engineered read-outs and relevant chemical matter has been identified.

A mass spectrometry approach to identify HPV16 T cell epitopes for therapeutic vaccine design

S. Hoppe,* R. Blatnik,* A. K. Grabowska,* M. Wühl,* T. Ruppert,† U. Warnken,‡ M. Schnölzer‡ & A. B. Riemer*
**Immunotherapy and -Prevention, German Cancer Research Center, Heidelberg, Germany,* †*ZMBH, Core Facility for Mass Spectrometry and Proteomics, Heidelberg, Germany,* ‡*Functional Proteome Analysis, German Cancer Research Center, Heidelberg, Germany*

Purpose/Objective: To rationally design therapeutic HPV vaccines it is important to know which T cell epitopes are present on HPV-transformed malignant cells. HPV affects the cellular antigen processing machinery, thus not every epitope derived from viral proteins is necessarily presented by MHC molecules on the cancer cell surface.

Human papillomavirus (HPV) 16 has been identified as the causative agent in 50% of all cervical cancer cases and in virtually all extra-cervical mucosal HPV-induced tumors. The transforming potential of high-risk HPVs is mediated by two consistently expressed viral oncoproteins, E6 and E7. As the induction and maintenance of the malignant phenotype depends on these two proteins, they are ideal targets for immunotherapy. A therapeutic vaccine that is applicable to everyone without prior HLA typing needs to contain epitopes for all HLA types. Definition of epitopes for the five major HLA supertypes allows >95% population coverage.

To date, HPV T cell epitopes have mostly been determined by indirect methods and for the most prevalent HLA type, HLA-A2. In this study, we aim to directly identify HPV16 E6 and E7 T cell epitopes for the HLA-A3/HLA-A11 and HLA-A24 supertypes by a mass spectrometry (MS) approach.
Materials and methods: Several web-based prediction algorithms were used to predict prospective epitopes from the HPV16 E6 and E7 proteins for the above mentioned HLA supertypes. These candidate epitopes were tested for actual HLA binding in competition-based cellular binding assays. The presence of binding peptides on HPV16-transformed cells was analyzed by nano-UPLC-ESI-MS^2 and -MS^3 of immunoprecipitated HLA-A2-peptide complexes.
Results: *In silico* prediction resulted in 48 candidate epitopes for HLA-A3, 86 for HLA-A11 and 66 for HLA-A24. The majority of predicted peptides were found to bind to their respective HLA allele. Several novel binding peptides derived from HPV16 E6 and E7 were identified. MS analysis was successfully established and validated for HLA-A2.
Conclusions: We show that ascertaining the actual cellular presentation of HPV T cell epitopes is feasible. Having shown proof-of-concept for this approach for HLA-A2, it will now be extended to other HLA supertypes. Verified epitopes are the basis of rational therapeutic vaccine design and also important for immunomonitoring purposes.

P1696

A toxoplasma gondii vaccine strain transforms immunosuppressive ovarian cancer dendritic cells into immunostimulatory cells that trigger therapeutic antitumor immunity

D. Bzik, K. L. Sanders, & B. A. Fox
Microbiology and Immunology, Geisel School of Medicine at Dartmouth, Lebanon, NH, USA

Purpose/Objective: Targeting tumor-associated immunosuppression may be necessary to stimulate effective therapeutic immunity against lethal epithelial tumors such as ovarian cancer, one of the most aggressive and most frequently occurring epithelial cancers. We examined efficacy and mechanisms of *Toxoplasma gondii* vaccine immunotherapy targeting $CD11c^+$ dendritic cells that exhibit proangiogenic and immunosuppressive activity and are the most abundant leukocyte present in the ovarian carcinoma microenvironment.
Materials and methods: Attenuated nonreplicating *T. gondii*; transplantable ID8-*Defb29/Vegf-A* and ID8-*Vegf-A* tumors; knockout mice; FACS analysis; cytokine analysis; tumor microenviroment.
Results: We show that an avirulent nonreplicating vaccine strain (*cps*) of *Toxoplasma gondii* preferentially targets and invades immunosuppressive $CD11c^+$ dendritic cells in the ovarian carcinoma microenvironment. Tumor $CD11c^+$ dendritic cells actively invaded by *cps* were activated into immunostimulatory phenotypes that expressed markedly increased levels of co-stimulatory molecules CD80 and CD86. In response to *cps* treatment of the immunosuppressive ovarian tumor environment, IL-12 was rapidly stimulated and antigen-presenting cells regained the ability to efficiently process and present antigen. Treatment of an extremely aggressive transplantable ovarian carcinoma (ID8-*Defb29/Vegf-A*) with *cps* provided a significant therapeutic survival benefit, and remarkably, *cps* treatment induced the rejection of a lethal aggressive model (ID8-*Vegf-A*) of established ovarian carcinoma. The therapeutic benefit of *cps* treatment was dependent on expression of IL-12 and interferon gamma. Surprisingly, the thera-

peutic effect was independent of MyD88 signaling as well as immune status to *Toxoplasma gondii*.
Conclusions: Our results establish that *cps* preferentially targets and activates tumor-associated dendritic cells to trigger the stimulation of potent antitumor responses. Immunotherapy based on *cps* reawakens natural immunity in immunosuppressive tumor environments and provides a new potent vaccine platform for engineering effective cancer vaccines based on the stimulation of tumor cell-specific $CD8^+$ T cells.

P1697
A tumor directed antibody_IL-15_IL-15Radomain fusionprotein for cancer immunotherapy

V. Kermer, V. Baum, R. E. Kontermann & D. Müller
Biomedical Engineering, Institute of Cellbiology and Immunology, Stuttgart, Germany

Purpose/Objective: Cytokines driving the immune response are powerful tools for cancer immunotherapy, but their application is generally limited by severe systemic toxicity. Targeted approaches by means of antibody-cytokine fusion proteins might enable to focus the cytokine activity to the tumor site, thereby reducing unwanted side effects. Here we investigated the possibility to improve the efficiency of IL-15 presentation in a targeted approach by the incorporation of an IL-15Rα chain fragment, mimicking physiological trans-presentation. Therefore, an antibody cytokine fusion protein (scFv_RD_IL-15) composed of an antibody moiety (scFv) targeting the tumor stromal fibroblast activation protein (FAP), an extended IL-15Rαsushi domain (RD) and IL-15 and according control proteins devoid of one of the components were generated.
Materials and methods: FAP-transfected B16 melanoma cells were used as target cells for *in vitro* and *in vivo* experiments. Binding capacity of the scFv to FAP was analysed by flow cytometry. Cytokine activity of soluble and targeted fusion proteins was analyzed in terms of proliferation of cytokine growth-dependent cell lines (determined by MTT-assay) and human PBMC subsets (CFSE-staining/flow cytometry) and cytotoxicity of T cells (CD107a/flow cytometry). Analysis of pharmacokinetic properties and the therapeutic effect in a lung metastasis model were performed in C57/BL6 mice.
Results: All components of the fusion proteins showed full functionality: the scFv mediated specific binding to target-expressing cells and IL-15 stimulated the proliferation of cytokine-dependent cell lines and PBMCs. Soluble and target-bound scFv_RD_IL-15 achieved stronger proliferation and cytotoxicity of unstimulated and activated T cells, respectively compared to scFv_IL-15. Furthermore the scFv_RD_IL-15 revealed best anti tumor effects in a lung metastasis mouse model compared to an untargeted or RD missing version of the protein.
Conclusions: Thus, an antibody_RD_IL-15 fusion protein appears as a promising approach to further improve the antitumor effect of IL-15.

Activation of human dendritic cells for immunotherapy in ovarian carcinoma

E. Brencicova,[*] A. Jagger,[†] H. Evans,[†] A. Laios,[‡] S. Montalto,[§] A. A. Ahmed,[‡] S. Raju-Kankipati,[§] L. S. Taams[†] & S. Diebold[*]
[*]Peter Gorer Department of Immunobiology, King's College London, London, UK, [†]Centre for Molecular and Cellular Biology of Inflammation (CMCBI), King's College London, London, UK, [‡]Nuffield Department of Obstetrics and Gynaecology, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, UK, [§]Department of Gynaecological Oncology, St Thomas' Hospital, London, UK

Purpose/Objective: In this study, we investigate the impact of ovarian carcinoma (OC)-associated ascites fluid (AF) on dendritic cell (DC) activation by Toll-like-receptor (TLR) agonists *in vitro*. DC have the potential to instigate a tumour-specific adaptive immune response, but their ability to induce differentiation of naïve lymphocytes into effector cells in lymphoid tissues is dependent on their activation status. We are interested in studying whether DC activation by TLR agonists * an approach often attempted in tumour immunotherapeutic concepts * is impeded by OC environment and if so, how these effects can be eleviated.
Materials and methods: AF was obtained from patients with epithelial OC or benign ovarian tumours with informed consent. Monocyte-derived DC from healthy volunteers were cultured overnight in the absence or presence of R848, LPS or poly I:C and AF. To investigate the role of different AF components, cytokine-neutralizing antibodies were added to selected cultures. DC activation was assessed by surface marker expression and cytokine production. Mixed leukocyte reactions with allogeneic naïve T-cells were performed to evaluate DC functionality.
Results: Our results show that AF reduces the up-regulation of the co-stimulatory molecule CD86 and partially inhibits the production of the pro-inflammatory cytokines IL-6, IL-12 and TNF-a in TLR-activated monocyte-derived DC. We further observe an impaired T-cell stimulatory capacity of monocyte-derived DC upon activation with TLR agonists in the presence of AF, which indicates that suppressed activation status of the monocyte-derived DC directly affects their function as antigen-presenting cells. We have identified IL-10 as the pivotal component in AF jeopardizing DC activation, and although further factors may play a role, our data show that selective blocking of IL-10 by neutralizing antibodies is sufficient to largely restore DC activation and function *in vitro*.
Conclusions: IL-10 is the key agent impeding TLR-mediated DC activation within OC environment *in vitro*. By selective neutraliziation, the immunosuppressive effects of IL-10 can be offset and DC functionality reinstated. Our findings can provide substantial insight into the feasibility and execution of DC-based vaccines and other immunotherapeutic intervention strategies in OC.

P1699
Actively personalized multi-peptide vaccination for primary liver cancers – a novel therapeutic approach for overcoming residual disease?

N. Trautwein,[*] M. Löffler,[*] M. Walzer,[*] D. Zieker,[†] P. Horvath,[†] C. Schroeder,[‡] P. Bauer,[‡] A. Königsrainer,[†] H. G. Rammensee[*] & S. Stevanovic[*]
[*]Immunology, Interfaculty Institute for Cell Biology, Tübingen, Germany, [†]Surgery, University Hospital Tübingen, Tübingen, Germany, [‡]Human Genetics, Medical Genetics, Tübingen, Germany

Purpose/Objective: Primary liver cancers, mainly hepatocellular carcinomas (HCC), are among the five most common cancers globally and a leading cause of cancer related death. More than half a million patients are diagnosed with HCC every year. Also in Europe and the USA incidence numbers have been rising over the last decades.

With chemotherapies and other adjuvant strategies showing only limited benefit, available therapeutic options are scarce. Therefore primary malignancies of the liver are a promising entity for targeted immune interventions after surgery.
Materials and methods: In order to evaluate this novel targeted adjuvant therapeutic approach, we focused on naturally processed and presented MHC-ligands eluted directly from tumor tissue. Our interest is particularly centered on mutated peptides representing neo-epitopes derived from specific mutations of the tumor exclusively present on malignant tissue. Those tumor specific peptides lack central tolerance and should thus be highly immunogenic. To identify those peptides we employ a dual approach.

On the one hand MHC-ligands are isolated by means of immunoaffinity chromatography of MHC molecules followed by acidic

elution of peptides. These peptides are subsequently identified using tandem mass spectrometry and database dependent search algorithms. On the other hand genomic mutations forming the basis for tumor specific MHC-ligands are analyzed by next generation exome sequencing. Based on sequencing results differences between tumor and germline genome are determined and specific databases are generated.
Results: Tumor specific peptides are predicted using SYFPEITHI database to facilitate a targeted search for mutated peptides in the MS^2-data. In addition to tumor tissue adjacent benign tissue of patients was analyzed in the same fashion. So far sample pairs from several patients have been investigated in this manner.
Conclusions: Based on this approach, we aim at providing an actively personalized vaccine cocktail comprising individual patient- and tumor-specific peptides for adjuvant tumor therapy. This approach is completely new and may offer the chance of overcoming residual disease, which is a major cause of tumor related death and relapse so far.

Adoptive immunotherapy utilizing genetically modified T cells in an orthotopic breast cancer model

L. B. John,* C. Devaud,* C. P. M. Duong,* C. Yong,* L. X. J. Wang,* W. Z. Wei,† R. L. Anderson,‡ Y. Cao,‡ M. H. Kershaw* & P. K. Darcy*
**Cancer Immunology Research, Peter MacCallum Cancer Centre, East Melbourne, Australia, †Department of Pathology, Karmanos Cancer Institute, Detroit, MI, USA, ‡Cancer Cell Biology Research, Peter MacCallum Cancer Centre, East Melbourne, Australia*

Purpose/Objective: Adoptive immunotherapy involving genetic modification of T cells with chimeric antigen receptors (CARs) is a promising approach for the treatment of cancer. We have recently shown that the anti-tumour effects observed in Her-2 transgenic mice bearing established Her-2^+ lung metastases, treated with anti-Her-2 T cells was not associated with any autoimmune pathology to normal tissue (breast, brain) expressing the target antigen. However, the efficacy and safety of this approach against tumor located directly within normal tissue expressing the Her-2 antigen has not been evaluated.
Materials and methods: We generated a spontaneously metastatic breast carcinoma cell line, E0771-LMC expressing the human Her-2 antigen which displayed comparable growth kinetics of primary tumor and formation of spontaneous lung metastases as the parental cells following orthotopic injection into the mammary fat pad (MFP). We then examined antigen-specific function by CAR T cells by investigating cytokine secretion, killing and proliferation *in vitro*. In adoptive transfer studies, primary tumor growth and survival of mice was evaluated in the Her-2 transgenic mouse model.
Results: We first demonstrated antigen-specific function by CAR T cells *in vitro*. In adoptive transfer studies, we demonstrated significant regression of established primary Her-2^+ tumours injected into the MFP and enhanced survival of mice treated with anti-Her-2 T cells compared to control T cells. Increasing the dose of anti-Her-2 T cells led to complete tumour eradication in a proportion of mice. The reduction in tumour growth correlated with localisation of transferred T cells at the tumour site. Interestingly, we observed no overt toxicity in mice following therapy. Future studies will examine the efficacy of anti-Her-2 T cells against spontaneous metastases in this model and examine more closely breast and brain tissue by immunohistochemistry for potential signs of pathology.
Conclusions: In conclusion, our study highlights for the first time that CAR T cells can distinguish and specifically eradicate Her-2^+ breast cancer cells without on target toxicity to surrounding normal tissue expressing the target antigen.

P1702

Anti-CD20 treatment induces long-term adaptive immune response by blocking $CD4^+$ $Foxp3^+$ Treg expansion and provoking an increase in $CD4^+$ IFNgamma$^+$ Th1 cell subset

C. Deligne, A. Metidji & J. L. Teillaud
Cordeliers Research Center UMRS872, Team 14 "Antibody BioEngineering", Paris, France

Purpose/Objective: We have recently demonstrated that anti-CD20 mAb exerts a long-lasting anti-tumor protection through the induction of an adaptive immune response (Abes *et al.*, Blood, 2010). This requires the presence of $CD4^+$ cells at the initiation of treatment but not $CD8^+$ cells, whereas both cell types are needed after tumor challenge for further protection. It is unclear how anti-CD20 mAb treatment impacts $CD4^+$ T cell subsets, enabling the development of this adaptive response despite the fact that tumor cells induce regulatory T cells (Treg). Thus, we have investigated if anti-CD20 mAb treatment modifies the balance between T cell subsets and has an impact on the expansion of Treg induced by tumor cells.
Materials and methods: C57Bl/6 mice were injected with EL4-huCD20 cells and treated with the anti-CD20 mAb CAT-13 (Abes *et al.*, 2010). $CD3^+CD4^+$ T cell subsets were analyzed by intracellular staining with anti-IFNγ, -IL10, -IL17, and -Foxp3 antibodies. The log-rank test was used to compare survival. In some experiments, Treg were depleted by anti-CD25 injection. In other experiments, a neutralizing anti-TGFβ antibody was injected repeatedly.
Results: Adoptive transfer of $CD4^+$ T cells from CAT-13-treated surviving mice into naïve recipients, followed by EL4-huCD20 injection, showed that $CD4^+$ T cells are responsible for the induction of the long-term protection. Analysis of $CD4^+$ T cells, at different time points after tumor cell injection, initially revealed the expansion of Treg in both untreated and CAT-13-treated mice. However, after completion of anti-CD20 treatment, CAT-13-treated mice exhibited a strong Th1 subset increase while Treg diminished markedly. When Treg were depleted by anti-CD25 treatment before tumor injection, the survival of CAT-13-treated mice was not increased, although most of the mice not treated with CAT-13 were protected. This suggests that combination of Treg depletion before tumor injection with anti-CD20 treatment does not potentiate anti-tumor protection. Finally, injections of neutralizing anti-TGFβ did not increase survival of CAT-13-treated animals, although it delayed death of untreated animals.
Conclusions: These data demonstrate that the balance between Treg and Th1 compartments, essential for controlling tumor progression, is fine-tuned by therapeutic mAb to switch the immune response from a pro- to an anti-tumor response.

P1703

Anti-IL-20 monoclonal antibody alleviates inflammation within oral cancer and suppresses tumor growth

H. Yu-Hsiang & C. Ming-Shi
Department of Biochemistry and Molecular Biology, National Cheng Kung University, Tainan, Taiwan

Purpose/Objective: IL-20 is a proinflammatory cytokine involved in rheumatoid arthritis, atherosclerosis, and osteoporosis. However, little is known about the role of IL-20 in oral cancer.
Materials and methods: We explored the function of IL-20 in tumor progression of oral cancer. IL-20 expression levels in tumorous and non-tumorous oral tissue specimens from 40 patients with four different stages oral cancer were analyzed with IHC staining and RTQ-PCR. Clinical oral tumor tissue expressed higher IL-20 and its receptor subunits than did non-tumorous oral tissue. The roles of IL-20 were examined in oral cancer OEC-M1 and OC-3 cells.
Results: *In vitro,* IL-20 promoted TNF-a, IL-1b, MCP-1, CCR4, and CXCR4, and enhanced proliferation, migration, ROS production, and

colony formation of oral cancer cells with activated STAT3 and AKT/JNK/ERK signals. To evaluate the therapeutic potential of anti-IL-20 monoclonal antibody 7E to treat oral cancer, an *ex vivo* tumor growth model was used. *In vivo*, 7E reduced tumor growth and inflammation within oral cancer cells.
Conclusions: IL-20 promoted oral tumor growth, migration, and tumor-associated inflammation. Therefore, IL-20 may be a novel target for treating oral cancer, and anti-IL-20 monoclonal antibody 7E may be a feasible therapeutic.

P1704
Anti-tumoral effects of anti-CD115 monoclonal antibody through inhibition of tumor associated macrophages and osteoclasts

L. Fend, J. Kintz, C. Reymann, N. Accart, R. Rooke, J. Y. Bonnefoy, X. Preville, & H. Haegel
Immunopharmacology, TRANSGENE S.A, Illkirch Graffenstaden Cedex, France

Purpose/Objective: Some aspects of tumor progression are controlled by Tumor-Associated Macrophages (TAMs) and metastasis-induced bone destruction by osteoclasts. Both cell types depend on the CD115-CSF-1 pathway for their differentiation and function. We studied the effects of targeting CD115 with a function-blocking monoclonal antibody (mAb) in 3 different mouse cancer models.
Materials and methods: Anti-CD115 mAb, isotype control or PBS was administered to (1) mice bearing sub-cutaneous EL4 tumors, (2) MMTV-PyMT mice developing spontaneous mammary tumors, and (3) mice injected with human breast cancer cells metastatic to bone.
Results: In mice bearing solid EL4 tumors, the anti-CD115 mAb depleted F4/80 macrophages and reduced tumor growth, resulting in prolonged mouse survival. In MMTV-PyMT mice, primary tumor growth was not detectable in mice treated with the anti CD115 mAb but became palpable only after termination of the immunotherapy. In the breast cancer model of bone metastasis, the anti CD115 mAb showed potent therapeutic effect by inhibiting the differentiation of osteoclasts and their bone destruction activity.
Conclusions: CD115 represents a promising target for cancer immunotherapy, since a blocking antibody may not only inhibit the growth of a primary tumor through TAM depletion, but also metastasis-induced bone destruction through osteoclast inhibition.

P1706
Azacytidine treatment sensitize tumour cells to T-cell mediated cytotoxicity in patients with myeloid malignancies

M. K. Brimnes,* A. O. Gang,† I. H. Dufva,‡ R. Lyngaa,† M. B. Treppendahl,§ M. H. Andersen,† K. Grønbæk,§ P. T. Straten† & S. R. Hadrup†
**Department of Rheumatology, Institut for Inflammtions Research, Copenhagen Univeristy Hospital Rigshospitalet, Copenhagen, Denmark, † Department of Haematology, Center for Cancer Immune Therapy, University Hospital Herlev, Herlev, Denmark, ‡Department of Haematology, University Hospital Herlev, Herlev, Denmark, §Department of Haematology, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark*

Purpose/Objective: We investigated a potential immunological effect of azacytidine (AZA) treatment in patients with myeloid malignancies, following the hypotheses that AZA-treatment may induce T-cell recognition of tumour-cells.
Materials and methods: Cytotoxicity of T cells was analysed by CD107a expression in co-cultures of purified tumour cells and CD8 T cells. Evaluation of CTA specific T cells was done using combinatorial encoded MHC-multimers after 7 days peptide restimulation.
Results: We could, in one patient, detect enhanced direct ex-vivo T-cell cytotoxicity against tumour-cells during treatment with AZA. Interestingly, tumour-cells were better recognized at later time-points during treatment, while T-cell functionality seemed to decline. In a larger group of patients, specific T-cell recognition of Cancer-Testis Antigens (CTA) was detected using a panel of 43 known CTAs.
Conclusions: Our data supports the hypotheses that AZA-treatment has an additional immunological effect that could be boosted in combination with immunotherapy.

P1709
Cancer immunotherapy by adoptive transfer of tumor-specific Th2 cells

A. Corthay,* C. Hammarström,* M. Fauskanger,† O. A. W. Haabeth,† M. Zangani,† H. Haraldsen,* B. Bogen† & K. B. Lorvik†
**Department of Pathology, University of Oslo, Oslo, Norway, †Department of Immunology, University of Oslo, Oslo, Norway*

Purpose/Objective: Adoptive transfer of tumor-specific T lymphocytes is a promising strategy to cure cancer.
Materials and methods: We tested adoptive transfer of tumor-specific Th2 cells for the treatment of mice with major histocompatiblity complex (MHC) class II-negative MOPC315 myeloma.
Results: Transfer of tumor-specific Th2 cells efficiently eradicated myeloma and conferred long-lasting immunity. Tumor-specific Th2 cells produced interleukin-4 (IL-4), IL-5, and IL-13, and kept a stable Th2 phenotype *in vivo* upon transfer. Successful Th2-based immunotherapy did not require B cells, natural killer (NK) T cells, $CD8^+$ T cells, or interferon-γ. Upon transfer, tumor-specific Th2 cells were shown to induce an inflammatory reaction at the tumor site. Tumor-specific Th2 cells eradicated myeloma by rendering tumor-infiltrating M2-type macrophages tumoricidal.
Conclusions: These results suggest that adoptive transfer of tumor-specific Th2 cells could be a very efficient treatment against multiple myeloma and other human malignancies.

P1710
CD28 aptamers as immune response modulators

F. Pastor, M. M. Soldevilla, H. Villanueva, S. Inoges, A. L. de Cerio & M. Bendandi
CIMA, Oncology, Pamplona, Spain

Purpose/Objective: CD28 is one of the main costimulatory receptors responsible for the proper activation of T lymphocytes. Agonistic antibodies and recombinant-protein blockers for the CD28 receptor have already been identified and shown to alter the immune response. Soluble protein therapeutic molecules derived from cell-based procedures need to pass through a lot of high-cost regulatory processes to get into the clinic. Aptamers are single-strand oligonucleotides that exhibit similar affinity and specificity to that of an antibody and its ligand. Aptamers can easily be chemically synthesized, therefore reducing the cost of the clinical regulatory approval process.
Materials and methods: In this study, two aptamers to the CD28 receptor were selected by SELEX (Systematic Evolution of Ligands by Exponential Enrichment). *In vitro* immunoassays were performed to characterize the immunomodulatory aptamers. The agonistic CD28 aptamer was tested as an adjuvant in a mouse idiotypic vaccine protocol for follicular lymphoma.
Results: We have isolated and characterized two aptamers that bind to the CD28 receptor. One of them interferes with the binding of CD28 to its ligand (B7), precluding the costimulatory signal. *Vice versa*, dimerization of any of the two anti-CD28 aptamers is enough to

provide an artificial costimulatory signal. Different dimer structures were tested, and they have shown different costimulatory properties. In a follicular lymphoma model, the agonistic CD28 aptamer enhances the antitumor immune response of the idiotypic vaccine.
Conclusions: The CD28 aptamers described could be used to modulate the immune response whether by blocking the interaction with B7 for certain autoimmune diseases or by enhancing the vaccine-induced immune response in cancer immunotherapy.

P1711
CD4 cells expressing an MHC class I restricted TCR can rescue CD8 cells tolerized to tumour-associated antigen

S. Ghorashian,* A. Holler,* B. Carpenter,† M. Ahmadi,* E. Nicholson,* M. Zech,* S. A. Xue,* C. Bennett,† H. J. Stauss* & R. Chakraverty†
*UCL, Department of Immunology, London, United Kingdom, †UCL, Department of Haematology, London, United Kingdom

Purpose/Objective: The efficacy of T cell therapies for cancer may be limited because tumour-associated antigens (TAA) are also self-antigens (Ag). Exposure to TAA on normal cells may lead to tolerance via deletion of Ag-specific T cells or their anergy/exhaustion. We designed a model of tolerance to TAA in which T cell receptor (TCR)-transduced CD8 T cells recognise pMDM2, a TAA that is also a ubiquitous self-Ag. We aimed to determine the mechanism of tolerance and whether this is reversed by CD4 help.
Materials and methods: CD8 T cells transduced with pMDM2-specific TCR (MDM-CD8) were transferred to sub-lethally irradiated B6 mice expressing cognate MDM2 antigen (MDM100:K^b). MDM-CD8 cells were traceable using a congenic marker. To assess their function we transferred CFSE-labelled target cells pulsed with MDM2 peptide and compared killing at 16 h to that of a control population.
Results: Four weeks after transfer, MDM-CD8 cells were detectable, but showed defective Ag-specific killing of target cells.

To determine whether tolerance was dependent upon recognition of cognate Ag within the host, we transferred MDM-CD8 cells into BALBc mice (where MDM100:K^b can not be expressed). In a host environment free of cognate Ag, they retained a full capacity to kill target cells presenting Ag.

To determine the effect of CD4 T cell help, we co-transferred MDM-CD8 cells and transgenic OT-II CD4+ cells. OT-II cells were primed with dendritic cells (DCs) loaded with cognate pOVA323-339 or irrelevant peptide. After activation through their TCR, OT-II cells increased both the frequency of MDM-CD8 cells and their cytotoxic functions, indicating that CD4 help can overcome CD8 tolerance to TAA.

A major limitation to providing CD4 help in T cell cancer therapies is a lack of known MHC class II-restricted TAA. We therefore tested whether CD4 cells transduced with the MHC Class I-restricted MDM2 TCR (MDM-CD4) could provide help upon transfer to Ag-expressing hosts. Co-transfer of MDM-CD4 along with MDM-CD8 cells improved Ag-specific killing of target cells when compared to either population alone.
Conclusions: CD4 cells rendered capable of responding to an MHC class I-restricted TAA by TCR transfer can rescue tolerance in a CD8 population with the same specificity. This is potentially a novel way to circumvent defective immune responses arising in adoptive populations due to prolonged exposure to TAA.

P1713
Chemoimmunotherapy of MC38 mouse colon carcinoma: effect of cyclophosphamide treatment followed by dendritic cell-based vaccines on induction of anti-tumor immunity

J. Kicielińska,* J. Wojas-Turek,† J. Rossowska‡ & E. Pajtasz-Piasecka*
*Laboratory of Experimental Anticancer Therapy, Institute of Immunology and Experimental Therapy, Wroclaw, Poland, †Laboratory of Virology, Institute of Immunology and Experimental Therapy, Wroclaw, Poland, ‡Laboratory of Glycobiology and Cell Interactions, Institute of Immunology and Experimental Therapy, Wroclaw, Poland

Purpose/Objective: The aim of this study was to analyze the effect of cyclophosphamide (CY) administration followed by bone marrow-derived dendritic cells (BM-DC) activated *ex vivo* with tumor antigens and applied with genetically modified dendritic cells of line JAWS II on trigger the antitumor response.
Materials and methods: Vaccines consisted of BM-DC activated with tumor lysate (BMDC/TAg) and IL-2-gene transduced JAWS II (JAWS II/IL-2) cells orneo-gene modified JAWS II/Neoused as a control. C57BL/6 mice were inoculated s. c. with MC38/0 colon carcinoma cells and on the 14thday, when tumors were palpable, mice were injected, i. p., with CY (150 mg/kg body weight). Starting on the 17thday, the cell vaccines were injected p.t., in 3 weekly intervals. Tumor growth delay was estimated. Spleens were obtained 1 week after the last injection. Splenocytes obtained from mice treated with CY +/- vaccines containing genetically modified cells or BM-DC/TAg cells were examined for their capacity of responding against growing tumor. Thus, the phenotype of freshly isolated cells as well as their *ex vivo* reactivity after TAg restimulation were analyzed.
Results: The administration of the CY combination with BM-DC/TAg and/or JAWS II/IL-2 strongly enhanced the effect of the cytostatic used alone. By contrast, the use of JAWS II/Neo cells caused no therapeutic effect. The combined therapy exploiting genetically modified DCs resulted in increase in percentage of $CD8^+$, $CD4^+$ and $CD49b^+$ cells. The 5-day cocultivation of splenocytes with MC38/0 cells induced cytotoxic activity to some extent associated with increase in percentage of $CD107a^+$ cells, augmented IFN-γ production and was accompanied by changes in percentage of $CD8^+$, $CD4^+$, $CD49b^+$ activated lymphocytes. The effect depended on the type of applied vaccines.
Conclusions: The obtained results suggest the strong augmentation of cytostatic effect by application of DC-based vaccines and may help to understand the mechanisms of the anti-tumor immune reactions initiated by combined chemoimmunotherapy of experimental murine tumors.

The financial support of the study is granted by the National Science Center of Poland (decision number DEC-2011/01/N/NZ4/01725).

P1714
Circulating specific antibodies enhance systemic cross-priming by delivery of complexed antigen to dendritic cells *in vivo*

W. van Maren, N. van Montfoort, S. M. Mangsbo & F. Ossendorp
Tumor Immunology, Leiden University Medical Center, Leiden, Netherlands

Purpose/Objective: DCs loaded with antigen-antibody complexes (ICs) have shown to confer tumor protection in mice. In the case of therapeutic antibodies directed to tumor-associated antigens (TAA), T cells may contribute to the induced anti-tumor response. To demonstrate the role of circulating antibodies in the priming of a naïve T cells, we applied a system in which mice, naïve for OVA, with circulating hapten (TNP)-specific antibodies were used.
Materials and methods: Mice were either vaccinated for a specific hapten (TNP) to induce hapten-specific antibodies, or passively transfered with the hapten-specific antibodies. These mice were then

injected with the TNP-OVA constructs to induce an immune response. The induction of an immune response was measure by *in vivo* antigen presentation assays, *in vivo* cytotoxicity assays and *in vivo* uptake experiments.
Results: Mice with circulating hapten-specific antibodies showed significantly enhanced cross-presentation of the injected antigen compared with mice that lacked these antibodies. Increased systemic CD8 and CD4 T cell proliferation was seen after TNP-OVA administration, demonstrating effective MHC class I and II (cross-) presentation. The enhanced cross-presentation in mice with circulating antigen-specific antibodies was associated with improved antigen capture by APCs. Importantly, CD11c+ APCs were responsible for the enhanced and sustained cross-presentation, although CD11c- APCs had initially captured a significant amount of the injected antigen. These results indicate that circulating antibodies aid *in vivo* antigen delivery to DCs, which improves vaccination by increased antigen uptake and FcR-mediated DC maturation.
Conclusions: *In vivo* formation of antigen*antibody immune complexes improves MHC class I cross-presentation, and CD8+ T-cell activation. This demonstrates that humoral immunity can aid the initiation of systemic cellular immunity. These findings have important implications for the understanding of the action of therapeutic antibodies against tumor-associated antigens intensively used in the clinic nowadays.

P1715
Combining a bispecific antibody with costimulatory antibody ligand fusion proteins in a human and murine model system for targeted cancer immunotherapy

N. Hornig, K. Reinhardt, R. E. Kontermann & D. Müller
Antibody Engineering, Institute of Cell Biology and Immunology, Stuttgart, Germany

Purpose/Objective: Bispecific antibodies have shown to be able to retarget cytotoxic T cells to tumor cells in a MHC-independent manner, triggering effector cell activation and consecutive tumor cell killing. Considering that costimulation is an essential requirement not only to initiate T cell activation, but also for cell expansion and the development of T cell effector functions, we propose a combinatorial approach by a recombinant bispecific antibody and targeted costimulatory ligands of the B7 and TNF family in order to achieve a highly efficient antitumoral immune response. Therefore, appropriate model systems were generated that take into account targeting of different tumor antigens, combinations of costimulatory ligands and mouse or human effector cells.
Materials and methods: Immunostimulatory effects of the recombinant proteins (bispecific antibody + antibody-ligand fusion proteins) were assayed by incubation on tumor cells in presence of unstimulated human PBMC/isolated naïve CD8+ T cells or murine splenocytes. Cytokine release was monitored via ELISA, while proliferation (CFSE labeling), activation and differentiation marker expression and cytotoxic potential (CD107a staining) of T cells was detected via flow cytometry.
Results: Model systems involving tumor cells expressing 2 target antigens for the combined application of a bispecific antibody and costimulatory antibody-ligand fusion proteins with human and mouse specificity were established. In both experimental settings, bispecific antibody-induced T-cell stimulation could be enhanced by targeted costimulation with an antibody-4-1BBL fusion protein in a concentration-dependent and ligand-specific manner. Furthermore, in the human model system, modulation of T cell response by the application of the bispecific antibody together with two costimulatory fusion proteins (B7.2, 4-1BBL) resulted in enhanced proliferation and activation marker expression, differentiation into an activation-experienced memory phenotype and in an increase of cytotoxic potential.
Conclusions: In our model systems we could show that the combination of a bispecific antibody and costimulatory antibody-ligand fusion proteins appears as a promising strategy for cancer immunotherapy.

P1716
Controlled local delivery of CTLA-4 blocking antibody induces CD8+ T cell dependent tumor eradication without systemic toxicity

M. Fransen, F. Ossendorp, R. Arens & C. J. M. Melief
Leiden University Medical Center, IHB, Leiden, Netherlands

Purpose/Objective: Blockade of CTLA-4 by monoclonal antibodies improves anti-tumor T cell responses in both pre-clinical models and clinical trials and is now approved for treatment of melanoma patients. However, treatment with CTLA-4 blocking antibodies is associated with auto-immune and inflammatory side-effects. In order to reduce side-effects we propose using a local administration for CTLA-4 blocking antibodies, previously shown to be very effective in CD40 agonistic antibody treatment of tumor.
Material and methods: We use an *in vivo* tumormodel to explore administration strategies of CTLA-4 blocking antibodies. By injecting the antibodies in a subcutaneous slow-release delivery formulation in the tumor area, we show that an eightfold lower dose of antibody is as effective in activating a tumor-eradicating T cell response as systemic delivery.
Results: Lower dose and slow release together result in 1000-fold decreased levels of antibody in the serum, reducing adverse events and the risk of auto-immunity. The main target and effector cells in this tumor-model are endogenous CD8+ T cells, whereas CD4+ T cells do not play a prominent role in the antibody-mediated tumor eradication.
Conclusions: These results call for exploration of a similar delivery principle in the clinic to reduce toxic side effects of CTLA-4 blocking antibody.

P1717
Culture expansion alters synthesis and content of actin binding proteins in T lymphocytes and mesenchymal stromal cells (MSCs)

I. Weber, K. Kollar, M. Giesen, E. Seifried & R. Henschler
DRK-Institute of Transfusion Medicine and Immune Hematology, University Hospital Frankfurt, Frankfurt am Main, Germany

Purpose/Objective: The expansion of T lymphocytes and MSCs in culture is pursued for adoptive therapy, however deficits in the migration potential and function of expanded cells have been reported. We asked here whether major elements of the cytoskeleton, including actin binding proteins (APBs) such as the actin-polymerizing factors cofilin and profilin, small intercalating molecules filamin A and alpha actinin, as well as components engaging into focal adhesion complexes paxillin, talin and vinculin are subject to alterations during culture in these two cell types.
Materials and methods: Magnetically separated CD3+ T lymphocytes from peripheral blood were expanded using immobilized anti-CD3 and anti-CD28 microbeads. MSCs were expanded from human bone marrow according to standard protocols. Cell size was monitored microscopically and by flow cytometry, using size-calibrated micro beads. Quantitation of ABP RNA was performed using qRT-PCR and of ABP proteins by flow cytometry in permeabilized cells.
Results: T lymphocytes expanded 15 ± 1 fold within 7 days, but over the culture period, the mean diameter of T lymphocytes increased from 7 ± 0.3 to 15 ± 4.4 μm reflecting a ninefold increase in cell volume from a mean 208 to 1828 μm^3. However, on a per cell base, protein levels of ABPs remained constant except for vinculin, which showed a statistically significant 1.6-fold increase. In contrast, RNA levels of all investigated ABPs decreased between five and 50-fold

during culture expansion, indicating major alterations in ABP protein turnover in the expanded cells. MSCs revealed two cell populations with mean diameters of 38 ± 5 and 71 ± 9.6 μm, respectively. Compared to expanded T lymphocytes, MSCs showed a four to13-fold lower content of all investigated ABPs on both, the protein and mRNA levels.

Conclusions: In conclusion, culture expansion resulted in maintenance of absolute levels of ABPs in T lymphocytes, but drastic decreases in the relation between ABPs and cytoplasmic volume. The strong decrease in transcription of ABP mRNAs indicates major alterations in the turnover of ABPs protein in both T cells and MSCs. Our data point to role of alterations in ABP turnover in the functional deficits observed in cultured versus freshly isolated cells which are used for immunotherapies in patients.

Cytosolically targeted isRNA induces melanoma destruction via type I interferon signaling on myeloid cells in the tumor microenvironment

M. Renn, T. Bald, J. Landsberg, A. Sporleder, S. Mikus & T. Tüting
Laboratory for experimental Dermatology, Clinic for Dermatolgoy and Allergology, Bonn, Germany

Purpose/Objective: Activation of the ubiquitously expressed cytosolic RNA recognition receptors with immunostimulatory RNA (isRNA) emerges as a new treatment option for cancer. This mimics a viral infection and induces a strong type I interferon response.

Materials and methods: Here we investigated the cell type specific role of type I IFNs using Ifnar1 competent and deficient melanoma cell lines established from Hgf-Cdk4^{R24C} mice in combination with global and tissue-specific Ifnar1 knockout mice.

Results: pI:C complexed with polyethylenimine but not naked pI:C induces regression of primary cutaneous melanomas in Hgf-Cdk4^{R24C}. This was accompanied by a strong infiltration of immune cells mostly of myeloid origin.

In vitro, we observed similar chemokine release and apoptosis of pI:C-PEI treated Ifnar1 competent as well as deficient melanoma cells. In contrast, BM-derived Ifnar1$^{-/-}$macrophages and DCs showed an impaired chemokine release compared to wildtype cells after pI:C-PEI stimulation.

In vivo, pI:C-PEI had significant antitumor activity against transplanted Ifnar1-competent or -deficient melanoma cells in syngeneic wildtype but not in Ifnar1 knockout mice, demonstrating the importance of type I interferon signaling in the tumor microenvironment, but not in tumor cells.

Because myeloid cells were the predominant immune cell population infiltrating the tumor after pI:C-PEI therapy, we treated Ifnar1 competent melanoma cells in LysMCre × Ifnar1$^{fl/fl}$ mice, that lack the type I IFN receptor on myeloid cells. Again, treatment efficacy was largely abrogated, indicating that myeloid cells are the primary target of type I interferons. To further delineate if cytotoxic cells were required for tumor destruction, we depleted NK and CD8 T-cells with monoclonal antibodies. Whereas the elimination of NK cells strongly reduced treatment efficacy, the elimination of CD8 T-cells had no affect.

Conclusions: Taken together, our data suggest that melanoma therapy with cytosolically targeted immuno-stimulatory RNA largely depends on a functional type I IFN system in myeloid cells of the tumor microenvironment and the presence of NK cells.

P1720

Effective activity of cytokine-induced killer (CIK) cells against autologous putative cancer stem cells in solid tumors

L. Gammaitoni,* G. Mesiano,* L. Giraudo,* V. Leuci,* M. Todorovic,* F. Picciotto,† F. Carnevale-Schianca,‡ G. Grignani,‡ M. Aglietta‡ & D. Sangiolo*
**Oncological Sciences, Institute for Cancer Research and Treatment, Candiolo, Italy, †Dermatologic Surgery, Institute for Cancer Research and Treatment, Candiolo, Italy, ‡Medical Oncology, Institute for Cancer Research and Treatment, Candiolo, Italy*

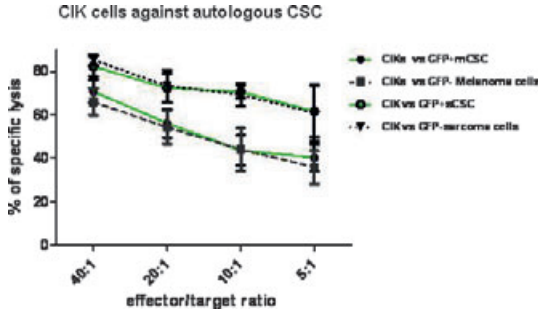
Purpose/Objective: Targeting the putative subset of cancer stem cells (CSC) within solid tumors is a crucial and still unmet issue as CSC are considered responsible for chemo-resistance and disease relapses. Cytokine-Induced Killer (CIK) Cells are ex-vivo expanded T lymphocytes, endowed with a promising MHC-independent tumor killing activity against several solid tumors.

We investigated the ability of CIK cells to kill autologous metastatic cells including the subset of putative CSC.

Materials and methods: CIK cells were expanded from PBMC of 10 patients with metastatic melanoma ($n = 5$) or bone and soft tissue sarcomas ($n = 5$); their tumor killing ability was assessed with standard cytotoxicity essays against autologous targets obtained from biopsies of metastatic samples. To identify putative CSC, we transduced bulk autologous metastatic tumor cells with a lentiviral vector encoding for the enhanced Green Fluorescent Protein (eGFP) regulated by the human OCT4 promoter. The underlying idea is that CSCs can be visualized based on their exclusive ability, proper of both normal and cancer stem cells, to activate the OCT4 promoter and consequently express eGFP.

Results: We efficiently generated metastatic autologous cells lines. The average presence of GFP+ putative melanoma CSC (mCSC) and sarcoma CSC (sCSC), within the bulk metastatic tumor cell population, was 12% and 15% respectively; these data were consistent with levels of protein expression. Both mCSC and sCSC displayed on average a 3 times reduced proliferative potential compared with their GFP- counterpart after 14 days of culture ($n = 6$), showing a slow-growing phenotype typical of CSC.

CIK cells efficiently killed both autologous mCSC and sCSC; the average specific killing was 71%, 57%, 44% and 41% against mCSC ($n = 4$), 82%, 72%, 71% and 60% against sCSC ($n = 4$) at 40:1, 20:1, 10:1 and 5:1 effector/target ratios respectively. The specific killing against CSC overlaid that observed against differentiated GFP- metastatic cells (Fig. 1).



Conclusions: We reported for the first time the preclinical activity of an immunotherapy approach with CIK cells against autologous CSC enriched fractions of metastatic melanomas and sarcomas. These data set biologic basis for further clinical investigations and picture CIK cells as promising candidates for effective immunotherapy in currently incurable clinical settings.

P1721

Elimination of MDSC and Treg cells after combined immunotherapy with cyclophosphamide and dendritic cell vaccines in MC38 tumor bearing mice

J. Rossowska,* E. Pajtasz-Piasecka,† A. Stepasiuk,* J. Wojas-Turek,‡ E. Piasecki‡ & D. Dus*

**Laboratory of Glicobiology and Intracellular Interactions, Institute of Immunology and Experimental Therapy, Wroclaw, Poland, †Laboratory of Experimental Therapy, Institute of Immunology and Experimental Therapy, Wroclaw, Poland, ‡Laboratory of Virology, Institute of Immunology and Experimental Therapy, Wroclaw, Poland*

Purpose/Objective: The microenvironment of solid tumors is characterized by excessive amounts of immunosuppressive factors e.g. VEGF, TGF-β, IL-10 which cause dysfunctions of immune competent cells as well as activation of suppressive cells. The tumor-infiltrating suppressive cells e.g. T regulatory cells (Treg), tumor associated macrophages and myeloid-derived suppressor cells (MDSCs) interact with one another and have an important impact on cancer disease progression. Recent work highlighted the immunostymulatory and anti-angiogenic effects of low dose of cyclophosphamide (CY). Thus, it could be successfully combined with new-generation anti-cancer vaccines.

The aim of the study was to estimate the anti-tumor effect of low dose of CY combined with dendritic cells stimulated with tumor antigens (BM-DC/TAg) and/or genetically modified dendritic cells producing IL-12.

Materials and methods: Mice with s.c. growing, advanced MC38 tumor were treated with CY followed by three consecutive injections of BM-DC-based vaccines. Tumors were measured every 2 days and the tumor growth inhibition was calculated. Seven days after the last injection of BM-DC based vaccines spleens and tumors were collected and the activation of systemic and local anti-tumor response were evaluated.

Results: It was observed that CY combined with BM-DC/TAg and/or BM-DC/IL-12 caused the highest tumor growth inhibition. Moreover, in these groups the immunohistological analysis of tumor tissues confirmed the most intensive influx of CD4+ and CD8+ lymphocytes into tumor. Restimulated *in vitro* spleen cells also showed increased anti-tumor activity. Spleen cells obtained from mice treated with CY and BM-DC/TAg and/or BM-DC/IL-12 showed the highest cytotoxic activity toward MC38 cells and among them the highest percentages of CD8+CD107a+ and CD49b+CD107a+ cells were detected. It was also observed that numbers of MDSC and Treg cells in spleens were different in all examined groups and decreased in mice treated with CY and BM-DC/TAg and/or BM-DC/IL-12.

Conclusions: Obtained results suggest that anti-tumor effect of chemoimmunotherapy with CY and DC-based vaccines is dependent on successful elimination of suppressor cells.

This work was supported by the Ministry of Science and Higher Education (grants: N N401 316239).

Exploring novel therapeutic antibodies against c-Met

J. Neijssen, B. De Goeij, L. Wiegman, A. Labrijn, J. Schuurman & P. Parren

Antibody Science, Genmab BV, Utrecht, Netherlands

Purpose/Objective: c-Met, a receptor tyrosine kinase overexpressed in many types of cancer, represents an attractive target for antibody therapy. Use of traditional bivalent IgG is often problematic due to agonistic activity of the antibody. Binding of bivalent IgG can induce dimerization of c-Met and induce downstream signaling, ultimately resulting in cell proliferation, invasion and survival. Here we present various strategies to circumvent the problem of agonism and we show *in vitro* and *in vivo* efficacy of novel antagonistic antibodies against c-Met.

Materials and methods: A diverse panel of human antibodies against c-Met was generates and characterized. The lead clones were subcloned in various monovalent and bivalent formats to determine the optimal format for c-Met targeting. The different antibody formats were tested in various *in vitro* assays including ligand inhibition, target down-modulation, receptor phosphorylation, proliferation and migration assays as well as *in vivo* xenograft models.

Results: We have generated a diverse antibody panel against c-Met including clones that could effectively block the ligand for c-Met and inhibit viability and growth of cells. Residual agonistic activity that was observed in some assays and conditions by bivalent IgG and could be modulated by either generating monovalent or engineering the backbone of the antibody to make the antibody more rigid. Efficacy in multiple cell lines both *in vitro* and *in vivo* models was shown with these engineered formats.

Conclusions: Here we present an overview of the required characteristics of therapeutic antibodies against c-Met with regard to epitope and antibody format. We were able to generate full c-Met antagonists by expressing antibodies in a monovalent format, without compromising the characteristics of the original IgG1 molecules. These novel antibodies have potential for successful targeting of c-Met expressing cancers.

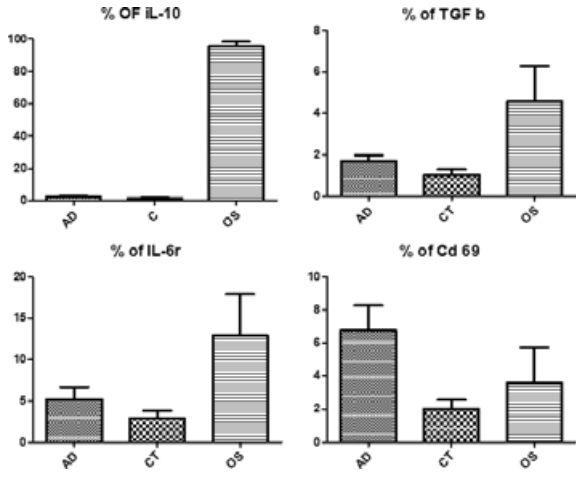
Expression of ganglioside GM1 in osteosarcoma and Alzheimer's disease and its significance in B-cell functions

G. kodandaraman,* M. M. Carneiro,* M. Goncalves,* J. Casanova,† V. Alves,* I. Santana‡ & P. Rodrigues-Santos*

**Immuno- CNC, Cento for Neuroscience and Cell Biology, Coimbra, Portugal, †Faculcidade de Medicina, Universidade de Coimbra, Coimbra, Portugal, ‡Immuno- CNC, Centro Hospitalar Universitario de Coimbra, Coimbra, Portugal*

Purpose/Objective: Introduction: In the immune system GM1 is found on the surface of natural killer cells (NK), T cells (both CD4+ and CD8+), B cells, plasmocytes and monocytes. The very low incidence of cancer among the AD patients, has led us to study the differences in GM1-expression in various B lymphocyte subpopulations of osteosarcoma (OS) and AD patients, and whether they show any alterations in the expression of the cytokines and cell-surface markers.

Materials and methods: Methodology: Peripheral blood mononuclear cells were isolated from blood samples were collected from OS patients (before starting chemotherapy, $n = 6$), early stage AD patients



($n = 10$) and matched healthy controls (no infection or chronic inflammatory disease, $n = 10$). The GM1-expressing B lymphocytes were identified using FITC-labeled CTxB. The changes in cell surface markers expression and intracellular cytokine production were determined by flow cytometry. Data were analyzed using a non-parametric one way ANOVA, and differences were considered different for $P < 0.05$.

Cell populations	Mean ± SEM	*P* value	Median	MS

OS	78.83 ± 6.74		80.610	

AD, Alzeimer's Disease; Os, osteosarcoma; CT, controls; SE, standard error; MS, mean square; NS − not significant. *P* value < 0.05 [***, **. *].

Conclusions: Discussion: Our data showsignificantly higher levels of expression of GM1 on the surface of peripheral B cells of OS and AD patients versus Controls (OS > AD > Cnt). Moreover, our present data show, for the first time, that the increased levels of expression of IL-6R, IL-10, TGF *β on GM1+ B cells might link GM1-expression to B cell function, thus opening new avenues for therapeutic modulation of these cells in the context of cancer and neurodegeneration.

Fast 3 days poly (I:C)-activated dendritic cells generated in CellGro for use in cancer immunotherapy trials are fully comparable to standard 5 days DCs

I. Truxova,* K. Pokorna,* S. Partlova,† R. Spisek* & J. Fucikova†
**Research Department, SOTIO a.s., Prague, Czech Republic,* †*Department of Immunology, Second Faculty of Medicine, University Hospital Motol, Charles University, Prague, Czech Republic*

Purpose/Objective: Dendritic cells (DCs) are professional antigen-presenting cells capable of inducing immune responses. DC-based vaccines are normally generated using a standard 5−7 days protocol by culturing blood monocytes in the presence of cytokines IL-4 and GM-CSF. In order to shorten the vaccine production for the use in the cancer immunotherapy protocol and to generate DCs in GMP quality in shorter time we have developed fast DC protocol by comparing standard DCs (5 days) and fast DCs (3 days).
Materials and methods: In this study, we tested D5 versus D3 DCs generation using GMP culture media CellGro and subsequent activation by two activation stimuli * Poly (I:C) (TLR-3) and LPS (TLR-4). We evaluated DCs morphology, viability, phagocytic activity, cytokine production and ability to stimulate antigen specific T cells.
Results: Our results demonstrate that although D5 DCs were larger in size compared to D3 DCs, they exhibited similar phagocytic capacity. Viability of D5 and D3 DCs was comparable (80%). Poly (I:C) activated D5 DCs expressed higher levels of costimulatory and surface molecules CD80, CD86 and HLA-DR compared to Poly (I:C) activated D3 DCs. Nevertheless LPS activated D5 and D3 were phenotypically similar. The cytokine production was generally stronger when LPS was used as maturation stimuli. Surprisingly LPS activated D3 DCs were able to produce higher levels of IL-12p70 compared to D5 DCs. Furthermore Poly (I:C) activated D5 DCs secreted higher amounts of IL-6, IFN-α and TNF-α compared to D3 DCs. Importantly, Day-3 and Day-5 DCs were able to induce comparable numbers of antigen-specific T cells.
Conclusions: In this study, we identified monocyte-derived DCs generated in CellGro for 3 days and activated using Poly (I:C) as similarly potent clinical-grade DCs when compared to DCs produced by the standard 5 day protocol. These results provide the rationale for the testing of the faster protocols for DCs generation in the clinical trials. Generation of fast DCs markedly reduces the time, work load and cost associated with *in vitro* culture of DCs precursors and thus may facilitate the use of DCs in clinical trials of cellular immunotherapy.

P1725

Functionalized dendrimer for the *in vivo* specific genetic regulation of tumor immunity

P. Serafini,* J. Vella,* P. Daftarian† & A. Delafuente*
**Microbiology and Immunology, University of Miami, Miami, FL, USA,* †*Biochemestry, University of Miami, Miami, FL, USA*

Purpose/Objective: While mature dendritic cells (DC) can support a strong tumor immunity leading to tumor immune surveillance or eradication, tumor conditioned myeloid cells (TCMC, aka Myeloid Derived Suppressor Cells, MDSC, and Tumor Associated Macrophage, TAM) promote tumor progression, invasion and metastasis. A specific modulation of these populations can be the key for the effective immune therapeutic treatment of malignacies. To boost tumor immunity while reversing TCMC tolerogenic program we used functionalized dendrimer to direct DNA encoding tumor antigen/s into immunogenic APC and STAT3 specific shRNA into suppressive TCMC. To this aim we generate two classes of nanoparticles in which a targeting peptide is covalently linked to G5 PAMAM dendrimers that serve as a loading surface for the desired nucleic acid. The first nanoparticle (HAPD) specifically target dendritic cells, the second one (4PD) instead deliver its cargo particularly to TCMC.
Materials and methods: MHC class II or IL4 derived targetting peptides were coupled to the dendrimer by maleidoamide chemistry and the complex purified by HPLC. Nucleic acids were loaded on the funcionalized dendrimer by electrostatic interaction at RT in <5 min in PBS. pcDNA3-gp70 conjugated to HAPD was used as targetted vaccine while STAT3 specific shRNA was used to modulate TCMC suppressive actions. The treatments were used in the colon carcinoma CT26 and mammary carcinoma TSA.
Results: The functionalized nanoplatforms were synthetyzed and characterized. Using either pcDNA3-GFP or Alexa555-shRNA their specificity was evaluated *in vitro* and confirmed *in vivo*. 4PD mediated STAT3 silencing in TCMC reduced the number of monocitic MDSC and increased the number of dendritic cells, promote tumor immunity, and significantly reduced tumor progression. HAPD mediated DNA vaccination against gp70 promote tumor immunity and delay tumor progression. Combination experiments are ongoing and will be presented.

Conclusions: By conjugating specific targeting peptides to G5-PA-MAM dendrimers we were able to modulate both the effector and the suppressive arm of the immune system. Our data indicate that the *in vivo* cell specific targeting of TCMC and DC can represent a new avenue for the immune therapeutic treatment of malignancies.

P1726
High throughput *in vitro* priming of tumor specific T cells

S. Souczek & L. Prokop
Immunology, Interfaculty Institute for Cell Biology, Tübingen, Germany

Purpose/Objective: Peptide-based cancer vaccines are one promising strategy for immunotherapy against cancer. Our group has characterized large numbers of HLA ligands from tumor cells; among them many that might be used for *in vivo* induction of tumor-specific immune responses. For the development of peptide-based immunotherapies such peptides should be able to induce *in vivo* tumor-directed immune responses, especially by $CD8^+$ T cells that have a key role in inducing death of tumor cells. The aim of our work is to establish a fast and efficient workflow to induce tumor-reactive T cells which is based on immunogenicity testing of tumor-extracted HLA ligands.
Materials and methods: T cells usually depend on professional antigen presenting cells such as autologous dendritic cells (DCs) for specific induction and expansion. Since the generation of dendritic cells is expensive and time consuming with varying quality and amount of differentiated DCs, we established an artificial system to replace cell-based *in vitro* priming of T cells: streptavidin-coated artificial antigen presenting cells loaded with defined amounts of recombinant HLA molecules and costimulatory antibodies such as anti-CD28 and anti-CD137 (4-1BB).
Results: We tested abundant self-peptides with a substitution of one amino acid. The mutation is a part of the TCR binding site and not affecting the anchor positions. We identified peptide-specific $CD8^+$ T cells after *in vitro* priming of healthy HLA-matched blood donors. Specific T cells are reactive to mutated peptides but not to native peptides.
Conclusions: Employing artificial APCs without the need for autologous DCs enables successful *in vitro* priming of specific T cells. Our strategy promotes the opportunities of multiepitope vaccines in tumor immunotherapy.

P1727
HLA ligandome analysis of acute myeloid leukemia reveal novel tumor-associated antigens for immunotherapy

C. Berlin,* D. J. Kowalewski,* H. Schuster,* L. Kanz,† H. R. Salih,† H. G. Rammensee* & S. Stevanovic*
**Immunology, Interfaculty Institute for Cell Biology, Tübingen, Germany,*
†Heamatology and Oncology, University Medical Hospital, Tübingen, Germany

Purpose/Objective: Acute myeloid leukemia (AML) is the most common acute leukemia in adults with an incidence rising with age. In the western world it is accounting for 25% of all leukemias. Owing to the therapeutic golden standard a remission is induced in 60−80% of all patients. However due to high relapse rates the 5 years survival ranges from 20% to 40%. To improve the overall survival the reduction or even eradication of remaining leukemia cells (minimal residual disease, MRD) by antigen-specific immunotherapy is a promising option. Therefore the major aim of this study is the identification of novel leukemia-associated, naturally presented HLA ligands (LEUKAPs) being able to induce a tumor specific T-cell response. Analyzing HLA class I ligands from primary AML-cells we have taken a special interest in peptides derived from AML-specific, mutated proteins.
Materials and methods: HLA class I ligands were isolated from patients' peripheral blood (blast count >80%) or PBMCs from healthy donors using immunoprecipitation. In order to identify HLA presented peptides, liquid chromatography coupled mass spectrometry (LC-MS/MS) based peptide sequencing was employed. The identified ligands were mined for leukemia associated peptides *via* comparing the HLA ligandomes of AML-patients with those of healthy donors, by analyzing gene expression databases and literature research. In order to identify veritable tumor specific peptides, acquired data has been mined for peptides derived from established leukemia associated mutations comprised in the COSMIC database (http://www.sanger.ac.uk/genetics/CGP/cosmic/).
Results: Having identified more than 6000 HLA ligands out of 6 AML patients, several new AML associated peptides (e.g. ligands derived from tumor protein p53, c-myc oncogene, KIS) were obtained by cross checking for occurrence on healthy tissues, especially on PBMCs. The sequences of identified LEUKAPs were verified by LC-MS/MS based peptide sequencing of their synthetic counterparts. Identified candidate peptides are currently checked for their immunogenicity after *in vitro* T cell priming.
Conclusions: This study provides several new leukemia associated antigens, for the first time directly obtained from AML patients' HLA ligandomes, offering promising options for a more efficient treatment of AML in the future.

P1728
HPMA copolymer-modified IL-2 possesses superior biological activity to free IL-2 *in vivo*

P. Votavová,* J. Tomala,* V. Subr,† K. Ulbrich,† B. Rihova* & M. Kovar*
**Department of Immunology and Gnotobiology, Institute of Microbiology Academy of Sciences of the Czech Republic, Prague, Czech Republic,*
†Department of Biomedical Polymers, Institute of Macromolecular Chemistry of Sciences of the Czech Republic, Prague, Czech Republic

Purpose/Objective: Interleukin-2 possesses strong stimulatory activity for activated T and NK cells and thus it is an attractive molecule for immunotherapy. However, its unfavourable pharmacological properties, extremely short half-life and severe toxicities associated with high-dose IL-2 are the most serious and limiting drawbacks. In order to increase IL-2 half-life and stability *in vivo*, we covalently conjugated IL-2 to synthetic semitelechelic polymeric carrier based on *N*-(2-Hydroxypropyl) methacrylamide (HPMA). Thus, we synthesized IL-2-pHPMA conjugate containing an average 2−3 polymer chains per IL-2 molecule.
Materials and methods: Expansion of CD8 ± T lymphocytes, NK and Treg cells *in vivo*. Purified OT-1 $CD8^+$ T cells (Ly5.2) were labeled with CFSE and injected i.v. into B6.SJL recipients (Ly5.1) on day 1. On day 2 the mice were injected i.p. with PBS, SIINFEKL peptide plus IL-2 (50 μg), and SIINFEKL peptide plus IL-2-pHPMA (1 μg of IL-2). Splenocytes were isolated day 7 and relative expansion of $Ly5.2^+$ $CD8^+$ T cells, NK cells, memory $CD8^+$ T cells and T regulatory cells was analyzed.

Kinetics of IL-2-pHPMA in blood. B6.SJL mice were injected i.v. with PBS, free IL-2 (2 μg) and IL-2-pHPMA (2 μg of IL-2). Blood sera were isolated at various time points after injection. Serum IL-2 concentrations were determined by sandwich ELISA with anti-mouse JES6.1A12 and anti-mouse JES6.5H4-biotin mAbs.

Determination of MTD. B6.SJL mice were injected i.p. with PBS or IL-2-pHPMA (25, 50 and 75 μg of IL-2) on day 0 . Weight of each mouse was recorded prior to injection (day -1) and for 6 days after. Average % weight change for each group was plotted.
Results: IL-2-pHPMA conjugate was found to be significantly more potent than free IL-2 in terms of expansion of NK, NKT, $\gamma\delta$T, memory

$CD8^+$ T and also T regulatory cells *in vivo*. IL-2-pHPMA conjugate also potently expanded adoptively transferred OT-1 $CD8^+$ T cells activated with SIINFEKL peptide while free IL-2 at the same dosage (1 μg IL-2 i.p. daily for 4 days) showed minimal activity. Moreover, activated naïve OT-1 $CD8^+$ T cells expanded by IL-2-pHPMA conjugate established a robust population of long-lived cells with memory phenotype, which were able to express effector functions upon re-activation. We also determined IL-2-pHPMA half-life in circulation upon intravenous administration. We found that short half-life of IL-2 is greatly prolonged by modification of IL-2 with HPMA polymeric carrier. Finally, we determined maximal tolerated dose of IL-2-pHPMA which is about 80 μg in case of single i.v. administration.
Conclusions: IL-2-pHPMA conjugate showed much longer biological half-time (~4 h versus <15 min) and superior biological activity than free IL-2 *in vivo*.

P1729

Human $CD8^+$ T cells engineered with supraphysiological TCRs are functionally inhibited via PD-1 and SHP-1 phosphatase

M. Hebeisen,* L. Baitsch,† D. Presotto,* P. Baumgärtner,† P. Romero,† O. Michielin,† D. E. Speiser† & N. Rufer*
**Department of Research, Lausanne University Hospital (CHUV), Lausanne, Switzerland, †Ludwig Center for Cancer Research, University of Lausanne, Lausanne, Switzerland*

Purpose/Objective: Protective $CD8^+$ T cell responses rely on TCR-dependent recognition of immunogenic peptides presented by MHC I. Cytolytic T lymphocytes directed against self/tumor antigens express TCRs of lower affinity/avidity than pathogen-derived T lymphocytes and elicit less protective immune responses due to mechanisms of central and peripheral tolerance. Anti-tumor T cell reactivity can be improved by increasing the TCR-pMHC affinity within physiological limits, while intriguingly further increase in the supraphysiological range (K_D < 1 μM) leads to drastic functional declines.

We aim at identifying the molecular mechanisms underlying the loss of T cell responsiveness associated with supraphysiological TCR-pMHC affinities in order to improve effectiveness of TCR-engineered T cells used in adoptive cell transfer (ACT) cancer immunotherapy.
Materials and methods: Using a panel of human $CD8^+$ T cells engineered with TCRs of incremental affinity for the HLA-A2-resticted tumor cancer testis antigen NY-ESO-1, we performed comparative gene expression microarray and TCR-mediated signaling analysis together with membrane receptors level analysis.
Results: As compared to cells expressing TCR affinities generating optimal function (K_D from 5to 1 μM), those with supraphysiological affinity (K_D from 1 μM to 15 nM) had an overall reduced expression of genes implied in signaling, cell activation and proliferation, and showed impaired proximal and distal TCR signaling capacity. This correlated with a decline in surface expression of CD8b, CD28 and activatory TNFR superfamily members. Importantly, expression of inhibitory receptor PD-1 and SHP-1 phosphatase was upregulated in a TCR affinity-dependent manner. Consequently, PD-L1 and SHP-1 blockade restored the function of T cells with high TCRs affinity. Moreover, SHP-1 inhibition also augmented functional efficacy of T cells with TCRs of optimal affinity.
Conclusions: Our findings indicate that TCR affinity-associated regulatory mechanisms control T cells responsiveness at various levels to limit potential auto-reactive cytotoxic effects. They also support the development of ACT therapies combined with blockade of inhibitory molecules such as SHP-1 to enhance effectiveness of T cell immunotherapy.

Identification of naturally presented tumor derived HLA Ligands — separating tumor and stroma origin

H. Schuster,* J. K. Peper,* P. Wagner,† J. Hennenlotter,‡ A. Stenzl‡ & S. Stevanovic*
**Department of Immunology, Interfaculty Institute for Cell Biology, Tübingen, Germany, †Department of Obstetrics and Gynecology, University Hospital Tübingen, Tübingen, Germany, ‡Department of Urology, University Hospital Tübingen, Tübingen, Germany*

Purpose/Objective: Renal cell carcinoma and ovarian cancer are both characterized by poor prognosis and high mortality due to late diagnosis and high resistance to conventional chemo- and radiotherapy. Looking for new and effective therapeutic options a lot of effort has been put into the development of a specific immunotherapy, aiming at the *in vivo* induction of a tumor-directed immune response. Our group is especially interested in the identification of tumor specific MHC ligands that can be used for the development of a multivalent peptide vaccine. For several years we have mainly relied on bulk tumor tissue to perform HLA ligand extraction and analysis by mass spectrometry. However information about the amount of isolated MHC molecules as well as bound peptides directly derived from tumor cells has so far never been obtained.
Materials and methods: In order to get a comprehensive view of the distribution of MHC expression within tumor tissue we used multi color flow cytometry to analyze the cellular composition and quantified the MHC expression of specific cell subsets. Single cell suspensions of fresh tissue samples were prepared by enzymatic digestion and stained with respective antibodies to distinguish between tumor cells and stroma (leukocytes, endothelial cells and fibroblasts). In a second step we further wanted to compare the overlap of identified HLA ligands directly on the peptide level. Therefore we started again from a bulk tissue derived single cell suspension but this time used MACS-technology to separate tumor from stroma cells before isolating and identifiying HLA ligands.
Results: Our results show that MHC molecules expressed by tumor cells represent only a small part of the overall MHC content. Furthermore tumor cells and surrounding stroma cells showed a completely distinct pattern of HLA presented peptides. With this approach we have identified new tumor specific MHC ligands derived from already established cancer related antiges (e.g. TMPRSS3, CA-125, hTERT) and could also reevaluate previously found peptides that were formerly claimed to be tumor specific and are now more likely to originate from the tumor stroma.
Conclusions: These results emphasize the importance of using specific cell subsets instead of bulk tissue for the identification of new tumor specific HLA ligands.

IL-2 expression enhances the anti-tumor effects of a DNA vaccine encoding HPV-16 E7 oncoprotein genetically fused with the HSV-1 gD protein

M. Diniz & L. C. S. Ferreira
Microbiology, Instituto de Ciências Biomédicas, University of São Paulo, São Paulo, Brazil

Purpose/Objective: Cervical cancer is the second most lethal cancer among women and all cases are associated with high-risk Human papillomavirus (HPV) persistent infections. Cellular malignization is attributed to E6 and E7 HPV oncoproteins, which represent ideal targets to the development of immunotherapeutic strategies against HPV-induced tumors. In this regard, our group has developed a cervical cancer DNA therapeutic vaccine encoding HPV-16 E7 protein genetically fused to the glycoprotein D (gD) of herpes simplex virus type 1 (HSV-1). Previous results showed that the vaccine encoding

HPV-16 E7 fused to gD (pgDE7), when administered in a four dose vaccine regimen (100 μg of DNA/dose) intramuscularly, induced significant activation of E7-specific $CD8^+$ T cells and 40% of therapeutic anti-tumor effect in mice.

Materials and methods: As an attempt to enhance the observed therapeutic anti-tumor effects, we tested the co-administration of plasmid encoding IL-2 (pIL-2) to the DNA vaccine administered in saline solution by the intramuscular route. Immune responses and tumor protection monitoring were evaluated in immunized mice previously challenged with tumor cells expressing HPV-16 E6 and E7 proteins (TC-1 cells).

Results: Combination of plasmid pIL-2 with pgDE7 increased the therapeutic protection to 100% after a single dose administration using only 50 μg of each plasmid. Co-administration of plasmid encoding IL-2 to pgDE7 DNA vaccine also increased the $CD8^+$ T cells IFN-g production and cytotoxic potency, as well as total and E7-specific $CD8^+$ T cell tumor infiltration when TC-1 cells were inoculated suspended in Matrigel. Moreover, IL-2 concomitant expression with the protein encoded by the DNA vaccine did not enhance the activation of regulatory T cells or myeloid derived suppressor cells in tumor bearing mice.

Conclusions: In summary, the data presented in this study describes the development of a new and potent therapeutic vaccine against HPV-16-associated tumors and encourages its further evaluation in clinical trials.

Immunogenic MUC1 glycopeptides can be generated when dendritic cells (DCs) are primed with microvescicle bound MUC1 tumor associated glycoprotein, but not with soluble MUC1

I. G. Zizzari,* H. Rahimi,* F. Battisti,* C. Napoletano,* F. Belleudi,† V. Visconti,* H. Wandall,‡ J. Burchell,§ M. R. Torrisi,¶ M. Nuti & A. Rughetti****

**Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy, †Department of Clinical and Molecular Medicine, Sapienza University of Rome, Rome, Italy, ‡Department of Cellular and Molecular Medicine, University of Copenhagen, Copenhagen, Denmark, §Breast Cancer Biology Group, King's Collego of London, London, UK, ¶Departement of Clinical and Molecular Medicine, University of Rome La Sapienza, Rome, Italy, **Department of Experimental Medicine, University of Rome La Sapienza, Rome, Italy*

Purpose/Objective: Efficient antigen cross-processing by Dendritic Cells (DCs) is a requirement to obtain efficacious anti-tumor immune responses (IR). Block of endocytated tumor associated antigen (TAA) in the early compartments of the intracellular processing machinery shifts the IR towards a Th2 balance. MUC1 is one of the most relevant tumor associated glycoprotein expressed by epithelial cells. Its soluble form has shown to be blocked in MHCII compartment of DCs. On the other hand, tumor associated glycoforms of MUC1 have been shown to be immunogenic *in vivo*.

Objective of this study is to investigate the processing pathways of different MUC1 formulations in DCs and to characterize the repertoire of glycoepitopes thus generated.

Materials and methods: MUC1 carrying microvesicles (MVs) were purified from ascites or from supernatant of MUC1 transfected DG75 cells. CHO-K1 and CHO-*ldl* cells were used to produce recombinant MUC1 carrying ST and Tn carbohydrates (ST-MUC1 and Tn-MUC1 respectively). Confocal microscopy and WB were used to study MUC1 intracellular localization in DCs after uptake. FACS and ELISA were employed to characterise MUC1 glycoforms with specific MoAbs.

Results: MUC1 as soluble molecule, independently by the glycosylation profile, appears to be blocked in the pre-endosomal compartment. Receptor-mediated endocytosis pushes further the processing in the HLAII compartment while only MUC1 carried by MVs localizes in both HLAII and HLAI compartments in DCs. The distinct processing of the MUC1 membrane bound is accompanied also by deglycosylation processes generating Tn-MUC1 immunogenic glycoepitopes as identified by the use of glycoepitope specific MoAbs.

Conclusions: These results strongly suggest that the antigen formulation is of crucial importance both for cross-processing and both for the generation of immunogenic glycoepitopes. Moreover the glycosylation complexity of the immunogen may be an additional parameter to be considered in the design of DC-based cancer vaccines.

Improved anti-tumor cellular response by combined therapy in an experimental model

A. Jamali,* A. Amari,† A. Pourgholaminejad,‡ A. Saei,‡ Z. Gheflati,‡ N. Sepanlou,§ N. Soufian* & J. Hadjati‡

**School of Allied Medical Sciences, Tehran University of Medical Sciences, Tehran, Iran, †School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, ‡School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, §Department of Radiotherapy Imam Khomeini Hospital, Tehran University of Medical Sciences, Tehran, Iran*

Purpose/Objective: Neither radiotherapy alone nor injection of dentritic cells (DCs) can successfully control the tumor growth. Radiation induces tumor cell apoptosis, resulting in the release of tumor antigens and danger signals, which are favorable for DC capturing antigens. Hence, the strategy of combined irradiation and activated DC vaccine may be a novel approach for inducing cellular anti-tumor response.

Materials and methods: WEHI-164 a Balb/c derived fibrosarcoma cell line was injected subcutaneously to female Balb/c mice. Bone marrow cells were cultured with GM-CSF and IL-4 for 5 days. Listeria monocytogenes antigens and tumor cell lysate had been added for another 2 days. Seven days after tumor challenge, localized single does (10 Gy) irradiation was applied. Activated DCs were injected SC around the tumor, the day after irradiation.

Tumor size was monitored every other day. Two weeks after immunization the splenocytes were isolated and cytotoxic activity was measured with a lactate dehydrogenase cytotoxicity detection kit. Intercellular INF_γ assessment was performed using a FACScalibur cytometer with WinMDI2.9 software.

Results: It has been shown immunotherapy with DCs after irradiation has more potent cellular response in comparison with irradiation alone, especially using activated Listeria monocytogenes DCs. The cytotoxicity of splenocytes in combined therapy specially in the group which received complete cocktail was more than other groups ($P < 0.016$).

Evaluation of intra-splenocyte INF_γ staining showed significant increase in the group of animal which had received both local irradiation and activated DC injection ($P < 0.001$).

Monitoring tumor size and mice survival showed reduced tumor size and increased survival in the combination treatment group ($P = 0.011$, $P < 0.001$).

Conclusions: Combination therapy using activated Listeria monocytogenes DCs and local irradiation resulted to achieve a more desirable and efficient cellular anti-tumor response against poorly immunogenic tumor as well as increased mice survival with tumor regression.

Therefore co-administration of local irradiation and activated DCs may be a promising strategy for inducing a potent response to radio sensitive solid tumors.

Improving dendritic cell vaccine immunogeneicity by lipid nanoparticle-mediated delivery of PD-1 ligand siRNA combined with target antigen mRNA electroporation

W. Hobo,* T. I. Novobrantseva,† H. Fredrix,* J. Wong,† S. Milstein,† H. Epstein-Barash,† J. Liu,† N. Schaap,‡ R. van der Voort* & H. Dolstra*

*Laboratory of Hematology, Department of Laboratory Medicine, Radboud University Medical Centre, Nijmegen, Netherlands, †Alnylam Pharmaceuticals, Cambridge, MA, USA, ‡Department of Hematology, Radboud University Medical Centre, Nijmegen, Netherlands

Purpose/Objective: Dendritic cell (DC)-based vaccination boosting antigen-specific immunity is being explored for the treatment of cancer and chronic viral infections. Although DC-based immunotherapy can induce immunological responses, its clinical benefit has been limited, indicating that further improvement of DC vaccine potency is essential.

Materials and methods: In this study, we explored the generation of a clinical-grade applicable DC vaccine with improved immunogenic potential by combining PD-1 ligand siRNA and target antigen mRNA delivery.

Results: We demonstrated that PD-L1 and PD-L2 siRNA delivery using DLin-KC2-DMA-containing lipid nanoparticles (LNP) mediated efficient and specific knockdown of PD-L expression on human monocyte-derived DC. The established siRNA-LNP transfection method did not affect DC phenotype or migratory capacity, and resulted in acceptable DC viability. Furthermore, we showed that siRNA-LNP transfection can be successfully combined with both target antigen peptide loading, as well as mRNA electroporation. Finally, we demonstrated that these PD-L silenced DC loaded with antigen mRNA superiorly boost *ex vivo* antigen-specific $CD8^+$ T cell responses from transplanted cancer patients.

Conclusions: Together, these findings indicate that our PD-L siRNA-LNP modified DC are attractive cells for clinical-grade production and *in vivo* application to induce and boost immune responses not only in transplanted cancer patients, but likely also in other settings.

IVAC: individualized vaccines for cancer

N. van de Roemer,* J. Diekmann,* S. Kreiter,* J. Castle,* M. Löwer,* C. Britten,† M. Diken,* O. Türeci‡ & U. Sahin*

*Immunotherapy, TRON-Translational Oncology at the Johannes Gutenberg-University Mainz, Mainz, Germany, †Immunotherapy, Ribological GmbH, Mainz, Germany, ‡Immunotherapy, Ganymed Pharmaceuticals AG Mainz Germany, Mainz, Germany

Purpose/Objective: Cancer is driven by multiple genetic events followed by further clonal evolution, rendering disease elimination with single-targeted drugs a difficult task. The multiplicity of gene mutations derived from sub-clone heterogeneity may represent an ideal setting for multi-epitope tumor vaccination. Vaccines are particularly suited for the activation of antigen-specific $CD4^+$ and $CD8^+$ T cells and allow precise targeting of tumor-associated molecular alterations. In the last years, multiple tumor- associated antigens (TAA) have been identified and categorized based on tumor-specific deregulation of gene expression. In addition, neo-epitopes can be created by non-synonymous, somatic mutations. As human cancers carry 100–300 non-synonymous mutations on average which are not subject to central immune tolerance, these mutations can be ideal candidates for individual vaccine development. We propose that cancer can be targeted by T cells induced by poly-neo-epitopic vaccines based on non-synonymous individual tumor-specific mutations.

Materials and methods: In order to test this hypothesis, we resorted to B16-F10 murine melanoma of which we have identified more than 500 non-synonymous mutations by whole exome sequencing. After selection of highly expressed genes and potential MHC binding affinities of the respective mutated epitopes, 50 mutations were chosen and validated by Sanger sequencing. In order to define the immunogenicity of the mutation-coding sequences, we designed 27-meric peptides incorporating either the mutated or the wild-type amino acid to immunize C57BL/6 mice and determined the immune response by *ex vivo* IFNg ELISpot.

Results: We found one third (16/50) of the mutation-coding peptides to be immunogenic, and out of these, 60% elicited immune responses preferentially directed against the mutated sequence as compared to the wild-type sequence. Anti-tumor potency of these epitopes was confirmed in a transplantable B16-F10 melanoma model where mice immunized with mutation-encoding peptides revealed tumor control in the protective and the therapeutic setting.

Conclusions: Thus we successfully showed that mutated epitopes containing single amino acid substitutions qualify as effective vaccines. Our study provides a comprehensive picture of the B16-F10 mutanome and strongly suggests that the combination of deep sequencing with systematic immunogenicity analysis of non-synonymous point mutations paves a new path for the individualized immunotherapy of cancer patients.

Low affinity HLA-A2 restricted melanocortin 1 receptor-derived peptides are recognized by melanoma-specific CTLs and TILs from melanoma patients

F. E. González,* M. Ramírez,† E. B. Allerbring,* A. D. Duru,* I. Poschke,‡ R. Kiessling,‡ A. Achour* & F. Salazar-Onfray†

*Department of Medicine, Center for Infectious Medicine (CIM), Karolinska Institutet, Stockholm, Sweden, †Program of Immunology, Faculty of Medicine, Institute of Biomedical Sciences, University of Chile, Santiago, Chile, ‡Department of Oncology and Pathology, Cancer Center Karolinska (R8:01), Karolinska Institutet, Stockholm, Sweden

Purpose/Objective: Melanocortin 1 Receptor (MC1R) is expressed on a majority of fresh melanoma biopsies and cell lines. Three low-affinity HLA-A2-restricted highly hydrophobic MC1R-derived peptides [MC1R291 (AIIDPLIYA), MC1R244 (TILLGIFFL) and MC1R283 (FLALIICNA)] can elicit cytotoxic T-lymphocytes (CTL) responses from normal donor peripheral blood lymphocytes (PBL). Peptide-specific CTL recognized MC1R-transfected targets as well as a panel of MHC class I-matched melanomas, demonstrating that MC1R epitopes are naturally processed and presented by human melanoma cell lines. Here, the presence of anti-MC1R specific CTLs precursors was assessed in a population of melanoma-specific T cells derived from PBL and tumour-infiltrating lymphocytes (TIL) from HLA-$A2^+$ melanoma patients.

Materials and methods: Tumour tissues and/or blood samples from eleven advanced stage IV melanoma patients were obtained and TILs, melanoma-specific CTLs and melanoma cell lines were generated from these samples. Cytotoxic activity was evaluated using a standard Cr^{51} release assay and MC1R-specific populations were obtained by tetramer staining and limiting dilution.

Results: Anti-MC1R HLA-A2-restricted cytotoxic activity was detected in 50% of TILs derived from HLA-$A2^+$ melanoma patients. While 5/10 CTLs lines recognized either MC1R244 or MC1R291, 2/10 CTLs lines also recognized HLA-A2/MC1R283 complexes. 4/5 HLA-A2/MC1R-specific CTLs lines displayed also cytotoxic activity against three HLA-A2-restricted gp100-derived epitopes ($gp100_{280-288}$; $gp100_{457-466}$ and $gp100_{476-485}$) demonstrating TILs multiple epitope-specificity. Moreover, two HLA-A2/MC1R-specific CTLs lines cross-reacted with the immunodominant MART-1/Melan-A_{27-35} peptide. Furthermore, 3/5 MART-1-specific TILs recognized only HLA-A2/MART-1_{27-35} complexes. Additionally, it should be noted

that the existence of MC1R244-reactive CTLs was demonstrated at a clonal level. Finally, using tetramers containing MC1R-derived peptides, anti-MC1R T cell subsets were detected in TILs populations from melanoma patients.

Conclusions: Taken together, our data support that HLA-A2-restricted MC1R-derived peptides are common immunogenic epitopes for melanoma-specific CTLs and may thus be useful for the development of melanoma peptide-based immunotherapy.

Monitoring of ADCC with a Fc-optimized CD19 antibody in post-transplant MRD treatment of paediatric patients with refractory B-lineage acute lymphoblastic leukemia

U. J. E. Seidel,* L. Grosse-Hovest,† P. Schlegel,* R. Handgretinger,* G. Jung,† S. Aulwurm,† M. Hofmann,† E. Pyz,† H. G. Rammensee† & P. Lang*

**General Paediatrics Oncology/Haematology, University Children's Hospital, Tübingen, Germany, †Department of Immunology, Interfaculty Institute for Cell Biology, Tübingen, Germany*

Purpose/Objective: Allogeneic stem cell transplantation is one of the major therapeutic options in paediatric patients with refractory B-lineage acute lymphoblastic leukemia. Despite significant improvement of bone marrow and peripheral blood stem cell (PBSC) transplantation over the last decade, relapse is still the major cause of death post-transplant due to persistent minimal residual disease (MRD). In order to prevent relapse in high-risk patients post-transplant, immunotherapy using a third-generation CD19 monoclonal antibody (mAb) is a promising approach and is deployed in an ongoing compassionate use program at our institution. Through its improved capability to recruit FcγRIIIA bearing effector cells, this Fc-optimized chimerized CD19 antibody mediates enhanced antibody-dependent cellular cytotoxicity (ADCC) by NK cells. Here we present preliminary results regarding ADCC efficacy and pharmacokinetics.

Materials and methods: Five paediatric patients with refractory B-lineage ALL received CD19 mAb (4G7SDIE) after allogenic stem cell transplantation. Donor derived PBMCs of the patients were analyzed by a 2-h europium release cytotoxicity assay. ADCC was measured by adding autologous serum taken after 4G7SDIE infusion or by adding 1 μg/ml 4G7SDIE to cryopreserved primary B-lineage ALL blasts *in vitro*. Titers of biologically active 4G7SDIE in patient serum samples were analyzed by a flow cytometry-based method. MRD levels were dermined by PCR and flow cytometry.

Results: Donor derived NK cells of the patients exerted insufficient lysis of primary B-lineage ALL blasts (mean specific lysis: 4.00%). However, lysis could be significantly increased by adding autologous patient serum taken after antibody treatment (mean specific lysis: 20.33%, $P = 0.0001$, student's t-test) or by adding 1 μg/ml 4G7SDIE (mean specific lysis: 34.84%, $P < 0.0001$). Activity of patient NK cells was similar to NK cells of healthy donors. ADCC relevant serum titers of biologically active 4G7SDIE were detectable up to 7 days after antibody infusion. In 3/4 patients significant MRD reduction was achieved.

Conclusions: ADCC mediated antileukemic effects for the 4G7SDIE antibody treatment have been shown *in vitro*. A further clinical trial will be necessary to investigate potential effects of this therapeutic antibody *in vivo*.

P1742

Mucosal imprinting of vaccine induced-CD8+ T cells is crucial to inhibit mucosal tumors

F. Sandoval,* M. Terme,* M. Nizard,* C. Badoual,* C. Bouguin,* J. Taieb,* L. Zitvogel,† H. Fridman,‡ L. Johannes§ & E. Tartour*

**Team 10, INSERM U970, Paris, France, †IGR, INSERM U1015, Paris, France, ‡Immunobiology, AP-HP HEGP, Paris, France, §Traffic Signaling and Delivery, Institut Curie, Paris, France*

Purpose/Objective: Although many human cancers are located in mucosal sites, most [F1] cancer vaccines were [F2] tested against subcutaneous tumors in preclinical models. We therefore wondered whether mucosa-specific homing instructions to the immune system might influence mucosal tumor outgrowth. We showed that the growth of orthotopic head and neck or lung cancers was only inhibited when a cancer vaccine was delivered by the intranasal (i.n) mucosal and not the intramuscular (i.m) route.

Materials and methods: We set up original orthotopic models of head and neck and lung cancers (on B6 mice injected with TC1 cells expressing the HPV16 E7 protein) and a cancer vaccine strategy based on a non replicative delivery system, the B subunit of Shiga toxin as mucosal vector which has previously been shown to target antigen to dendritic cells.

We analyzed the expression of chemokine receptors and integrin molecules expressed by T cells after intranasal or intramuscular immunization with STxB-E7 at mucosal and systemic compartments.

We blocked CD49a interaction with anti-CD49a mABs to demonstrate his role on T cell trafficking to orthotopic tumors.

Results: We found that mucosal immunization induced a response compartmentalized to the regional mucosal site for the $CD8^+$ T cells response, as we did not detect antigen specific $CD8^+$ T cells in genital draining lymph node after i.n immunization. Also we demonstrated a preferential recruitment of $CD8^+$ T cells in mucosal head and neck tumors after intranasal immunization which may be explained by the role of DC at the site of initial priming to imprint homing receptor expression onto T cells favouring their homing to the site of their initial activation. We found that intranasal immunization preferentially upregulated CD49a and CD103 on $CD8^+$ T cells at mucosal site. Intratumoral E7-specific T cells expressed high levels of CD49a, the $CD8^+$ T cells infiltrating head and neck cancer after i.n STxB-E7 administration significantly decreased when the vaccine was co-administered with anti-CD49a mAb and partially inhibited the therapeutic efficacy of the i.n STxB-E7 vaccine.

Conclusions: We provide direct evidence for the compartmentalization of mucosal tumor immunity, a critical finding for the rational design of better cancer vaccines. This work demonstrates for the first time that the efficacy of a mucosal cancer vaccine for head and neck or lung cancer is linked to its ability to trigger a mucosal program in vaccine-elicited $CD8^+$ T cells, which may represent a prerequisite and a surrogate marker of clinical efficacy.

P1743

Naive T cells showing HLA-restricted reactivity against unpulsed autologous dendritic cells hamper enrichment by *in vitro* priming of low-frequency antigen-specific T cells

T. S. Lam, M. van de Meent, J. H. F. Falkenburg & I. Jedema

Hematology, Leiden University Medical Center, Leiden, Netherlands

Purpose/Objective: *In vitro* induction of primary T cell responses by priming of naïve T cells against selected antigens (Ags) is feasible, but still poorly reproducible. In recent experiments we observed a profound proliferative response of human adult or cord blood-derived naïve T cells against autologous dendritic cells (autoDCs) in the absence of foreign Ags. This autoDC reactivity hampered the enrichment of low-frequency Ag-specific T cells.

Materials and methods: Purified, PKH-labeled naïve T cells (CD3+CD45RO-CD27+) were exposed to unpulsed autoDCs (R/S ratio 1/1) for 7–10 days in medium supplemented with 10 ng/ml IL-7 and 0.1 ng/ml IL-15. Based on their proliferative response, autoDC-reactive (PKH-low) and non-reactive (PKH-high) T cells were isolated 1 cell/well or in bulk by flow cytometric cell sorting. Secondary stimulations were done with autologous or allogeneic HLA-(mis) matched stimulator cells with or without HLA-blocking antibodies.
Results: AutoDC reactivity was found to be mediated by a polyclonal CD4+ and CD8+ T cell response, which occurred even under entirely serum-free conditions and could be inhibited by Tregs. The autoDC-reactive T cells, representing 1–3% of the total naïve T cell pool, acquired CD45RO expression, while the non-reactive counterparts remained naïve in response to autoDCs, but could still mount Ag-specific responses. Although both CD4+ and CD8+ naïve T cells showed autoDC reactivity, we could only generate CD4+ clones retaining their reactivity against autoDCs. The autoDC-reactive CD4+ clones showed IFN-γ and/or IL-4 production, and TCR/CD3 down-regulation upon stimulation, but most of them were not cytotoxic against autoDCs. Moreover, these clones responded to autologous monocytes, and immature DCs, but not to non-myeloid cells (EBV-LCL, PHA-blasts and (activated) B cells), indicating their myeloid-lineage specific reactivity. A panel study with allogeneic DCs matched for 1 or more of the HLA class II molecules and analyses using HLA blocking antibodies revealed that from individual donors both HLA-DP, -DQ and -DR restricted clones were isolated, further illustrating the polyclonality of this autoDC reactivity.
Conclusions: Our data showed the existence of T cells in the normal naïve repertoire harboring HLA-restricted and myeloid lineage-specific reactivity against autologous and HLA-matched allogeneic cells.

Nanobodies as potential diagnostic tools for *in vivo* imaging of lymphomas

A. Lenz,* V. Kunick,* L. Well,* B. Rissiek,† F. Haag,† H. Ittrich,* G. Adam,* F. Koch-Nolte† & P. Bannas*
**Department of Diagnostic and Interventional Radiology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, †Department of Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Purpose/Objective: There is a great potential for probes and techniques that allow for a specific detection of tumors *in vivo*. While monoclonal antibody-based probes offer good target specificity there has been a move towards smaller probes, which circumvent obstacles presented by conventional antibodies. Here we compared llama-derived nanobodies as alternative to monoclonal antibodies analysing the *in vivo* fluorescence imaging properties of lymphomas in a mouse model.
Materials and methods: In our study we used lymphoma cells that were transfected with the ecto-enzyme ART2 and compared the ART2-specific monovalent nanobody *s+16a* (15 kD) with a conventional monoclonal rat IgG_2a antibody (*Nika102*, 150 kD). Both constructs were labeled with the near-infrared fluorochrome AlexaFluor680. Athymic nude mice, bearing both, ART2-positive and ART2-negative lymphomas, were injected i.v. with the AF680-conjugates and monitored over 24 h. Properties of AF680-conjugates were investigated *in vivo* and *ex vivo* using near-infrared fluorescence (NIRF) imaging. Individual differences in tissue penetration and target binding efficiency were further analyzed by flow cytometry and fluorescence microscopy of dissected tumors.
Results: *In vivo* imaging revealed significant differences between the two antibody constructs in terms of biokinetics, biodistribution and labeling efficiency, which could be confirmed by *ex vivo* flow cytometry and fluorescence microscopy of dissected tumors. Both constructs revealed specific labeling of ART2-positive tumors but not of ART2-negative tumors. Rapid renal elimination of *s+16a* resulted in a good signal-to-background ratio of ART2-positive tumors *in vivo* already 6 h after injection. By contrast, the larger construct *Nika102* showed longer persistance in the plasma, leading to diffuse background signals with tumor-to-normal tissue ratios significantly lower as compared to nanobody *s+16a*..
Conclusions: Our results highlight the advantages of nanobody-conjugates as imaging tools for the specific detection and characterization of lymphomas *in vivo*. Compared to larger conventional antibodies, nanobodies are characterized by their favorable biodistribution and high signal-to-background ratio, which makes them particularly suited for short-term diagnostic imaging.

Naturally presented HLA ligands derived from histone deacetylases provide novel targets for T-cell mediated immunotherapy of ovarian carcinoma

J. K. Peper,* H. Hörzer,† H. Schuster,* B. Gückel,† R. Schäfer,‡ P. Wagner,† H. G. Rammensee* & S. Stevanovic*
**Department of Immunology, Interfaculty Institute for Cell Biology, Tübingen, Germany, †Department of Obstetrics and Gynecology, University Hospital Tübingen, Tübingen, Germany, ‡Institute of Clinical and Experimental Transfusion Medicine, University Hospital Tübingen, Tübingen, Germany*

Purpose/Objective: Late diagnosis and resistance to chemotherapy are the main reasons for the high mortality among women suffering from ovarian carcinoma (OvCa). New strategies to circumvent this drug resistance are urgently needed. One approach is to develop immunotherapies, including peptide-based cancer vaccines which should induce tumor-specific T cells. This strategy requires the identification of MHC-presented, immunogenic peptides derived from tumour-associated antigens (TAA).

The purpose of this study is to identify novel peptides for developing a multipeptide vaccine targeting OvCa.
Materials and methods: MHC class I ligands of OvCa samples were analysed by liquid chromatography coupled mass-spectrometry. Peptides from TAA or proteins which might be involved in tumorigenesis were selected for *in vitro* priming performed with PBMCs from healthy blood donors. T cells were isolated by magnetic activated cell sorting and stimulated with peptide-pulsed autologous DCs and B cells.
Results: Altogether we identified 8544 HLA ligands from nine different OvCa samples including 25 peptides derived from TAA. Up to know, *in vitro* priming of these candidate peptides revealed eight immunogenic epitopes.

The most promising epitope we found is an HLA-A*02 restricted peptide derived from HDAC1 (histone deacetylase 1), an established TAA highly overexpressed in OvCa and associated with poor prognosis. *In vitro* priming of healthy PBMCs induced T-cell responses directed against the HDAC1 peptide in 11 of 21 donors, as determined by positive intracellular stainings for IFNγ, TNFα, IL-2, CD107a and MIP-1β. In addition, those T cells were cytotoxic shown by lysis of HLA-A*02$^+$ tumour cells in chromium release assays whereas HLA-A*02-negative cells were not killed.

Moreover this peptide is also a natural HLA-A*02 ligand of HDAC2 and has been identfied on several other tumor types, allowing the simultaneous targeting of two different tumor-associated HDACs and the usage in vaccination trials for different tumor entities. Up to now 3 more HDAC1 dervied natural MHC peptides have been discovered suggesting a frequent presentation of HDAC1 peptides on tumor cells.
Conclusions: Based on our experimental data we are going to use the HDAC1/2 derived peptide in an upcoming multipeptide Phase I/II vaccination trial in HLA-A*02$^+$ OvCa patients.

Neutralization of IL-10 And TGFß1 rescues T cells from tolerogenic mechanisms induced by HER2 vaccine in cancer patients

S. Occhipinti,* L. Sponton,* A. Amici,† C. Marchini,† E. Quaglino,‡ A. Novarino,§ M. Donadio,§ A. Sapino,¶ F. Novelli* & M. Giovarelli*
*Experimental Medicine and Oncology, University of Turin, Turin, Italy, †Molecular Cellular and Animal Biology, University of Camerino, Camerino, Italy, ‡Molecular Biotechnology Center, University of Turin, Turin, Italy, §Giovanni Battista Hospital, C.O.E.S. Subalpine OncoHematology Cancer Center, Turin, Italy, ¶Biomedical Sciences and Human Oncology, University of Turin, Turin, Italy

Purpose/Objective: Dendritic cells (DCs) are the most potent antigen presenting cells in the immune system, which are capable of priming naïve T cells and can stimulate memory T cells and B cells to generate antigen-specific responses. Recent clinical trials were designed to stimulate immune system against HER2+ tumor by using HER2-peptides-based or peptides-loaded-DCs vaccine, but no clinical reponses was elicit, probably due to self tolerance mediated by natural and peripheral-induced Tregs.
Materials and methods: In our work, CD14+ monocytes were separated from PBMC of healthy subjects or patients with pancreatic and breast cancer overexpressing HER2, to generate dendritic cells (DCs). This DCs were matured and transfected with plasmids coding for extracellular and transmembrane domains of human HER2 then used to activate autologous T cells. Activation of T cells were assessed by intracellular staining, IFNγ-ELISpot, ELISA and cytotoxicity assays.
Results: Results showed that Human-DCs were able to trigger IFNγ release by autologous T cells in healthy donors, but not in cancer patients. Failure of Human-DCs could be ascribe to higher induction of Tregs activity and to higher amount of IL-10 and TGFβ1 found in cultures, since neutralization of these two cytokines restored the ability to induce IFNγ production.
Conclusions: From these we can conclude that cancer vaccine based on self antigen can induce an antitumor response but also activate immune tolerance mechanisms. This finding represent an important point thatbe consider to design cancer vaccines in future.

P1747

Next generation HLA ligandomics: defining the targetome for the immunotherapy of cancer

D. J. Kowalewski, A. Rabsteyn, H. G. Rammensee & S. Stevanovic
Department of Immunology, Interfaculty Institute for Cell Biology, Tübingen, Germany

Purpose/Objective: The identification and selection of appropriate targets is basic prerequisite for the success of peptide based immunotherapy of cancer. Due to the complex mechanisms underlying antigen presentation, indirect approaches towards target identification (e.g. reverse immunology) cannot warrant success. Furthermore the patient specific individuality of malignancies calls for flexible and informed selection of targets (from a vaccine warehouse) rather than standardized vaccine cocktails. Thus the objective was to devise a strategy to characterize the malignancy derived HLA ligandome in a direct, semi-quantitative and patient individualized manner.
Materials and methods: HLA ligands were isolated from bulk tumor tissue and corresponding autologous benign tissue of clear cell renal cell carcinoma (ccRCC) patients. Liquid chromatography coupled mass spectrometry (LC-MS/MS) based peptide sequencing in technical replicates and subsequent reproducibility analysis yielded semi-quantitative information of ligand and source protein representation in malignancy and benign tissue derived HLA ligandomes.
Results: Exhaustive HLA ligandome analysis was performed for several patients yielding more than 2500 HLA ligand identifications in every instance. KEGG pathway analysis and literature research showed great concordance of high-ranking tumor associated peptides (TUMAPs) and tumor associated antigens (TAAs) identified by our approach with antigens implicated in ccRCC and cancer in general (e.g. WT1, MUC1, EGFR, JUNB, MYC, NNMT). Furthermore we identified a large array of novel TAAs and corresponding HLA ligands. A high grade of tumor individuality became evident from overlap analysis of the top ranking TAAs from all samples analyzed.
Conclusions: The presented strategy enables the identification of novel TAAs directly based on the immunologically pivotal feature of HLA restricted presentation while readily providing the corresponding HLA ligands. Proof of principle was provided by the robust identification of well-known TAAs from all ccRCC samples analyzed. Furthermore this approach provides the rationale for the patient specific selection of the most promising peptide vaccine combination.

Purpose/Objective: Cancer cells are genetically unstable and, therefore, single therapies like chemotherapy or oncogene inactivating drugs frequently select resistant clones. A priori, one would expect that adoptive T cell therapy similarly selects escape variants.
Materials and methods: We established mouse cancer models, which allowed targeting of an oncogene by drug-mediated inactivation or monospecific $CD8^+$ effector T (T_E) cells. Cancer cells expressed a doxycycline (dox)-regulatable SV40 large T-firefly luciferase (TagLuc) fusion protein, which allowed oncogene regulation and visualization *in vivo*.
Results: Switching off TagLuc expression in large tumors resulted in rapid regression, followed by growth of dox-unresponsive variants. Each variant revealed a unique point mutation in the dox-binding domain of the transactivator, demonstrating a seemingly unlimited reservoir of genetic variants in the tumor. In contrast, Tag peptide I-specific T_E cells completely rejected large tumors ($\geq$500 mm^3), which did not require antigen cross-presentation by stromal cells. While drug-mediated oncogene inactivation selectively killed the cancer cells and left the tumor vasculature intact, which likely facilitated survival and growth of resistant clones, T_E cell treatment led to blood vessel destruction and probably 'bystander' elimination of escape variants.
Conclusions: Adoptive T cell therapy and drug-based cancer treatment were both highly effective but only T cells killed cancer cells and simultaneously destroyed the tumor vasculature, which may be critical to prevent escape.

Overcoming immunoescape mechanisms and induction of CD8$^+$ T cell-mediated resistance to tumor by polymer-bound doxorubicin conjugate targeted to tumor-specific antigen

M. Kovar,* J. Tomala,* T. Etrych,† K. Ulbrich,† M. Sirova* & B. Rihova*

*Department of Immunology and Gnotobiology, Institute of Microbiology ASCR, v.v.i, Prague, Czech Republic, †Laboratory of Biomedical Polymers, Institute of Macromolecular Chemistry ASCR, v.v.i, Prague, Czech Republic

Purpose/Objective: This study was focused on interactions of immune system of the host with the tumor during and after the treatment course with doxorubicin bound to HPMA copolymer carrier and targeted with mAb to tumor-specific antigen.

Materials and methods: BALB/c mice bearing syngeneic BCL1 leukemia, a mouse model of human chronic lymphocytic leukemia, were used in this study. B1 mAb recognizing the idiotype of membrane IgM expressed on BCL1 cells was used to target HPMA copolymer with covalently bound doxorubicin to tumor cells.

Results: Treatment with the conjugate can cure up to 100% of mice and significant proportion of cured mice show long-lasting resistance to BCL1 leukemia. We show that both CD4$^+$ and CD8$^+$ T cells are required for establishment of the resistance, but only CD8$^+$ T cells are necessary for its maintenance. We found that BCL1 cells paradoxically express MHC I, II and also costimulatory molecules CD80 and CD86 which can aid eliciting of anti-tumor response. On the other hand, we figured out that BCL1 cells also employ several immunoescape mechanisms, such as expression of PD-L1, PD-L2 and IL-10. Moreover, BCL1 leukemia progression is accompanied by significant increase of CD4$^+$CD25$^+$Foxp3$^+$ regulatory T (T_{reg}) cells relatively to other CD4 T$^+$ cells. In this study, we provide first direct evidence that expanded T_{reg} cells can indeed promote tumor progression by using mice with selectively expanded T_{reg} cells prior to inoculation of BCL1 leukemia. Finally, we have also shown that elimination of some immunoescape mechanism, e.g. deletion of T_{reg}, can significantly improve the therapeutic outcome of chemotherapy.

Conclusions: BCL1 cells can be recognized by BCL1-specific T cells, but instead of effective priming, such T cells are anergized or deleted by apoptosis. Treatment with doxorubicin bound to HPMA copolymer carrier and targeted specifically to the tumor cells is capable of overcoming these immunoescape mechanisms of BCL1 leukemia and establish long-lasting CD8$^+$ T cell-mediated tumor-specific resistance.

PDE5 inhibitors for the immune therapy of head and neck squamous cell carcinoma

P. Serafini,* D. Weed,† J. Vella,* A. Delafuente,* C. R. Gomez,‡ Z. Rodriguez§ & G. Walker¶

*Microbiology and Immunology, University of Miami, Miami, FL, USA, †Department of Otolaryngology, University of Miami, Miami, FL, USA, ‡Pathology, University of Miami, Miami, FL, USA, §Research Administration Med, University of Miami, Miami, FL, USA, ¶Biostatistics and Bioinformatics Core, University of Miami, Miami, FL, USA

Purpose/Objective: Head and neck squamous cell carcinoma (HNSCC) is a deadly disease with significant social and economic impact that is characterized by a strong accumulation of suppressive Myeloid Derived Suppressor Cells (MDSC) and macrophage and Treg in the perypheral blood and at the tumor site. We have previously shown in tumor murine models that PDE5 inhibitors (Tadalafil, Cialis, and Sildenafil, Viagra), commonly used for the treatment of erectile disfunction, can modulate the immune system by blocking MDSCs suppressive mechanisms and by promoting a spontaneous anti-tumor immunity. To verify if these findings hold true also in human, we are conducting a clinical Trial in which patients with HNSCC treated daily with tadalafil are immune monitored.

Materials and methods: Enrolled patients with Squamous cells carcinoma of the oral cavity, are treated with two doses of tadalafil or with placebo for 20 days before surgery. Immunological endpoints are evaluated before treatment, at the time of the surgery and 6 weeks after surgery. Functional assays, flow cytometry based characterization and immune fluorescence are performed on the blood and on the tumor specimen.

Results: Interim analyses indicate that MDSC and Treg are downregulated by PDE5 blockade in the peripheral blood and in the tumor and, more importantly, tumor specific immunity seems to be enhanced. Indeed, T cell proliferation stimulated by autologous dendritic cells pulsed with the autologous tumors is significantly increased after the *in vivo* regimen with Tadalafil. Furthermore, an higher infiltration of activated (CD69$^+$) CD8$^+$ T cells is observed by Immune fluorescence in the tumor specimen after tadalafil treatment compared to the pre-treatment baseline.

Conclusions: If our results will be confirmed when all the patients will be enrolled, PDE5 blockade will emerge as an effective and safe strategy to restore the optimal tumor micro- and macro- environment for an effective immunotherapy of HNSCC.

Peritumoral treatments with poly IC or MSU+ *M. smegmatis* enhance the anti-tumour response by activating both innate and adaptive immunity

S. Kuhn,* F. J. Rich,† E. J. Hyde,* J. L. Harper,‡ J. R. Kirman† & F. Ronchese*

*Immune Cell Biology Group, Malaghan Institute of Medical Research, Wellington, New Zealand, †Infectious Diseases Group, Malaghan Institute of Medical Research, Wellington, New Zealand, ‡Arthritis and Inflammation Group, Malaghan Institute of Medical Research, Wellington, New Zealand

Purpose/Objective: Tumours can escape immune responses by subverting immune cells to an immuno-suppressive phenotype. We wished to investigate the potential of microbial stimuli and sterile danger signals, which are known to provide activation signals to dendritic cells (DCs) and other innate cells, to overcome this suppression and stimulate an effective anti-tumour immune response.

Materials and methods: We injected non-pathogenic *Mycobacterium smegmatis*, the TLR ligands CpG, poly IC and LPS, and the sterile danger signal monosodium-urate crystals (MSU) peri-tumorally into immuno-competent mice bearing established subcutaneous B16F1, B16-OVA or E.G7-OVA tumours. Tumour growth was recorded and changes in immune cell types, activation state and cytokine production were assessed by flow cytometry, multiplex assay and RT-PCR. Metastasis formation was studied in the orthotopic 4T1 breast carcinoma model. RAG1-/- mice and *in vivo* cell depletion were employed to assess the requirement of T cells and NK cells.

Results: We found that CpG and poly IC treatment delayed tumour growth, whereas LPS, *M. smegmatis* or MSU alone showed no effect. Combination of *M. smegmatis* with MSU, however, significantly delayed tumour growth and prolonged survival. In addition, treatment with poly IC or MSU+ *M. smegmatis* reduced the formation of metastases.

The anti-tumour immune response elicited by poly IC or MSU+ *M. smegmatis* treatment required CD8 T cells as well as NK cells. In addition, both treatments increased infiltration of CD8 T cells and NK cells in tumours and enhanced their capacity to produce IFN-γ and TNFα. Successful treatments induced expression of IL-6, iNOS, G-CSF and CXCL10 in the tumour, and correlated with an early increase in

inflammatory monocytes and as well as induction of monocyte-derived inflammatory DCs in the tumour-draining lymph nodes.
Conclusions: Poly IC and MSU+ *M. smegmatis* induce local inflammation that recruits inflammatory monocytes to the tumour site, and their maturation into DC. These cells may then take up tumour antigen and become sufficiently activated to migrate to the draining lymph node where they initiate the anti-tumour immune response. We conclude that selected adjuvants can modify the tumour environment to promote adaptive and innate immune responses and induce tumour rejection.

Pilot clinical trial of type 1 dendritic cells loaded with autologous tumor lysates combined with GM-CSF, pegylated IFN, and cyclophosphamide for metastatic cancer patients

M. F. de Sanmamed,* C. Alfaro,* J. L. Perez-Gracia,† N. Suarez,‡ B. Sangro,§ S. Martín-Algarra,¶ A. Calvo,** S. Hervas-Stubbs,* I. Peñuelas†† & I. Melero*
*CIMA, Hepatología e Inmunoterapia Génica, Pamplona, Spain, †CUN, Oncología Médica, Pamplona, Spain, ‡SERGAS-INIBIC, Inmunología del Trasplante e Insuficiencia Cardiaca, A Coruña, Spain, §CUN, Medicina Interna, Pamplona, Spain, ¶CUN, Oncología, Pamplona, Spain, **CIMA, Oncología, Pamplona, Spain, ††CIMA, Técnicas instrumentales. Micro-PET, Pamplona, Spain*

Purpose/Objective: Dendritic cell (DC) can be artificially manipulated to present tumor antigens either in the form of defined protein sequences or as antigenic material obtained from autologous tumor cells. We have tested the safety and biological activity of immunotherapy based on type 1 DC in advanced cancer patients. Our combination strategy was based on preclinical data that we developed in mouse models.
Materials and methods: Twenty-four patients with metastatic cancer received two cycles of four daily immunizations with monocyte-derived dendritic cells. DC were incubated with preheated autologous tumor lysate and subsequently with IFN-α, TNF-α, and polyinosinic: polycytidylic acid to attain type 1 maturation. One DC dose was delivered intranodally, under ultrasound control, and the rest intradermally in the opposite thigh. Cyclophosphamide (day 27), GM-CSF (days 1*4), and pegIFN alpha-2a (days 1 and 8) completed each treatment cycle.
Results: Pretreatment with cyclophosphamide decreased regulatory T cells to levels observed in healthy subjects both in terms of percentage and in absolute counts in peripheral blood. Treatment induced sustained elevations of IL-12 in serum that correlated with the output of IL-12p70 from cultured DC from each individual. NK activity in peripheral blood was increased and also correlated with the serum concentration of IL-12p70 in each patient. Circulating endothelial cells decreased in 17 of 18 patients, and circulating tumor cells markedly dropped in six of 19 cases. IFN-γ*ELISPOT responses to DC plus tumor lysate were observed in four of 11 evaluated cases. Tracing DC migration with [^{111}In] scintigraphy showed that intranodal injections reached deeper lymphatic chains in 61% of patients, whereas with intradermal injections a small fraction of injected DC was almost constantly shown to reach draining inguinal lymph nodes. Five patients experienced disease stabilization, but no objective responses were documented.
Conclusions: This combinatorial immunotherapy strategy is safe and feasible, and its immunobiological effects suggest potential activity in patients with minimal residual disease. A randomized trial exploring this hypothesis is currently ongoing.

P1753

Polyclonal stimulation of conventional T cells *in vitro* is sufficient to prevent acute graft versus host disease while maintaining anti-tumor activity

N. Beyersdorf, S. Werner, N. Wolf, T. Hünig & T. Kerkau
Chair for Immunology, Institute for Virology and Immunobiology, Würzburg, Germany

Purpose/Objective: Acute graft versus host disease (aGvHD) is still a major complication of allogeneic bone marrow transplantations often precluding successful therapy of hematological malignancies. Alloreactive conventional, i.e. non-regulatory, T cells contained in the graft not only mediate the desired graft versus tumor (GvT) effect but they are also responsible for the induction of aGvHD. Therefore, novel immunotherapeutic approaches for aGvHD must aim at modulating T cell function without abrogating allo-reactivity.
Materials and methods: To this end we studied the aGvHD-inducing potential of conventional T cells from C57BL/6 mice polyclonally pre-expanded *in vitro* before transplantation into lethally irradiated allogeneic BALB/c recipients *in vivo*. As polyclonal T cell activators we used paramagnetic beads coated either with a superagonistic anti-CD28 mAb (CD28-SA) or with an anti-CD3 plus a conventional anti-CD28 mAb (co-stimulation).
Results: Both stimulatory protocols efficiently protected BALB/c recipient mice from aGvHD. Tracking experiments using carboxyfluorescein succinimidyl ester diacetate-labeled cells further revealed that *in vitro* pre-expansion did not abrogate allo-reactivity of the transferred T cells *in vivo*. Preserved allo-reactivity could also be observed in short-term *in vivo* killing assays against allogeneic target cells where CD28-SA-stimulated T cells showed superior cytotoxic activity in comparison to T cells pre-activated with co-stimulatory beads. Efficient killing in the short-term *in vivo* assays was predictive for long-term protection in the BCL-1 lymphoma model as CD28-SA-stimulated conventional T cells significantly increased the survival of lymphoma-bearing mice as compared to recipients receiving no allogeneic T cells.
Conclusions;Polyclonal stimulation of conventional T cells *in vitro*, thus, inhibited aGvHD induction *in vivo* while maintaining the desired GvT effect. This study was supported by a grant from the Wilhelm Sander-Stiftung (2005.133.2).

Potentiation of the production and cytotoxic activity of the FasL-based chimeric proteins by concomitant expression of the non-apoptotic FasL

A. Morello,* S. Daburon,* M. Castroviejo,† J. F. moreau,* J. Déchanet-Merville* & J. L. Taupin*
CNRS UMR 5164, Bordeaux, France, †CNRS UMR 5234, Bordeaux, France

Purpose/Objective: One aim of the laboratory is to develop soluble FasL fusion proteins, an attractive approach to treat cancer by triggering Fas apoptosis. To induce a productive death signal, soluble form of FasL requires an oligomerization beyond the homotrimeric state. A polymeric soluble FasL chimera (pFasL) was thus generated by fusing to the soluble FasL an immunoglobulin-like domain. A second generation of chimeras was designed to selectively induce apoptosis of malignant cells by fusing targeting modules, such as gdTCR or HLA-A2, to the pFasL molecule. The purpose of this study consists into potentiating production and cytotoxic activity of these FasL-based chimeras. We hypothesized that concomitant expression of the non-apoptotic soluble FasL improves structure of the FasL-based chimeras.
Materials and methods: For this purpose, we co-transfected the cDNA encoding FasL-based chimeras and the sFasL into mammalian cells. Only, the FasL based-chimeric constructs contain a FLAG epitope

tag, in order to discriminate them from the sFasL molecule. The secreted amount of recombinant proteins was assessed by a specific ELISA and the chimeras cytotoxic activity performed with MTT or iodide propidium assays. Their biochemical structures were also analyzed by (FasL co-) immunoprecipitation and gel filtration experiments.
Results: The concomitant expression of the soluble FasL considerably increases the secretion of FasL based-chimeras. The increasing production fluctuates between two to ninefold depending on the complexity of the FasL-based unit constituting the polymers. We demonstrated that sFasL was indeed physically attached to the FasL-chimeras and remodels their polymeric structures with a decreased size. Interestingly, FasL incorporation drastically potentiated their cytotoxic activities without hindering cell targeting of the FasL-chimeras.
Conclusions: Taken together, we describe an original approach that allows the improvement of polymeric FasL-based chimeric proteins, both at the level of the cellular production, and at the level of the cytotoxic activity. This approach may apply to a broad variety of FasL-derived chimeras used for anti-tumor therapy.

P1755
Pre-clinical assessment of EpCAM as a target for antibody based therapies of gastric cancer

S. Kobold,* J. Henkel,* J. Steffen,* J. Grassmann,* W. Zimmermann,† C. Bourquin* & S. Endres*
**Division of Clinical Pharmacology, Center of Integrated Protein Science Munich (CIPS-M) Department of Medicine IV Ludwig, Maximilians Universität, München, Germany, †Tumor Immunology Laboratory, LIFE Center Ludwig-Maximilians-Universität, München, Germany*

Purpose/Objective: The epithelial cell adhesion molecule (EpCAM) is highly expressed in gastrointestinal malignancies. EpCAM is suggested to be a marker of cancer stem cells and to be involved in processes such as metastasis. These characteristics and its surface expression render EpCAM a highly interesting target for antibody-based immunotherapies. To this end new antibodies need to be identified and tested in appropriate preclinical models.
Materials and methods: We investigated two EpCAM-specific antibodies in a spontaneous model of gastric cancer, the CEA424-SV40-T antigen-transgenic mouse (SV40 TAg) both *in vitro* and *in vivo*. Antibodies were characterized by Biacore measurements. Expression of EpCAM was addressed by flow cytometry and immunofluorescence.
Results: Antibodies with murine or rat backbone had affinities for EpCAM in the nanomolar range and recognized recombinant and naturally processed murine EpCAM protein. Both the primary tumor and a cell line established from the SV40 TAg mouse expressed EpCAM at high levels (range 60−100% of all tumor cells). *In vitro*, both antibodies had cytotoxic activity through the classical pathway of complement activation (range 20−40% of cell lysis) and through antibody-mediated cell-dependent cytotoxicity (range 50−80% of cell lysis). When administered *in vivo*, the EpCAM-specific antibodies were found evenly distributed in the EpCAM-positive tumor as well as in other EpCAM-expressing tissues. Distribution of the antibodies tightly correlated with the expression of EpCAM in the given tissue. Next, tumor-bearing SV40 TAg mice were treated three times i. v. with 300 μg of anti-EpCAM antibody. Remarkably, survival in this otherwise therapy resistant model was prolonged on average by 11 days ($P = 0.06$).
Conclusions: EpCAM targeting antibodies demonstrate good cytotoxicity in an *in vitro* model of gastric cancer. First *in vivo* data indicate that our antibody specifically targets cancer cells in a spontaneous model of gastric cancer which is known to be therapy-resistant. These data are of high relevance, as *in vitro* cytotoxicity as well as penetrance and accumulation into a tumor are prerequisites for *in vivo* use. Our data suggest that EpCAM represents an attractive target for the treatment of gastric cancer

P1756
Predicting tumor infiltrating lymphocyte (TIL) adoptive transfer clinical response in metastatic melanoma patients by T cell subpopulation-based rules

R. Mehr,* Y. M. Pickman,* D. Levy† & M. J. Besser†
**The Mina & Everard Goodman Faculty of Life Sciences, Bar Ilan University, Ramat Gan, Israel, †Sheba Medical Center, He Ella Institute for Treatment and Research of Melanoma and Skin Cancer, Tel Aviv, Israel*

Purpose/Objective: Tumor-infiltrating lymphocytes (TILs) are an immune population composed of different lymphocytic subpopulations (mostly T cells), that are derived from a tumor mass and have specificity and potential reactivity against the tumor. TILs are used in a clinical protocol called adoptive cell transfer for metastatic melanoma treatment with a success rate of about 50%. The collective outcome of using such a heterogeneous cell population is dictated by a complex network of interactions that span the molecular, cellular, and environmental levels. In a Previous study, we showed that the in-vitro reactivity of the TILs can be predicted from their subpopulation composition.
Materials and methods: In this study, we used machine learning techniques for retrospective analysis of the clinical in-vivo response of TIL treatment of 55 melanoma patients, aiming to find rules connecting TIL subpopulation frequencies to the clinical response.
Results: We have found that a simple set of subpopulation-based rules can predict the clinical response with an accuracy of 85−95%.

P1757
Rapid analysis and selection of antigens with clinical relevance for T cell therapy of hematological malignancies by microarray gene expression analysis

M. J. Pont, M. W. Honders, A. N. Kremer, E. G. A. Lurvink, S. A. P. van Luxemburg-Heijs, C. A. M. van Bergen, J. H. F. Falkenburg & M. Griffioen
Experimental Hematology, Leiden University Medical Center, Leiden, Netherlands

Purpose/Objective: Patients with hematological malignancies can be successfully treated with allogeneic hematopoietic stem cell transplantation (alloSCT). In HLA-matched alloSCT, donor T cells can mediate beneficial Graft versus Leukemia (GvL) reactivity due to recognition of minor histocompatibility antigens (MiHA) on patient malignant cells. These T cells may also induce Graft versus Host Disease (GvHD) when ubiquitously expressed MiHA are recognized. Novel MiHA are now efficiently identified by whole genome association analysis. In this study, we investigated whether antigens can be rapidly selected for clinical relevance for T cell therapy of hematological malignancies by microarray gene expression (MGE) analysis.
Materials and methods: Various (malignant) hematopoietic cells and non-hematopoietic cells from target tissues in GvHD were collected. Non-hematopoietic cell types were also cultured in the presence of IFN-γ to mimick the inflammatory milieu early after alloSCT. Total RNA was isolated and processed for MGE profiling. T cell recognition of malignant hematopoietic and (cytokine treated) non-hematopoietic cell types was measured by IFN-γ ELISA.
Results: Quality control of the MGE database included cell type specific markers and expression patterns of well-known tumor associated antigens. Expression profiles of 15 novel MiHA were investigated by MGE. The genes encoding these antigens were all broadly expressed, except for two hematopoietic restricted genes,

which included ARHGDIB and EBI3. EBI3 is selectively expressed in mature dendritic cells, whereas ARHGDIB is expressed in all hematopoietic lineages. T cell experiments showed that 11 of the 15 antigens were recognized on (cytokine treated) fibroblasts. The four remaining antigens included the two selected hematopoietic restricted as well as two broadly expressed antigens, which were not selected due to potential *in vivo* reactivity towards non-hematopoietic tissues by higher avidity T cells. The experiments confirmed recognition of the ARHGDIB antigen on primary leukemic cells, illustrating its therapeutic relevance.

Conclusions: Our data demonstrate that gene expression analysis allows rapid analysis and selection of clinically relevant antigens for novel T cell therapies aiming to induce a more favorable balance between GvL/GvHD after alloSCT.

P1758

Reactivated human endogenous retrovirus K (HERV-K) in cancer patients: new antigens for cancer vaccination

B. Schnierle, B. Kraus & R. Löwer
Virology, Paul-Ehlich-Institut, Langen, Germany

Purpose/Objective: Around 8% of the human genome consists of human endogenous retrovirus (HERV) sequences and HERVs can be further subdivided into 20 different families. HERV-K is the only known family encoding all structural and enzymatic proteins and is able to form retroviral particles however these particles are not infectious. Enhanced expression of HERV-K genes accompanied by the emergence of anti-HERV-K antibodies has been observed in patients for different tumor entities (e.g. germ cell tumor; melanoma). Because HERV-K expression is usually silenced in non-malignant cells, it fulfils the requirements to be used as a tumor-associated antigen (TAA).

Materials and methods: We generated recombinant poxvirus vaccine candidate based on the highly attenuated, avirulent vaccinia virus MVA (modified vaccinia virus Ankara). We inserted the HERV-K Env gene into the MVA genome and confirmed transgene expression. Mice immunized with the recombinant MVA were protected from engraftment of HERV-K Env expressing syngenic tumor cells. In addition to this prophylactic setting, mice had significantly reduced metastasis count in a therapeutic vaccination approach. Protection of mice correlated with an increase of HERV-K Env-specific lymphocytes. In addition, Balb/C mice immunized with the recombinant poxviruses showed a humoral immune response against HERV-K Env protein.

Results: Vaccination of mice with a recombinat MVA expressing HERV-K-Env as a phophylactic or a therapeutic approach showed significant anti-tumor effects.

Conclusions: Our results indicate that the generated recombinant poxvirus is suitable to induce a strong HERV-K-directed immune response and thus might be promising vaccine candidate against tumor entities which show a reactivated expression of HERV-K.

P1760

Selective targeting of membrane Hsp70 positive tumour cells by recombinant human granzyme B: a novel therapeutic approach for cancer?

G. A. Foulds,* M. Gehrmann,† A. G. Pockley‡ & G. Multhoff†
**Department of Surgical Oncology, University of Sheffield, Sheffield, UK,* †*Department of Radiation Oncology, Technische Universität München, Munich, Germany,* ‡*John van Geest Cancer Research Centre, Nottingham Trent University, Nottingham, UK*

Purpose/Objective: One way by which natural killer cells and cytotoxic T cells are able to induce apoptosis is via the delivery of serine proteases such as granzyme B into target cells. Although perforin has been traditionally thought to be necessary for granzyme B uptake, current opinion over the precise role of perforin in the uptake mechanism is now divided. Even in the absence of perforin, it is possible for granzyme B to enter a target cell and induce apoptosis if that cell expresses a membrane form of heat shock protein 70 (Hsp70). This membrane form of Hsp70 is expressed in a large proportion of tumours (~50%), but not healthy tissue. Granzyme B could therefore provide a novel strategy for targeting tumours.

Materials and methods: To better investigate the role of membrane Hsp70 and granzyme B in tumour targeting, a method for producing biologically active recombinant human granzyme B was developed. For this, human granzyme B was stably transfected into the human embryonal kidney cell line HEK293. The addition of a (His)6 tag ensured successful protein retrieval from the cell supernatant and an inactivation site protected the HEK293 cells from apoptosis. Granzyme B was purified using a nickel column and activated by enterokinase digestion of the inactivation site. The resulting protein exhibits high purity and enzymatic activity.

Results: Granzyme B induction of apoptosis in membrane Hsp70 positive tumour cell lines (MCF7, CT26, 4T1) was observed both by morphological changes and by caspase-3 activation. There was evidence of apoptosis occurring after 4 h, with complete cell death after 24 h. Flow cytometric and confocal microscopy analysis reveals that the binding and uptake of granzyme B requires glycosylation. Blocking studies demonstrated that neuraminic acid was the most important for efficient granzyme B uptake. Current work is examining the intracellular pathways of granzyme B uptake using confocal microscopy of cells that are co-stained with antibodies specific for endosomal (early with Rab-4 and -5, late with Rab-7 and -9, recycling with Rab-11, -15, -17 and -25) and lysosomal (LAMP1 and LAMP2) compartments, and MitoTracker Green dye to identify the mitochondria.

Conclusions: Taken together, these findings indicate that granzyme B could offer a new therapeutic option for the targeting cancer in those patients that bear membrane Hsp70 positive tumours.

P1761

Spontaneous $CD4^+$ T-cell responses against indoleamine 2,3-dioxygenase

S. Munir, S. K. Larsen, M. Donia, I. M. Svane, P. T. Straten & M. H. Andersen
Department of Hematology, Center for Cancer Immune Therapy (CCIT), Copenhagen University Hospital, Herlev, Denmark

Purpose/Objective: Indoleamine 2,3-dioxygenase (IDO) suppresses T cell immunity in the tumor microenvironment and IDO expression is commonly elevated in tumors and draining lymph nodes. Recently, we described cytotoxic CD8+ T-cell reactivity against IDO. In the present study, we show that CD4+ helper T cells additionally spontaneously recognize IDO. Hence, we scrutinized the vicinity of the previously described HLA-A*0201-restricted IDO-epitope for CD4+ T-cell epitopes.

Materials and methods: We demonstrated the presence of naturally occurring HLA class II-restricted, IDO-specific CD4+ T cells in cancer patients and in healthy donors using INFγ, TNFα and IL-17 EliSpot assay.

Results: IDO-reactive CD4+ T cells released INF-γ, TNF-α, as well as IL-17. In some donors, we observed that activation of IDO-reactive CD4+ T cells suppressed IL-10 production, whereas in PMBC from additional donors we could detect IL-10 release in response to the class II-restricted IDO-derived peptide.

Conclusions: IDO-specific T cells may participate in immune-regulatory networks where the activation of pro-inflammatory IDO-specific CD4+ responses may well overcome or delay the immune suppressive actions of the IDO-protein, which are otherwise a consequence of the early expression of IDO in maturing antigen presenting cells. In

contrast, IDO-specific regulatory T cells may enhance IDO-mediated immune suppression.

P1763

The 5T4 tumour associated antigen as a target for CAR-T cell therapy

C. T. Mansbridge, M. Abdulaziz, Y. Al-Muftah, P. L. Stern & D. Gilham

Clinical and Experimental Immunotherapy Group, School of Cancer and Enabling Sciences, The University of Manchester, Manchester, UK

Purpose/Objective: The 5T4 oncofetal antigen is expressed on many tumour types including renal, colorectal, ovarian and gastric carcinomas but has limited expression on normal adult tissues. Hence, 5T4 is an attractive target for immune-based cancer therapies. In this study, we develop and test mouse 5T4 (m5T4) specific Chimeric Antigen Receptor (CAR) T cells for *in vitro* functionality.

Materials and methods: A m5T4 specific CAR was generated by amplification of the relevant single chain antigen-binding domain (scFv) from a high-affinity m5T4 specific antibody-producing hybridoma cell line and fusing to the CD3z transmembrane and signalling domain. Retroviral vectors encoding this m5T4 specific CAR were used to transduce C57 bl/6 T cells.

Results: Over multiple experiments, T cells were efficiently transduced to a level of approximately 75%. These CAR-T cell populations showed antigen-specific cytotoxicity against mouse tumours that expressed the m5T4 antigen but only background levels of activity against tumour cell lines lacking the target antigen. Moreover, T cells bearing the m5T4 scFv fused to a non-signalling transmembrane anchor failed to lyse $5T4^{+}$ target cells indicating that target binding and signalling by the CAR was required for effector T cell function. m5T4 CAR-T cells also produced significant levels of IFNg after co-culture with antigen-expressing target cells.

Conclusions: These observations confirm that a CAR specific for the mouse 5T4 antigen is functional in mouse T cells and warrants further examination of anti-tumour efficacy in relevant *in vivo* model systems.

P1764

The anti-tumor effects of an adenoviral vaccine expressing 4-1BB ligand in a murine melanoma model

E. Ragonnaud, A. Andersson, B. A. H. Jensen, A. R. Thomsen & P. J. Holst

Faculty of Health and Medical Sciences, University of Copenhagen, Isim, Copenhagen, Denmark

Purpose/Objective: In therapeutic tumor vaccination, replication deficient adenovirus expressing a glycoprotein of LCMV linked to the MHC class II associated Invariant chain (Ad5-IiGP) was found to delay B16.F10 tumor growth expressing the epitope GP^{33-41}. However, in this mouse model, a complete regression of established palpable tumors has never been demonstrated by vaccination alone. A major reason could be that T cells are not sufficiently stimulated, and this is supported by the observation that general activation of antigen presenting cells enhance tumor protection. 4-1BB Ligand (4-1BBL) is an inducible co-stimulatory molecule necessary for proper T-cell expansion and treatment with an agonistic anti-4-1BB antibody has been found to eradicate established subcutaneous tumors in mice.

Materials and methods: Here, we investigated the effects of 4-1BBL expression into replication deficient adenovirus-based IiGP vaccine vector on the T cell immune responses in mice with and without tumor as well as in tumor protection.

Results: We show that this vaccine was as efficient as Ad5IiGP in stimulating naïve TCR transgenic CD8+ T cells, and there were no significant differences in the immune response induced by these two vaccines, in mice. In contrast, in tumor bearing mice, Ad5-IiGP-4-1BBL was found to decrease the CD8+ T cell expansion as compare to non-tumor bearing mice. This difference did not alter the therapeutic efficacy, however when 4-1BBL was added to a less immunogenic vaccination vector, Ad5-GP, the therapeutic anti-cancer activity was completely lost.

Conclusions: This new strategy does not improve vaccine efficacy. The reason for the apparent reduction in efficacy warrants further studies.

P1766

Treatment of experimental tumors with polymer-bound cytotoxic drugs revealing anti-tumor and immunomodulatory activity

M. Sirova,* T. Etrych,† P. Chytil,† M. Kabesova,* L. Uherkova,* K. Ulbrich† & B. Rihova*

**Laboratory of Tumor Immunology, Institute of Microbiology, Academy of Sciences of the Czech Republic, Prague, Czech Republic, †Laboratory of Biomedicinal Polymers, Institute of Macromolecular Chemistry, Academy of Sciences of the Czech Republic, Prague, Czech Republic*

Purpose/Objective: Cancer treatment with established low-molecular-weight drugs can induce severe side effects, including impairment of anti-cancer immune responses. It was already demonstrated that these drugs, when bound to a polymer carrier display anti-cancer activity devoid of systemic toxicity. We previously documented that *N*-(2-hydroxypropyl) methacrylamide (HPMA)-based prodrugs bearing doxorubicin or taxanes exhibit direct anti-cancer effect as well as immunomodulatory activity, leading to development of tumor-specific resistance.

Materials and methods: High-molecular-weight (Mw $\sim$ 250 kDa) polymer carriers were designed in order to achieve water-soluble prodrugs with tunable drug content and high accumulation in the tumor. Conjugates binding either doxorubicin (Dox) or docetaxel (Dtx), or combination of both drugs were prepared. The drugs were bound to the carrier via hydrazone linkage, allowing for liberation of active drug in a pH-dependent manner and resulting in killing of the target tumor cells. The anti-cancer activity was studied in experimental models (EL4 T cell lymphoma in C57BL/6 mice, or 4T1 mammary carcinoma in BALB/c mice). The tumor resistance was proved in animals with completed tumor regression by a second challenge without any further treatment.

Results: Treatment of the murine tumors with the conjugates containing Dox or Dtx led to complete regression of EL4 and 4T1 tumors and development of treatment-dependent tumor resistance. The effective doses of the conjugates did not induce any apparent side toxicities. The Dox-containing conjugates induced immunogenic cancer cell death, already described for the free Dox, such as translocation of calreticulin to the cellular membrane and HMGB1 release. During the therapy, downregulation of MDSC was detected both in the tumor tissue and in the periphery. Interestingly, the conjugate containing both drugs showed higher anti-cancer activity when comparing with a mixture of two conjugates containing either Dox or Dtx, suggesting synergy between the drugs.

Conclusions: HPMA-based conjugates designed for increased tumor accumulation, bearing Dox and Dtx, are potent inducers of solid tumor regression and immunomodulatory activity, resulting in development of treatment-dependent immune-mediated tumor-specific resistance.

Two step selection protocol based on the expression of T cell activation marker CD137 increases efficacy in generating high-affinity allo-HLA restricted T cells

L. Jahn,* P. Hombrink,* C. Hassan,† M. G. D. Kester,* J. H. F. Falkenburg,* P. A. van Veelen† & M. H. M. Heemskerk*
*Hematology, Leiden University Medical Center, Leiden, Netherlands, †Immunohematology and Blood Transfusion, Leiden University Medical Center, Leiden, Netherlands

Purpose/Objective: The broad application of adoptive immunotherapy targeting tumor-associated self-antigens is often hampered by the lack of an effective immune response targeting these antigens. As a consequence of self-tolerance high-affinity T-cells targeting self-antigens are often lacking. An attractive strategy is to exploit the immunogenicity of foreign leukocyte antigen molecules to generate an effective immune response against these antigens. Here we aimed to develop a protocol to efficiently isolate high-affinity peptide-specific allo-HLA restricted T-cells targeted to the B-cell compartment.
Materials and methods: A set of 18 novel HLA-A*0201 and B*0701 epitopes, encoded by B-cell specific genes, was selected from a large scale peptide-elution library. MHC-tetramers were generated for all peptides and used to isolate antigen-specific T-cells from HLA-mismatched PBMC donors. Expanding cultures were analyzed by multi-color combinatorial-coding MHC-tetramer screen and hundreds of clones were generated by FACS sort. Subsequently these clones were screened for exclusive B-cell recognition using a broad panel of various hematopoiesis restricted target cells. In a second isolation step MHC-tetramer positive T-cell lines were co-cultured with a CD40L-activated HLA-A*0201/B*0702 positive B-cell line. Following isolation of reactive T-cells based on CD137 expression, activated T-cells were clonally expanded and tested again for their recognition pattern.
Results: The implementation of the CD137 based selection step led to an increased isolation of high-affinity peptide-specific allo-HLA restricted T cells unparalleled by the isolation protocol lacking the selection procedure. In addition, the CD137 based selection step led to the isolation of novel high-affinity peptide-specific allo-HLA restricted T-cells targeting antigens against which no reactivity could be elicited previously.
Conclusions: Applying the methods of this study we were able to generate large numbers of high-affinity B-cell specific allo-HLA restricted T-cells including some CD79B reactive candidates. However, no T-cells suitable for adoptive T-cell therapy could be isolated. We speculate that implementing an additional selection step separating T-cells exerting unwanted reactivity from T cell with a desired recogniton pattern will further increase the selection efficiency and lead to the isolation of therapeutically relevant T-cells.

P1768

Virus-like particle mediated delivery of a-galactosylceramide improves the generation of anti-tumour responses

S. L. Young,* V. Young,† M. A. Baird,† V. Ward,† I. F. Hermans‡ & S. M. McKee§
*Pathology DSM, University of Otago, Dunedin, New Zealand, †Microbiology and Immunology, University of Otago, Dunedin, New Zealand, ‡Malaghan Institute, Wellington, New Zealand, §University of Otago, Pathology Department, Dunedin, New Zealand

Purpose/Objective: Virus-like particles (VLP) derived from the Rabbit Hemorrhagic Disease Virus (RHDV) are highly efficient vehicles for delivery of antigen to antigen-presenting cells (APC), however VLP do not provide the stimulatory signals required to generate optimal cytotoxic T lymphocytes (CTL). The glycolipid α-galactosylceramide (α-GalCer) is a potent stimulator of a subset of CD1d-restricted T cells, natural killer T (NKT) cells. Recognition of α-GalCer by NKT cells promotes production of interferon-γ and CD40/CD40L interactions that can provide an adjuvanting boost, assisting in APC priming of CTL. This research developed a composite particle of VLP with α-GalCer (VLP/α-GalCer).
Materials and methods: C57BL/6 mice ($n = 10$) were vaccinated intra-venously (i.v.) with 100ug of VLP/α-GalCer, α-GalCer or VLP alone. Splenocytes were isolated 24 h later and cell populations were analysed by flow cytometry for their activation status. In further studies mice were vaccinated (i.v.) with α-GalCer, VLP/α-GalCer or VLP alone and the ability to resist B16 tumour challenge was determined by inhibition of growth of tumours and by induction of cytotoxic T cells. Finally we assessed whether the production of IgG to the parent VLP could enhance the uptake of VLP *in vivo* and increase the overall ability of mice to resist tumour challenge.
Results: VLP/α-GalCer significantly increased the level of dendritic cell activation, inflammatory cytokine production, promoted antibody class switching and protected against growth of subcutaneous tumour. HPLC analysis of VLP/α-GalCer estimated that a 100 μg of VLP/α-GalCer was associated with ~20 ng of α-GalCer. Interestingly, VLP/α-GalCer was able to stimulate CTL responses equivalent to a 100 μg of VLP + 200 ng of unassociated α-GalCer.
Conclusions: This data demonstrates a 10-fold benefit to the adjuvanting activity of α-GalCer when it is associated with the VLP. Co-delivery of antigenic peptides and adjuvants on the scaffold of a VLP provides promise as a novel immunotherapeutic for the treatment of cancer.

Effects of heat-killed Lactobacillus on allergic immune responses in a murine model of asthma

T. Y. Lai & B. F. Lin
Biochemical Science and Technology, National Taiwan University, Taipei city, Taiwan

Purpose/Objective: *Lactobacillus* NTU101 (NTU101) is a Taiwan-native strain of lactic acid bacteria isolated from human infant feces. It resists gastric acid and bile salts and has immunomodulatory capacity. In this study, we investigated the effects of heat-killed NTU101 with inulin (NTU101 sample) on allergic and gut immune responds.
Materials and methods: BALB/c mice sensitized intraperitoneally and challenged with ovalbumin (OVA) were oral administrated with NTU101 sample for 22 weeks. The effects of NTU101 on airway hyperresponsiveness (AHR), airway inflammation, serum antibody levels, natural killer cell activity and cytokine secretions from splenocytes, mesenteric lymph node and Peyer's patch were evaluated.
Results: NTU101 supplementation reduced the levels of inflammatory mediators, such as interleukin IL-4, IL-6, and TNF-a in bronchoalveolar lavage fluid (BALF) when compared with those of the control group. Feeding NTU101 sample can increase the levels of IL-2 secretion from ConA-stimulated splenocytes, mesenteric lymph node, and Peyer's patch. It also significantly increased IFN-g secretions from ConA-stimulated splenocytes, and Peyer's patch. Further, oral administration of NTU101 sample can reduce IL-5 and IL-10 secretions from ConA-stimulated splenocytes, and increase IL-10 secretion from ConA-stimulated mesenteric lymph node.
Conclusions: Although NTU101 can't improve AHR, it can alleviate bronchoalveolar inflammation, and has the immune tendency toward Th1 response.

Immunomodulating effects of exopolysaccharides produced by a cyanobacterium from the Blue Lagoon in Iceland

J. Freysdottir,* A. B. Gudmundsdottir,† S. Omarsdottir,† A. Brynjolfsdottir‡ & E. S. Olafsdottir†
**Department of Immunology, Faculty of Medicine, Centre for Rheumatology Research Landspitali The National University Hospital of Iceland, University of Iceland, Reykjavik, Iceland, †Faculty of Pharmaceutical Sciences, University of Iceland, Reykjavik, Iceland, ‡Research and Development, Blue Lagoon, Grindavik, Iceland*

Purpose/Objective: The Blue Lagoon is located on the geothermally active Reykjanes peninsula in Iceland. Beneficial effects of regular bathing on psoriasis, a T cell mediated disease, were discovered shortly after its formation in 1976. The Blue Lagoon coccoid cyanobacterium *Cyanobacterium aponinum* is a dominating member of the microbial ecosystem of the Blue Lagoon geothermal seawater, where it releases polysaccharides into its surroundings (exopolysaccharides, EPS). The aim of the study was to investigate whether EPS isolated from cultured *C. aponinum* affected maturation of human dendritic cells (DCs) and their ability to activate allogeneic $CD4^+$ T cells *in vitro*.
Materials and methods: Human monocyte-derived DCs were matured in the absence or presence of EPS (0.1−100 μg/ml) and the effect determined by measuring cytokine secretion by ELISA and expression of surface molecules by flow cytometry. Furthermore, DCs matured in the presence of EPS at 100 μg/ml were co-cultured with allogeneic $CD4^+$ T cells and the effect determined by measuring cytokine prodcution by ELISA and flow cytometry and expression of surface markers and transcription factors by flow cytometry.
Results: Human monocyte-derived DCs matured in the presence of EPS at 100 μg/ml secreted increased levels of IL-10 compared with DCs matured without EPS, whereas no changes were observed in IL-6 and IL-12p40 secretion. Allogeneic $CD4^+$ T cells co-cultured with DCs that had been matured in the presence of EPS secreted increased IL-10 levels compared with allogeneic $CD4^+$ T cells co-cultured with DCs matured without EPS, without any difference in secretion of IFN-γ, IL-17 and IL-22. There was a tendency towards increased frequency of $Foxp3^+$ and $IL\text{-}10^+$ $CD4^+$ T cells and decreased frequency of $PD1^+$ $CD4^+$ T cells when they were co-cultured with DCs matured in the presence of EPS.
Conclusions: EPS isolated from *C. aponinum* stimulate DCs to secrete increased levels of IL-10 without affecting secretion of IL-6 or IL-12p40. In co-culture, these DCs induced allogeneic $CD4^+$ T cells to secrete IL-10, and to upregulate Foxp3 and reduce PD1 expression, a phenotype resembling Tregs. This raises the question whether treatment in the Blue Lagoon induces upregulation of Tregs, which in turn could suppress the overly active T cells in inflammatory skin diseases like psoriasis.

Pharmacological characteristics of *Polygonum viscosum* Buch.-Ham. ex D. Don and its application in immunological disorders

M. A. H. Mollik
Biological Sciences, Practical Academy on Wise Education and Research Foundation, Dhaka, Bangladesh

Purpose/Objective: Scientists are searching for new leads from the natural sources to combat different disorders. Until recently an insignificant part of the plants has been scientifically evaluated for their medicinal values. The studies were undertaken to discover new drugs from the natural sources. *Polygonum viscosum* Buch.-Ham. ex D. Don belongs to the plant family Polygonaceae Juss. and is widely distributed throughout Bangladesh. It is locally known as Bish-katali. *Polygonum viscosum* Buch.-Ham. ex D. Don is used for the remedy of killer diseases as well as debilitating diseases. The studies were leads to the development of a range of secondary metabolites of diversified structural types such as flavonoids, terpenoids, and cinnamic acid derivatives.
Materials and methods: The structures of the isolated compounds were elucidated mainly by high field Nuclear magnetic resonance (NMR) and other spectroscopic techniques.
Results: Quercetin 3-O-(6'-feruloyl)-β-D-galactopyranoside was found to exert a mild anticholinergic activity. A total of fifteen compounds were isolated, of which six compounds viz. viscozulenic acid, viscosumic acid, viscoazucine, viscoazulone, viscoazusone, and quercetin 3-O-(6'-feruloyl)-β-D-galactopyranoside appeared to be novel natural products. From the *in vivo* cytotoxicity assay of the novel compounds against two cancer cell lines (LOX and OVCAR-3), only quercetin 3-O-(6'-feruloyl)-β-D-galactopyranoside was found to be active against ovarian cancer cell line (OVCAR-3) with an IC_{50} value of 13.26 μg/ml. In the *in vitro* anti-HIV-1 assay, viscoazulone and quercetin 3-O-(6'-feruloyl)-β-D-galactopyranoside exhibited anti-HIV-1 activity at IC_{50} value of 33.13 μg/ml and 25.61 μg/ml, respectively, while no such activity was observed with other compounds.
Conclusions: The studies will increase the potentially of *Polygonum viscosum* Buch.-Ham. ex D. Don for the production of various pharmaceutical raw materials and new drugs of worldwide to a large extent.

Phytochemical isolated from *Ramalina farinaceae* showed anti-RSV activity and immune modulatory effects

D. C. Odimegwu,* L. Daowan,† V. Temchura,* C. O. Esimone,‡ K. Überla,* P. Proksch† & T. Grunwald*

**Department of Molecular and Medical Virology, Ruhr University, Bochum, Germany, †Institute of Pharmaceutical Biology and Biotechnology, Heinrich-Heine University, Düsseldorf, Germany, ‡Faculty of Pharmaceutical Sciences, Nnamdi Azikiwe University Awka, Awka Anambra State, Nigeria*

Purpose/Objective: Respiratory syncytial virus (RSV) is a member of the Paramyxoviridae family. Disease arising from RSV infection in humans is driven by a combination of host immune alteration and extensive viral replication. Phytochemical extracts of *Ramalina farinaceae* (*Rf*) was analyzed on the inhibitory effect on RSV infectivity/replication, and extractive-induced immune modulation.
Materials and methods: *Ramalina farinaceae* was screened for anti-RSV and immune modulatory activities using a combination of standard viral plaque reduction systems, and FACS-based cell proliferation assays.
Results: *Ramalina farinaceae* inhibited RSV in a dose-dependent manner with IC_{50} 22.45 μg/ml. Screening for immune modulation was analyzed using naïve splenocytes from BALB/c mice. *Rf* extracts showed to have no effect on CD4+ or CD8+ T-lymphocytes nor dendritic cell activation analyzed by a FACS based cell proliferation assay. However a stimulation and expansion of the B-lymphocytes population could be observed. Further screening of Sekikaic acid, a pure chemical compound isolated from *Rf* showed a fourfold enhancement of anti-RSV activity (IC_{50} 5.69 μg/ml). Time-of- addition studies showed that *Rf* and Sekikaic acid inhibited RSV at a post-entry stage of the virus replication cycle.
Conclusions: A compound Sekikaic acid isolated from *Rf* together showed high anti-RSV activity, and promising immune modulatory effect. This remains to be proven in *in vivo* studies.

P1775

Screening chemical libraries for immunosuppressive compounds

M. Lukasiak & J. Dastych

Laboratory of Cellular Immunology, Institute of Medical Biology of PAS, Lodz, Poland

Purpose/Objective: The purpose of this study was to identify novel compounds with immunosuppressive activity by *in vitro* screening of chemical libraries using method called Fluorescent Cell Chip (FCC).
Materials and methods: Previously described EL-4 murine T cell derived reporter cell lines stably expressing transgenes with promoter regions from mouse β-actin, IL-2, IL-4, IFN-γ and IL-10 and ORF for EGFP were employed in the study. In the first round of screening 1120 compounds from chemical library of marketed drugs and 500 compounds from library of flavonoids were incubated respectively at 0.4 and 50 μg/ml for 20 h with reporter cell line for IL-2 either activated with PMA/ionomycin or not. Following incubation cell viability and EGFP-mediated fluorescence was assessed by flow cytometry. Compounds that caused the most significant decrease in fluorescence while not significantly affecting viability were further analyzed. In the second round of screening dose response effect of selected substances on viability and EGFP-mediated fluorescence of all five reporter cell lines was assessed. The tested concentration range was 0.05−3.2 μg/ml for marketed drugs and 1.56−50 μg/ml for flavonoids.
Results: Screening of the library of marketed drugs allowed for identification of 11 drugs that could possibly exert immunosuppressive action. Among drugs that inhibited EGFP-mediated fluorescence of PMA/Ionomycin activated EL-4-derived cell lines in FCC test there were compounds already used as immunosuppressants (e.g. cyclosporine) as well as several drugs used in treatment of diseases not related to immune system, such as anthelmintic agent niclosamide or respiratory inhibitor and antifungal and antibacterial agent antimycin A. Screening of flavonoid library by means of FCC test identified 50 compounds that inhibited EGFP-mediated fluorescence of several EL-4-derived cell lines. Structure-dependence was observed.
Conclusions: FCC has been shown to be a good tool for the screening for immunosuppressive compounds as in a screening of chemical library of marketed drugs it was able to 'rediscover' immunosuppressive drugs, such as cyclosporine. In this study we have identified several naturally occurring flavonoids and their derivatives as compounds that potentially could exert immunosuppressive action on T cells.

P1776

The anti-inflammatory effects of Bitter Gourd between adipocytes and macrophages

Y. Liu & B. Lin

Department of Biochemical Science and Techonology, National Taiwan University, Taipei, Taiwan

Purpose/Objective: Obesity is associated with a state of low-grade chronic inflammation. Many studies have demonstrated that increased infiltration of macrophages is characterized in the obese adipose tissue, suggesting that a paracrine loop between adipocytes and macrophages causes an inflammatory vicious cycle. Bitter gourd (*Momordica Charantia*) is a tropical vegetable that has also been used in a traditional medicine for treating diabetes. The ethyl acetate extracts of Bitter gourd powder (EA-BGP) has been shown to have anti-inflammatory effects, but the influence on macrophages and adipocytes is unclear.
Materials and methods: We investigated the EA-BGP on inflammatory changes in differentiated 3T3-L1 adipocytes and Raw 264.7 macrophages. The pro-inflammatory cytokine secretions were examined after 24 h treatment with EA-BGP. To elucidate the interaction between adipocytes and macrophages, Raw 264.7 cells were pretreated with different concentrations of EA-BGP and co-cultured with 3T3-L1 cells.
Results: We showed that EA-BGP decreased the production of MCP-1 and IL-6 in 3T3-L1 adipocytes. TNF-α and IL-6 secretions in LPS-stimulated Raw264.7 was also inhibited. Coculture of 3T3-L1 adipocytes and RAW 264.7 macrophages markedly enhanced the production of MCP-1 and IL-6 compared with control cultures. However, the production of these cytokines was decreased when Raw264.7 were pretreated with EA-BGP.
Conclusions: This study provides evidence for the anti-inflammatory effect of EA-BGP on macrophages and adipocytes. The inflammatory changes induced by the interaction between adipocytes and macrophages were also improved by the pretreatment of Raw264.7 with EA-BGP. The ethyl acetate extracts of bitter gourd may have potential to ameliorate the inflammation in obese adipose tissue.

Acetaminophen application during murine pregnancy triggers metabolic and immunological changes in dams and impairs fetal development

K. Thiele,* T. Kessler,† M. E. Solano,* P. Arck,* G. Tiegs† & A. Erhardt†
*Department of Obstetrics and Fetal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, †Institute of Experimental Immunology and Hepatology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Purpose/Objective: Recently, human studies revealed a significant correlation between acetaminophen (APAP; e.g. paracetamol, tylenol) use during pregnancy and an increased risk of asthma development in the children later in life. Insights on how APAP interferes with maternal adaptation to pregnancy and fetal development are still elusive. Therefore, we studied the effects of prenatally APAP-induced liver injury on immunological parameters in non-pregnant and pregnant females as well as fetal development.
Materials and methods: Therapeutic (0–150 mg/kg) or toxic doses (250–450 mg/kg) of APAP were injected i.p. into non-pregnant and pregnant mice on gestation day (gd) 12.5. Liver injury was quantified by measurement of plasma transaminase activity (ALT) 24 h (gd 13.5) or 96 h (gd 16.5) after APAP challenge. The maternal immune cell profile was analysed by flow cytometry. Embryo implantation and abortion rate, fetal body weight and total cell numbers of fetal liver and thymus as well as hematopoetic stem cell (HSC) counts were calculated.
Results: Pregnant mice were more susceptible to APAP-induced liver injury compared to non-pregnant mice indicated by significantly elevated transaminase activities and displayed increased frequencies of hepatic NKT and activated T cells. APAP challenge had no effect on implantation and abortion rate on gd 13.5 or gd 16.5. However, fetal development was delayed in prenatally APAP-challenged mice mirrored by reduced fetal body weight. The number of total cells in liver and thymus as well as percentage and absolute number of hematopoietic stem cells within the liver was significantly reduced in fetuses from APAP-treated mice compared to non-treated ones.
Conclusions: Pregnant mice are more susceptible toward APAP-induced liver damage. Prenatally induced liver injury severely impairs fetal development along with damage of the liver progenitor cell reservoir and primary lymphoid organs. Interestingly, the differences between pregnant and non-pregnant mice were particularly profound at the limit from therapeutic to toxic APAP doses. We now intend to identify how maternal APAP-medication causes liver damage and deregulation of maternal and fetal liver progenitor cell reservoir, as this may be an early indicator of APAP-induced increase of children's risk for allergic or autoimmune diseases.

P1778

Adapting vaccine formulation to the neonatal context is required to obtain safe protection against the respiratory syncytial virus

A. Remot,* X. Roux,† C. Dubuquoy,* J. Bernard,* J. Fix,* M. Moudjou,* S. Bouet,‡ J. F. Eleouët,* A. Petit-Camurdan* & S. Riffault*
*INRA, Molecular Virology and Immunology, JOUY-EN-JOSAS, France, †Immunotherapix, Institut Pasteur, Paris, France, ‡INRA, Animal Genetics and Integrative Biology, JOUY-EN-JOSAS, France

Purpose/Objective: The human respiratory syncytial virus (hRSV) is the leading cause of severe bronchiolitis in infants worldwide. The most severe RSV diseases occur between 2 and 6 months-of-age, so pediatric vaccination will have to be started within the first weeks after birth, when the immune system is prone to Th2 responses that may turn deleterious upon exposure to the virus. So far, the high risk to prime for immunopathological responses in infants has hampered the development of vaccine.
Materials and methods: In the present study we investigated the safety and efficacy of ring-nanostructures formed by the recombinant nucleoprotein N of hRSV (N^{SRS}) as a mucosal vaccine candidate against RSV in BALB/c neonates, which are highly sensitive to immunopathological Th2 imprinting.
Results: A single intranasal administration of N^{SRS} with detoxified *E. coli* enterotoxin LT(R192G) to 5–7 days old neonates provided a significant reduction of the viral load after an RSV challenge at 5 weeks of age. However, neonatal vaccination also generated an enhanced lung infiltration by neutrophils and eosinophils following the RSV challenge. Analysis of antibody subclasses and cytokines produced after an RSV challenge or a boost administration of the vaccine suggested that neonatal vaccination induced a Th2 biased local immune memory. This Th2 bias and the eosinophilic reaction could be prevented by adding CpG to the vaccine formulation, which, however did not prevent pulmonary inflammation and neutrophil infiltration upon viral challenge.
Conclusions: In conclusion, protective vaccination against RSV can be achieved in neonates but requires an appropriate combination of adjuvants to prevent harmfull Th2 imprinting.

P1780

Deficient IFN-gamma response to *Mycobacterium tuberculosis* antigens in infants improved since 1 year of age

A. Blandinieres,* H. See,† N. Gourgouillon,* A. De Lauzanne,† V. Guerin-El Khourouj,* B. Pedron,* A. Faye† & G. Sterkers*
*Laboratory of Immunology, Robert Debre Hospital, Paris, France, †Department of Pediatrics, Robert Debre Hospital, Paris, France

Purpose/Objective: How interferon (IFN)-γ responses mature in early age is poorly known. Here we analysed IFNγ response to *Mycobacterium tuberculosis* antigens across different ages and different clinical conditions.
Materials and methods: Two hundred and twenty-seven immunocompetent children (<15 years old) were included. 30 were not infected despite TB contact. Fifty-one presented TB disease, 40 latent TB and 106 had clinical signs mimicking TB disease but alternative diagnosis. 23 HIV-infected children were also analysed. The Tuberculin-Skin Test (TST) consisted in intradermal injection of 5 IU PPD (Tubertest Aventis Pasteur MSD, Lyon, France). The IFNγ release assay QuantiFERON-TB gold In-Tube assay (QF-TB-IT, Cellestis, Ltd, Australia) was used. QF-TB-IT specificity was defined as the proportion of negative results identified within uninfected cases. QF-TB-IT sensitivity was defined as the proportion of positive results within TB disease cases.
Results: In immunocompetent children: (1) QF-TB-IT specificity was 100%; (2) low sensitivity of QF-TB-IT in infants (40%) increased with aging (77% and 85% in $1 \leq 5$ years and in ≥ 5 years subgroups respectively); (3) in Latent TB, agreement between TST and QF-TB-IT was 0% in infants but 40% in $1 \leq 5$ years and 65% in ≥ 5 years groups; (4) combining QF-TB-IT and TST improved diagnosis of both TB disease and Latent TB; (5) finally, indeterminate results were <5% in children exposed to TB (TB-disease, Latent TB and uninfected-contact) but 24% in young children with TB excluded (bacterial pneumonitis in most instances).

In HIV-infected children, indeterminate results ($n = 5/23$) were mostly observed at diagnosis of symptomatic HIV infection (4/5). 6/23 children were co-infected with *M. tuberculosis*. Immunological results

were $TST^-/QF\text{-}TB\text{-}IT^+$ in 2/6, $TST^+/QF\text{-}TB\text{-}IT^-$ in 1/6, $TST^+/QF\text{-}TB\text{-}IT^+$ in 1/6 and $TST^-/QF\text{-}TB\text{-}IT^-$ in 2/6.

Conclusions: Impaired IFNγ secretion limits the use of IFNγ release assays in <1 year old children and likely leads to high risk of progression *in vivo*. Combining TST and QF-TB-IT improved diagnosis in ≥1 year old children especially in HIV infected children. Indeterminate results were mostly observed in bacterial pneumonitis unrelated to TB. Studies are in progress to address the mechanisms of IFNγ inhibition by ongoing bacterial infections.

P1781

Dose sparing effect of the adjuvant covaccine HT on neonatal immune responses to a whole H5N1 influensa vaccine from cell culture

S. F. Eiðsson,* T. A. Ólafsdóttir,† L. Hilgers,‡ K. Duckworth§ & I. Jónsdóttir¶

**Department of Immunology, Landspitali University Hospital, Reykjavík, Iceland, †Gothenburg University, Gothenburg, Sweden, ‡Nobilon Part of MSD Laboratories, Boxmeer, Netherlands, §Protherics PLC, Swansea, UK, ¶Department of Immunology, Landspitali University Hospital, Reykjavik, Iceland*

Purpose/Objective: Influenza pandemics are associated with high mortality and morbidity rates. The objective of this study was to evaluate the immunogenicity of a whole H5N1 virus influensa vaccine (WIV) produced in cell culture, in a neonatal murine model. Furthermore, to access whether the adjuvant CoVaccine HT could enhance neonatal immune responses to WIV.

Materials and methods: NRMI mice (1 week) were vaccinated in the scapular girdle with increasing doses of H5N1 WIV (HA 0.1; 0.25; 0.5, 1 μg) w/wo 0.2 mg (1st imm) and 0.5 mg (2nd imm) of Covaccine HT and boosted 16 days later. Blood was obtained from the tail vein before the 2nd immunization and weekly thereafter. WIV specific IgG antibodies were measured by ELISA. A Hemagglutination inhibition assay using horse RBC was used to measure the HAI titers.

Results: The H5N1 WIV was immunogenic in neonatal mice, all WIV-vaccinated groups had significantly higher IgG anti-WIV than unvaccinated controls. Co-administration of CoVaccine HT with WIV significantly enhanced IgG anti-WIV response and 0.5 μg HA along with 0.2/0.5 mg CoVaccine HT elicited significantly higher IgG levels than the optimal HA dose of 5 μg HA alone ($P = 0.0148$) after one vaccination. WIV elicited dose dependantHAI titers. Thus, mice that recived 0.5 μg HA + 0.2/0.5 mg CoVaccine HT had significantly higher HAI titers than mice that received 0.1 μg HA ($P = 0.0024$) or 0.25 μg HA ($P = 0.0369$) with the same CoVaccine HT schedule. A low WIV dose of0.5 μg HA given with 0.2/0.5 mg CoVaccine HT elicited significantly higher HAI titers than 1 μg ($P = 0.0335$) and 5 μg ($P = 0.003$) HA alone.

Conclusions: The results demonstrate that the WIV H5N1 vaccine is immunogenic in neonatal mice. WIV-specific Abs and HAI titers were significantly enhanced by CoVaccine HT, and a 10-fold dose reduction could be achieved compared to non adjuvanted WIV. The results encourage us to further study CoVaccine HT«s mechanisms of action and its dose sparing effects on neonatal immune responses to WIV.

Purpose/Objective: Because of the immature immune function, the newborn is susceptible to intestinal and systemic infections. *Escherichia coli* and *Staphylococcus aureus* are prevalent infectious agents in neonatal intensive care units, responsible for outbreaks of sepsis. The aim is to investigate whether cord blood monocytes and neutrophils have an impairment of development in its ability to phagocytize Gram-positive and negative rods, compared to septic neonates and adults.

Materials and methods: Monocytes and neutrophils from umbilical cord blood of healthy preterm <34 weeks of gestation (Group 1), ≥34 and <37 weeks of gestation (Group 2) and term (Group 3) newborns, and from peripheral blood of term newborns diagnosed with late-onset sepsis and healthy adults, used as controls, were exposed to propidium iodide-labeled *E. coli* and *S. aureus* to analyze their phagocytic capacity using flow cytometric method.

Results: Compared with adults, monocytes and neutrophils from extremely preterm neonates revealed decreased phagocytic capacity, with the exception of *S. aureus* by neutrophils. Monocytes and neutrophils from late preterm neonates showed decreased phagocytic ability only for *E. coli*. Term newborns demonstrated similar phagocytic ability compared with adults. Regarding neonates with sepsis, neutrophils exhibited a marked decrease in phagocytic capacity for both *E. coli* and *S. aureus*, but monocytes showed equivalent results, when compared to adults.

Conclusions: Until now, these data demonstrate that the observed impairment in the intake of *E. coli* and *S. aureus* by phagocytes is correlated with gestational age at birth. In addition, the diminished phagocytic ability of neutrophils from septic neonates could explain the inability of these newborns to control infections.

Phenotypic differences in leukocyte populations among septic and healthy preterm and full-term newborns

C. Quinello,* A. L. Silveira-Lessa,† C. Rennó,* M. A. Cianciarullo,* A. C. C. Redondo,* M. E. J. R. Ceccon,* M. Carneiro-Sampaio* & P. Palmeira*

**Pediatrics, Instituto da Criança, São Paulo, Brazil, †Parasitology, Instituto de Ciências Biomédicas, São Paulo, Brazil*

Purpose/Objective: Evaluate the absolute numbers of dendritic cells (DCs), monocytes, T and B lymphocytes and the frequencies of myeloid (mDCs) and plasmacytoid (pDCs) DC subtypes and T and B lymphocyte subsets in cord blood of healthy preterm and term newborns and in peripheral blood of septic newborns.

Materials and methods: The absolute numbers and frequencies of DCs, monocytes, T and B lymphocytes and their subsets were determined in umbilical cord blood of healthy preterm <34 weeks of gestation (Group 1, $n = 5$), ≥34 and <37 weeks of gestation (Group 2, $n = 8$) and term (Group 3, $n = 16$) newborns, and in peripheral blood of term newborns diagnosed with late-onset sepsis ($n = 23$), all of them analyzed by flow cytometry. In septic neonates, leukocyte populations were determined at time of diagnosis. Sepsis was diagnosed by a positive blood culture and/or accompanied by

compatible signs and symptoms of clinical sepsis at a mean age of 25.3 days.

Results: The results showed that the absolute numbers of circulating DCs ($Lin^-HLA\text{-}DR^+$) were similar between all groups, as well as the frequency of DC subtypes, mDCs ($CD11c^+/CD123^-$) and pDCs ($CD11c^-/CD123^+$) and immature mDCs and pDCs ($CD11c^+CD1a^+$ and $CD123^+CD1a^+$, respectively). Monocyte ($CD14^+HLA\text{-}DR^+$) numbers were equivalent among the groups and further analyzed regarding the expression of activation markers CD80 and CD86. The frequencies of monocytes $CD80^+$ were equivalent among the groups and, regarding monocytes $CD86^+$, the frequency in septic neonates was lower compared with groups 2 and 3. T $CD3^+CD4^+$ lymphocyte numbers did not differ among the groups, as well as the frequencies of naïve, central memory, effector memory and effector T $CD4^+$ subsets. The $CD19^+$ B lymphocytes were present in equivalent numbers among the groups. The frequency of naïve B cells ($CD19^+CD27^-$) was significantly higher in group 3 and, inversely, the frequency of memory B cells ($CD19^+CD27^+$) was significantly lower in group 3 compared with all the other groups.

Conclusions: In general, the frequencies of DC subtypes, as well as, monocytes, T $CD4^+$ and B subsets were not affected by both the clinical condition of sepsis and the chronological age of the newborns.

P1784

Polysaccharide-induced hyporesponsiveness in neonatal mice depends on the polysaccharide type

H. Benonisson,* S. P. Bjarnarson* & I. Jonsdottir†

**Department of Immunology Landspitali The National University Hospital of Iceland, Faculty of Medicine, University of Iceland, Reykjavík, Iceland, †Department of Immunology Landspitali The National University Hospital of Iceland, Faculty of Medicine, University of Iceland and Decode Genetics, Reykjavík, Iceland*

Purpose/Objective: We have shown that neonatal vaccination with a serotype 1 pneumococcal polysaccharide (PPS) induces hyporesponsiveness to serotype 1 pneumococcal conjugate vaccine (PCV) and meningococcal C PS induces hyporesponsiveness by depleting MenC-PS specific B-cells. 23valent PPS (PPS23) induces hyporesponsiveness to 4 of 6 serotypes of a 7-valent PCV (Prevnar), while for 2 serotypes PCV7 could overcome the hyporesponsiveness.

The aim of the study was to assess if neonatal PPS23-vaccination induces hyporesponsiveness to PCV10 (Synflorix), that has protein carriers that differ between serotypes and from PCV7.

Materials and methods: Neonatal NMRI mice (1 week old) were primed with 1/5 dose of PPS23 or saline and boosted 16 days later with 1/4 human dose of PCV10 (serotypes 1, 4, 5, 6B, 7F, 9V, 14, 18C, 19F, 23F) or saline. Blood samples were taken weekly from 2-weeks and at 12 weeks. IgG antibodies (Ab) to 7 PCV10 serotypes were measured by ELISA. The number of Ab secreting cells (AbSC) specific for serotypes 4, 9V and 18C was enumerated in spleen of mice primed with PPS-23 or saline and boosted with PCV10.

Results: Mice primed with PPS-23 as neonates and boosted with PCV10 as infants mounted significantly lower IgG response to 3 of 7 PCV10 serotypes measured (serotypes 1 $P < 0.001$, 4 $P = 0.001$, 6B $P = 0.021$, ns for 9V, 14.18°C, 19F) compared to mice primed with saline. Neonatal PPS23-priming also significantly reduced the number of PCV10-induced AbSC specific for the two of three serotypes tested (serotypes 4 $P = 0.01$, 9V $P = 0.3$, 18°C $P = 0.01$) compared to saline priming, suggesting that PPS23 has depleted B-cells specific for these serotypes.

Conclusions: Neonatal priming with PPS23 induces hyporesponsivenss to some of the PCV10 serotypes, which can be overcome by PCV10 for serotypes 9V and 14, as previously shown for PCV7 and for 18C as well. The results show that PPS-induces hyporesponsiveness in neonatal mice varies depending on the type of polysaccharide rather than the conjugate.

P1786

TLR-2 and TLR-4 mediated responses in monocytes from preterm and term newborns are distinct from those of adults

A. L. Silveira-Lessa,* C. Quinello,† M. A. Cianciarullo,† M. E. J. R. Ceccon,† M. Carneiro-Sampaio† & P. Palmeira†

**Parasitology, Instituto de Ciências Biomédicas, São Paulo, Brazil, †Pediatrics, Instituto da Criança, São Paulo, Brazil*

Purpose/Objective: The neonatal immune system, particularly in very-preterm newborns, has been considered functionally immature and recent studies suggest that this susceptibility to infections may be due to functional alterations in antigen-presenting cells that can lead to secondary deficiencies in adaptive responses. The aim is to evaluate the activation and response of monocytes derived from umbilical cord blood of healthy adequate-for-gestational-age term and preterm newborns, after *ex-vivo* Toll-like receptor 2 and 4 (TLR-2 and TLR-4) stimulation.

Materials and methods: Cord blood mononuclear cells (CBMC) from healthy preterm <34 weeks of gestation (Group 1), ≥34 and <37 weeks of gestation (Group 2) and term (Group 3) newborns, and peripheral blood mononuclear cells (PBMC) from healthy adults were isolated by density gradient centrifugation. Adherent cells (monocytes) were stimulated with TLR-2 and TLR-4 agonists, Pam3CSK4 (5 μg/ml) and LPS (10 ng/ml), respectively, for 24 h at 37°C. The functional outcome of the stimulation was determined by pro- and anti-inflammatory cytokine secretion in the supernatants (measured by cytometric bead array) and the expression profile of activation markers on monocytes exhibiting normal forward- and side-scatter properties by flow cytometry and staining normally for CD14 and HLA-DR.

Results: After LPS or Pam3 stimulation, interleukin (IL)-8, IL-6, TNF-a and IL-1β production by monocytes was substantially higher in term and both preterm groups when compared with adults, but inversely, IL-10 production was lower in the three groups of newborns compared to adults. Regarding the expression profile of activation markers on monocytes after stimulation with Pam3 or LPS, very-preterm newborns from Group 1 showed reduced expression of HLA-DR, CD80 and CD86 when compared with the other groups.

Conclusions: So far, our data suggest that neonates present greater capacity of developing an inflammatory response, which gets even more accentuated by the apparent lower production of IL-10. These results indicate an imbalance in cytokine production in the neonatal period which can increase the susceptibility to develop sepsis.

Consumption of *Bifidobacterium animalis* subsp. lactis Bi-07 in a clinical trial enhances ex vivo phagocytic activity in healthy elderly adults

M. J. Lehtinen,* S. Maneraat,† C. E. Childs,† S. D. Forssten,‡ E. Alhoniemi,§ P. Yaqoob,† A. C. Ouwehand‡ & R. A. Rastall†
*Nutrition and Health, DuPont, Kantivk, Finland, †Food and Nutritional Sciences, University of Reading, Reading, UK, ‡Nutrition and Health, DuPont, Kantvik, Finland, §Pharmatest Services Ltd, Turku, Finland

Purpose/Objective: Immunosenescence and ageing have been associated with changes in gut microbiota composition, susceptibility to infections, and metabolic disorders. Potential functional foods to counteract immunosenescence are probiotic bacteria and prebiotic complex oligosaccharides that have been shown to beneficially modulate gut microbiota and to improve immune function.
Materials and methods: A randomized double-blinded placebo-controlled cross-over human clinical trial was designed (ClinicalTrials.gov Identifier: NCT01586247) where 37 healthy elderly volunteers consumed probiotic *Bifidobacterium animalis* subsp. *lactis* Bi-07 (Bi-07, 10^9 cfu/day), prebiotic galacto-oligosaccharides (GOS, 8 g/day), their synbiotic combination (Bi-07 + GOS), or placebo (maltodextrin, 8 g/day). Cytokine production of LPS stimulated whole blood cultures were quantificated by multiplex ELISA. Cellular innate immune function was determined *ex vivo* by quantification of phagocytosis and oxidative burst activity in mono- and granulocytes. Gut microbiota composition and metabolic activity was determined using 16S rRNA sequencing and short-chain fatty acid quantification from fecal samples.
Results: Consumption of Bi-07 improved phagocytic activity of granulocytes *ex vivo* ($P < 0.001$), while decreasing the percentage of granulocytes showing oxidative burst activity ($P = 0.06$). LPS induced cytokine production in whole blood showed reduction of IL-1beta concentration in probiotic group ($P = 0.03$). Analyses of fecal samples showed that consumption Bi-07 significantly increased the total number of bacteria ($P = 0.046$) and number of *Bifidobacterium animalis* subsp. *lactis* ($P = 0.03$).
Conclusions: Consumption of probiotic Bi-07 may be beneficial for improving gut and immune system function in healthy elderly adults and could thus counteract the detrimental effects of immunosenescence. Probiotics may provide a cost-effective solution to improve quality of life in the elderly population.

Folate deficiency elevates inflammatory responses but lowers Th1 and Treg responses *in vivo*

C. H. WU & B. F. Lin
Biochemical Science and Technology, National Taiwan University, Taipei, Taiwan

Purpose/Objective: The aim of the study is to investigate the effects of folate deficiency on T-cell and inflammatory responses.
Materials and methods: Two groups of 7-weeks-old Foxp3-eGFP reporter mice were fed an AIN-76 diet containing either 0 (F0) or 2 (F1) mg folic acid per kg diet for 13 weeks.
Results: After 3 weeks of the folate deficient diet feeding, the serum folate concentrations of F0 mice decreased significantly. Total $Foxp3^+$ Treg % and $CD25^+$ $Foxp3^+$ Treg % of $CD4^+$ T cell in spleen, and total $Foxp3^+$ Treg % in Peyer's patch (PP) decreased significantly in the F0 group. Moreover, Th1 cytokine IFNγ, Treg-related cytokine IL-10 and Th2 cytokine IL-4 secretions from splenocytes of the F0 group after ConA stimulation decreased significantly, but there were no significant differences in other Th2 cytokines such as IL-5 and IL-13. However, TNFα produced by LPS-stimulated peritoneal excudate cells (PEC) was significantly increased in the F0group.
Conclusions: Folate deficiency may lower Th1 and Treg responses but enhance inflammatory responses *in vivo*.

IL-1, IL-6 concentration and apoptosis induction in BALB/c 3T3 cells after simultaneous incubation with iron and chromium

A. K. Siwicki
Department of Microbiology and Clinical Immunology, University of Warmia and Mazury, Olszyn, Poland

Purpose/Objective: Chromium and iron are essential microelements playing a vital role in many cellular processes. The aim of this study was to examine the effect of simultaneous treating with chromium and iron on IL-1α, IL-6 concentration and the effect of induction of apoptosis on BALB/c 3T3 cells.
Materials and methods: Cells were cultured as adherent monolayers in plastic tissue-culture dishes in Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% (v/v) heat-inactivated Fetal Bovine Serum and antibiotics. The cells were cultured on 96-well dishes (2×10^5 cells/ml) in medium. After 24 h of incubation, the medium was exchanged for fresh DMEM (control), DMEM supplemented with 50, 100, 300, 500 and 700 μM $CrCl_3$, 50, 100, 300, 500 and 700 μM $FeCl_3$, one supplemented with 50 μM $CrCl_3$ and 500 μM $FeCl_3$ or 50 μM $FeCl_3$ and 500 μM $CrCl_3$. After 24 h of incubation cytokines concentration and apoptosis were measured according to the original manufacture's instruction.
Results: Iron and chromium used separately increase statistically significant IL-1α concentration after incubation with iron chloride or chromium chloride, whereas they decrease statistically significant IL-6 concentration when compared with control cells. Moreover, chromium decreases statistically significant number of apoptotic cells, while iron increases apoptotic cells. Simultaneously, incubation with 50 μM $CrCl_3$ and 500 μM $FeCl_3$ decreases statistically IL-1α concentration and the number of apoptotic cells when compared with cells incubated with iron chloride at the concentration of 500 μM $FeCl_3$. Moreover, a statistically significant decrease was observed in IL-6 concentration when compared with cells incubated with control cells and fibroblasts incubated with 50 μM $CrCl_3$ or 500 μM $FeCl_3$. Simultaneously, the incubation with 50 μM $FeCl_3$ and 500 μM $CrCl_3$ increases statistically significant IL-1α concentration and the number of apoptotic cells when compared with control cells and cells incubated with iron chloride at the concentration of 50 μM $FeCl_3$, whereas it decreases IL-6 concentration when compared with control cells.
Conclusions: The increase of IL-6 concentration after the simultaneous treatment with chromium and iron suggests the synergistis interaction between these elemnts.

Impact of coffee galactomannans on Pneumococcal vaccine response in a preclinical model

C. R. Santana,* I. Segura-Roggero,* A. Joubin,† T. Neville,† J. Benyacoub* & K. Vidal*
*Nutrition & Health, Nestlé Research Center, Lausanne, Switzerland, †Bioanalytical Science, Nestlé Research Center, Lausanne, Switzerland

Purpose/Objective: Antibody (Ab) responses to vaccination are a useful measurement in the assessment of immune status, especially in suspected immune deficiency. Although Pneumovax (pneumococcal polysaccharide (PPS) vaccines) are safe and effective in reducing the

incidence of pneumococcal invasive disease in healthy adults, they are weakly immunogenic in children <2 years old and in the elderly, the two groups at higher risk. The new generation vaccine Prevenar® 13 has coupled the PPS to a protein carrier, converting the PPS to T cell-dependent type of antigens (Ag), characterized by affinity maturation and extensive Ab subclass switching. Previous studies have shown that nutritional intervention is able to increase the specific Ab response to Pneumovax vaccine. Coffee infusion polysaccharides are composed mainly by galactomannans, on average they account for 68%. Acetylated mannans from coffee have shown immunostimulatory activities in an experimental model, illustrated by the activation of B-and T-lymphocytes. The aim of this study was to evaluate whether coffee galactomannans modulate Pneumococcal vaccine response.

Materials and methods: Balb/c female mice (6 weeks old) were fed *ad libitum* 1% galactomanans from coffee or control diet through pelleted chow during 3 weeks before immunization with Prevenar® 13 (200 μl subcutaneously) and maintained in the same diet for four additional weeks. In order to evaluate the specific antibody response to the vaccine, blood samples were collected just before immunization and 28 days after. Levels of specific IgG Ab anti-PPS in sera were assessed by ELISA.

Results: Among the 13 PPS present in the vaccine, animals responded to 10 PPS at different percentages: PPS4, PPS5, PPS19A, PPS18C, PPS3, PPS6B, PPS19F, PPS9V, PPS1 and PPS7F, showing PPS4 and PPS5 the highest percentage of responders. In fact, significant increases in the IgG anti-PPS4 and PPS5 titers were observed at day 28 post-immunization. A slight increase was observed for PPS19A and PPS18C, whereas no effect was shown for the other PPS.

Conclusions: The present results show for the first time that coffee galactomannans are able to increase the systemic Ab responses to a conjugated Pneumococcal vaccine, encouraging the possibility to use them as bioactive polysaccharides.

P1792

Sulforaphane induces neutrophil death and alters the mechanism of death in a dose dependent manner with implications for resolution of inflammation

E. K. Y. Green & D. J. Sexton
MED, University of East Anglia, Norwich, UK

Purpose/Objective: Neutrophil (PMN) apoptosis is an essential component of inflammatory resolution. Sulforaphane (SFN) in cruciferous vegetables has been demonstrated to have therapeutic potential for tumours as an inducer of apoptosis at high doses in neoplastic cells. Here we test the hypothesis that SFN induces PMN death. The objective is to investigate the impact of dietary SFN doses on PMN viability, and determine whether the mode of death is apoptotic.

Materials and methods: PMN from healthy volunteers were cultured for 20 h with SFN (5–40 μM) and inhibitors of different modes of PMN death including wortmanin (100 nM), Z-VAD FMK (20 μM) and necrostatin (25 μM). Apoptosis was measured by flow cytometry using annexin V PI and JC-1 staining. Morphological markers of cell death were observed with Diff-Quik and MitoTracker staining.

Post-hoc pairwise comparisons were conducted using one-tailed Dunnett's test. Significance was taken as $P < 0.05$.

Results: SFN 5 μM increased PMN apoptosis, mean annexin V PI determined viability (APV) of cells reduced from 23.1% to 14.7% ($n = 28$, $P = 0.044$). Apoptosis as the primary form of death is supported by morphological markers and successful inhibition of SFN 5 μM's action by general caspase inhibitor Z-VAD FMK. Mean APV was not reduced by the addition of SFN 5 μM to Z-VAD FMK 20 μM treated cells.

Paradoxically, higher doses of SFN (40 μM) increased APV to 39.0% ($P < 0.001$). However JC-1 staining showed an altered profile of reduced yellow and green fluorescence, mitotracker showed oncotic mitochondria (fig.1) and Diff-Quik staining showed condensed nuclei in oncotic cells. Consequently we believe that the absence of positive annexin fluorescence is due to alternative modes of death involving cell swelling and failure to express phosphatidylserine. SFN 40 μM's effects were undeterred by Z-VAD FMK 20 μM, necrostatin 25 μM and wortmanin 100 nM suggesting that the mechanism of death is not caspase dependent, necroptotic or autophagic.

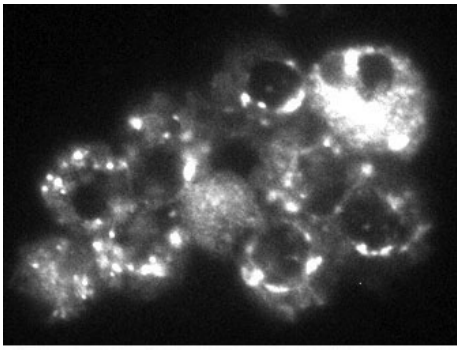

Fig 1. MitoTracker labelled 20h PMN treated with SFN 40uM

Conclusions: SFN increases PMN apoptosis at low dietary doses, therefore as apoptosis is anti-inflammatory low dose SFN may have a therapeutic role. However at higher doses an alternative mode of death is induced that may not be anti-inflammatory, for instance necrosis can perpetuate inflammation. Further research is required to elicit the mechanism occurring and its inflammatory significance.

P1793

The immuno-regulatory effects of olive oil in murine model

M. L. Chen* & C. H. Yu†
**Department of Nutrition and Health Sciences, Chang Jung Christian University, Tainan, Taiwan, †Graduate Institute of Medical Science, Chang Jung Christian University, Tainan, Taiwan*

Purpose/Objective: The quantity of dietary lipid ingestion has increased during the past decade, which inducing the development of many disease. It has been know that the quality and quantity of dietary oil could regulate immune responses. Furthermore, in recent years the olive oil was the first choice for cooking oil in Taiwan. In general, the immunomodulatory effects of dietary lipid were investigated the diet rich in *n*-3 or *n*-6 polyunsaturated fatty acids, but less attention has been paid to the effects of monounsaturated fatty acid (MUFA). In order to study the regulatory effects of MUFA-rich diet on the immune responses, we like to use a murine model.

Materials and methods: The BALB/c mice were fed with AIN-76 diet that contain 5% or 20% olive oil for 8 weeks.

Results: The results showed that body weight, feed efficiency, serum IgM, IgE and total antibody levels were higher than control group, especially in 20% MUFA group. Otherwise, mice fed with 5% olive oil significantly reduce the amount of PGE2 production from peritoneal cells, IL-2 and IFNγ secretion form splenocytes. In addition, olive oil increased TGF-β1 production, which was negatively correlated with IL-2 secretion.

Conclusions: These results indicated that MUFA-rich could regulate T cell cytokines secretion. And the inhibition of lymphocyte activity might correlate with regulatory T cells activation.

Differential mechanisms of resistance to pulmonary *Aspergillus fumigatus* infection in immunocompetent rats

A. Popov,* I. Mirkov,* A. A. M. El-Muzghi,* J. Glamoclija,† D. Miljkovic,‡ J. ?okic,* M. Ninkov,* D. Kataranovski* & M. Kataranovski*

**Department of Ecology, Institute for Biological Research "Sinisa Stankovic", Beograd, Serbia, †Department of Plant Physiology, Institute for Biological Research "Sinisa Stankovic", Beograd, Serbia, ‡Department of Immunology, Institute for Biological Research "Sinisa Stankovic", Beograd, Serbia*

Purpose/Objective: Immunity to pulmonary infection by *Aspergillus fumigatus* is investigated mainly in immunosuppressed mice in settings of lethal outcome, but there are few data concerning nonlethal infection as well as antifungal responses in other animal species. The aim of this study was to examine immune mechanisms of resistance of immunocompetent rats to nonlethal *A fumigatus* infection by analyzing response in two rat strains (Dark Agouti/DA/and Albino Oxford/AO/) known to differ in the type of reactivity to variety of stimuli.

Materials and methods: Antifungal pulmonary response (1×10^7 conidia, intratracheally) was investigated by: (1) fungal elimination, (2) the type of cytokine response (IFN-γ, IL-17, IL-4) measured in lung homogenates (overall response) and in cells from different compartments (draining lymph nodes/DLN/, recovered from lungs by enzymatic digestion/lung cells/ and bronchoalveolar lavage/BAL/), and (3) fungicidal capacity (lung cells).

Results: Progressive decrease in fungal burden was observed in both rat strains, but more efficient in DA rats (fungal elimination at day 15 versus day (d) 30 in AO rats). Conidia removal took place in proinflammatory *milieu*, as increased IFN-γ and IL-17 content in lung tissue (significantly higher in DA rats) and unchanged IL-4 (both strains) was observed. Increased DLN activity (cellularity, proliferation) was observed in both strains, but differences between these strains were noted in dynamic/intensity of IFN-γ (two phases of increase, day 3 and day 15, in DA*vs* continuous, day 3 to day 15, in AO) and magnitude of IL-17 production (significantly higher in DA rats). Later during infection (d 15) higher production of proinflammatory cytokines by BAL cells was observed in AO rats. Similar IFN-γ production was noted by lung cells in both strains at all time points, with higher levels of IL-17 in AO rats from day 7 to day 15. However, more pronounced fagocytic and fungicidal activity was observed in DA rats.

Conclusions: Differences in induction and expression of cytokine response and effector activities may contribute to differences in the efficacy of *A. fumigatus* conidia elimination in these strains.

P1795

Expression of virulence-related genes of Brucella melitensis and *B. abortus* in murine macrophages

R. López-Santiago,* E. Gonzalez-Gonzalez,* C. Garcia-Cabrera* & M. J. Perea-Flores†

**Immunology, NationalPolytechnic Institute, Mexico City, Mexico, †Lab of Characterization, Center for NanoSciencies and Micro Nanotechnology, Mexico City, Mexico*

Purpose/Objective: Brucellosis is a worldwide-distributed zoonosis. *Brucella* evades the immune response and survives inside the macrophages by using different mechanisms. Finally, the bacteria are located into membrane vesicles in between the endoplasmic reticulum. A better understanding of the molecular mechanisms that lead the intracellular trafficking may help to explain one of the main *Brucella* attributes of virulence. The aim of the present study was to follow the expression of virulence-related genes of *B. melitensis* and *B. abortus* strains along their intracellular trafficking in murine macrophage, and correlate it with the virulence of the strain.

Materials and methods: Complementary probes for the mRNA of the *sodC*, *omp25* and *bvrR/bvrS* genes and for the 16S rRNA as positive control were synthesized coupled to different fluorochromes at 5«-OH. *Brucella*-infected J774A.1 macrophages were hybridized with the fluorescent probes at different time points post-infection and observed under the confocal microscopy. The macrophages were also stained with specific antibodies to markers of the membrane vesicle-containing *Brucella* to trace the bacteria traffic.

Results: The *sodC* and *omp25* genes were expressed into early endosomes by both, virulent and no virulent strains. However, the expression of the *bvrR/bvrs* genes was diminished in the early endosomes, and thereafter peaked along the intracellular trafficking in vesicles pertaining to the endocytic pathway, in a way dependent of the virulence of the strain.

Conclusions: The products of the genes expressed differentially appear to be related with the pathway and fate of *Brucella* within the host cells.

P1796

Oxidative modification of lipoprotein by periodontopathic bacteria

T. Kurita-Ochiai, R. Jia, T. Hashizume & M. Yamamoto

Microbiology and Immunology, Nihon University School of Dentistry at Matsudo, Matsudo-shi, Japan

Purpose/Objective: Periodontal disease is a highly prevalent disorder affecting up to 90% of the global population. Several studies support an association between periodontal disease and atherosclerosis with a crucial role for the major periodontal pathogens. We previously reported that *Porphyromonas gingivalis* (*P. g.*) or *Aggregatibacter actinomycetemcomitans* (*A. a.*) accelerated atherosclerotic plaque formation in hyperlipidemic apoE−/− mice by initiating inflammation. Because oxidative modification of lipoproteins plays a major role in atherosclerosis, the present study was designed to test the oxidative activity of *P. g.* or *A. a.* on low-density lipoprotein (LDL).

Materials and methods: Atherosclerotic plaque formation in the aortic sinuses of Apoe^{shl} mice i.v. challenged with *P. g.* 381 or *A. a.* HK1651 was assessed by oil red-O staining. Anti-mouse Hocl-oxidized LDL and 4HNE antibodies were used for immunohistochemistry. Detection of intracellular ROS generation was performed using H2DCF-DA. Quantitative RT-PCR was performed using primers specific for LOX-1, NOX-1, NOX-2, NOX-4, p22phox, p47phox and β-actin. Oxidation of LDL by monocytes exposed to bacteria was assayed by ox-LDL ELISA kit.

Results: *P. g.*- or *A. a.*-challenge markedly induced ox-LDL and 4HNE positive areas in proximal aortic lesions. TLR-2, LOX-1 and NADPH oxidase subunit-specific mRNA levels were significantly increased. Furthermore, *P. g.* exposure caused monocytes to oxidize LDL in a dose dependent manner. Inhibition of gingipain with KYT-1 (Arg-gingipain inhibitor) or KYT-36 (Lys-gingipain inhibitor) significantly suppressed the modification of LDL by *P. g.*

Conclusions: These results suggest that *P. g.* or *A. a.* promotes the oxidation of LDL and contributes to atheroma development. This study was supported by a grant (no.22390398) from the Ministry of Education, Science, Sports and Culture, in Japan.

P1798

Preliminary evaluation of suppressive activity of rHsp60_Pb18 in the immune response in experimental paracoccidioidomycosis

F. Fernandes,* T. N. Landgraf,* A. A. M. Coelho-Castelo* & A. P. Castelo†

*Biochemistry and Immunology, Faculdade de Medicina de Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, †Biochemistry and Immunology, School of Philosophy Sciences and Literature of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil

Purpose/Objective: Paracoccidioidomycosis (PCM), caused by the dimorphic fungus *Paracoccidioides brasiliensis*, is a chronic, granulomatous and progressive disease. PCM has been associated with various degrees of suppressed cell-mediated immunity. Previous data from our group has shown that complete Freund's adjuvant (CFA) induced a protective effect in mice previously infected with *P. brasiliensis*. However, the beneficial effect was utterly reversed when CFA was emulsified with a fraction containing fetuin-binding proteins (FBP) from *P. brasiliensis*.

Materials and methods: The identification of FBP was done by in-gel digestion with trypsin and nLC-MS-MS peptide analysis. The heterologous protein expression was obtained in *Escherichia coli* transformed with pET28a subcloned with the *HSP60* gene of *P. brasiliensis* strain 18. To evaluate the possible role of Hsp60 in suppressing immune response, recombinant protein (rHsp60_Pb18) wascultured with spleen cells under polyclonal stimulation of T (ConA) or B (LPS) cells or popliteal lymph nodes cells from ovalbumin (OVA)-immunized mice stimulated with OVA.

Results: We identified the major protein 60-kDa and two minor 58 and 50-kDa proteins that comprise the FBP fraction as heat shock protein 60 kDa from strain 18 of *P. brasiliensis* (Hsp60_Pb18). When spleen cells of male BALB/c mice were incubated with spleen cells stimulated with mitogens (ConA or LPS) in the presence of different rHsp60_Pb18 concentrations, we observed that 50 μg of rHsp60_Pb18 induced a remarkable decrease in the number of lymphocytes when compared to control cells. Significant decrease of lymphocyte number was also observed with mitogen-stimulated culture treated with 10 μg of Hsp60_Pb18. Similar results were obtained when we carried out an assay of antigen-specific proliferation by using popliteal lymph node cells.

Conclusions: These results suggested that Hsp60_Pb18 can induce cell death when lymphocytes are activated. This actvity of Hsp60_Pb18 might be important in *P. brasiliensis* virulence, based on which we suggest that the death of lymphocytes can be involved in immune suppression seen in PCM. Other assays *in vitro* and *in vivo* are being conducted to determine the suppressive activity of rHsp60_Pb18 in the immune response.

P1799

Surface layer proteins as important virulence factors in *Clostridium difficile* infection

M. Lynch,* K. Kennedy,* D. Kelleher,† M. O'Connell* & C. Loscher*

*Biotechnology, Dublin City University, Dublin, Ireland, †Institute of Molecular Medicine, Trinity College Dublin, Dublin, Ireland

Purpose/Objective: *Clostridium difficile* (*C. difficile*) is a nosocomial pathogen and the cause of *Clostridium difficile* infection (CDI) in hospitals worldwide. In recent years, hypervirulent strains have emerged, resulting in increased mortality rates amongst those suffering from CDI. The bacteria possess a surface layer composed of two distinct Surface Layer Proteins (SLPs), High Molecular Weight (HMW) and Low Molecular Weight (LMW) proteins. These SLPs are important virulence factors that play a role in adherence and evasion of the immune system. We have previously shown that ribotype 001 evokes an immune response by activating both innate and adaptive immunity. The purpose of this study was to determine if SLPs from different PCR ribotypes induced different immune responses.

Materials and methods: In this study we have used molecular evolutionary tools to analyse HMW and LMW proteins of the SLP from a diverse range of *C. difficile* ribotypes. We have prepared a multiple sequence alignment and phylogenetic tree, and examined the selective pressure variation across ribotypes for both LMW and HMW proteins. We examined ribotypes 001, 002, 005, and 017 for the effect of SLPs on the activation of bone marrow derived dendritic cells (BMDCs) and macrophages by Enzyme-linked immunosorbent assay (ELISA).

Results: Positive selective pressure is synonymous with protein functional shift and we have found evidence of positive selection in both the HMW and LMW proteins in different ribotypes. Mapping the signatures of positive selection onto of the phylogeny of the ribotypes revealed a single branch separating those ribotypes with positive selection in the HMW protein from those with positive selection in the LMW protein. While all ribotypes induced cytokine production in immune cells, with some upregulation of IL-1β, IL-6, IL-10, IL-12p40, IL-23, TNF-alpha and IL-12p70, the strength of the response differed with some only weakly inducing these cytokines. Indeed, the SLPs least related to ribotype 001 showed the strongest activation.

Conclusions: The results of the bioinformatics study were indicative of a potential correlation between positive selection and the ability of the ribotype to elicit an immune response. This is seen in the diference in response strength of immune cells to SLPs from different ribotypes. By analysing the ribotypes that show the greatest and weakest response in immune cells, and comparing those results with our evolutionary analysis, we can now determine functionally relevant residues for the induction of an immune response.

T cells specific for the *Aspergillus* proteins Crf1 and catalase1 develop in patients recovering from invasive aspergillosis

H. Jolink,* R. S. Hagedoorn,† J. T. van Dissel,‡ J. H. F. Falkenburg† & M. H. M. Heemskerk†

**Hematology/Infectious diseases, Leiden University Medical Center, Leiden, Netherlands, †Hematology, Leiden University Medical Center, Leiden, Netherlands, ‡Infectious Diseases, Leiden University Medical Center, Leiden, Netherlands*

Purpose/Objective: Impaired T cell mediated immunity may play a role in the increased risk of aspergillosis, a severe complication of allogeneic stem cell transplantation (alloSCT). To allow development of new therapeutic strategies including adoptive transfer of antigen specific T cells, we investigated the role of *Aspergillus*-specific T cells in the clearance of aspergillus infection.

Materials and methods: We analyzed the T cell response against *A. fumigatus* in seven patients who had received an alloSCT because of a hematological malignancy and were diagnosed with invasive aspergillosis 1−10 months after SCT. PBMC were stimulated with the overlapping peptides of Crf1 and Catalase1 at several time points before and after the diagnosis of aspergillosis and analyzed by flowcytometry using intracellular staining for IFNy and CD154.

Results: When PBMC were stimulated with Crf1 and Catalase1 and restimulated with Crf1 and Catalase1 after 7 days, we detected clear populations of *Aspergillus*-specific T cells in six out of six patients with regression of aspergillus lesions or stable disease. In these six patients a peak of Crf1- and Catalase1-specific CD154+ CD4+ T cells was present around the time of regression of aspergillus lesions. The peak frequency of Crf1- and Catalase1-specific CD154+ T cells varied between 0.5% and 3% of CD4+ T-cells. In most patients both Crf1- and Catalase1-specific T cells were present. After clearance of the infection the frequency of *Aspergillus*-specific CD4+ T cells decreased to low or undetectable levels. In one patient no Crf1- or Catalase1-specific T cells could be identified. This patient had progressive aspergillus infection while suffering from severe GvHD of the skin, liver and colon and died shortly after the diagnosis of invasive aspergillosis.

Conclusions: Using only 2 *A. fumigatus* proteins as target antigens, we demonstrated the induction of *Aspergillus*-specific T cells in six patients, coinciding with the decline of aspergillus lesions. These data indicate that an immune response directed against *A. fumigatus* proteins helps to clear an aspergillus infection. Adoptive T cell therapy with *Aspergillus*-specific T cells generated *in vitro* by stimulating with *A. fumigatus* proteins like Crf1 and Catalase1, may therefore be an attractive strategy to treat patients with invasive aspergillosis.

Novel frequently recognized T-cell epitopes from adenoviral species C restricted to HLA-B*44

K. Artzner, H. G. Rammensee & S. Stevanovic
Immunology/Rammensee, Interfaculty Institute for Cell Biology, Tübingen, Germany

Purpose/Objective: Adenoviral infections are common and widespread in a civilian population. Besides the mild and self-limiting infections, adenovirus is described in immune compromised individuals to lead to severe pathogenesis with a mortality rate of up to 76%. The most prevalent species are HAdV 2 and HAdV 5 of Mastadenovirus serotype C.

Adenovirus can establish a persistent presence in its host for a long time after clinical symptoms have subsided which could be an explanation for endogenous virus infection in patients with impaired immune system. Besides, low T cell counts have been shown to correlate with severity of infection and mortality.

Thus, immunotherapeutic strategies using adoptively transferred AdV-specific T cells appear promising.

Materials and methods: The prevalence of adults in the general population that have endured adenoviral infection in their life and therefore possess memory CTL varies between 65% and 100%. Accordingly a sufficient amount of PBMCs of healthy donors exhibit significant proliferative responses to HAdV antigens. In this study we follow the strategy of reverse immunology to identify CTL epitopes of several adenoviral proteins restricted by HLA-B*44. Epitopes predicted by SYFPEITHI were screened for recognition by PBMCs from HLA-matched healthy donors using IFN-y-ELISPOT after 12 days of pre-stimulation. Specificity and HLA restriction were confirmed by tetramer staining. Candidate epitopes were tested on at least fifteen donors to characterize their dominance and frequency of recognition and further examined for multifunctional immune response via intracellular cytokine staining and flow cytometry. Furthermore, cytotoxicity assays were performed and promiscuity of the T cell epitopes was determined by testing non-HLA-B*44 and HLA-B*44 supertype donors for reactivity.

Results: Fifteen peptides from HAdV antigens were positive by IFN-y-ELISPOT, two of them with high frequency of recognition (>60% of tested PBMCs) and multifunctional T-cell response. In addition, several less frequently recognized peptides were identified which induced promiscuous responses within the HLA-B*44 supertype.

Conclusions: The novel identified frequently recognized epitopes (FREPs) will be relevant for immunotherapy using autologous adenovirus-specific memory T cells or for vaccination strategies in order to cope with fatal HAdV infections.

A role of anti MICA antibodies in humoral rejection mechanisms after kidney transplantations

M. Buc,* S. Chrenova,† Z. Zilinska,‡ V. Durmanova,* D. Kuba† & M. Sapak*

Department of Immunology, Comenius University School of Medicine, Bratislava, Slovakia, †Slovak Centre of Organ Transplantations, Slovak Medical University, Bratislava, Slovakia, ‡Urology Clinic, University Hospital, Bratislava, Slovakia

Purpose/Objective: Allogeneic transplantations are connected with a risk of a rejection of the transplanted organ. Rejections can be mediated by cellular or humoral mechanisms or by both of them. It is well established that humoral mechanisms are based on the induction of antibodies in a recipient that recognise miss-matched HLA-antigens of a donor. However, there are some reports that anti-MICA antibodies take part in the rejection mechanisms too. The aim of our work was to investigate if anti class I and class II HLA and anti MICA antibodies, respectively, are present in our group patients who underwent the kidney transplantation.

Materials and methods: Forty-nine kidney transplanted patients who developed antibody dependent rejection were investigated. The rejection was verified by biopsy * by detection of C4d fragments of the complement system in histological samples. Antibodies against MICA antigens were analysed by multiplex analysis (LUMINEX) using diagnostic kits 'LABScreen Mixed Class I and II' and 'LABScreen MICA Single Antigen' from the OneLambda Company. We established also specificities of the MICA antibodies, i.e. which MICA antigens they recognise.

Results: Anti MICA antibodies were detected in 13 patients (26.5%). However, 10 out of them (77%) possessed also anti HLA antibodies (both, anti class I as well as class II). We suppose that in the patients left, i.e. in three (23%) who were anti MICA positive, however anti HLA negative, the anti MICA antibodies were responsible for the antibody dependent rejection mechanisms. By investigating specificities of the detected anti MICA antibodies, we found that they recognised mostly MICA18 and MICA01 antigens. Sera of patients with MICA antibodies were usually polyspecific, only 30% of them were directed against one or two MICA antigens, all others reacted with three or more. We didn't find a correlation between the specificity of MICA antibodies and MICA molecules of the donor.

Conclusions: MICA antibodies are induced after allogeneic kidney transplantations either together with anti HLA antibodies or also independently from them. As such patients underwent the humoral type of rejection, it can be supposed that anti MICA antibodies are responsible for.

P1804

Analysis of polyclonal antithymocyte globulin preparations

I. Popow,* J. Leitner,* O. Majdic,* J. J. Kovarik,† M. D. Saemann,† G. J. Zlabinger* & P. Steinberger*

Institute of Immunology, Medical University of Vienna, Vienna, Austria, †Clinical Devision of Nephrology and Dialysis, Internal Medicine III Medical University of Vienna, Vienna, Austria

Purpose/Objective: Antithymocyte globulins (ATGs) are purified IgG fractions derived from rabbits immunized with the Jurkat T cell line (ATG-Fresenius) or human thymocytes (Thymoglobulin). They are widely used as strong immunosuppressive agents for prevention and treatment of allograft rejection episodes and graft versus host disease. The clinical efficacy of different batches of ATGs could be potentially influenced by differences in the targeted antigens or in the amount of leukocyte reactive antibodies.

Materials and methods: Four batches of ATG-Fresenius and Thymoglobulin were compared regarding their capacity to interact with human leukocytes from transplant recipients and healthy donors. The reactivity of ATG preparations with Jurkat cells and with human leukocytes was analysed by flow cytometry. Additionally, ATGs derived from different batches were probed with a panel of cell lines expressing high levels of ATG antigens. Furthermore, the ability of ATGs to mediate complement-mediated lysis of human monocytes and lymphocytes was also compared.

Results: The high conformity in ATG preparations of both manufacturers found in our study makes variations of different batches of ATGs in respect of their clinical efficacy unlikely.

Conclusions: The methods described in this study allow for a comprehensive evaluation of ATG preparations in clinical use regarding their antibody composition and their ability to mediate lysis of human leukocytes.

P1805

Anti-HLA antibodies monitoring in kidney transplant recipients: high prevalence of donor specific anti-HLA class II antibodies

O. M. Ares,* A. T. Ruiz,* E. F. Tagarro,† R. G. Samper,‡ R. G. Rodriguez,† F. H. Palop,‡ M. A. P. Valentin,† R. S. Estupiñan,‡ J. C. R. Perez‡ & M. D. C. Andres†

Immunology, Complejo Hospitalario Universitario Insular Materno Infantil, Las Palmas de Gran Canaria, Spain, †Nephrology, Complejo Hospitalario Universitario Insular Materno Infantil, Las Palmas de Gran Canaria, Spain, ‡Nephrology, Hospital Universitario de Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria, Spain

Purpose/Objective: Anti-HLA antibodies post transplant follow up has been suggested by several studies as a useful tool to identify patients with acute or chronic rejection risk, and therefore useful to implement the necessary therapeutic measures that would help us minimize its clinical impact.

Materials and methods: We had carried out a transversal and prospective study of 304 kidney recipients. Anti-HLA antibodies were tested using Luminex technology, screening and single antigen (Genprobe). The median number of tests performed per patient was 3.3. Single antigen with MFI > 1500 and specificity against any HLA donor antigen, determined by HLA-A/B/DR typing or linkage disequilibrium when HLA-DQB1* was not available, was assigned as donor specific antibody (DSA). De novo anti-HLA II DSA were tested for complement-fixing HLA antibodies using a C1q single antigen bead assay (One Lambda).

Results: Post transplant anti-HLA antibodies were detected in 109 patients (38.8%): 29% (28/109) were antibodies anti-HLA class I and II, 9.2% (10/109) were anti-HLA class I and 65.1% (71/109) were anti-HLA class II.

Within the 109 positive patients, 35 (32%; 35/109) were de novo and most of them anti-HLA class II (34/35; 97.1%). De novo anti-HLA class II antibodies were DSA in 27 patients (77%; 27/35), anti-DQB1* was the most frequent specificity (81%; 22/27), anti-DR was found in five patients (18.5%; 5/27) most of them anti-DRB4* (3/5). DSA anti-DR and anti-DQB1* was only present in one patient. Anti-DP antibodies were not considered as we lacked typing data. Within the 22 anti-DQB1* patients, 16 (73%; 16/22) were de novo complement-fixing DSA as detected by the C1q assay.

Fifteen patients from the group with de novo anti-DQB1* DSA (55.5%; 15/27) suffered a rejection episode, causing graft failure in four recipients who failed to respond to therapy. The low number of cases does not allow us to determine whether complement-fixing DSA might influence evolution or therapy response.

Conclusions: Anti HLA antibodies monitoring allowed us to discover a high frequency of de novo anti-HLA class II DSA in kidney recipients, most of them against HLA-DQB1* specifities. These patients were found to have a higher rejection incidence. HLA-DQB1* typing should be recommended in donors and patients in order to take its compatibility into account.

P1806

Antibodies against intracellular antigens develop as a result of tissue damage induced by donor lymphocyte infusion after allogeneic stem cell transplantation

J. C. van der Griendt,* M. Eefting,* E. D. van der Meijden,* B. Ayoglu,† J. M. Schwenk,† P. Nilsson,† J. H. F. Falkenburg* & M. Griffioen*

**Hematology, Leiden University Medical Center, Leiden, Netherlands, † Royal Institute of Technology, School of Biotechnology KTH, Albanova University Center, Proteomics, Stockholm, Sweden*

Purpose/Objective: Allogeneic hematopoietic stem cell transplantation (alloSCT) is an effective treatment for hematological malignancies. Graft-versus-host disease (GvHD), however, often is a life-threatening complication. To reduce GvHD incidence and severity, T-cells can be depleted from the stem cell graft and re-administered later as donor lymphocyte infusions (DLI) to preserve graft-versus-tumor (GvT) effect.

Whereas T-cells are key mediators of clinical responses (GvHD and GvT) after alloSCT, the role of antibody responses is still largely unknown. Antigens encoded by the Y-chromosome (histocompatibility-Y or H-Y antigens) have been described as targets for T-cells and antibodies in female-to-male transplantation. In this study, we investigated the dynamics and specificity of antibody responses against H-Y antigens and their X-encoded homologs during treatment with T-cell depleted alloSCT and DLI.

Materials and methods: Two broadly expressed intracellular H-Y antigens, ZFY and DBY, and their X-variants were produced in two overlapping protein fragments in *E. coli* and coupled to fluorescent beads. In a high-throughput Luminex bead assay, 1300 serum/plasma samples collected from 38 female and 54 male patients with acute myeloid leukemia or myelodysplastic syndrome during treatment with alloSCT and DLI were screened for antibody binding to antigen-coupled beads. Mean fluorescence signals were normalized for unspecific binding as defined by signal on a bead coated with an irrelevant viral protein.DLI.

Results: In 5/17 (29%) female-to-male transplantations, high titer antibodies reactive against DBY ($n = 2$) or ZFY ($n = 3$) developed shortly after DLI and were accompanied by antibodies binding to the respective X-variant. Three of these patients experienced extensive GvHD after DLI, leading to major tissue damage in the affected organs. Signal on the X-antigen could be fully blocked using the homologous Y-antigen as cold target, whereas *vice versa* signal on the Y-antigen could not always be inhibited by the X-antigen, indicating antibody binding to polymorphic (Y-specific) as well as monomorphic (X/Y-shared) epitopes.

Conclusions: Our data suggest that antibodies develop against intracellular H-Y antigens and their X-homologs when they are released in the extracellular milieu after tissue damage induced by T-cell mediated GvL or GvHD responses after DLI.

Blocking dendritic cell maturation with Mitomycin-C yields tolerogenic cells: studies of human cells *in vitro* and of rat cells in a heart allograft model

L. Dittmar,* F. Sandra-Petrescu,* C. Kleist,* E. Mohr,* J. Greil,† G. Opelz* & P. Terness*

**Transplantation Immunology, Institute of Immunology, University of Heidelberg, Heidelberg, Germany, †Department of Hematology and Oncology, Center for Child and Adolescent Medicine, University of Heidelberg, Heidelberg, Germany*

Purpose/Objective: We aim to generate suppressive cells for tolerance induction in clinical organ transplantation. As immature dendritic cells (DC) have immune inhibitory functions we tried to block the maturation of human monocytes to DC with Mitomycin C (MMC), a chemotherapeutic drug. The resulting cells were analyzed *in vitro*. The action of corresponding rat cells was studied in a heart allotransplant model.

Materials and methods: Human monocytes were incubated with MMC, matured to DC, analyzed by qPCR for immunosuppressive molecules and tested in T-cell proliferation assays. Replacing monocytes with peripheral blood mononuclear cells (PBMC) would be more practical for clinical use. The tolerogenic action of PBMC was tested, in a heterotopic DA (donor) to PVG rat (recipient) heart transplant model. Recipients were injected with MMC-treated donor PBMC and transplanted with a heart from the same donor. Tolerance was defined as graft survival of >70 days.

Results: (1) MMC treatment inhibits the maturation of human monocytes to DC. (2) The cells express slightly increased levels of mRNA for arginase-1, iNOS, NOX2, TGF§, TNF-α and strongly increased levels for CEBP§, IL-10 and COX2 * all potential mediators of immunosuppression. (3) DC generated from MMC-treated monocytes suppress the primary T-cell response. Suppressed T-cells can not be restimulated. (4) Similar results are obtained with MMC-treated PBMC. (5) Like in humans, rat monocytes treated with MMC give rise to suppressive DC. (6) In a transplant model donor MMC-treated PBMC injected into recipients significantly prolong heart allograft survival (65 ± 17 versus 8.6 ± 0.3 days), 50% of animals becoming tolerant. The effect is abolished when monocytes are removed from PBMC. (7) Tolerant recipients reject third-party allografts indicating donor-specific suppression. (8) Tolerant rats display an increased number of CD4+CD25+ FoxP3+ cells in peripheral lymphoid organs. (9) Tolerance can be transferred with blood cells to naïve syngeneic animals.

Conclusions: MMC-treated monocytes or PBMC matured to DC suppress T-cell responses. The effect is due to arrest of DC maturation and probably mediated by suppressive molecules. MMC-treated donor PBMC injected into recipients induce Tregs and lead to long-lasting allograft survival. This model has clinical relevance.

P1808

Blood miR-142-5p expression in renal transplanted patients exhibiting chronic antibody mediated rejection and chronic allograft dysfunction

R. Danger,* A. Lavault,* Y. Foucher,† M. Durand,* N. Degauque,* A. Pallier,* J. P. D. Van Huyen,‡ K. Renaudin,§ M. Giral,¶ J. P. Soulillou¶ & S. Brouard¶

**INSERM U1064, Itun, Nantes, France, †EA 4275 "Biostatistics Clinical Research and Subjective Measures in Health Sciences", Université de Nantes, Nantes, France, ‡Service d'Anatomie Pathologique, Hôpital Européen Georges Pompidou, Paris, France, §Anatomie et Cytologie Pathologiques, CHU Hôtel Dieu, Nantes, France, ¶CHU Hôtel Dieu, INSERM U1064, Nantes, France*

Purpose/Objective: The unresponsiveness of patients undergoing chronic antibody mediated rejection (CAMR) to classical treatment

stress on the need for accurate biomarkers to improve its diagnosis. Because of their high stability, miRNA are pointed out as possible biomarkers.

Materials and methods: We performed expression profiling of miRNA in peripheral blood mononuclear cells from kidney transplanted recipients with CAMR, stable graft function, acute rejection episode, chronic graft dysfunction and renal failure. Our objectives were to study whether miRNA expression pattern may be associated to a diagnosis of CAMR and to determine if change in these miRNA may be a way to predict graft dysfunction.

Results: Among a total of 257 expressed miRNA and using non-parametric supervised analysis, we identified 15 miRNA differentially expressed in blood from patients with CAMR. Among them, we pointed on miR-142-5p, an hematopoietic specific cell lineage miRNA, significantly over-expressed in blood and biopsies from patients with CAMR. This miRNA was not increase in PBMC from patients with renal failure, suggesting that its over-expression is associated to immunological disorders in CAMR rather than to renal dysfunction. Furthermore, its expression is decreased in PHA-activated PBMC and not modulated in blood from patients with acute rejection, getting rid of an aspecific T cell activation effect in patients with CAMR. Finally, the absence of modulation of this miRNA in blood from patients under immunosuppression compared to healthy volunteers suggests that its expression is not influenced by the treatment. We then evaluated if its expression may be correlated with the risk of renal dysfunction in a cohort of 133 stable kidney transplant recipients among which 112 patients remained stable and 21 degrade their renal function in time. We identified two classes of patients according to the miR-142-5p expression, with a low (expression >0.73) and a high risk of degradation (expression<0.73). High risk patients had 2.2 times more risk of renal dysfunction (CI 95% = [0.85, 5.88], $P = 0.0991$). Finally, analysis of miR-142-5p predicted targets suggest that its over-expression in a situation of CAMR may be a way to control activation.

Conclusions: Our results suggest miR-142-5p could be used as a specific blood biomarker of CAMR and to predict chronic graft failure.

P1809

Circulating pro-inflammatory CD4+ CD28null T cells increase the risk for a cardiovascular event shortly after kidney transplantation

N. Litjens, L. E. A. De Wit, W. Weimar & M. G. H. Betjes
Internal Medicine Nephrology and Transplantation, Erasmus Medical Center, Rotterdam, Netherlands

Purpose/Objective: An unusual population of pro-inflammatory $CD4^+$ T cells that have lost the co-stimulatory molecule CD28 ($CD4^+CD28$null T cells) is expanded in patients with end-stage renal disease (ESRD). $CD4^+CD28$null T cells are associated with cardiovascular disease and may cause atherosclerotic plaque instability by their highly pro-inflammatory nature. In this study we tested the hypothesis that expansion of $CD4^+CD28$null T cells in ESRD poses a risk factor for an atherosclerotic vascular event (AVE) after kidney transplantation.

Materials and methods: In a prospective study the number of circulating $CD4^+CD28$null T cells was established in 295 ESRD patients, prior to receiving a kidney allograft. All patients were screened for a history of symptomatic atherosclerotic disease and routinely evaluated for cardiovascular disease (CVD) by a cardiologist before kidney transplantation. Besides age and gender, the traditional risk factors for atherosclerotic disease were recorded. During the first year after transplantation, patients were followed for the occurrence of an AVE.

Results: In 31% of all ESRD patients a medical history of CVD was present (CVDpos). The percentage (10.3% versus 5.6%, $P = 0.002$) and absolute number (38 versus 22×10^3/ml, $P = 0.01$) of $CD4^+CD28$null T cells were increased in CVDpos patients compared to patients without documented CVD (CVDneg). Within the first year after transplantation, an AVE occurred in 20 patients, five cases (2.3%) in the CVDneg group and 15 cases (18.3%) in the CVDpos group. Over 80% of all AVEs occurred within 3 months after transplantation with a median time from transplantation to event of 5 days. Univariate analysis showed that besides CVDpos (HR 8.1, $P < 0.001$), age (HR 1.04, $P = 0.02$), dyslipidaemia (HR 8.8, $P = 0.004$) and the % of $CD4^+CD28$null T cells (1.04 per % increase, $P = 0.01$) were significantly associated with the occurrence of a post-transplantation AVE. In a multivariate analysis, only CVDpos remained a significant risk factor with a significant and positive interaction between the terms CVDpos and the % of $CD4^+CD28$null T cells (HR 1.05, $P < 0.001$). Within the CVDpos group, the incidence of an AVE was 13% in the lowest tertile compared to 25% in the highest tertile of % of $CD4^+CD28$ null T cells.

Conclusions: The expansion of circulating $CD4^+CD28$null T cells is highly associated with the presence of CVD in ESRD patients and increases the risk for a cardiovascular event shortly after kidney transplantation.

P1810

CMV-specific CD8+ T-cell immunity is a co-factor for acute rejection in lung transplantation

G. Mourin,* V. Appay,* M. C. Iglesias,* S. Fastenackels,* B. Autran,† D. Sauce,‡ D. Price,§ J. Almeida,¶ M. Stern & A. Roux‡**
**Infections and Immunity, Inserm UMR S 945, Paris, France, †Laboratoire d'Immunologie Cellulaire et Tissulaire, AP-HP Groupe Hospitalier Pitié-Salpêtrière, Paris, France, ‡Infections and Immunity, Inserm UMR S 945, Paris, France, §Cardiff University School of Medicine, Institute of Infection and Immunity, Cardiff, UK, ¶Human Immunology Section, NIH, Bethesda, MD, USA, **Hôpital Foch, Service de Pneumologie, Suresnes, France*

Purpose/Objective: Lung transplantation is the definitive treatment for terminal respiratory disease, but the associated mortality rate is high. Acute rejection of the transplanted lung is a key determinant of adverse prognosis. An epidemiological relationship has been established between acute lung rejection and CMV. However, the reasons for this association remain unclear.

Materials and methods: We performed a longitudinal study of CMV-specific T-cell responses and immune activation status, in PBMC and bronchoalveolar lavage fluid of lung transplant patients. Four groups were designated according to donor/recipient CMV serostatus: D^-/R^-, D^+/R^-, D^-/R^+ and D^+/R^+.

Results: Forty-four patients were included in this study. In D+ and D-/R- patients, in PBMC and in BAL, acute rejection was associated with higher levels of cellular activation (respectively $P = 0.0280$ and $P = 0.0143$). In D+/R- patients, CD38 expression on total memory $CD8^+$ T-cells was strongly correlated with those on CMV-specific $CD8^+$ T-cells ($r = 0.78$; $P < 0.0001$), and with the frequency of CMV tetramer$^+$ $CD8^+$ T-cells ($r = 0.63$; $P < 0.0001$).

CD38 levels on memory $CD8^+$ T-cells, frequency of CMV tetramer$^+$ were strongly correlated in blood and BAL from D^+/R^- patients ($r = 0.63$; $P = 0.012$ andr = 0.73; $P < 0.0001$), in contrast to D^-/R^- patients ($r = 0.08$; $P = 0.6$ and $r = 0.1$; $P = 0.7$).

We observed the same dominant clonotypes in CMV-specific $CD8^+$ T-cell populations from lung and blood, suggesting migration from periphery to CMV infected graft.

Conclusions: These findings provides further support that CMV-specific $CD8^+$ T-cell immunity links the observed relationship between CMV infection and the occurrence of acute lung rejection.

P1811

Comparative MHC region identity analysis between patients and HLA-identical unrelated donors in hematopoietic stem cell transplantation

V. G. López, V. G. López, P. Caro, J. Gil, E. Campos, S. Mantecon, C. Ambros, L. Mongay, I. Salvador, R. Faner & E. Palou
LIRAD (Immunology Laboratory) Blood and Tissue Bank, Germans Trias i Pujol Hospital, Badalona, Spain

Purpose/Objective: In hematopoietic stem cell transplantation with HLA-identical unrelated donors, the risk of acute graft-versus-host disease is increased if there is incompatibility in the MHC haplotype as a whole, even in the presence of complete classical HLA loci identity. The aim of this study was to determine the degree of actual MHC haplotype identity between transplant patients and their HLA-identical unrelated donors.
Materials and methods: We studied 46 pairs of patient and HLA-identical unrelated donor from three hospitals (Vall d'Hebron, Germans Trias i Pujol, ICO-Duran i Reynals) in which a high-resolution study of 5 HLA loci (HLA-A, HLA-B, HLA-C, HLA-DRB1, HLA-DQB1) had been performed. Seven MHC region DNA microsatellites (STRs) were analyzed by multiplex PCR.
Results: The most conserved microsatellites were D6S273 and D6S265, both in the classical HLA gene region with 14 and 20 pairs fully matched and with only 0 and 1 couple mismatched, respectively. The least conserved microsatellites were located at the ends of the extended class I and II regions. The pair disparity rate varied between 5 out of 14 possible identities and 12 out of 14 possible identities (average, 7.8).
Conclusions: Globally, the MHC region identity rate between patients and their HLA-identical unrelated donors was 55%. Identity was particularly related to the classical HLA genes while disparity was higher at the extended regions.

Cyclosporine A impairs renal host defenses through NFATc1-dependent inhibition of Nod1-mediated bacterial phagocytosis

E. Tourneur,* S. Dr Ben Mkaddem,† C. Dr Chassin,* M. Bens,‡ A. Dr Hertig,§ R. C. Pr Monteiro,† E. Pr Rondeau,§ C. Pr Elbim,¶ C. Dr Werts & A. Dr Vandewalle‡**
**U699, Microrna & inflammation, Paris, France, †U699, Immunopathologie rénale récepteurs et inflammation, Paris, France, ‡U773, Epithelium and Inflammation, Paris, France, §U702, Service Urgences Néphrologiques et Transplantation Rénale, Paris, France, ¶UMR-S 945, Laboratoire d'Immunologie Cellulaire, Paris, France, **Pasteur, G5 Biologie et Génétique des parois bactériennes, Paris, France*

Purpose/Objective: Urinary tract infections (UTI) and acute pyelonephritis (APN), mainly caused by uropathogenic *Escherichia coli* (UPEC), is the most frequent bacterial complication in renal transplant recipients receiving immunosuppressive treatment. However, it remains unclear how immunosuppressive drugs, such as Cyclosporine A (CsA), decrease renal resistance to UPEC.
Materials and methods: We use an experimental model of APN, administration of CsA and 11R-VIVIT, and SiRNA of *NFATc1*.
Results: Using an experimental model of APN, we show that mice treated with CsA exhibitgreater susceptibility to UPEC than vehicle-treated mice. The expression of the nucleotide-binding oligomerization domain 1 (Nod1), and neutrophil functions, including neutrophil migration capacity and phagocytic killing of *E. coli* were markedly reduced in CsA-treated mice infected by UPEC. *In vitro*, CsA markedly downregulated *Nod1* mRNA expression in neutrophils and macrophages. One of the main functions of calcineurin inhibitors is to impair the activation of the nuclear factor of activated T-cells (NFATs). Silencing the*NFATc1* mRNA isoform, similar to CsA, downregulated *Nod1* mRNA expression in macrophages, and administration of the 11R-VIVIT peptide inhibitor of NFATs to wild-type mice decreased their resistance to UPEC. Conversely, administration of synthetic Nod1 stimulating agonists, which partially restored *Nod1* mRNA expression without affecting NFATs inhibition caused by CsA, increased the resistance of CsA-treated mice to UPEC infection.
Conclusions: Collectively, these results indicate that CsA directly alters Nod1-mediated innate immune responses, and suggest that the prophylactic effects of Nod1 agonists might be helpful to reduce the incidence of bacterial infection of renal grafts.

Detection of rhesus cytomegalovirus as a viral reactivation marker in monkeys treated with immunosuppressants

J. Kim,* J. Kim,* J. Choi,† M. Kim,† W. Wee,† C. Park,* S. Kim,‡ J. Lee§ & E. Hwang*
**Department of Microbiology and Immunology, Seoul National University College of Medicine, Seoul, Korea, †Department of Ophthalmology, Seoul National University College of Medicine, Seoul, Korea, ‡Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, §Animal Resource Center, Seoul National University College of Medicine, Seoul, Korea*

Purpose/Objective: Human cytomegalovirus (HCMV) is reactivated frequently in immunocompromised patients, such as transplant recipients. Transplant patients with CMV disease are likely to develop acute rejection after CMV infection or reactivation. The immunosuppressive regimens are usually used to overcome immunological barriers in transplantation, but they induce the reactivation of latent viruses. It is favorable to develop the immune control method for transplantation with minimal reactivation of latent infectious agents. Rhesus CMV (RhCMV) has a similar characteristics to HCMV and was adopted to study the virological and immunological responses in monkey with transplant.
Materials and methods: Total 8 Rhesus macaques (Macaca mulatta) were included in this experiment; five with low dose steroid treatment, and three with regimen accompanying depletion of immunocytes. All experiments were performed after receiving approval from the Institutional Review Board and the Institutional Animal Care and Use Committee and according to the National Institutes of Health guidelines. The quantification of RhCMV in blood was determined by real time polymerase chain reaction. Anti-RhCMV antibody titer was measured by indirect immunofluorescent staining using RhCMV 68-1-infected HEL299.
Results: All the monkey included in these experiments had IgG antibody to RhCMV with the titers from 1:80 to 1:1280. No or low level of RhCMV DNA was detected through 6 months in five monkeys, which were grouped into treatment with low dose of steroid before transplantation. Antibody titer to RhCMV in this group did not change at large. Other three monkeys were grouped with the aspect of applying immunosuppressant of immunocyte depletion. They were treated with the combination of the immunosuppressants, (Tacrolimus, Leflunomide, Mycophenolate mofetil (MMF) and Campath), (Tacrolimus, Leflunomide, MMF, Basiliximab and Rituximab), or (anti thymocyte globulin (ATG), anti-CD154, Leflunomide, FTY720 and Rapamycin). They all showed decreased lymphocyte counts and increased copy number of RhCMV, peaked $4600-7500/mm^3$ in blood, and minimal changes of anti-RhCMV antibody titers.
Conclusions: Strong immunosuppressants could induce the reactivation of latent virus and maybe do harmful effect on transplantaion. Therefore it is needed to adopt the mild immunosuppressant regimens or new methods to overcome the immunologic barrier and virologic reactivation.

P1815

Donor cell composition and reactivity can predict risk of acute graft-versus-host disease

D. Sairafi, J. Gertow, J. Mattsson & M. Uhlin
Laboratory Medicine Division of Therapeutic Immunology, Karolinska Institutet, Stockholm, Sweden

Purpose/Objective: Graft-versus-host disease (GVDH) is a potentially fatal complication after allogeneic hematopoietic stem cell transplantation (AHSCT). There are limited possibilities to predict the risk for this adverse reaction. The aim of this project was to design a functional strategy for assessing the probability of acute GVHD in each individual case.

Materials and methods: Blood samples were collected from patients and donors prior to AHSCT. Two groups of seven patients each were identified, one where all individuals developed moderate to severe acute GVHD and the other where none showed any clinical signs of GVHD. Peripheral blood mononuclear cells (PBMCs) isolated from each donor were cultivated in a mixed lymphocyte reaction (MLR) with cells from the corresponding patient. The cells were phenotypically characterized by flow cytometry before and after MLR. In addition, levels of 27 cytokines and granzyme-B in the surrounding medium were measured using Luminex multiplex assay and ELISA respectively.

Results: Donor cells prior to the MLR had significantly lower frequencies of $\gamma\delta$ T-cells and T-cells expressing the NK-cell markers CD56 and CD94 in the GVHD-group. Donor samples from this group also exhibited a lower proportion of T-cells that expressed CD95, compared to those from the control group.

Both groups had comparable frequencies of the major lymphocyte populations at the onset. However at day 6 of the MLR there was a significant difference in the distribution of CD4+ and CD8+ T-cells: the proportions in the GVHD groups were more or less unchanged (68% $CD4^+$/30% $CD8^+$) while the non-GVHD group showed a reversed ratio (26% $CD4^+$/43% $CD8^+$) ($P = 0.03$). The differences in frequencies remained significant for the naïve $CD4^+CCR7^+CD45RO^+$ T-cells ($P = 0.02$). Regarding levels of soluble factors in the MLR, we could only detect a trend towards lower concentrations of IFN-γ in the GVHD group ($P = 0.07$).

Conclusions: We conclude that differences in the composition of the allogeneic graft could be used to predict its allo-reactive potential. Donor derived $\gamma\delta$ T-cells and NKT cells could be beneficial for promoting peripheral tolerance and protecting against GVHD. It would also seem that expression of CD95 on donor T-cells might be coupled to lower allo-reactivity, possibly because these cells are more likely to be deactivated through apoptosis. Further, a relative increase in the naïve CD4+ T-cell population after allogeneic MLR might be predictive for acute GVHD *in vivo*.

P1816

During aGVHD low-dose IL-2 activates allogeneic T cells and fails to induce Treg-mediated tolerance

L. Pérol,* G. H. Martin,† J. L. Cohen† & E. Piaggio*
**Immunology-Immunopathology-Immunotherapy, UMR7211, Paris, France, †Institut Mondor de Recherche Biomédicale, INSERM U955, Créteil, France*

Purpose/Objective: Acute graft-versus-host disease (aGVHD) is the main life threatening complication of allogeneic stem cell transplantation (allo-HCT). Recent clinical trials suggest that administration of regulatory T cells (Treg) can reduce GVHD but this approach needs optimization. An alternative is the use of interleukin-2 (IL-2) that can directly boost Treg *in vivo*. We have previously shown that a low-dose short course of IL-2 can cure type 1 diabetes (T1D) in mice by specifically activating Treg in the pancreas. Here, we tested this strategy in a mouse model of aGVHD.

Materials and methods: aGVHD was induced by grafting lethally irradiated [B6 × DBA/2] F1 mice with B6 bone marrow and B6 $CD3^+$ lymphocytes. Donor or recipient mice were daily treated (5–10 days) with IL-2 at low (25000 IU) or high dose (250000 IU). Immune reconstitution and T cell activation were assessed by *in vivo* bioluminescence imaging and flow cytometry.

Results: IL-2 administration to donor mice resulted in a dose-dependent expansion of Treg in the graft but had no effect on aGVHD development. Treatment of grafted mice with IL-2 beginning on the day of grafting or in a curative schedule did not lead to aGVHD control and higher IL-2 doses accelerated mortality. Mechanistically, IL-2 administration to recipient mice activated all donor T cell subsets, including protective Treg and pathogenic conventional alloreactive T cells. Remarkably, IL-2 induced a dramatic and sustained increased expression of CD25 on donor conventional $CD4^+$ and $CD8^+$ T cells, endowing them with a higher capacity to respond to IL-2 and possibly explaining the loss of selectivity of IL-2 effect on Treg. This loss of IL-2 specificity for Treg was independent of the conditioning of the recipients as it was confirmed in mouse models of GVHD without irradiation and/or lymphopenia.

Conclusions: IL-2 effects can be radically different depending on the immune pathology (T1D, aGVHD), and IL-2 use during aGVHD should be reconsidered.

P1817

Early and gut aGvHD characterize with lowering of blood levels of IFN-gamma and IL-17 producing lymphocytes

A. Lange,* S. Mizia† & D. Dlubek*
**Clinical Immunology/BMT, Institute of Immunology and Experimental Therapy/Lower Silesian of Cellular Transplantation with National Bone Marrow Donor Registry, Wroclaw, Poland, †Lower Silesian of Cellular Transplantation with National Bone Marrow Donor Registry, BMT, Wroclaw, Poland*

Purpose/Objective: Alloreactivity is a major challenge post HSCT.

Materials and methods: The cytoplasmic expressions of IL-17, FoxP3 and IFN-γ were studied in stimulated PBMC (BFA, Ionomycin and PMA) of alloHSCT pts (83 pts, median age: 41 years, range from 1 to 64 years), 13 pts manifested aGvHD at the time of hematological recovery (early) and in 18 pts with aGvHD was clinically apparent later time post HSCT (late from 26 to 93 days, median 34 days). The cells were labeled for CD4 and intracellulary for IFN-γ (BD, CA), IL-17A and FoxP3 (e-biosciences, CA) detection.

Results: (1) IL-17 ± cells contribution to blood CD4 ± lymphocyte pool: pts with early aGvHD had lower values of IL-17+ cells (median 0.15% versus 0.47%, $P = 0.040$, Mann-Whitney U test), similarly but only tendency was seen in pts developing skin aGvHD later time post HSCT (0.20% versus 0.47%, $P = 0.087$). Gut aGvHD pts behaved rather differently as sharp lowering of IL-17+ cells was seen just at the time of clinical manifestation (0.45% versus 0.20%, $P = 0.063$, Wilcoxon matched pairs test).

(2) IFN-γ ± cells contribution to blood CD4 ± lymph. Pool: tended to be low in pts with clinically apparent early aGvHD (0.09% versus 0.68%, $P = 0.06$), later manifested aGvHD pts had low values only when gut was involved (0.88%,1.12% versus 0.15%, for lacking, having skin and gut aGvHD, respectively, $P = 0.033$).

(3) FoxP3 ± cells contribution to blood CD4 ± lymph. pool: pts prior to overt onset of aGvHD had rather lower values from those seen in cases with overt manifestation of the disease irrespective whether only skin or also gut were involved. However the differences only for skin aGvHD pairs were statistically significant (1.88% versus 6.87%, $P = 0.037$). Notably, contributions of IFN-γ and FoxP3 cells to CD4+ lymph in aGvHD pts tended to be correlated ($R = 0.385$, $P = 0.063$) what was not seen when IL-17+ cells were analyzed.

Conclusions: Both IFN-γ and IL-17 producing lymphocytes levels, being low in blood of the affected cases, mirror aGvHD activity. This is most striking in early aGvHD and in cases with gut manifestation. Low FoxP3 lymphocytes may herald aGvHD then they increase at the time of clinically apparent alloreactivity. FoxP3 lymphocytes take a part in the network rather with IFN-g but not IL-17 producing lymphocytes. Immunologically active lymphocytes likely marginalize in affected tissues.

Effect of cord blood regulatory T cells on natural killer cell differentiation and function

I. Pedroza, M. Luevano, R. Duggleby, A. Madrigal & A. Saudemont
Anthony Nolan Research Institute, Royal Free Hospital, London, UK

Purpose/Objective: Regulatory T cells (Tregs) may offer a promising treatment for graft versus host disease, the main complication of haematopoietic stem cell transplantation (HSCT). To assess the feasibility of this therapy, it is important to consider their interaction with natural killer (NK) cells, which are described as key effector cells of graft versus leukaemia (GvL). Several groups have studied NK cell suppression by Tregs. However, a better understanding of this interaction using cord blood (CB) as a cell source is necessary, since CB is being increasingly used as a source of stem cells for HSCT.
Materials and methods: This study examined CB cells as a model of transplantation and focused on the effect of Tregs on (1) NK cell phenotype and cytotoxicity and (2) NK cell differentiation from $CD34^+$ stem cells to mature NK cells during a 5-week culture. Phenotype and viability (7AAD-Annexin V) were assessed by flow cytometry and NK cell killing capacity by ^{51}Cr-release assay. To assess Treg effects on different stages of differentiation, Tregs were added at 1:4 ratio with NK cells at 2, 9, 16, 23 and 30 days of culture.
Results: When Tregs were added at day 16, there was a significant decrease in the percentage of committed iNK cells (median, 27.16% NK cells v. 6.24% NK cells with Tregs, $P < 0.01$) and $CD56^{bright}$ NK cells (median, 29.05% NK cells v. 4.78% NK cells with Tregs, $P < 0.05$); yet NK cell killing capacity was not affected ($P > 0.05$). Similarly, whilst isolated NK cells co-cultured with Tregs decreased the expression of activating receptors (CD16, NKG2D, NKp46 and DNAM-1), this effect was not maintained.
Conclusions: So far, no persistent effect of Tregs on NK cell differentiation and function has been detected; therefore, a complete study with activated Tregs is required. This study may help to determine if NK cell-mediated GvL is adversely impacted by CB Treg therapy.

Embryonic and induced pluripotent stem cell lines are deficient in the processing of minor histocompatibility antigens

S. Monecke,* L. Elsner,* J. Nolte,† A. Mansouri,‡ K. Guan§ & R. Dressel*
**Molecular and Cellular Immunology, University of Göttingen Medical School and Deutsches Zentrum für Herz-Kreislauf-Forschung, Göttingen, Germany, †Human Genetics, University of Göttingen Medical School, Göttingen, Germany, ‡Molecular Cell Biology, Max-Planck-Institute for Biophysical Chemistry, Göttingen, Germany, §Cardiology and Pneumology, University of Göttingen Medical School and Deutsches Zentrum für Herz-Kreislauf-Forschung, Göttingen, Germany*

Purpose/Objective: Embryonic stem cells (ESCs) and induced pluripotent stem cells (iPSCs) might be useful to generate cells for new transplantation therapies to treat, e.g. heart failure or Parkinson's disease. Among the major problems of these transplantations are the risks of immune rejection and teratoma formation. Therefore, the susceptibility of stem cells and their derivatives to immune rejection mechanisms has to be determined. We have previously shown that mouse stem cells can be killed by activated CTL despite expressing only trace amounts of MHC class I molecules. Now, we wanted to assess the capability of stem cells to process endogenous proteins that function as minor histocompatibility antigens and to become targets of alloreactive CTL.
Materials and methods: ESCs, iPSCs, and as control RMA lymphoma cells (all $H2^b$) were transfected with Ovalbumin (OVA) expression constructs and used in ^{51}Cr release assays as targets for CTL derived from TCR transgenic OT-I mice or alloreactive CTL obtained by immunisation of wild type mice. Expression of MHC class I molecules and major components of the antigen processing machinery was determined by qRT-PCR or flow cytometry.
Results: OVA expressing ESC and iPSC lines were not killed by CTL from OT-I mice in contrast to OVA expressing RMA cells. Stem cells pulsed with the SIINFEKL peptide were killed although less efficiently than RMA cells. Alloreactive CTL also killed the stem cell lines and IFN-γ treatment further increased the lysis although the MHC class I expression was not substantially enhanced as assessed by flow cytometry. Interestingly, the stem cell lines failed to express *TAP2* mRNA in contrast to other genes of the antigen processing machinery.
Conclusions: The data indicate that antigen processing is impaired in ESCs and iPSCs. The very low expression of MHC class I molecules itself is not the limiting factor for recognition and killing by activated CTL. Upon transplantation pluripotent stem cells might become targets for CTL using the direct pathway of allorecognition. However, in allogeneic but MHC-matched transplantations undifferentiated ESCs and iPSCs can be expected to be protected against CTL recognizing minor histocompatibility antigens. This might contribute to the tumour risk of transplants containing undifferentiated stem cells.

P1820

Establishing the role of lymphocytes in hepatic Ischemia reperfusion Injury

J. Richards, S. Howie, L. Devey, S. Wigmore & S. Anderton
Centre for Inflammation Research, University of Edinburgh, Edinburgh, UK

Purpose/Objective: Background: Ischemia reperfusion injury (IRI) is a significant cause of morbidity and mortality (MI, stroke, acute renal failure). Furthermore, it limits the resectability of tumours in liver surgery and the availability of organs for transplantation. Evidence from other groups in a variety of IRI models suggests that IRI is a CD4+ T cell dependent phenomenon.
Aim: Assess the role of lymphocytes in a warm model of hepatic IRI.
Materials and methods: Using a surgical murine model of warm hepatic IRI, the extent of injury was measured using biochemical (ALT) and histopathological parameters to assess liver injury. A number of transgenic mice (RAG1-/-, IL-17RA-/-, OT-II) were used to evaluate the effects various immune populations and antigen specificity of effector populations. Anti-asiola GM1 antibody was used to deplete natural killer (NK) cells.
Results: RAG1-/- mice were protected from IRI, implying that T or B cells are important in the pathogenesis of IRI. Flow cytometric data showed a profound and rapid influx of neutrophils into the site of injury, which appears to be independent of IL-17. There was a relative enrichment of regulatory T cells following reperfusion. Depletion of NK cells was not protective. Injury was not reduced using transgenic mice with limited a repertoire of TCR on conventional T cells, suggesting this is an antigen independent phenomenon.

Conclusions: IRI appears to be dependent on lymphocytes in an antigen independent manner. Recruitment of neutrophils into the site of injury is not IL-17 dependent.

P1821

Evaluation of the use of an immortalized human dermal microvascular cell line as an *in vitro* model to monitor post-transplant endothelial complications

S. A. Kesikli,* G. Eissner,† E. Kansu* & E. Holler‡
**Basic Oncology, Hacettepe University Institute of Oncology, Ankara, Turkey, †Herzchirurgische Klinik, Universität München, Munich, Germany, ‡Department of Hematology and Oncology, University of Regensburg Medical Center, Regensburg, Germany*

Purpose/Objective: A number of syndromes have been identified which occur after allogeneic hematopoietic stem cell transplantation (HSCT), including Graft-versus-Host Disease (GVHD), affecting many organ systems. These syndromes are believed to be directly related to microvascular endothelial activation and damage, causing elevated rates of morbidity and mortality. Moreover, anti-endothelial immune responses have not yet been well defined. This study aimed to investigate the use of an immortalized human dermal microvascular endothelial cell line, namely HMEC-1, as an *in vitro* model to effectively monitor and predict post-transplant endothelium-related complications.
Materials and methods: Endothelial cell characteristics of HMEC-1 and their responses to proinflammatory stimulation were evaluated by determining the surface and intracellular expression of molecules common to endothelial cells, employing immunofluorescent stainings and flow cytometry. The stimulation of allogeneic T cell proliferation and allocytotoxicity was analyzed by flow cytometry and the standard 4-h ^{51}Cr release assays, respectively. The immunophenotypic properties of T cells were investigated by determining the flow cytometric surface molecule expression as well as the evaluation of cytokines using commercially available ELISA kits.
Results: This study confirmed that the immortalized HMEC-1 cell line carried most of the characteristics of human microvascular endothelial cells. They responded to proinflammatory stimulation with tumor necrosis factor α, interleukin-1β and interferon-γ by increasing the surface expression of adhesion and class-I MHC molecules. HMEC-1 cells under continuous, uni-directional, non-laminar flow responded similar to HMEC-1 cells under *in vitro* conditions. These cells efficiently stimulated the proliferation of allogeneic T-cells and class-I MHC-restricted allocytotoxic responses. Immunophenotypic analyses of activated $CD4^+$ and $CD8^+$ T cells revealed that they carried the properties of activated $T_{HELPER}1$ and $T_{CYTOTOXIC}1$ lymphocytes, respectively.
Conclusions: The generation of responses similar to primary endothelial cells by HMEC-1 cells after proinflammatory stimulation and their apparent antigen presenting capacity suggest that HMEC-1 cells might be an appropriate option for individual patient-based *in vitro* monitoring of post-transplant complications, using either patient derived cells or sera.

Gaining an advantage: mycophenolate-resistance for adoptively transferred cells

J. Griffin,* B. Carpenter,* E. Nicholson,† S. Ghorasian,* A. Holler,† P. Velica,* S. Xue† & R. Chakraverty*
**UCL Cancer Institute, Academic Haematology, London, UK, †Immunology, UCL Infection and Immunity, London, UK*

Purpose/Objective;Post-transplant lymphoproliferative disorder and viral infection with CMV are attractive targets for use of adoptive immunotherapy. In the post-transplant period, continued treatment with immunosuppressive drugs to prevent rejection or graft versus host disease suppresses adoptively transferred cells. A T333I, S351Y mutant inosine-5'-monophosphate dehydrogenase (mIMPDH2), confers 2400-fold resistance to MMF. We aim to transduce CD8 T cells with both a TCR specific for CMV or EBV antigens in addition to mIMPDH2 to enable treatment of infection or post-transplant lymphoproliferative disorder (PTLD) during ongoing mycophenolate mofetil (MMF) therapy.
Materials and methods: Cells were retrovirally transduced using SFG based vectors. To track transduced cells, the mIMPDH2 gene is fused with eGFP. Either a hypofunctional (C331A) IMPDH2 mutant fused to eGFP or eGFP alone were used as controls. Both murine MACS sorted CD8 T cells and a thymoma cell-line (BW 5147) were used for *in vitro* study. Murine CD8 cells were either restimulated with cognate peptide or cultured with media containing interleukins 2, 7 and 15. The active metabolite of MMF, mycophenolic acid (MPA), was used *in vitro*.
Results: Murine CD8 T cells transduced with mIMPDH2 exhibit a selective advantage compared to control transduced cells when exposed to MPA *in vitro*. Enrichment of transduced cells is most marked following restimulation of mIMPDH2 transduced OT1 transgenic T cells with cognate peptide, using ratios of %GFP positive in MPA versus no MPA to correct for different levels of transduction, mIMPDH2 = 7.12, eGFP = 0.77 (two-tailed paired t-test $P = 0.002$). Selection is also seen in an antigen-independent fashion during culture in the presence of IL-2, IL-7 and IL-15 (mIMPDH2 = 4.37; eGFP = 1.10 $P = 0.018$). Cells transduced with mIMPDH2 exhibit less apoptosis (Ratio %annexin V positive MPA:No MPA, mIMPDH2 = 1.16; C331A = 2.93 $P = 0.0101$) and are able to overcome the MMF-induced cell cycle arrest in G1 phase, when compared to non-transduced cells.
Conclusions: *In vitro* experiments have confirmed the resistance phenotype conferred by mIMPDH2. Work is ongoing using *in vivo* murine models of PTLD and viral antigen challenge to assess the function of adoptively transferred cells co-transduced with TCR and mIMPDH2 during ongoing MMF therapy.

HLA-DR expressing endothelial cell expansion of allogeneic $CD4+$ T towards either pro-inflammatory Th17 or suppressive Treg is regulated by HLA-DR mediated signaling

C. Taflin,* B. Favier,† M. Peraldi,* D. Charron,‡ D. Glotz§ & N. Mooney‡
**INSERM U940 & Service de Nephrology, Institut Universitaire d'Hématologie, Paris, France, †CEA 12BM Service de Recherche en Hémato-Immunologie, Institut Universitaire d'Hématologie, Paris, France, ‡Hôpital Saint Louis, INSERM U940, Paris, France, §Hôpital Saint Louis, INSERM U940 & Service de Néphrologie, Paris, France*

Purpose/objective: The major obstacle to organ transplantation is chronic rejection due to the persistence of the alloimmune response due to Major Histocompatibility Complex molecule (MHC) expression on donor cells. Allograft microvascular endothelial cells (ECs) express both MHC class I and class II molecules and therefore have a dual role as both stimulators of, and targets for the allo-immune response. We have recently shown that ECs can generate either regulatory $CD4^+$ T cells (Tregs) or pro-inflammatory $CD4^+IL\text{-}17^+$cells (Th17) but the mechanisms regulating the balance between Tregs and Th17 remain to be determined.
Materials and methods: We have established a model of either inducible or constitutive HLA-DR expression in microvascular endothelial cells using lentiviral vector infection. This model was used to study (i) the mechanisms of EC induced activation of allogeneic CD4+ T cells and (ii) the outcome of HLA-DR antibody pre-activation of

endothelial cells on their ability to polarize towards the Treg or Th17 lineages.

Results: Under inflammatory conditions, HLA-DR expression of human microvascular ECs allows them to orient the $CD4^+$ T lymphocyte response towards either a Th17 pro-inflammatory response or towards a regulatory T cell response. Expansion of Th17 depended upon IL-6 secretion by endothelial cells which led to STAT-3 activation in allogeneic $CD4^+$ T cells associated with their proliferation, while Treg expansion was dependent upon their interaction with endothelial cells mediated by the adhesion molecule ICAM-1 (CD54). Pre-treatment of ECs with HLA-DR antibody induced increased secretion of IL-6 leading to increased expansion of alloreactive Th17 cells.

Conclusions: These data reveal that firstly the human microvascular EC can regulate polarization of the memory $CD4^+$-T cell response towards either cytokine-dependent inflammation or contact-dependent regulation and secondly that HLA-DR antibody pre-activation of EC increases their ability to induce a pro-inflammatory Th17 response. Together these results provide evidence for a link between the role of the EC as a target of HLA-DR antibody binding and as an allostimulator of the pro-inflammatory Th17 response. These data may contribute to our understanding of complement independent mechanisms of endothelial cell damage in the presence of HLA class II alloantibodies.

IL-10 haplotypes associated with infection susceptibility in autologous bone marrow transplantation in multiple myeloma patients

F. M. B. Trigo,* M. R. Luizon,† H. S. Dutra,‡ M. H. S. Scaffo,§ A. L. Simoes,¶ A. Maiolino,‡ M. Nucci‡ & B. P. Simoes*

**Departament of Internal Medicine, Faculty of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil, †Departament of Pharmacology, Faculty of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil, ‡Federal University of Rio de Janeiro, University Hospital – Clementino Fraga Filho Hospital, Rio de Janeiro, Brazil, §Departament of Internal Medicine, Clinical Hospital of Faculty of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil, ¶Departament of Genetics, Faculty of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil*

Purpose/Objective: Bacterial, viral and fungal infections are major obstacles to the success of onco-hematological patients undergoing stem cell transplantation (SCT). SCT increases patient's vulnerability to infections due to immunological changes related to the conditioning regimen. The introduction of Autologous Stem Cell Transplantation (ASCT) increased the overall survival of these patients, but infection still remains an important complication of the procedure. The increased expression levels of cytokines have an important relationship with the immune response. Single Nucleotide Polymorphisms (SNPs) in the promoter region of cytokine genes are responsible for altering the levels of expression, thereby affecting the immune response. Therefore, we hypothesized that SNPs in the IL-10 gene, as well as the haplotypes formed by them, are associated with the susceptibility to infection in multiple myeloma patients submitted to ASCT.

Materials and methods: We have clinically assessed the infection status of the patients for the following conditions: fever of unknown origin, death during the neutropenia phase, *fungous* blood stream infection (F.BSI), superinfection, bacteremia (Gram-positive and Gram-negative), invasive *fungous* infection. Genomic DNA was extracted from mobilized peripheral-blood stem cells of 148 patients from the Bone Marrow Transplantation unit of Federal University of Rio de Janeiro. Genotyping was carried out for the IL-10 SNPs A-1082G, A-592C and T-819C using the Real-time PCR assays. Haplotype frequencies were estimated with Haplo.stats® and all the other statistical analysis were performed with SPSS®.

Results: We have not observed deviations from the Hardy-Weinberg equilibrium for the genotypes. The SNP A-1082G was associated with superinfection ($P = 0.020$). Interestingly, the ATA haplotype was also associated with superinfection ($P = 0.016$). In addition, the ATA haplotype was associated with F.BSI ($P = 0.004$). Finally, the ACC haplotype was associated with Gram-negative bacteremia ($P = 0.040$) and superinfection ($P = 0.048$).

Conclusions: The results showed that despite the primary predisposition to infection typical of multiple myeloma, the presence of the variants studied significantly affected the susceptibility to serious infections and outcomes of ASCT.

Immunological markers in early prognostic of cardiac allograft vasculopathy (CAV) on heart transplantation

C. R. Francisco,* S. Mirabet,† E. Roig,† C. Cecilia,* V. Brossa,† L. López,† M. Sabaté,* F. Lozano* & C. Gelpí*

**Immunology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, †Cardiology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*

Purpose/Objective: Cardiac allograft vasculopathy is a diffuse form of coronary atherosclerosis on transplanted heart (TH), progresses to chronic rejection and is one of the major causes of graft failure. Although it is a multifactor process, the recipient immunologic response against allogeneic graft is the major factor of this endothelial dysfunction. Since the TH is denervated, CAV is a silent phenomenon and it's frequently diagnosed at an advanced stage of the disease. There is a need to develop early, non-invasive and accessible diagnostic techniques.

Allospecific Th1 lymphocytes have been described as effector cells in CAV development. In a previous study, we reported the usefulness of the Th1/Treg ratio as a prognostic marker of CAV. The objective of this study is to identify early changes in effector $CD4^+$ $CD45RO^+CD25^{-/low}CD127^{hi}$ (Tact) and regulatory $CD4^+CD45RO^+$ $CD25^{hi}CD127^-$ (Treg) lymphocyte subsets on peripheral blood that correlate with CAV development.

Materials and methods: Thirty-two heart transplanted (HTx) patients were studied during 2 years follow-up at Hospital de Sant Pau. In addition 24 long-term patients (14 CAV-diagnosed, 10 no CAV) and 12 blood bank volunteers were studied as the HTx and healthy control groups respectively.

Flow cytometry analysis of $CD3^+$, $CD4^+$, $CD8^+$, $CD19^+$, $CD56^+$, Th1, Tactand Treg from periodically obtained peripheral blood lymphocytes were studied. Endomyocardial biopsies and coronariography were conducted to complete the global study.

Results: A progressive increase in the Th1 and Tact subsets and Th1/Treg and Tact/Treg ratios was detected during follow-up. Patients with CAV displayed a significant Tact/Treg increase versus long-term patients without CAV ($P < 0.0002$). Significance of the Tact values was $P = 0.03$.

Tact/Treg ROC analyses showed an area under de curve AUC of 0.962, the estimate sensitivity was 92.3%, specificity, 90.0%, the positive prediction value PPV, 92.9%, and the negative prediction value NPV, 100%. Th1/Treg ROC results were AUC 0.90, sensitivity 91.6%, specificity 90.0%, PPV 92.3% and NPV 100%.

Conclusions: These results indicate that the Tact/Treg ratio may represent a valuable marker to monitor allospecific T cell responses in peripheral blood and in addition changes in Tact/Treg ratio may help in the early detection of patients at risk of CAV.

P1827

Impact of urinary tract infections and CMV infections on renal graft function: is there anything to do for an immunologist?

B. Wojciuk

Public Clinical Hospital no. 2, Pomeranian Medical University, Szczecin, Poland

Purpose/Objective: The current research in transplantology, focused mostly on rejection mechanisms, corresponds with last years' discoveries at autoimmunity which refers to the place of Th17 cells in inflammation and recurrent infections. However little is known about transplant immunity in the context of recurrent infections according to basic as well as translational studies. The aim of the following study was first to analyze the impact of urinary tract infections (UTI) and cytomegalovirus infections (CMV) on long term- renal graft function, second to compare the demographic profile of group with impaired graft function in terms of infections with the patients suffering from autoimmune diseases.

Materials and methods: Group of 159 renal transplant recipients was analyzed. The subgroup with at least one confirmed UTI or CMV episode was differentiated with age, sex and the number of episodes. Creatinine level during the first 24 months post-transplant was followed. Trends in creatinine level as well as glomerular filtration rate (GFR) 24 months post-transplant in groups with and without UTI and CMV were analyzed. Regarding normal distribution displayed in every subgroup, the average GFR rates were compared with t *Student test.

Results: The total incidence of 41% was observed and the total number of 171 of infectious episodes was diagnosed, including 116 UTI episodes (68%) and 18 CMV episodes (11%). The increasing creatinine level was observed in group with at least one UTI or CMV episode which was positively correlated to the trend in patients with recurrent UTIs and negatively to the trend in patients without infections. Increasing creatinine level was observed in recipients with at least one UTI episode, younger than average for the analyzed group (<43) comparing to the older recipients (>44) with at least one UTI episode. Stable creatinine level was observed in women with at least one UTI episode by the opposite to decreasing creatinine level in women without infections. Lower GFR scores 24 months post-transplant were observed in patients with recurrent infections and women with at least one UTI/CMV episode comparing to the patients without infections in general as well as to men and women separately.

Conclusions: Recurrent UTIs and CMV infections negatively influence long-term renal graft function. The profile of patients with impaired graft function (women and younger patients) resembles the epidemiology of autoimmune diseases. The role of recurrent UTIs in this phenomenon points the need of further immunological studies on this area.

P1828

Importance of TNF-alpha and but not by of interleukin 17 in allogeneic hematopoietic stem cell transplantation (HSCT)

A. Gutiérrez-Hoya,* R. López-Santiago,* V. Paredes-Cervantes,* T. Vega-Ramírez,* L. Montiel-Cervantes,† J. Vela-Ojeda† & M. Moreno-Lafont*

**Immunology, Escuela Nacional de Ciencias Biologicas-Instituto Politecnico Nacional, Mexico City, Mexico, †Hematology, Unidad Médica de Alta Especialidad (UMAE) Centro Médico Nacional La Raza Instituto Mexicano del Seguro Social, Mexico City, Mexico*

Purpose/Objective: The allogeneic hematopoietic stem cell transplantation HSCT is a technique that can restore bone marrow function; the main complications are development of graft versus host disease (GVHD), relapse and graft loss. Among the factors that influence the success of allogeneic HSCT include the good reconstitution and correct control of immune response to prevent the development of GVHD which is a response triggered by recognition of alloantigens and produces an immune response characterized by an inflammatory reaction in which cytokines play an important role. Determinate the Th1, Th2 and Th17 cytokine profile and TNFα in patients with hematological diseases after HSCT and correlate them with the development and severity of GVHD.

Materials and methods: We analyze samples of patients with hematologic malignancies undergoing HSCT submitted to the Unidad M*dica de Alta Especialidad, Centro M*dico Nacional La Raza, IMSS. Samples were taken prior to the HSCT, and at 30, 60, 100 and 180 days after transplantation. The following cytokines were quantified by flow cytometry: IFNγ, IL10, IL17A, IL17F in CD4+ cells, IFNγ in CD8+ cells and TNFα in CD14+ cells; And by CBA: IFNγ, IL2, IL10, IL4, IL17A, and TNFα.

Results: We studied 7 patients were included and divided, into two groups: The first group patients with GVHD and the second group patients without GVHD. Seven healthy donors were included as controls. Also we analyzed a patient with syngeneic transplant, who was used as alternative control.

In the first group, it was observed an increase of TNFα without co-stimulation. In cell cultures showed an increase in of the Th1 cytokine profile as IFNγ and IL2. This correlated with the onset and severity of GVHD.

In the second group, it was observed a lack of production of cytokines, such as basal in the presence of co-stimulation. This pattern was observed correlated with graft loss, infections with opportunistic microorganisms and relapse. Unlike other reports in murine models, no significant changes in the Th17 cytokine profile.

Conclusions: High levels of TNFα play an important role in the development and severity of GVHD, but not in the maintenance of the graft. We didn't observe that an apparent role of Th17 profile play an important role in the development or severity of GVHD. In contrast, the fact that the patients' cells were capable to respond to polyclonal stimuli correlates with graft success.

P1829

In vitro-generated myeloid-derived suppressor cells inhibit graft-versus-host disease in a MHC class I mismatched bone marrow transplantation model

J. J. Messmann,* M. B. Lutz,† K. M. Debatin* & G. Strauss*

**Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany, †Institute of Virology and Immunobiology, University of Würzburg, Würzburg, Germany*

Purpose/Objective: Bone marrow transplantation (BMT) is a curative treatment modality for hematologic malignancies, since alloantigen specific donor T cells in the graft eliminate residual tumor cells (graft-versus-tumor effect: GVT). However, these T cells are also responsible for the induction of graft-versus-host disease (GVHD) by attacking alloantigen expressing recipient tissue, leading to significant morbidity and mortality. Therapeutic goal in allogeneic BMT is the inhibition of GVHD induction while maintaining the GVT effect. Myeloid-derived suppressor cells (MDSCs) represent a population of myeloid precursors able to suppress T cell activation and proliferation and were therefore tested for their ability to prevent GVHD after allogeneic BMT.

Materials and methods: BM cells were cultured in the presence of GM-CSF and G-CSF to generate MDSCs. To test, whether MDSCs inhibit GVHD induction, B6-derived MDSCs were co-injected at different concentration with B6-derived allogeneic BM and spleen cells (SC) into lethally irradiated B6.bm1 mice and weight loss, GVHD score and survival of transplanted mice were determined. Immunosuppressive effects of MDSCs were defined by analyzing donor chimerism, allogeneic T cell activation and homing and survival of MDSCs.

Results: Culturing BM cells in the presence of GM-CSF and G-CSF induced in 90% of the cells a $CD11b^{+}Gr\text{-}1^{+}$ MDSC phenotype. These MDSCs effectively suppressed allogeneic T cell proliferation *in vitro*. Co-transplantation of *in vitro*-generated MDSCs together with allogeneic BM and SC inhibited GVHD in a dose-dependent manner. A single injection of $1*10^{7}$ MDSCs totally protected from GVHD-induced death. Transplanted MDSCs were detected in the blood, spleen, liver and bone marrow of transplanted mice throughout the whole experiment. However, transplanted MDSCs did not interfere with phenotype and activation of allogeneic T cells and did not affect donor chimerism.

Conclusions: In summary, we could show that transplantation of *in vitro*-generated MDSCs efficiently prevented clinical GVHD, suggesting that MDSCs might be a useful cellular GVHD-therapy after allogeneic BMT. Defining their mechanisms of immunosuppression and their effect on T cell mediated tumorcytotoxicity will further elucidate whether usage of MDSCs might be applicable in the clinic.

Induction of immunosuppressive MDSC by extracorporeal photopheresis in patients with chronic GvHD

B. Schilling, K. Griewank, A. Sucker, E. Cesko, D. Schadendorf, U. Hillen & A. Paschen

Department of Dermatology, University Hospital Essen, Essen, Germany

Purpose/Objective: Chronic Graft-versus-Host-Disease (cGvHD) remains the main non-relapse related cause of death in allogeneic hematopoietic stem cell transplantation. In general, treatment of cGvHD is based on administration of immunosuppressive drugs. However, extracorporeal photopheresis (ECP) has become a well-accepted treatment for cGvHD. Induction of regulatory T cells (Treg) by ECP seems to be important against cGvHD, though the mechanisms of Treg differentiation still remain enigmic. Recently, $CD14^{+}HLA\text{-}DR^{low}$ monocytic myeloid derived suppressor cells (moMDSC) were found to support Treg differentiation in humans. Therefore, we hypothesize that ECP induces moMDSC which in turn facilitates Treg differentiation in patients with cGvHD.

Materials and methods: cGvHD was diagnosed according to NIH criteria and confirmed by skin biopsy. Two consecutive cycles of ECP were performed per week for 12 weeks. Blood was obtained after informed consent from patients with cGvHD and from age and gender matched healthy donors (HD). After peripheral blood mononuclear cells (PBMC) isolation by Ficoll, Treg and moMDSC frequencies were determined by flow cytometry. MoMDSC function was tested in autologous CFSE-based-proliferation assays. In addition, the ability moMDSC to drive differentiation of Treg was tested in autologous co-cultures of moMDSC and $CD4^{+}$ T-cells.

Results: Patients ($n = 4$) with cGvHD showed lower Treg and moMDSC frequencies as compared to healthy donors ($n = 6$) ($P < 0.05$). Serial measurements performed at week 4, 8 and 12 after starting ECP treatment showed a significant increase of moMDSC and Treg frequencies in three out of four patients ($P < 0.05$). *In vitro*, moMDSC inhibited polyclonal T cell proliferation and were found to induce T cells with the phenotype of Treg.

Conclusions: Our preliminary data indicate that ECP increases the frequency of $CD14^{+}HLA\text{-}DR^{low}$ moMDSC in patients with cGvHD. *In vitro*, moMDSC suppress T-cell proliferation and support Treg differentiation. Thus, moMDSC induction by ECP might be of great therapeutic relevance in patients with cGvHD.

Interleukin-7 receptor polymorphisms: Impact on regulatory T cells in patients undergoing myeloablative allogeneic stem cell transplantation (SCT)

Z. Shamim,* T. Frisch,† L. Ryder,† H. O. Madsen,† C. Heilmann,‡ N. Jacobsen§ & K. Müller¶

**Institute for Inflammation Research, Rigshospitalet, Copenhagen, Denmark, †Tissue Typing Laboratory, Rigshospitalet, Copenhagen, Denmark, ‡Paediatric Department, Rigshospitalet, Copenhagen, Denmark, §Haematologic Department, Rigshospitalet, Copenhagen, Denmark, ¶Paediatric Department and Institute for Inflammation Research, Rigshospitalet, Copenhagen, Denmark*

Purpose/Objective: Interleukin-7 (IL-7) is a cytokine essential for T cell development in the thymus and maintenance of the peripheral T cell population. The receptor (CD127) is highly expressed in most naïve T-cells, but is expressed at low levels in FoxP3+ T regulatory cells. The CD127 chain is shared with the receptor of Thymus Stromal LymphoPoietin, a cytokine with a key role in the development of natural FoxP3+ T cells in the thymus in Hassal's corpuscles and in the induction dendritic cells with low IL-12p40 release, that drive the generation of induced FoxP3+ T cells. We have identified a number of single nucleotide polymorphisms in the exons of the gene encoding IL-7Rα, including rs1494558 C/T and rs1494555A/G, and found that the minor alleles are associated with acute graft versus host disease (aGvHD) and mortality in patients undergoing SCT. We hypothesized that the generation of regulatory T cells in SCT patients is influenced by IL-7Rα genotypes of the donor.

Materials and methods: Blood CD4+ T cells were isolated using immunomagnetic beads and mRNA profiles related to regulatory functions (FoxP3, CD25 and CTLA-4) were measured by Taqman semi quantitative RT-PCR. mRNA profiles were expressed as ΔCt using CD4 as a reference gene. IL-7R SNPs were determined by a sequence specific PCR system. Two study populations were included: 1) 155 healthy individuals aged 33.5 years (4.7;62) and 2) 92 SCT patients aged 23.1 years (1.8;53.0). The latter were investigated 1 year after the transplant, and T cell phenotypes were analyzed for associations with donor IL-7R genotypes.

Results: In SCT, rs1494555 genotypes of the donor were significantly associated with CTLA-4 mRNA levels in CD4+ T cells (AA ΔCt: 1.2 (-4.0;3.9) (median, ranges) ($n = 46$), AG/GG: 2.0 (-0.8;3.6) $P = 0.012$). For FoxP3 a borderline significant association was seen (AA: 1.0 (0.8;1.5), AG/GG: 1.2 (-0.4;3.9), $P = 0.075$), while this SNP was unassociated with CD25 mRNA levels ($P = 0.21$). A similar pattern was observed for the closely linked SNP rs1494558. No significant associations were found in healthy donors.

Conclusions: These data indicate that the genotypes previously associated with aGvHD, are related to reduced levels of regulatory T cells, thus providing a biological mechanism for the previous clinical associations. In contrast, IL-7Rα genotypes are not associated with the level of regulatory T cells in healthy adults, suggesting a differential role of genetic variations in IL-7Rα, depending on whether the lymphocyte population is in a steady state or in a regenerative phase.

P1832

Intravenous immunoglobulin selectively enhances CD4+CD25+FoxP3+ Tregs function in patients

A. S. W. Tjon,* T. Tha-In,† S. Mancham,* P. A. W. te Boekhorst,‡ L. van der Laan,† H. J. Metselaar,* P. M. van Hagen§ & J. Kwekkeboom*

*Gastroenterology and Hepatology, Erasmus University Medical Center, Rotterdam, Netherlands, †Surgery, Erasmus University Medical Center, Rotterdam, Netherlands, ‡Hematology, Erasmus University Medical Center, Rotterdam, Netherlands, §Internal Medicine, Erasmus University Medical Center, Rotterdam, Netherlands

Purpose/Objective: Intravenous immunoglobulins (IVIg) are used as anti-inflammatory therapy for autoimmune diseases. We and others have shown that IVIg treatment also protects against acute rejection in liver transplant patients. In mice we observed that prevention of allogeneic skin allograft rejection by IVIg is mediated by $CD4^+CD25^+FoxP3^+$ regulatory T cells (Tregs). To determine whether IVIg stimulates Treg in humans *in vivo*, we studied Treg activation and suppressive function in patients treated with IVIg.

Materials and methods: We included 26 patients who where treated with IVIg monotherapy because of hypogammaglobulinaemia or autoimmune diseases. Blood was collected before, immediately after, and 7 days after IVIg infusion. Changes in Treg markers, serum cytokine and IgG levels were measured by flowcytometry and ELISA. The suppressive capacity of $CD4^+CD25^+CD127^-FoxP3^+$ Treg was studied *ex vivo* by co-culturing purified Treg with conventional $CD4^+CD25^-CD127^+$ T-helper cells (Tconv) from the patients stimulated with phytohemagglutinin (PHA). To study the mechanism of Treg activation *in vitro*, purified $CD4^+CD25^+CD127^-$ were cultured with IVIg and activation markers were measured by flowcytometry.

Results: Serum IgG levels increased 2.2-fold directly after IVIg treatment ($P < 0.001$). IVIg treatment selectively activated $CD4^+CD25^+$ $FoxP3^+$ Tregs, as revealed by enhanced HLA-DR expression ($T = 0$ to $T = 7$: +31%, $P < 0.01$), while this remained unchanged on conventional $CD4^+$ T cells. In addition, FoxP3 expression increased significantly after treatment ($T = 0$ to $T = 1$: +23%; $P < 0.01$ and $T = 0$ to $T = 7$: +30%; $P < 0.01$). Serum concentration of the anti-inflammatory cytokine IL-10 increased 2.5-fold shortly after treatment ($P = 0.02$). In *ex vivo* suppression assays, the Treg suppressive capacity increased 2.2-fold after IVIg treatment ($P = 0.02$). *In vitro*, we observed that Tregs internalized IVIg rapidly, which was followed by upregulation of the activation marker CD69.

Conclusions: We show that IVIg, which has been proven to be a safe immunosuppressive agent, selectively activates and enhances the suppressive capacity of Tregs in humans *in vivo*. Since proper activation of Treg protect against allograft rejection, IVIg may be introduced as a safe alternative immunosuppressive treatment after organ transplantation.

P1833

Lymphocyte subpopulations recovery post alloHSCT and herpes viruses reactivation influenced themselves in a mutual fashion

J. Lange,* D. Drabczak-Skrzypek,† E. Jaskula,‡ D. Wolowiec§ & A. Lange†

*Lower Silesian of Cellular Transplantation with National Bone Marrow Donor Registry, BMT, Wroclaw, Poland, †Clinical Immunology, Institute of Immunology and Experimental Therapy/Lower Silesian of Cellular Transplantation with National Bone Marrow Donor Registry, BMT, Wroclaw, Poland, ‡Clinical Immunology, Institute of Immunology and Experimental Therapy, Wroclaw, Poland, §Hematology, Medical University of Wroclaw, Wroclaw, Poland

Purpose/Objective: Immunological recovery post alloHSCT is influenced by the conditioning regimen, cellular profile of transplant material and further post transplant is shaped by environmental factors. CMV, EBV and HHV-6 predominately infect lymphoid cells and also influence thymic and bone marrow microenvironment.

Materials and methods: We followed 44 patients (age 1 to 64 median 45 years, 21 ric/mac, 21/23, sib/mud 21/23, BM/PBPC 4/40) for the pace of lymphocyte recovery at four consecutive time points beginning when the number of lymphocytes in blood exceeded 200 cells/μl after transplantation (median day 35 range 31−53). We used the method of flow cytometry to determine lymphocytes of CD4(+), CD8(+), CD20(+) profile and CD4+ T cell subsets: Central memory (CM) CD4(+) CCR7+CD45- and Effector memory (EM) CD4+CCR7-CD45+. CMV, EBV and HHV-6 copies were measured in blood with the use of QT-PCR.

Results: It appears that: Herpes viruses reactivations were seen in 27 (61%) patients, HHV-6 in 11 patients, EBV 15 and CMV in four patients. HHV-6 reactivation occured rather early after transplantation and was followed by reactivation in eight cases.

At the beginning of immune recovery CD4+ lymphocyte and their EM subset were lower in patient with CMV copies when compared to those without them (CD4+ cells 44/μl versus 120/μl $P = 0.066$ Mann Whitney U test) (CD4+ EM cells 25/μl versus 75/μl $P = 0.088$ Mann Whitney U test) .

Three weeks later the presence of HHV-6 was associated with a decrease in number of CD4+ cells, CD4+ CM and CD4+ EM cells for patients with HHV-6 copies when compared to group without HHV-6 copies, which was independent of aGvHD manifestation. (CD4+ cells 93/μl versus 190/μl; $P = 0.044$ Mann Whitney U test); (EM cells 41/μl versus 142/μl; $P = 0.015$ Mann Whitney U test) (CM cells 6/μl versus 18/μl; $P = 0.015$ Mann Whitney U test).

All CMV infected patients survived and showed an increase in CD8(+) lymphocytes in comparison with those lacking CMV infection 5−6 weeks after transplant. (182 k-k/μl versus 535 k-k/μl $P = 0.017$ Mann Whitney U test).

Patients having EBV copies had higher proportion of CD20(+) cells when compared to those lacking EBV copies (19/μl versus 9/μl; $P = 0.077$ Mann Whitney U test).

Conclusions: Low lymphocyte CD4(+) and CD4+ EM count precedes CMV and results from HHV-6 infection. HHV-6 infection leads to a decrease of lymphocyte CD4+ CM count.

P1834

Mixed chimerism after allogeneic stem cell transplantation for severe aplastic anemia

A. Bosch

Immunology, Hospital Universitario Virgen de la Arrixaca, Murcia, Spain

Purpose/Objective: Aplastic anemia (AA) is an autoimmune disorder involving the hematopoietic stem cell progenitors (HSCP) in the bone marrow (BM). As a result, the lymphocyte mediated attack to HSCP produces a BM failure, with a variable degree of cytopenias in the peripheral blood cell counts.

Donor«s chimerism after allogeneic stem cell transplantation (Alo-SCT) measures the proportion of blood cells provided by the donor's HSCP in contrast with the ones coming from the recipient. Patients with increased or prolonged mixed chimerism (MC) are at high risk for graft failure and relapse of the disease. The value of MC after Alo-SCT for non malignant disorders as AA is less established.

We present two cases of AA that underwent Alo-SCT from a full matched sibling donor, after the same conditioning regimen, graft versus host disease (GVHD) prophylaxis and stem cell source. Both patients achieved a complete response of the AA with normalization of their peripheral blood counts despite an opposite evolution of their chimerism analysis monitoring.

Materials and methods: Stem cell source G-CSF 10 μg/kg per 5 days, and BM harvest (mobilized BM).

1 Conditioning regimen: cyclofosfamide 200 mg/kg (total dose) and ATG 6 mg/kg (total dose)
2 GVHD prophylaxis: methotrexate (d +1, +3, +6, +11) and cyclosporine from day-2 onwards.
3 Patient A: a 36 years old man who underwent Alo-SCT from his 33 years old brother donor.
4 Patient B: a 53 years old woman who underwent Alo-SCT from her 48 years old sister donor.
5 Chimerism assay was made analyzing Short Tandem Repeats in two cells populations in peripheral blood: total mononuclear cells (TMC) and T lymphocites (CD3+).

Results: Patient A achieved full donor chimerism at d+213 after cyclosporine reduction. Patient B did not achieve full donor chimerism at d +530 (75% in TMC, 60% in CD3+). In patient B, a progressive increased in MC did not correlate with impairment in blood cell counts.

Conclusions: Chimerism assay after Alo-SCT is a useful tool that measures the kinetics of the engraftment of donor derived blood cells. MC and even the complete conversion to recipient full chimerism and autologous reconstitution of recipient HSCP may occur without the relapse of the AA, showing an immunomodulatory effect of the Alo-SCT beyond its effect of replacing the HSCP from the recipient to the donor«s derived ones.

P1835
NK cells in kidney transplantation

C. Blume,* C. Neudörfl,† B. Müller,† K. Daemen,† M. Stevanovic-Meyer† & C. S. Falk†
**Nephrology and Hypertension, Hannover Medical School, Hannover, Germany,* †*Transplant Immunology, Hannover Medical School, Hannover, Germany*

Purpose/Objective: Following kidney transplantation, the involvement of NK cells in rejection episodes or immunological tolerance is discussed controversially. The peripheral NK cell repertoire of KTx patients at 3 or 6 months post Tx was investigated in parallel to the protocol biopsy for histopathological evaluation of the graft. The alterations were correlated to the biopsy status ('unsuspicious', T cell-mediated rejection TCMR or borderline changes) and immunosuppression, respectively.

Materials and methods: Peripheral blood lymphocytes of KTx patients ($N = 100$) at the time of the protocol biopsy at 3 or 6 month after Tx were isolated after informed consent of the patients. In addition to the 'truecount' quantification of T, B, NK cells (cell/μl), the composition of the NK cell repertoire was determined by flow cytometry for the expression of several NK receptors including KIR and CD94/NKG2. In addition to NK cells, receptor expression was also addressed in T cell subsets. In some cases, protocol biopsies and peripheral blood was available at multiple time points after Tx and, thus, changes over time and immunosuppression (CsA versus Tac versus mTOR inhibitors) could be defined.

Results: The numbers of NK cells/μl blood differed between patients after KTx with 'unsuspicious' grafts and TCMR or borderline histopathology although not at a significant level. However, the distribution of $CD56^{bright}$ versus $CD56^{dim}$ NK cells in these patient cohorts displayed significant differences compared to healthy donors. In addition, the NK subset analyses revealed substantial differences in the numbers of KIR+ NK cells between the patient cohorts.

Conclusions: In our first analyses with patients between 3 and 12 months after KTx, we could demonstrate that the numbers of NK cells in peripheral blood differs between patients with kidney grafts unsuspicious of rejection and biopsy-proven TCMR or borderline changes. In addition, a more detailed NK cell subset analysis revealed significant differences in NK subset distribution between the patient cohorts and also, for some subsets, the immunosuppressive treatment groups mTOR inhibitors, in particular. Therefore, we assume that the composition of peripheral NK cells represents an important hallmark of the immune status, rejection versus tolerance, in kidney transplantation. (This work was funded by the IFB-Tx, DFG TRR77, A3 snd SFB738 B8 projects and the HGF Alliance Immmunotherapy).

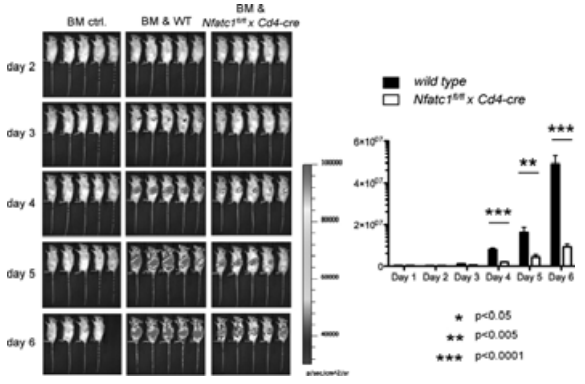
P1836
Nuclear factor of activated T cells (NFAT) regulates acute graft versus host disease

M. Väth,* A. Jordan-Garotte,† R. Rudolf,* G. Lessner,* E. Serfling,* A. Beilhack† & F. Berberich-Siebelt*
**Institute of Pathology, University of Würzburg, Würzburg, Germany,* †*Centre for Molecular Medicine, University of Würzburg, Würzburg, Germany*

Purpose/Objective: Acute graft versus host disease (aGvHD) is a life-threatening immunological complication after allogenic stem cell transplantation. Patients with ongoing aGvHD are treated with cyclosporin A (CsA) or tacrolimus (FK506), both inhibiting the calcium-calcineurin pathway. Blockade of calcineurin results at first in repression of Nuclear Factor of Activated T cells (NFAT) activation, but may also affect other transcription factors such as NF-κB. Given the side effects of (long term) calcineurin-inhibition we explored the contribution and specific function of individual NFAT-factors in T cells to the overall pathogenic mechanisms in a mouse model of aGvHD.

Materials and methods: We transplanted luciferase-labeled allogeneic T cells from NFATc1- and NFATc2-deficient donor mice along with bone marrow stem cells and monitored the progression of aGvHD by an *in vivo* bioluminescence imaging technique.

Results: Inactivation of both, NFATc1 or NFATc2 resulted in a milder and decelerated clinical course of aGVHD, apparently due to impaired secretion of Th1 cytokines such as IFNγ, TNFα, or IL-2.



Conclusions: We anticipate that more specific therapeutics to block NFAT activation might benefit the clinical treatment of aGvHD by reducing overall side effects, nevertheless facilitating graft versus leukemia/tumor reaction.

P1838

Pentraxin 3: a new potential biomarker for predicting and monitoring graft-versus-host disease (GvHD) in allogeneic hematopoietic stem cell transplantated (HSCT) patients

E. Dander,* P. Vinci,* P. De Lorenzo,† I. Cuccovillo,‡ M. Migliavacca,§ S. Bonanomi,§ A. Balduzzi,§ F. Pavan,§ L. Di Maio,§ F. Masciocchi,§ E. Teruzzi,¶ C. Garlanda,‡ A. Mantovani,‡ A. Rambaldi,** M. G. Valsecchi,† A. Rovelli,§ B. Bottazzi,‡ A. Biondi§ & G. D'Amico*

*Department of Pediatrics, Research Center "M. Tettamanti", University of Milano-Bicocca, Monza, MB, Italy, †Centro di Biostatistica per l'Epidemiologia Clinica, University of Milano-Bicocca, Monza, MB, Italy, ‡Immunology and Inflammation Department, Istituto Clinico Humanitas IRCCS, Milano, Italy, §Department of Pediatrics, San Gerardo Hospital, Monza, MB, Italy, ¶Hematology Department, San Gerardo Hospital, Monza, MB, Italy, **Hematology Department, Ospedali Riuniti di Bergamo, Bergamo, Italy*

Purpose/Objective: GvHD is a major obstacle to safe HSCT. Reliable biomarkers facilitating the monitoring of this invalidating disease are warranted to improve its management. The long pentraxin (PTX) 3 is locally produced at sites of inflammation. Its rapid increase in several inflammatory diseases and the correlation between PTX3 levels and disease severity suggest its potential usage as GvHD marker.

Materials and methods: We collected plasma samples from 71 HSCT pediatric patients, before the beginning of the conditioning regimen and weekly from the transplant day (day 0), until day 100. Thirty-three patients developed acute GvHD within day 28, 21 between day 28 and 100, while 17 never developed it. Concerning GvHD patients, plasma was further collected the day of GvHD onset. PTX3 levels were monitored by ELISA.

Results: To investigate the possible use of PTX3 as GvHD marker, we evaluated its plasma levels at disease onset. Since PTX3 values could be influenced by infections, we compared PTX3 levels at GvHD onset before day 28 after HSCT, time-frame free from infectious complications in our cohort, with time-matched levels of patients who did not develop GvHD within day 28 (no GvHD). The median PTX3 level at GvHD onset was 33 ng/ml (range = 11−847), significantly higher (Wilcoxon P-value<0.0001) than the no GvHD group (median level = 14, range = 4−58 ng/ml). To investigate its predictive potential, we compared PTX3 levels at day 0, 7 and 14, normalized for each patient by his baseline (PTX3 value before conditioning regimen), between patients with early GVHD occurrence (within day 28) and no GVHD patients. We observed that the conditioning regimen induced an increase of PTX3 levels compared to the baseline in both groups, without significant differences. On the contrary, at day 7 and 14 the median PTX3 level were significantly higher in patients experiencing GVHD within day 28 (normalized change = 3.03) compared to the no GVHD group (normalized change = 1.1; Wilcoxon P-value = 0.05).

Conclusions: These results show that PTX3 increases rapidly in patients with acute GvHD, candidating this molecule as an easily measurable soluble factor useful to corroborate the clinical monitoring of the pathology. Furthermore, if confirmed in a larger cohort of patients, PTX3 could represent a sensitive biomarker for predicting patients at high risk for developing GvHD early after HSCT.

P1839

Pretransplant IFNgamma secretion by CMV-specific CD8+ T cells (Quantiferon®-CMV) can predict the risk of cytomegalovirus replication after solid organ transplantation

S. Cantisán,* J. Torre-Cisneros,* R. Lara,* J. Redel,† A. Rodríguez-Benot,‡ J. Gutiérrez-Aroca,§ M. Montejo,¶ A. Rivero* & R. Solana*

Immunology and Infectious Diseases, Reina Sofia Hospital/IMIBIC, Cordoba, Spain, †Department of Neumology, Reina Sofia Hospital, Cordoba, Spain, ‡Department of Nephrology, Reina Sofia Hospital, Cordoba, Spain, §Department of Microbiology, Reina Sofia Hospital, Cordoba, Spain, ¶Infectious Diseases Unit, Cruces Hospital, Bilbao, Spain

Purpose/Objective: We analyzed pretransplant CMV-specific CD8+ T cells secreting IFNγ using the QuantiFERON®-CMV assay to determine whether this assessment provides prognostic value of CMV replication after transplantation.

Materials and methods: This longitudinal study was carried out in two centers of the REIPI network (Reina Sofia University Hospital, Cordoba, and Cruces University Hospital, Bilbao, Spain). Adult patients awaiting lung or kidney transplantation were recruited from March 2009 to June 2010. A total of 55 were evaluable patients. IFNγ production by CMV-specific CD8+ T-cells was assessed pretransplant using the QuantiFERON®-CMV assay. A result was considered positive when the CMV antigen response minus the negative control response was >0.2 IU/ml of IFNγ. CMV load (copies/ml) was monitored for 12 months after transplantation.

Results: All CMV-seronegative recipients were QuantiFERON®-CMV negative [QF_{CMV}(-)], (11/11). However, in CMV-seropositive recipients [R(+)] 30/44 (68.2%) were QF_{CMV}(+) and 14/44 (31.8%) were QF_{CMV}(-). When we analyzed the incidence of post-transplant CMV in these two groups within R(+) recipients we found that 7/14 (50%) of R(+) QF_{CMV}(-) recipients developed CMV replication after transplantation, whereas the virus replicated only in 4/30 (13.3%) of R(+) QF_{CMV}(+) patients. In the kidney transplant recipients group, CMV replicated earlier post-transplant, reached a higher peak CMV load, replication episodes were longer and the frequency of CMV disease was higher in R(+) QF_{CMV}(-) patients than in R(+) QF_{CMV}(+) recipients.

Conclusions: The determination of pretransplant IFNg production using the QuantiFERON®-CMV assay might be useful in predicting the risk of post-transplant CMV replication in solid organ transplantation as it re-classifies patients more accurately than serostatus. R(+) kidney transplant patients with pretransplant QF_{CMV}(-) should, therefore, be managed as high risk patients, by which this pretransplant assay could be used in the clinical setting to guide physicians in applying the adequate anti-CMV therapy after solid organ transplantation.

Radiation-free conditioning for the establishment of mixed chimerism and allogeneic tolerance in aged mice

J. Morison, T. Heng, A. Chidgey & R. Boyd

Monash Immunology and Stem Cell Laboratories, Monash University, Melbourne, Australia

Purpose/Objective: Mixed hematopoietic chimerism is a powerful means of inducing allogeneic tolerance. Clinically, this is a favourable outcome as it allows long-term acceptance of the allograft, eliminates toxicities associated with lifelong immunosuppression and maintains immunocompetence. We aimed to develop a radiation-free protocol to induce tolerance to MHC-mismatched skin allografts and apply this model to an aged setting, combining aged experiments with strategies to boost thymic output.

Materials and methods: Young (6−8 week) or old (12 month) B6.SJL-Ly5.1 (H-2^b) mice received low-dose busulfan on day -4, followed by two doses of T cell-depleting antibodies to CD4 (GK1.5)

and CD8 (2.43) on days -3 and -1. On day 0 mice were transplanted with B10.Br (H-2^k) allogeneic whole BM, T cell-depleted BM or purified lineage negative Sca-1^+ c-Kit^+ (LSK) progenitor cells. Rapamycin was administered at 3 mg/kg/day for 28 days following BMT. Mice received a full-thickness allograft, derived from B10.Br and Balb/c (H-2^d) tail skin at 12 and 24 weeks post BMT respectively. To boost thymic function via sex steroid reduction, aged mice received a 3-month depot administration of Lupron (leuprolide acetate), a luteinising hormone releasing hormone agonist, 28 days prior to chemotherapy.

Results: Long-term tolerance to donor skin grafts was achieved when mice were transplanted with whole BM; T cell-depleted BM or purified LSKs. However, the ability to induce thymic tolerance with this protocol was diminished with age and was not restored with endocrine modulation, which we have previously shown to enhance immune reconstitution. We found instead that donor engraftment was inhibited in aged mice due to a higher proportion of chemotherapy-resistant BM LSKs.

Conclusions: Our model demonstrates that low-dose chemotherapy can be used in conjunction with T cell-depleting antibodies and transient immunosuppression to induce mixed chimerism and allogeneic tolerance in young mice. Preliminary results indicate that robust levels of chimerism are harder to achieve in the aged mouse, due to low levels of donor engraftment. As hematopoietic growth factors have been shown to increase the sensitivity of stem cells to myeloablative treatment, we are currently investigating if pre-treatment with such factors facilitates the induction of hematopoietic chimerism and thus allogeneic tolerance in aged mice.

Rebound of lymphoid progenitors after allogeneic hematopoietic stem cell transplantation in humans in the absence of acute graft-versus-host disease

S. Glauzy,* I. André-Schmutz,† J. Larghero,‡ R. Peffault de Latour,§ S. Ezine,¶ S. Servais, G. Socié,†† A. Toubert* & E. Clave***

**IUH — Paris Diderot, Inserm UMRS 940, Paris, France, †Hôpital Necker, Inserm U768, Paris, France, ‡Unité de Thérapie Cellulaire et CIC de Biothérapies Hôpital Saint Louis AP-HP, Inserm UMRS 940, Paris, France, §Service d'Hématologie-Greffe de Moelle Hôpital Saint-Louis AP-HP, Inserm UMRS 940, Paris, France, ¶Hôpital Necker, Inserm U1020, Paris, France, **Service d'Hématologie-Greffe de Moelle, Hôpital Saint-Louis AP-HP, Paris, France, ††Service d'Hématologie-Greffe de Moelle Hôpital Saint-Louis AP-HP, Paris Diderot, Inserm UMRS 940, Paris, France*

Purpose/Objective: Allogeneic Hematopoietic Stem Cell Transplantation (HSCT) is an effective treatment for malignant and nonmalignant blood diseases. The long term T-cell reconstitution after HSCT is dependent on patient thymic function and affected by acute graft-versus-host disease (aGVHD). Data in mice showed that T-lineage reconstitution after HSCT is limited by progenitor supply to the thymus. In humans, a subset of $CD34^+lin^-CD10^+CD24^-$ lymphoid progenitors have a very low myeloid potential but can generate B, T and NK lymphocytes. They belong to the most immature thymic population, are present in cord blood, bone marrow and, most importantly, in the peripheral blood in adults.

Materials and methods: We analysed by flow cytometry this $CD34^+lin^-CD10^+CD24^-$ Thymic Seeding Progenitor (TSP) population in the peripheral blood of 39 patients, 3 months after HSCT, in comparison to 15 healthy donors.

Results: The rate of TSP in peripheral blood was more heterogeneous in patients than in healthy donors. TSP counts in peripheral blood from patients without aGVHD or patients with a grade I aGVHD were higher than for healthy donors. aGVHD clearly impacted the number of TSP. Patients without aGVHD ($n = 11$) and patients with an aGVHD grade I ($n = 7$) had significantly ($P = 0.005$) more TSP than patients with severe aGVHD [grade II, III and IV ($n = 21$)]. The number of TSP decreased with the worsening of disease. We didn't observe any effect of recipients' age or conditioning regimen on TSP counts. The source of grafted cells (bone marrow or mobilized peripheral blood stem cells) had a low impact on TSP variation. In patients without aGVHD and with aGVHD grade I, the number of TSP was significantly correlated with the number of $CD34^+$ cell contained in the graft. Functionally, T-cell commitment and progenitor frequency was determined using limiting dilution assay on OP9 3T3-L1 cells? Mean T-cell progenitor frequency of TSP sorted from patients without aGVHD was at least as high as for healthy donors (1/13 versus 1/20, respectively).

Conclusions: In conclusion, at 3 months after HSCT, we observe in patients without aGVHD a rebound of circulating TSP, which retain a T cell potential. Understanding the precise role of these cells in the T cell recovery and the mechanisms of action of aGVHD on TSP could give important clues for improving T-cell reconstitution after HSCT in humans.

Rejection of a kidney transplant for a lymphocyte alogentigen non — human leucocyte antigens: a case report

R. Lavado-Valenzuela,* M. J. Bravo,† J. M. Miranda-Sayago,† N. Fernández-Arcás,‡ M. Cabello,§ A. Alonso‡ & A. Caballero‡

**Immunology, Hospital R. U. Carlos Haya, Málaga, Spain, †Bioquímica Biología Molecular e Inmunología, Universidad de Málaga, Málaga, Spain, ‡Inmunología, Hospital R. U. Carlos Haya, Málaga, Spain, §Nefrología, Hospital R. U. Carlos Haya, Málaga, Spain*

Purpose/Objective: Antibodies anti human leucocytes antigens (anti-HLA), anti-endothelium cells and anti-mayor histocompatibility complex class I chain-related (anti-MIC) are the most frequent antibodies in the humoral rejection of transplanted organs. In this study we present a clinical report of a humoral response against a transplanted kidney associated with an antibody with a non-previously described specificity and presents in peripheral blood lymphocytes.

Materials and methods: A peripherical blood sample was extracted from a 50-year-old renal patient. The serumwas separated for using in the cross-match and DNA was obteined from lymphocytes. The HLA alleles was typed by PCR-SSO. The antibodies specificity was determinated by bead array (Luminex thecnology).

Results: A 50-year-old patient with negative screening for anti-HLA antibodies received a kidney from a partially HLA-mismatched related donor (HLA-A24, A-; B18, B61; DR11; DR3 and HLA-A2, A29, B27, B35, DR11 DR12, respectively). Three days after the transplant, the renal function failed. The biopsy showed a capillary periarteritis compatible with a humoral rejection. However, the deposits of C4d were negative. Likewise, the determination by bead array of anti-HLA and anti-MIC antibodies was negative. However, a flow cytometry cross-match, with serum from the fourth day after transplant, showed positive results. The patient was treated with plasma exchange and intravenous human immunoglobulin injection according with the usual protocol. After seven sessions of plasmapheresis, the renal function was recovered and the cross-match became negative.

Conclusions: In summary, we believe that this patient suffered an acute humoral rejection related with complement non-fixing antibodies with non-HLA, non-endothelium cells and non-MIC specificity but present in peripheral blood lymphocytes. These results suggest that this new alloantigen could have more impact in the rejection of transplanted kidneys. Therefore we propose a second cross match and not only the determination of antibodies anti-HLA using bead array before an acute humoral rejection post-transplant.

P1843
Risk factors for relapse in patients with myeloid malignancies

M. Uzunel,* J. Mattsson,* P. Ljungman,† O. Ringden* & M. Remberger*
*Clinical Immunology, Karolinska Institute, Stockholm, Sweden, †Hematology, Karolinska Institute, Stockholm, Sweden

Purpose/Objective: The past 10 years, there has been an increase in using reduced intensity conditioning regimens (RIC) in allogeneic stem cell transplantation (SCT) for different diseases. Long term effects of these conditioning regimens on outcome factors like relapse is now being investigated in different studies. In this study, we studied risk factors for relapse in patients with acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS).
Materials and methods: Two hundred and sixty-seven patients transplanted between 1999 and 2011 were included. Most patients had AML ($n = 193$) and 74 had MDS. RIC was given to 92 patients and myeloablative conditioning (MAC) to 175 patients. The RIC regimens consisted mainly of a combination of Fludarabine and Busulphan.
Results: Four different risk factors for relapse were found in univariate analysis.

Unrelated transplantation (33% relapse incidence at 5 years) versus sibling transplants (22%), $P = 0.05$.

Acute GVHD, any grade, (23%) versus no aGVHD (40%), $P = 0.02$.

RIC (37%) versus MAC (26%), $P = 0.02$.

A donor sero-positive for 3–4 herpes viruses (CMV, HSV, VZV and EBV) was correlated with decreased incidence of relapse (27%), compared to if the donor was positive for only 0–2 of these viruses (38%), $P = 0.03$.

Higher relapse risk in unrelated donor SCT is partly explained by the use of ATG in these patients. Especially in unrelated transplants with RIC, ATG in combination with long immunosuppression may have hampered the antileukemia effect. In fact, the highest risk of relapse was found in unrelated transplants with RIC (40%). In sibling transplants, no effect of RIC on relapse was found.
Conclusions: In this study, we could find that the use of ATG in unrelated transplants after RIC was correlated with high risk of relapse. Interestingly, the donor virus serology seems to have an effect on relapse. It may be speculated that donor T-cells with previous virus infections may be more immune reactive. It could also be that virus specific T-cells may cross-react with leukemia cells.

P1844
Role of IL17 following T cell depletion in baby rat keratoplasty

A. Hildebrand, Y. Kern, T. Reinhard & J. Schwartzkopff
Cornea Lab, University Eye Hospital, Freiburg, Germany

Purpose/Objective: Corneal transplantation (keratoplasty) is the most frequent and successful form of tissue transplantation in adults (<10% rejections). The rejection rate is dramatically increased in infants younger than 3 years of age (~85% rejections). In children, any corneal opacity should be corrected as early as possible to prevent life lasting reduced vision. We established the keratoplasty baby rat model that reproduces the increased rejection rate in the young experimentally. The purpose of this set of experiments was to analyze the impact of T cells following keratoplasty in baby rats.
Materials and methods: Orthotopic keratoplasty was performed between Fisher donor and Lewis recipient rats. Recipients were 3 weeks of age (keratoplasty baby rat model) and were either treated during 1 week with a T cell depleting (clone R73) or an isotypic antibody. Corneal grafts were monitored clinically until rejection occurred but no longer than 35 days postoperatively. In a second set of experiments, animals were examined until the T cell compartment recovered. Lymph nodes and cornea were analyzed by qPCR for mRNA amounts of IL17, IL6, TGFβ, and RORγt.
Results: We could clearly show that T cell depletion abrogated graft rejection. Infiltration of CD3+, CD4+ and CD8+ T cells in the graft of R73-treated recipients was significantly reduced even after recovery of the T cell compartment. Simultaneously, mRNA levels for IL6, TGFβ, IL17 as well as RORγt was increased in draining lymph nodes of R73-treated animals. Surviving grafts of R73-treated animals also showed increased mRNA levels for IL17 and RORγt.
Conclusions: These results lead to the conclusion that IL17-producing cells may contribute to long-term graft survival following T cell depletion in baby rats.

P1845
Strategies for hematopoietic stem cell donor searching: Implications of haplotypic and allelic HLA frequencies

R. González,* B. Manzanares,† M. Frias,† L. Castro-Orgaz,† M. Santamaría‡ & R. Solana,* J. Peña*
Service of Immunology, Hospital Reina Sofía/IMIBIC, Córdoba, Spain, † Area of Immunology, IMIBIC, Córdoba, Spain, ‡Service of Immunology, Hospital Reina Sofía, Córdoba, Spain

Purpose/Objective: The availability of matched donors depends on the frequency of the patient's alleles and haplotypes. Therefore, data regarding HLA distribution for each population are needed to evaluate the donor searching approach. Our objective is to establish what HLA alleles and haplotypes are most common in our area. These results can be used to delineate search strategies for potential donors including other related donor no matching sibling.
Materials and methods: This study includes 184 families residing in Cordoba y Jaen (Andalusia, Spain) with a total of 548 haplotypes analyzed. They were HLA-A, B, C and DRB1 typed by high-resolution (High Res SSP Unitray Kit, Invitrogen, Wisconsin, USA and Inno-Lipa HLA, Innogenetics N.V. Ghent, Belgium).
Results: Only 26 HLA-A, 47 HLA-B, 25 HLA-C and 31 HLA-DRB1 alleles were found. These alleles have been previously described in Caucasians as expected from the geographic origin of the studied families. The distribution of predominant alleles studied herein reveals great similarities with those in Spain, Western European and North American populations. In the analysis of haplotypes, a high number were included within the most frequent haplotypes described in Spain. However, the results reveal that the ten most frequent haplotypes in our population were not the same as in other populations. Presence of infrequent HLA associations, showed a negative value for finding a suitable donor, whereas the presence of haplotypes with a frequency ≥ 1% in our sample was a positive factor influencing donor searching.
Conclusions: The data we present here may help to predict the chance of getting a suitable related donor, and it also suggests strategies for improving success in the search

P1846
Study of luminex SA C1q assay in sensibilized renal patients

F. B. G. F. B. Gienr,* S. L. S. Llorente,† J. E. J. Eguía,* H. M. H. Martínez,* G. S. G. Salgado,* J. A. C. J. A. Campillo,* R. M. R. Moya,* A. M. A. Minguela,* L. G. L. Gimeno,† M. R. A. L. M. R. Álvarez-López* & M. M. M. Muro*
Immunology Service, Hospital Universitario Virgen de la Arrixaca, Murcia, Spain, †Nephrology Service, Hospital Universitario Virgen de la Arrixaca, Murcia, Spain

Purpose/Objective: Assessment of rejection risk based on preformed or *de novo* donor specific antibody (DSA) is based on the luminex (LMX) IgG median fluorescence intensity (MFI) strength. Widespread

debate exists over the suitable MFI cutoff value of Single Antigens Beads (SAB) for calling an antibody *positive*. The complement-fixing ability of the antibody, irrespective of IgG MFI strength could be a key component of clinical outcome. Recently, it has been developed a C1q-SAB assay that identifies complement-fixing HLA antibodies with high sensitivity and specificity. C1q is the first step in the classical complement cascade. Thus, we aimed to determine the correlation between IgG SAB and C1qSAB assays in patients in renal waiting list.

Materials and methods: These assays use pooled luminescent beads, each uniquely color code distinguishable and coated with a different purified single HLA class I antigen ($n = 97$).

Samples of immunized renal patients and negative and positive controls by LMX were used for validation. These sera were tested by LMX-IgG and LMX-C1q in parallel for HLA class I.

LMX-IgG assay was performed using SAB kits (LABScreen, Onelambda, CA) according to the manufacturer and analyzed on a Luminex platform (LABScan 100). Data were analyzed by Fusion 2.0 (OL, CA). Normalized MFI values from Fusion software were used to assign positive («real« MFI > 1000) and «possible« (MFI = 500−999). These assay detects all IgG binding antibodies irrespective of their complement-fixing ability.

C1qSAB assay. The serum were inactivated by heating 30 min at 56°C. Five millilitres of serum were incubated with 5 ml of LabScreen SAB for 20 min at room temperature (RT) and then incubated with 5 ml of PE-conjugated sheep anti-human C1q for 20 min at RT, washed twice with 80 ml LMX wash buffer and adquired on the LMX. The data were analyzed using «Raw« MFI values. In C1qSAB assay, antibodies were assigned as «posible« when the first increase more than 33% (but at least 400 MFI) over the prior lower MFI bead was observed.

Results: Comparison of antibody detection revealed no correlation based on MFI levels between IgG SAB and C1qSAB assay. IgG positive sera with MFIs as low as 700 were able to fix C1q, whereas other sera with MFIs as high 14500 did not. In our series, only 34% class I IgG SAB antibodies were also C1qSAB+. In several patients, we detected C1qSAB+ against IgG SAB+ that was surely due to IgM antibodies.

Conclusions: C1qSAB assay can detect IgM antibodies that can fix complement. These data suggest that C1q assay could be an important method to evaluate the pre-transplant virtual cross-match and to define the non-permitted specificities (C1q-fixing) in kidney transplantation.

P1847

T Cell subsets responsible for CMV reactivation control in patients after hematopoietic stem cell transplantation

J. Stuchly,* J. Krol,* P. Keslova,* P. Hubacek,* O. Pelak,† P. Sedlacek,‡ J. Stary,* O. Hrusak* & T. Kalina*

**Department of Paediatric Hematology/Oncology, 2nd School of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic, †CLIP Childhood Leukemia Investigation Prague, 2nd School of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic, ‡HSCT Unit, Department of Pediatric Hematology & Oncology, 2nd School of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic*

Purpose/Objective: Depletion of cellular immunity as a consequence of conditioning before allogeneic hematopoietic stem cell transplantation (HSCT) frequently results in CMV reactivation, which may in turn lead to life-threatening infections and require timely antiviral treatment.

Materials and methods: We have investigated the ex vivo response of CMV-specific CD4+ and CD8+ T-cells to CMV antigen (combined CMV total lysate, pp65 and IE-1 peptide mix) in 191 samples from 118 individuals. We included patients with either high or undetectable viral loads, and those who controlled or did not control their CMV reactivations. All patient subsets were compared to healthy donors. Polychromatic flow cytometric measurements of CD154 (CD40L), intracellular cytokines (IFNγ, IL2), and a degranulation marker (CD107a) revealed the functional status of various T-cells simultaneously.

Results: We found that dual IFNγ/IL2 producing CD8+ T-cells were significantly increased in patients controlling their CMV reactivations (average 0.33%, SD = 0.4%) compared to non-controllers (average = 0.02%, SD = 0.07%). In contrast, CD8+ T-cells that produced IFNγ only were the most abundant subtype but they were present in a substantial number of both, controllers (average 4.36%, SD = 4.8%) and non-controllers (average 1.64%, SD = 3.7%). Hierarchical clustering of distinct functional signatures revealed that polyfunctional CD8+ T-cells were acting in concert with other subsets, whereas the isolated production of IFNγ by CD8+ T cells heralds insufficient collaboration with others. On a subset of patients with reactivation of CMV post HSCT, we have evaluated the sensitivity and specificity of functional signature test ($n = 64$ samples) to predict reactivation control. When dual IFNγ/IL2 producing cells above 0.1% cut-off were considered protective, sensitivity of 75% and specificity 93% was achieved, while IFNγ-only production by more 0.3% cells had sensitivity of 88% but specificity of 73% only.

Conclusions: Our study revealed functional signatures that are useful readout of immune monitoring. Furthermore, our data may modify the interpretation of previous studies that assessed only IFNγ.

P1849

Terminally differentiated CD8+ T cells reduce the risk for acute kidney allograft rejection

N. Litjens, L. E. A. de Wit, R. W. J. Meijers, C. C. Baan, W. Weimar & M. G. H. Betjes

Internal Medicine Nephrology and Transplantation, Erasmus Medical Center, Rotterdam, Netherlands

Purpose/Objective: End-stage renal disease (ESRD) is associated with lymphopenia and increased T cell differentiation. This phenomenom may be the cause of the ESRD-related impairment of T-cell immunity but clinical evidence in support for this conclusion is scarce. We tested the hypothesis that a more profound ESRD-related T cell dysregulation reduces the risk for acute rejection (AR) in kidney transplants.

Materials and methods: In a prospective study, 185 ESRD patients receiving a kidney allograft were included and followed for 1−2 years. Prior to transplantation, circulating $CD4^+$ and $CD8^+$ T cells were quantified. T cell differentiation was established by determining the percentages of naïve T cells, central-memory T cells, effector-memory T cells and the highly differentiated Tem cells which have regained CD45RA expression (Temra cells). In addition, the frequency of T cells without expression of the co-stimulatory molecule CD28 was measured. Data from age-matched healthy individuals were used for comparison.

Results: In 47 patients, a biopsy-proven AR occurred. Confirming previous results, the ESRD patients had significantly lower T cell counts with a more differentiated phenotype compared to healthy controls. Patients with AR showed the least signs of T cell dysregulation with significantly higher absolute numbers of CD4 T cells, naïve CD4 and CD8 T cells and less terminal differentiation of memory CD4 and CD8 T cells compared to non-rejecting (NR) patients. For instance the percentage of $CD8^+$ Temra cells was significantly lower ($P < 0.05$) in patients with AR when compared to NR patients, i.e 16% versus 25%, respectively. After multivariate proportional hazard logistic regression analysis, only the frequency of terminally differentiated $CD8^+$ Temra cells (per percent 4% decrease of risk, $P = 0.006$; per tertile 34% decrease in risk, $P = 0.002$) and the number of HLA mismatches (per mismatch 33%, $P = 0.005$) predicted the risk for AR.

The CD28 cell surface expression was lost in over 80% of these $CD8^+$ Temra cells, confirming their status of highly differentiated T cells.
Conclusions: Advanced ESRD-related T cell dysregulation yielding an increased frequency of terminally differentiated $CD8^+$ T cells is associated with less AR after kidney transplantation. This confirms the results of previous studies which indicated that these cells may act as suppressor CD8 T cells and expansion of CD28null CD8 T cells is associated with decreased T cell immunity.

P1852

The magnitude of ischaemia and reperfusion injury of the transplanted liver correlates with distinct adaptive immune responses from the hepatic resident lymphocytes

E. Xystrakis, X. Huang, Y. Ma & W. Jassem
Institute of Liver Studies, King's College London, London, UK

Purpose/Objective: During organ retrieval for transplantation, the liver is subjected to ischaemia followed by reintroduction of oxygen supply (reperfusion). This ischaemia/reperfusion (I/R) phase induces a sequence of cellular and molecular modifications which can lead to graft dysfunction, thereby increasing recipient's morbidity. Studies in animal models of liver I/R injury suggest that parenchymal cells release damage-associated molecular patterns (DAMP) which trigger a variety of receptors including Toll-like Receptors (TLR) expressed on antigen presenting cells in the liver. This activation induces the release of pro-inflammatory molecules which initiate a cascade of immune responses, including T-cell differentiation programs. However, it is currently unclear whether the resulting activated immune effectors have a damaging or protective effect on the graft tissue.
Materials and methods: In order to test the impact of the magnitude of I/R injury on the adaptive immunity driven by the graft, we compared phenotypically and functionally liver-resident lymphocytes (LRL) from organs subjected to various degrees of I/R injury. We isolated LRL from either living donors (LD), heart beating donors (donation after brain death or DBD) and non-heart beating donors (donation after cardiac death or DCD). DBD and DCD livers are subjected to more severe I/R injury compared to LD grafts.
Results: We found that in the group of DBD, LRL are enriched in CD8 T cells which exhibit an activated phenotype (CD8+CD69+) suggesting that the inflammatory environment of DBD donors promotes activation of CD8 T subsets. Assessment of cytokine production revealed a significant increase in IFN-g production by CD8 T cells in DBD grafts. Together these data suggest that donor-derived activated CD8 hepatic resident cells may account for the significant increase in the graft morbidity observed in the DBD group of recipients. In contrast to DBD livers, LRL from DCD livers preferentially produce IL-17. The potential source (CD8 or gamma/delta T cells) and the functional significance of this IL-17 secretion are under investigation.
Conclusions: Our data suggest that the magnitude of ischaemic injury leads to distinct adaptive immune responses in the graft which may account for the different rejection and liver dysfunction rates observed in cohorts of liver transplant recipients.

Poster Session: Vaccine Development

P1853
'Omic'-based comparison of different formulation of vaccine DC

C. Massa,* C. Thomas,* E. Wang,† F. Marincola† & B. Seliger*
*Institute of Medical Immunology, Martin Luther University, Halle, Saale, Germany, †Department of Transfusion, Medicine Clinical Center, National Institutes of Health, Bethesda, MD, USA

Purpose/Objective: Dendritic cells (DC) based vaccination for cancer immunotherapy has not yet fulfilled the expectations, providing only low clinical response rates. In an attempt to optimise DC production, various protocols for differentiation and maturation of monocytes have been proposed. The aim of this study was a comparison of different DC formulations using transcriptome analysis.
Materials and methods: Monocytes derived from the peripheral blood of healthy donors were differentiated for 2 days in serum free medium in the presence of GM-CSF and IL4. Resulting DC were then stimulated for 18h with the gold standard cytokine cocktail (namely TNFα, IL1β, IL6, and PGE_2) or with alternative cocktails, where TLR ligands are combined with IFNγ alone (the MPLA cocktail: MPLA and IFNγ) or in combination with other proinflammatory cytokines (the pIC cocktail: polyIC, IFNγ, TNFα, IL1β and IFNα) alone (the āMPLA cocktailÒ: MPLA and IFNγ) or in combination with other proinflammatory cytokines (the pIC cocktail: polyIC, IFNγ, TNFα, IL1β and IFNα).
Results: Transcriptomic evaluation via cDNA array revealed almost 500 genes differently expressed among immature and the three differently matured DC. Unsupervised clustering suggested that the gene expression pattern of the gold standard DC represents an intermediate between immature and alternatively matured DC. The canonical pathways mostly upregulated in the alternative DC were involved in interaction with innate and adaptive effector cells and comprised for example many chemokine genes. Quantitative real time PCR and ELISA assays were used to validate the array data in the respective immature and mature DC subsets. In addition, the functional relevance of the differentially expressed chemokine genes in attracting immune cell subpopulations was determined.
Conclusions: The 'omi'-based identification of differentially expressed genes in vaccine DC formulations and their functional relevance will lead to the optimization of cancer immunotherapeutic approaches.

A fusion protein based pneumococcal vaccine

J. Ma,* K. S. Ross,† R. Ritchie,‡ G. Douce‡ & T. J. Mitchell§
*Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, UK, †Strathclyde Institute for Pharmacy & Biomedical Sciences (SIPBS), University of Strathclyde, Glasgow, UK, ‡Institute of Infection Immunity and Inflammation, University of Strathclyde, Glasgow, UK, §School of Immunity and Infection, University of Birmingham, Birmingham, UK

Purpose/Objective: The Gram-positive bacterium *Streptococcus pneumoniae* is a major human pathogen, causing otitis media, pneumonia, bacteremia and meningitis worldwide. Currently available vaccines are based on the capsular polysaccharide. Polysaccharide vaccines are poorly immunogenic in those most at risk of disease. More recently developed polysaccharide/protein (PS) conjugated vaccines showed increased efficacy in the at risk group, yet are too expensive for developing countries where the burden of disease is greatest. Serotype replacement and capsular switching post vaccine introduction have shown clear limitations to the long-term potential of these vaccines. There is therefore a need to develop cheap serotype independent vaccines against pneumococcal disease.
Materials and methods: Pneumolysin (PLY) acts as a powerful mucosal adjuvant to induce both systemic and mucosal immunity to proteins genetically fused to PLY after delivery intranasally or subcutaneously. In this work, *S. pneumoniae* virulence factors, PsaA, PspA, PspC and PhtD have been genetically fused to PLY and Δ6PLY, a PLY toxoid that lacks haemolytic activity but retains its immunogenic and adjuvant activity. The immune response to these fusion proteins was measured by ELISA. The ability of these fusion proteins to stimulate protective immunity against infection with *S. pneumoniae* was investigated in a murine colonisation model.
Results: Here we show that proteins genetically fused to pneumolysin (PLY) become capable of generating an antibody response that is not seen when they are administered as a mix. Serum IgG responding to PsaA, PspA, PspC and PhtD were at a level comparable to those produced by parental administration. We also report the protective efficacy of these responses in a murine colonisation model.
Conclusions: Pneumococcal antigens genetically fused to Δ6PLY are immunogenic when administered to mucosal surfaces and generate immunity that is protective in a colonisation model.

A novel adjuvant system based on insoluble H7 flagellin containing microparticles induces enhanced humoral immune responses in Quil A-adjuvanted vaccines

T. N. McNeilly,* D. Frew,* Y. Bartley,* A. Aumeunier,† C. Lyle,‡ A. Mahajan,§ D. G. E. Smith,† D. L. Gally,§ J. Vos‡ & B. D. Moore‡
*Moredun Research Institute, Vaccines, Edinburgh, UK, †Disease Control, Moredun Rsearch Institute, Edinburgh, UK, ‡Xstal Bio ltd, C.I.D.S., Glasgow, UK, §Infection and Immunity Division, Roslin Institute, Edinburgh, UK

Purpose/Objective: The saponin Quil A is a potent adjuvant capable of promoting both humoral and cell-mediated immune responses and has been successfully used in ruminant vaccinations targeting parasite hidden antigens (Hags) where protection is antibody mediated. Protection in these vaccines is critically dependent on the levels of vaccine induced Hag-specific antibodies, as Hags are effectively hidden from the host immune response and no natural boosting of the vaccine induced immune response occurs. In order to develop an enhanced Quil A-based Hag vaccine cable of inducing higher titres of antibody, we evaluated the effect of the toll-like receptor 5 (TLR5) ligand flagellin, which is known to drive Th2-polarized responses to co-administered antigen, on Quil A vaccine induced immune responses to the model antigen, ovalbumin.
Materials and methods: Four groups of sheep ($n = 6$) were immunized with either Quil A plus H7 flagellin (purified from *Escherichia coli* O157:H7) and ovalbumin incorporated into the same insoluble microparticles (H7-OVA-MP), Quil A plus H7 flagellin and ovalbumin incorporated into separate microparticles (H7-MP and OVA-MP, respectively), Quil A plus ovalbumin containing microparticles (OVA-MP) or H7-OVA-MP without Quil A. Prior to immunization, bioactivity of H7 flagellin within the microparticles was confirmed using a TLR5 reporter cell line.
Results: Significantly higher titres of anti-OVA IgG were induced following immunization with H7-OVA-MP plus Quil A or H7-MP + OVA-MP plus Quil A compared to immunization with OVA-MP plus Quil A ($P < 0.01$ and 0.05, respectively), with the highest titres observed in the H7-OVA-MP plus Quil A group. Antibody responses were critically dependent on Quil A as immunization with H7-OVA-MP without Quil A failed to induce an anti-OVA antibody response. OVA-specific lymphocyte proliferation and interferon-γ release by peripheral blood lymphocytes were highest in the OVA-MP immunized group compared to all other groups.
Conclusions: These results suggest that H7 flagellin microparticles skew the immune response generated by Quil A adjuvanted vaccines from a Th1 to a Th2-type response, and by inducing increased titres of antigen-specific antibodies may be improve the efficacy and duration of protection of existing Hag-based vaccines.

P1856

A novel replication impaired virus vaccine strategy is effective against congenital cytomegalovirus infection

A. McGregor,* K. Y. Choi,† M. Schleiss,* D. Kronneman* & M. Root*
*Medical School, University of Minnesota, Minneapolis, MN, USA, †Veterinary School, University of Minnesota, Minneapolis, MN, USA

Purpose/Objective: Congenital HCMV infection can lead to serious symptomatic disease including mental retardation and hearing loss in newborn. The greatest risk of congenital HCMV is to mothers who acquire a primary infection. Hence, the impact of a vaccine is potentially substantial. Any proposed intervention therapy for HCMV should be evaluated in a pre-clinical animal model. HCMV is extremely species-specific, making direct study of infection in animal models untenable. The guinea pig is unique as the only small animal model for congenital CMV infection using the species specific guinea pig CMV (GPCMV).
Materials and methods: We investigated a disabled infectious single cycle (DISC) vaccine strategy, where the virus lacks the ability to express an essential gene, except when grown on a complementing cell line. The minor capsid gene (UL85 homolog, GP85) was selected as it is essential for virus capsid assembly but in itself not an importnat immune target. A series of GPCMV mutants were generated via mutagenesis of an infectious BAC clone of GPCMV. In the DISC strain, the GP85 late promoter/upstream intergenic sequence was removed and a tet-off promoter and an upstream SV40 poly A cassette were substituted to place GP85 expression under strict control of a tet-off trans-activating system. Transfection of mutants onto tet-off fibroblast cells resulted in virus from the mutant BAC containing the tet-off promoter (vDISCGP85).
Results: The DISC vaccine immune response was investigated. Animals ($n = 6$) induced an anti-GPCMV antibody response (ELISA titer >1:1260; neut. titer approx. 1:160) and a cell mediated response to the pp65 and IE1 homologs, verified by a novel guinea pig INFgamma ELISPOT assay. Next, female guinea pigs ($n = 15$) were vaccinated (vDISCGP85, 10^3 pfu). All animals seroconverted and were given a booster dose and mated. At late second trimester of pregnancy animals were challenged with a pathogenic strain of GPCMV (1×10^5 pfu). A control group, non-vaccinated pregnant animals ($n = 15$) were similarly challenged. Animals were allowed to go to term and viral load in target organs of pups was analyzed.
Conclusions: Based on live pup numbers in the vaccinated and non-vaccinated groups (94.4% versus 63.6%) the vaccine strategy was successful ($P = 0.002$). Pups from the vaccinated group had zero or reduced viral load in target organs. However, the vaccine failed to prevent brain infection in all pups (11% positive in vaccinated group versus 50% in control) but the outcome was statistically significant and indicates that this is a promising new approach.

P1857

A novel virus-like particle-based anticancer vaccine using the mimotope strategy

M. Klausberger,* M. Wilde,* D. Palmberger,† W. Ernst* & R. Grabherr*
*Department of Biotechnology, Institute of Applied Microbiology, University of Natural Resources and Life Sciences (BOKU), Vienna, Austria, †Division of Biochemistry, Department of Chemistry, University of Natural Resources and Life Sciences (BOKU), Vienna, Austria

Purpose/Objective: Virus-like particles (VLPs) resemble infectious viruses in structure, are highly immunogenic and were shown to induce vigorous innate and adaptive immune response to antigens exposed on their surface. Due to their immunogenic properties, VLPs are promising candidates for vaccine strategies in serving as versatile scaffold for the delivery of a wide range of vaccine antigens * especially of epitopes that are normally difficult to evoke an immune response. In contrast to viral epitopes, antigenic determinants of cancer antigens can often be solely presented as peptide mimotopes. VLPs are well suited for the display of epitopes, however they have never been used as carrier for mimotopes. This research project deals with the utilisation of influenza VLPs as antigen-carrier platform for the presentation of a cancer-associated antigen mimotope. Immunisation studies in mice should elucidate whether the elicited antibodies are able to recognise their original epitope.
Materials and methods: Four different insertion sites in the antigenic sites A and B located in the globular head domain (HA1) on the influenza hemagglutinin (HA, H3 subtype) were tested for their capability in tolerating insertion of the 14 aa sequence of the peptide mimic. Influenza VLPs were generated using the Baculovirus Expression Vector (BEV) system and analysed by flow cytometry and Western Blot.
Results: We were able to demonstrate that insertion of the mimotope did not greatly interfere with the overall structure of some chimeric hemagglutinins, however the presentation of the mimotope needs to be optimised. In order to perform fine-tuning of the microenvironment of the peptide within the HA-frame, adjacent residues are being randomised in a library approach.
Conclusions: By introducing unique restriction sites downstream the polyhedrin promoter into the baculovirus genome, we created a platform that enables us to directly clone our HA-mimotope amplicon library into the baculovirus genome. This will allow us for convenient high-throughput screening of our clones for optimal binding characteristics of the displayed chimeric protein to the mimotope-specific mAb using FACS. Moreover, the establishment of an optimised eukaryotic expression library system should enable us to optimise the display of any epitope on a VLP carrier and thereby enhance its antigenicity.

P1858

A plant-derived oral vaccine against HBV in a tablet form

T. Pniewski,* J. Kapusta,† P. Bociag,* M. Czyz,* A. Kostrzak,‡ J. Wojas-Turek,§ E. Pajtasz-Piasecka,¶ M. Milczarek,¶ J. Wietrzyk¶ & A. Pluciennicak†
*Laboratory of Biotechnology, Institute of Plant Genetics PAS, Poznan, Poland, †Laboratory of Bioengineering, Institute of Biotechnology and Antibiotics, Warszawa, Poland, ‡Institut Pasteur, Unité de Rétrovirologie Moléculaire, Paris, France, §Laboratory of Virology, Institute of Immunology and Experimental Therapy, Wroclaw, Poland, ¶Laboratory of Experimental Anti-Tumor Therapy, Institute of Immunology and Experimental Therapy, Wroclaw, Poland

Purpose/Objective: Hepatitis B is still one of the most common human infectious diseases, despite the fact that effective anti-HBV subunit vaccines have been available for 30 years. Oral vaccines, including plant-based formulas, have been being considered as commonly available alternatives or supplements for standard injection vaccines, due to assumed low-cost production and simplified vaccination. The aim of research was to study an appropriate host producer, composition and administration protocol to make an efficient anti-HBV plant-derived oral vaccine.
Materials and methods: HBV antigens were expressed in transgenic lettuce, as confirmed by ELISA, Western blot and electron microscopy observation. Plant tissues bearing antigens were lyophilised, powdered and delivered orally to BALB/c mice as suspension in PBS or converted into tablets administered to humans. Immune responses were analysed by assay of anti-HBs antibodies and FACS analyses of T cells.
Results: Individual native HBV antigens were produced in lettuce at levels 5–200 μg/g FW. Vegetative propagation of superior producers enabled scaling-up multiplication of antigen-bearing material.

Efficiency of freeze-drying and long-term storage of plant tissues ranged vastly (10 * 90%) depending on a particular antigen. Powdered lyophilised tissue facilitated controlled oral administration and enabled conversion into tablets for human vaccination.

Relatively low antigen dosage and extended timing between immunisations correlated with higher responses. However, solely oral delivery of lyophilised tissue containing S-HBsAg induced systemic humoral response in mice at the minimal protection level (≥10 mIU/ml of anti-HBs antibodies) with higher sIgA response in intestinal mucosa and immediate stimulation of Treg lymphocytes. Yet, significant reaction was triggered by combination of injection priming and oral boosting (hundreds mIU/ml). Tablets used as a booster vaccine for humans previously immunised by a classical three-dose injection pattern, increased anti-HBs level from 0 up to 100 mIU/ml or two * threefold when pre-immune anti-HBs were detectable.

Conclusions: The prototype technology for a potent plant-derived anti-HBV oral vaccine has been developed. The study provides some basic insight into immunisation using a tablet formula which would serve as a booster component of a vaccine.

P1860
Adjuvanted influenza vaccines in young and aged BALB/c mice

K. K. Yam, J. Gupta, E. Allen & B. J. Ward
Experimental Medicine, McGill University Health Center Research Institute, Montreal, Canada

Purpose/Objective: Although influenza vaccines are generally safe, they are far from ideal. They have reduced efficacy in the groups most at risk: the very young and the elderly. To address these concerns, the vaccine industry is increasingly turning its attention to the use of adjuvants to enhance the immune responses generated by these vaccines. During the 2009 pandemic H1N1 influenza outbreak, an adjuvanted influenza vaccine was selected for administration to most Canadians; it was formulated with the oil-in-water adjuvant AS03 and contained 25% of the usual antigen dose of vaccine. This study investigated the immune responses generated following immunization with adjuvanted influenza vaccines in aged and young mice.

Materials and methods: We tested two ages of BALB/c mice (2 months, 1.4 years), two doses of Influenza A/Uruguay H3N2 split vaccine (0.75, 3 μg), and two adjuvants (AS03, alhydrogel). Mice were given two intramuscular immunizations 3 weeks apart. Serum was collect before and 3 weeks after each immunization. Three weeks following the final immunization, mice were sacrificed and the immune status was investigated in splenocytes.

Results: The use of an adjuvant increased serum hemagglutination inhibition (HAI) titers compared to vaccination with antigen alone. With both adjuvants, we found no significant difference between using the low or high antigen doses, and at all immunization conditions tested, aged mice produced significantly lower HAI titers than young mice. Furthermore, in aged mice, AS03 was found to be the stronger adjuvant for the induction of influenza-specific cellular immune responses. With AS03, aged mice were able to produce equivalent levels of influenza-specific splenocyte proliferation and cytokine secretion (IL-4, IL-5) as young mice.

Conclusions: Following immunization, aged mice produce lower antibody responses in comparison to young mice; however, the use of the oil-in-water adjuvant AS03 can induce some cellular immune responses in aged mice to levels that are equivalent to young mice. We are investigating additional differences in the immune responses of young and aged mice with a goal of designing more effective vaccines, especially for the elderly.

Analysis of the vaccine induced immune response against the abomasal parasite *Ostertagia ostertagi* in cattle suggests a pivotal role for NK cells

S. Van Coppernolle, F. Van Meulder, B. Mihi, I. Peelaers, J. Vercruysse, E. Claerebout & P. Geldhof
Virology Parasitology and Immunology, Ghent University, Merelbeke, Belgium

Purpose/Objective: Control of gastrointestinal nematodes by vaccination would offer a valuable alternative to the use of anthelmintic drugs. However, the development of such vaccines is largely hampered by a lack of knowledge on the protective immune responses needed against these parasites. In this study, the immune responses to three different experimental vaccines against the abomasal nematode *Ostertagia ostertagi* in cattle were analysed and compared: the protective native ASP (nASP) + QuilA vaccine, and two non-protective versions of this vaccine, one combining nASP with $Al(OH)_3$ and one combining recombinant ASP (rASP) with QuilA.

Materials and methods: Three groups of four animals were immunized with the vaccines three times intramuscularly with 3-week interval. After the final immunization, all animals were challenged with 1000 infective L3 larvae/day until necropsy 5 weeks later. Mononuclear cells (MC) isolated from peripheral blood (PB) were phenotyped weekly during the experiment and their *in vitro* proliferation to the vaccine antigens analysed. At necropsy, MCs from the abomasal mucosa and lymph nodes (LN) were collected and analysed as described above and mucosal antibody levels induced by the vaccinations were measured.

Results: No significant changes in frequencies of ab T cells, gd T cells, natural killer (NK) cells and B cells in PB were observed following vaccination. Both nASP/QuilA and rASP/QuilA vaccination resulted in detectable *in vitro* proliferation of PBMC to vaccine antigens, with markedly the highest proliferation in the nASP/QuilA vaccinated animals. The proliferating cells were identified as NK cells. At necropsy, no significant changes were observed in frequencies of ab T cells, gd T cells, NK cells and B cells in the abomasal mucosa and LN. Although MC isolated from the abomasal LN of all animals responded to nASP, likely caused by the challenge infection, proliferation was highest in the nASP/QuilA vaccinated group, again with NK cells being the strongest responders. Analysis of the mucosal antibody response indicated a significant increase in ASP-specific IgG1 levels in the nASP/QuilA vaccinated animals.

Conclusions: The outcome of this study suggests a previously unidentified role for NK cells and IgG1 antibodies in vaccine induced immunity against gastrointestinal parasites.

P1862
Antigen delivery by ß-sheet aggregated protein potentiates efficient immune response

J. H. Huang,* A. P. Bussink,* C. S. Seinen,* T. M. Poplonski,* M. F. B. G. Gebbink† & T. Mutis*
**Department of Clinical Chemistry and Haematology, UMC Utrecht, Utrecht, Netherlands, †Crossbeta Biosciences, Utrecht, Netherlands*

Purpose/Objective: The accumulation of β-sheet aggregates, such as amyloids or amyloid-like proteins, is a hallmark of protein misfolding diseases as this structure element is absent in natively folded proteins. Although the role of the immune system in the progression or control of these diseases has been widely studied, the connection between β-aggregation and its immunological effects remains unclear. Here we demonstrate that β-sheet aggregates act as important adjuvant of cellular immune responses.

Materials and methods: We used the well-established model antigen ovalbumin (OVA) and its transgenic mice for our study. Employing a

standardized thermic misfolding technology, we induced b-sheet aggregates in OVA (cbOVA). Uptake was accessed by confocal microscopy and flow cytometry; while processing and presentation was measured by cytokine release and cellular proliferation. Blocking antibodies to scavenger receptors (SR) and SR-A knockout mice were used to determine the receptor mediating the uptake.
Results: cbOVA was generated by misfolding native OVA thermically. DCs that were pulsed with cbOVA showed improved antigen presentation via both MHC class I and class II pathways, enabling OVA specific $CD4^+$ and $CD8^+$ T cell priming, proliferation and Th1-like cytokine production. cbOVA is taken up more efficiently in DC, but it does not maturate DC nor does it induce inflammasome activation. Pre-incubation of cbOVA with specific b-sheet aggregation structure ligand FnF4-5 would inhibit its uptake and presentation. Moreover, coupling the $CD8^+$ T cell epitope to b-sheet forming peptides induced robust T cell response. Finally, we found uptake and presentation of cbOVA is mainly mediated by SR-A.
Conclusions: We demonstrated that β-sheet aggregation significantly improves immunogenic properties of misfolded proteins and peptides by enhanced uptake into DCs via a SR-mediated fashion. Furthermore, we identified SR-A as one of the major receptors that mediates the stimulatory effect of b-sheet aggregation structure. Given the notion that controllable b-sheet aggregation is inducible in most proteins, we propose that our fundamental study may be highly relevant for future vaccine design; paving ways to a widely applicable, simple and reproducible technique.

P1863
Antigen size impacts on duration of antigen presentation and dictates Tfh development

R. A. Benson, P. Garside & J. M. Brewer
Institute of Infection Immunity and Inflammation, College of Medical-Veterinary & Life Sciences, Glasgow, UK

Purpose/Objective: Revealing the fundamental processes controlling the initiation, maintenance and phenotype of an adaptive immune response will make a significant contribution to rational vaccine design. Previous approaches have overcome the inherently low immunogenicity of subunit vaccines through combination with particulate delivery systems e.g. biodegradable polymers and liposomes. While each delivery system has its own merits, it is unclear how changing the physical characteristics of a vaccine antigen could impact on the magnitude and duration of antigen persistence and presentation *in vivo*, and the impact this has on the subsequent adaptive immune response. By modulating delivery of antigen to the LN simply by changing particle size, we aimed to establish the functional outcome for specific T and B cell responses and the potential mechanisms underlying this.
Materials and methods: Proteins covalently linked to inert nanospheres of varying size were used as particulate antigen. The EαGFP protein combined with the monoclonal antibody YAe were used to determine kinetics of peptide/MHCII presentation. An established adoptive transfer model using TcR transgenic T cells and BcR transgenic B cells was used to study functional antigen specific responses.
Results: Challenge with a 200 nm particulate antigen promoted sustained peptide/MHCII presentation by DCs. 200 nm antigen also promoted differentiation of T follicular helper cells (Tfh), supported germinal centre responses and enhanced antibody production. Smaller particulate (40 nm) and soluble antigen were able to drive T cell proliferation but without sufficient differentiation of Tfh cells to support germinal centre or antibody responses.
Conclusions: With the increased focus on using particulate delivery systems to target LN resident cells in vaccination strategies, our data reveal a rationale for antigen delivery strategies to promote high affinity class switched antibody responses.

P1865
Apolipoprotein B-100 peptide conjugate confers tolerogenic properties to dendritic cells

S. Rattik, H. Björkbacka, G. Nordin-Fredrikson, J. Nilsson & M. Wigren
Clinical Sciences, Lund University, Malmö, Sweden

Purpose/Objective: We have previously shown that immunization with an apolipoprotein B peptide vaccine (aBp210), with peptide 210 coupled to cationized BSA (cBSA), decreases the development of atherosclerosis with up to 60%. Further studies have demonstrated the involvement of T regulatory cells (Tregs) as a part of the protective mechanism. Moreover, our studies also point towards an independent role of cBSA in reducing atherosclerosis. Therefore, we investigated the effect of these individual vaccine components on dendritic cells (DC), $CD4^+$ T effector cells and Tregs in an *in vitro* setting to further elucidate the protective mechanism behind the aBp210 vaccine.
Materials and methods: $CD11c^+$ DCs, T effector cells ($CD4^+CD25^-$) and Tregs ($CD4^+CD25^+$) are isolated from mouse C57Bl6 spleens. T effector cells are pre-activated using plate bound anti-CD3 and DCs plus Tregs are co-cultured together with antigen (p210-cBSA, cBSA or BSA) over night. The pre-activated T effector cells are then cultured with DC/Tregs for 72 h and proliferation is measured after 16 h of [3H]Thymidine incorporation.
Results: Results from our *in vitro* assay demonstrate that both cBSA and p210-cBSA when pre-incubated with DCs and Tregs overnight are able to inhibit the proliferation of anti-CD3 activated T effector cells in a dose dependent manner. The suppressive effect of cBSA was dependent on the cationization as BSA in itself was without effect. Adding the antigen directly to polyclonally activated T effector cells did not suppress proliferation. Moreover, the inhibition of proliferation was associated with a dose dependent decrease in IL-12 production and addition of IL-12 to the culture system could completely remove the inhibitory effect of p210-cBSA.
Conclusions: Our findings suggest that p210-cBSA induce tolerogenic dendritic cells by inhibiting their IL-12 production in a dose dependent manner. This might be one of the protective mechanisms behind aBp210s role in inhibiting atherosclerosis and vascular inflammation. cBSA is a common carrier used in vaccine formulations such as aBp210. Here, we are also able to show a direct immune-suppressive effect of cBSA, reducing the proliferation of T effector cells. These observations suggest that cBSA is an attractive carrier in vaccines aiming to induce tolerance.

P1867
Association of Th17/Treg in NALT with pneumococcal carriage in children and adults

A. Mubarak,* A. Kasbekar,† M. McCormick,‡ H. Beer,‡ N. Cunliffe,* P. S. McNamara† & Q. Zhang*
**Department of Clinical Infection Microbiology and Immunology, Institution of Infection and Global Health, Liverpool, UK, †Alder Hey Children's Hospital, Liverpool, UK, ‡ENT Department, Royal Liverpool University Hospital, Liverpool, UK*

Purpose/Objective: Background: CD4+CD25+ Regulatory T (Treg) cells play an important role in the regulation of the immune response to infection, whereas Th17 have been suggested to be crucial in bacterial clearance from the host. In this study, we have studied the association between the ratio of Th17/Treg cells and nasopharyngeal carriage of pneumococcus in children and adults. We have also studied

the induction of those cells by pneumococcus in human nasal-associated lymphoid tissue (NALT).
Materials and methods: Methods: Mononuclear cells (MNC) from adenotonsillar tissues were isolated from children and adults undergoing adenotonsilectomy. Treg and Th17 cells were enumerated in adenotonsillar MNC by intercellular staining of Foxp3 and IL 17 with or without stimulation by concentrated pneumococcal culture supernatant (CCS) derived from a type II pneumococcus D39. IL-17 production in adenotonsillar MNC was measured by ELISA.
Results: There was a significant difference in the proportion of Th17 in adenotonsillar MNC between adults and children, which was higher in the former in whom pneumococcal carriage was low. The same trend was also shown in the ratio of Th17/Foxp3+ Treg between adults and children. There was a significant increase in both Treg and Th17 in adenotonsillar MNC after stimulation by the pneumococcal CCS. Significant increase in IL17 production in adenotonsillar MNC after CCS stimulation was shown by ELISA.
Conclusions: It is suggested that the development and balance of Th17 cells and Foxp3+ Treg in the local mucosal immune tissues play an important role in modulating the specific immunity against pneumococcal carriage in humans.

Cellular and humoral immunity elicitated by influenza vaccines in pediatric hematopoietic-stem cell transplantation

M. Duchamp,* V. Guerin-El Khourouj,* A. Krivine,† B. Pedron,* M. Ouachee-Chardin,‡ K. Yakouben,‡ A. Baruchel,‡ J. H. Dalle‡ & G. Sterkers*
**Laboratory of Immunology, Robert Debre Hospital, Paris, France, † Department of Virology, Cochin Hospital, Paris, France, ‡Department of Haematology, Robert Debre Hospital, Paris, France*

Purpose/Objective: Immunity induced by influenza vaccines following hematopoietic stem-cell transplantation (HSCT) is poorly known.
Materials and methods: In this case serie study, proliferative T-cell and humoral responses to influenza vaccines evaluated vaccine immunogenicity in 14 pediatric recipients (mean age: 6 years). Cases were vaccinated against the 2009 H1N1 pandemic strain (H1N1pdm2009), either alone ($n = 9$) or in association with the seasonal trivalent vaccine ($n = 5$). Median lag time from HSCT to vaccination was 5.7 months. The nature of HSC was HLA-identical related bone marrow graft in 10/14 recipients. Fourteen age-matched non-vaccinated recipients were included as controls. In addition, cytokine (IL2 and IFN-gamma) responses to influenza were evaluated by an intracellular accumulation method in part of the recipients.
Results: Vaccinees opposed to non-vaccinated recipients evidenced higher proliferative responses to H1N1 ($P = 0.0001$; median stimulation index: 42 versus 1; median lag time from HSCT to investigation: 335 days in both groups) and higher titers of antibodies specific for the 2009 H1N1 pandemic strain ($P < 0.02$; geometric mean: 160 versus <10; median lag time from HSCT to investigation: 107 days). Specifically, 11/14 (79%) vaccinees evidenced proliferative responses to H1N1, of whom 5/7 evaluable had protective (>1/40) antibody titers. Five out of seven recipients vaccinated against H1N1 but not against H3N2, evidenced proliferative responses to both H1N1 and H3N2 strains (median stimulation-index: 96 and 126 respectively). Finally, IL2 responses predominated over IFN-gamma responses ($P < 0.02$) to influenza viruses in responders.
Conclusions: Influenza vaccination elicitated substantial cell-mediated immunity and to a lesser extent protective humoral immunity at early times post-HSCT in this pediatric series. Monovalent H1N1pdm2009 vaccine induced cross-reactive T-cell responses to seasonal H1N1 and H3N2 strains. Protective (IL2) rather than effector (IFN-gamma) cytokinic profiles were elicitated.

P1869

Cellular immune response to influenza A (H1N1) pandemic vaccine in kidney transplant (KTR) or HSCT recipients, HIV infected and SLE immunocompromised populations

N. Le Corre,* A. Guihot,* B. Barrou,† N. Dhédin,‡ A. Mathian,§ A. Samri,* C. Katlama,¶ Z. Amoura§ & B. Autran*
**Département d'Immunologie Cellulaire et Tissulaire Hôpital Pitié Salpêtrière, INSERM UMRS 945, Paris, France, †Service d'Urologie, Hôpital Pitié-Salpêtrière, Paris, France, ‡Service d'Hématologie, Hôpital Saint Louis, Paris, France, §Service de Médicine Interne 2, Hôpital Pitié Salpêtrière, Paris, France, ¶Service de Maladies Infectieuses et Tropicales, Hôpital Pitié Salpêtrière, Paris, France*

Purpose/Objective: Influenza vaccines are recommended for immunosuppressed patients. Cellular response to vaccines is essential for a long term protection, but has not been characterized in these patients. We evaluated the cell responses to the inactivated influenza A (H1N1)v 2009 vaccine in different immunocompromised patients.
Materials and methods: The study included 125 patients receiving: A one or two doses of influenza H1N1 pandemic vaccine with adjuvant in 36 treated HIV-infected patients [18 with maraviroc, a CCR5 antagonist (MVC), and 18 without] and 30 HSCT recipients B two doses of the non-adjuvanted vaccine in 29 KTR and 30 SLE patients. H1N1v-specific CD4 and CD8 T cells producing IFNγ, IL2, TNFα, MIP1β or expressing CD40L were evaluated at D0, D21, D42 and M6/M9 of vaccination using intracellular cytokine staining with overlapping H1N1v 2009 hemagglutinin peptides.
Results: In group A, frequencies of H1N1v-specific CD4, but not CD8, T cells significantly increased after one dose at D21 and M6 in non-MVC patients ($P = 0.023$, $P = 0.021$) but not in MVC patients, and only after two doses in HSCT patients ($P = 0.04$). Only frequencies of H1N1v-specific CD8 T cells at D21 differed between the non-MVC patients and HSCT recipients ($P = 0.03$). Similar proportions of responders, defined as twofold increase in frequencies of H1N1v-specific T cells from D0 to D21, D42 or M6/M9, were identified in 38%, 50% and 50% for CD4 and 61%, 55% and 45% for CD8 T cells in MVC patients, non-MVC patients and HSCT recipients respectively. In group B, a significant increase in frequencies of H1N1v-specific CD4 T cells were detected from D0 to D21 in SLE patients ($P = 0.02$) but not in KTR. Proportions of responders were twofold higher in SLE (70%) than in KTR (34%) for CD4 T cells and 70% versus 51% for CD8 T cells in SLE and KTR patients respectively. Among responders, a significant increase in frequencies of H1N1v-specific CD4 and CD8 T cells was observed until M9 in KTR ($P = 0.01$ and 0.007) but not for SLE patients.
Conclusions: The pandemic influenza A-H1N1v vaccine, whether adjuvanted or not, induced only modest T cell responses in these different immunocompromised populations. Patients characteristics seem to influence both short and long term protection and the benefits of the adjuvant or the 2nd dose, indicating new strategies are required to improve the immunogenicity of vaccination in these immunocompromised patients.

**Christian Doppler Laboratory for Immunomodulation, Institute of Immunology, Medical University of Vienna, Vienna, Austria, †Institute of Immunology, Medical University of Vienna, Vienna, Austria*

Purpose/Objective: Decoration of VNP with functionally active, immunomodulatory molecules enhances particle immunogenicity and

promotes selective immune recognition of the antigens they bear. In this study we investigated the influence of membrane characteristics of artificially membrane-bound cytokines applied as 'natural adjuvants' to improve the immunogenicity of VNP co-expressing viral antigens.
Materials and methods: One (1Ig), two (2Ig) or four (4Ig) immunoglobulin (Ig)-like domains of CD16b were inserted between the model cytokine Interleukin 2 (IL 2) and the minimal GPI-anchor acceptor sequence of CD16b (GPI). We compared targeting of IL 2 fused to different membrane anchors to lipid rafts and VLP and tested the influence of the membrane anchor on the biological activity and co-stimulatory potency in antigen-specific and non-specific assays.
Results: We identified a membrane anchor * '2IgGPI' * conferring an up to 10-fold increase of targeting of IL 2 onto VNP, when compared to the minimal GPI-anchor acceptor sequence. This effect was particularly prominent in cases where additional molecules were targeted onto VNP and space seemed to be restricted. When co-expressed on VNP with H2-D^b presenting the lymphocytic choriomeningitis virus glycoprotein peptide 33−41 (LCMV-GP_{33-41}), as antigen-specific signal 1, IL 2::2IgGPI was superior to IL 2::GPI to co-stimulate proliferation of primary LCMV-GP-specific P14 TCR transgenic T-cells *in vitro*, particularly when antigen was limited. Correspondingly, the proportion of IFNγ producing and $CD107^+$ $CD8^+$ antigen-specific T cells was significantly increased. Upon *in vivo* challenge of mice with antigen-specific VNP co-expressing IL-2::2Ig-GPI larger proportions of adoptively transferred LCMV-specific T-cells proliferated when compared to IL-2::GPI co-expressing VNP. Corresponding loss-of-function variants of IL-2 induced consistently less pronounced T-cell proliferation.
Conclusions: The requirements for the optimal biological activity of artificially membrane-anchored cytokines decorating VNP used as convenient immunization platform cannot be predicted *a priori* but has to be evaluated *in vitro* and *in vivo* with scrutiny.

Comparison of the efficacy of protein and adeno−based influenza vaccines targeting M2e

A. Andersson, P. J. Holst, A. R. Thomsen & J. P. Christensen
Faculty of Health and Medical Sciences, University of Copenhagen, Isim, Copenhagen, Denmark

Purpose/Objective: There is an urgent need for a more practical influenza vaccine that can be used not only during seasonal epidemics but also in the event of occasional pandemics. Whereas recent focus has been placed on targeting conserved sites on the major glycoprotein hemagglutinin (HA), due to the variability of this protein, it faces the dilemma of only inducing group specific protection. The highly conserved ectodomain of the M2 protein (M2e) has been presented as a promising alternative target since it is conserved amongst all human strains. Our previous results showed that a protein mimicking the tetrameric conformation of M2e (named M2e-NSP4) was superior to an M2e peptide in immunogenicity at low protein concentrations and at providing local early protection. In this complementary study we made a comparison between the M2e peptide, the tetrameric M2e vaccine, and two adeno viral based vaccines encoding three M2e's linked to the invariant chain and the whole M2 sequence respectively.
Materials and methods: Balb/c mice were immunized with either M2e peptide or the M2e-NSP4 protein. In a separate experiment, balb/c mice were primed twice with DNA-gold encoding three M2e's linked to the invariant chain (M2e × 3Ii) and the whole M2 (M2) sequence respectively, and then boosted with adenoviral vaccines encoding the same antigen. The mice were challenged with a lethal dose of influenza A PR8 2 weeks the adenoviral immunization. Serum samples from both the peptide/protein and the adenoviral vaccine experiment were analyzed in a M2e peptide based ELISA assay and in a HeLa-M2 cell based FACS assay.
Results: Interestingly, DNA-gold priming twice followed by adenoviral vaccine boost using either antigen design, induced an increased number of antibodies recognising the native M2 protein as presented on HeLa-M2 cells compared to either M2e peptide and M2e-NSP4 vaccine. However, in a PR8 challenge model comparing only the adenoviral vaccines, the M2 group was inferior to the M2e × 3Ii group.
Conclusions: The results presented here, suggest that a protective correlate of M2e based vaccination cannot simply be deduced from M2 binding, but are potentially influenced by other factors such as isotype of IgG and/or T cell responses.

CrossTope: a curate repository of three-dimensional structures of MHC: epitope complexes

G. F. Vieira, D. A. Antunes, M. M. Rigo, J. A. B. Chies & M. Sinigaglia
Genetics, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

Purpose/Objective: The CrossTope is the first repository of three-dimensional structures of peptide: MHC complexes, including curated data on immunogenicity, similarity relationships and cross-reactivity.
Materials and methods: The complexes hosted by this databank were obtained in protein databases and by large-scale *in silico* construction of MHC: peptide structures, using a new approach (D1-EM-D2 − *Docking1-EnergyMinimization-Docking2*) developed by our group. In both modeled structures and those acquired in databases, we included only non-redundant structures containing immunogenic epitopes with experimental evidence supporting this feature (in the case of two deposited structures in proteins database from the same MHC: peptide complex, we chose the structure presenting better resolution).
Results: At this moment the database contains 182 *non-redundant* MHC: epitope complexes (169 models and 13 crystals) from two human (HLA-B*27:05 and HLA-A*02:01) and two murine alleles (H2-Kb and H2-Db). A web server (http://www.crosstope.com.br) provides interface for database query. The user can download the (1) structures files in .pdb extension (2) topology and charge distribution files (-5 and -10 kiloteslas), in .jpg format, from the TCR-interacting surface of MHC: epitope complexes. The files can also be viewed online. The retrieved structures and topological maps can be used to cluster similar epitopes in cross-reactivity approaches (i.e. using HCA − Hierarchical Cluster Analysis), to analyze viral escape mutations in a structural level or even to improve the immunogenicity of tumor antigens.
Conclusions: In this way, CrossTope database opens a way for the exploration of an additional level of complexity on immunogenic epitopes, the comparison at the molecular level, hitherto confined to analysis of scarce pMHC complexes.

Cytokine-mediated modulation of coronavirus vector-induced antitumor immunity

C. G. Cruz,* C. Perez-Shibayama,* M. Nussbacher,* L. Cervantes-Barragan,† R. Züst,‡ V. Thiel* & B. Ludewig*
**Cantonal Hospital St. Gallen, Institute of Immunobiology (IMMBIO), St. Gallen, Switzerland, †Department of Pathology and Immunology, Washington University School of Medicine, St. Louis, MO, USA, ‡Agency for Science Technology and Research, Singapore Immunology Network, Singapore, Singapore*

Purpose/Objective: Efficient vaccination against infectious agents and tumors depends on specific antigen targeting to dendritic cells (DCs).

The use of viral vectors represents a superior strategy to elicit both innate immune activation and optimal induction of T cell immunity. We recently described a novel biosafe coronavirus-based vaccine approach that facilitates delivery of viral or tumor antigens to DCs *in vivo* (Cervantes-Barragan *et al.*, 2010, MBIO e00171-10). Since the microenvironment during T cell priming is of great importance for the outcome immune response (i.e. memory or effectors activities), we designed vectors containing either 'myeloid' (Flt3L) or 'lymphoid' cytokines (IL-2 or IL-15) together with a viral model antigen.
Materials and methods: Vectors were produced from cloned cDNA using purified vaccinia virus DNA and cytokine production after vector administration was measured by ELISA. Lewis lung carcinoma and B16 melanoma cells encoding for the viral model antigen were used to assess both prophylactic and therapeutic vaccination regimen.
Results: Single immunization with only 10^5 cytokine-encoding coronavirus-based particles was sufficient to elicit vigorous expansion of antitumor $CD8^+$ T cells, and to achieve prophylactic and therapeutic tumor immunity. Importantly, the Flt3L-encoding vector elicited superior immune responses response showing protective antitumor immunity at doses as low as 100 particles.
Conclusions: Taken together, we have developed a novel coronavirus-based vaccine approach that facilitates antigen delivery to DCs and allows for immune-modulation through expression of different cytokines.

P1874
Development of a therapeutic vaccine against chronic Hepatitis C virus infection

P. P. Ip, J. Wilschut & T. Daemen
Medical Microbiology Molecular Virology Sector, GUIDE, Groningen, Netherlands

Purpose/Objective: Approximately 170 million people worldwide are chronically infected with Hepatitis C virus (HCV). There is no effective vaccine available. Treatment with a combination of pegylated interferon-a and ribavirin, which is associated with a high toxicity, is effective in <50% of these chronically infected patients. HCV resolution in acute patients is correlated with vigorous and broad spectrum of both CD8 and CD4 T cells responses demonstrating that the cellular immune system in principle has the potency to develop an effective anti-HCV response. The aim of our study is to increase and broaden HCV-specific immune responses to control viral replication and eliminate the virus.
Materials and methods: We developed a novel immunization strategy based on a viral vector derived from the alphavirus, Semliki Forest Virus (SFV). We generated different SFV replicon particles encoding various part of non-structural proteins (nsPs) of HCV. The expression of nsPs in infected BHK21 cells was measured by ^{35}S-methionine labeling. While the immune-stimulating potency of these rSFV replicon particles was studies *in vivo* by prime and boost intramuscular immunizations in C57BL/6 mice. IFNg production, degranulation and CTL activity of HCV-specific T cells were analyzed *ex vivo*.
Results: Here we show that these SFV replicon particles *in vitro* produce significant amount of nsPs. Furthermore, mice immunized with SFV replicon particles encoding either all nsPs or NS3/4A induces comparable amount and activity of HCV-specific cytotoxic T cell against an HCV NS3 peptide.
Conclusions: In this study we demonstrate that SFV replicon particles can encode foreign nucleotides up to 6 kb (all nsPs) without affecting the immunogenicity of the proteins expressed. This may enable our goal to broaden the HCV-specific response. By augmenting both breadth and strength of HCV-specific cellular immune response, HCV-infected cells could be eliminated, lowering the viral burden. In summary, we show that an SFV vector-based vaccine is a potential candidate for the induction of wide and robust HCV-specific cellular response. Further analysis on the specificity of T cells against other nsPs epitopes will be performed. Next we will explore strategies to augment antiviral efficacy that do not affect healthy liver tissue.

Development of an improved recombinant MVA vaccine vector able to induce strong innate and adaptive immune responses

H. Lauterbach,* J. Pätzold,* R. Kassub,* B. Bathke,* K. Brinkmann,† P. Chaplin,‡ M. Suter§ & H. Hochrein*
**Bavarian Nordic GmbH, Immunology Research, Martinsried, Germany, †Vaccine Development, Bavarian Nordic GmbH, Martinsried, Germany, ‡Infectious Diseases Division, Bavarian Nordic GmbH, Martinsried, Germany, §Dekanat Vetsuisse Faculty, University of Zurich, Zurich, Switzerland*

Purpose/Objective: Vaccines against cancer and pathogens such as HIV and Plasmodium falciparum need to induce high numbers of multi-functional antigen-specific CD8 T cells. While replicating viral vectors efficiently induce CTL responses, safety concerns restrict their usage. A combination of good CD8 T cell inducing capacities and a favorable safety profile is given with MVA-BN®, a replication deficient derivative of CVA.
Materials and methods: In order to further enhance innate and adaptive immune responses after MVA immunization, we generated a recombinant vector expressing a TNF superfamily member and the model antigen Ovalbumin.
Results: This new vector amplified DC activation and cytokine synthesis *in vitro* and *in vivo*. Antigen-specific primary and memory CD8 T cell responses were drastically enhanced. Importantly, the generated CTLs also showed improved functionality as demonstrated by intracellular cytokine staining and *in vivo* killing activity. The superior CTL responses were able to protect B cell deficient mice against a fatal virus infection.
Conclusions: Taken together, we developed a new recombinant vaccine vector, able to induce strong CTL responses with enhanced functionality.

P1876
Evaluation of adenovirus-based single antigen-administration schedules for immunization against retrovirus infection in mice

S. Windmann, M. Kaulfuss, U. Dittmer & W. Bayer
**Institute for Virology, University Hospital Essen, Essen, Germany*

Purpose/Objective: Adenovirus (Ad)-based vectors are very potent tools for the induction of strong CTL responses, and we have developed a so-called expression-display vector that induces strong $CD4^+$ T cell and antibody responses against an antigen that is encoded and displayed on the Ad capsid. As repeated administrations of Ad vectors can quickly give rise to anti-vector immunity, we aimed at establishing a vaccination protocol based on single administrations of the respective vectors. Experiments were performed in the Friend retrovirus model in mice.
Materials and methods: Highly FV susceptible mice were immunized with an adenoviral vector encoding a fusion protein of murine thioredoxin and an FV CTL epitope, or with an adenoviral gp70 expression-display vector that encodes and displays a fusion protein of FV Env gp70 and the Ad capsid protein pIX. Each vector was administered once, either following one another or as a single immunization in the presence of pre-existing anti-Ad immunity. Immune responses and protection from FV challenge were analyzed.
Results: The order in which vectors were administered proved crucial for the vaccination outcome. The single application of a CTL inducing vector is sufficient for induction of a robust CTL response, but is significantly hampered if the other vector was applied first. Antibody

responses induced by the gp70 expression-display vector were not hampered by anti-vector immunity, but were actually enhanced, probably due to help from anti-Ad $CD4^+$ T cells. The combination of a first immunization with a CTL inducing vaccine, followed by immunization with an expression-display vector, proved to be the most effective and conferred a high degree of protection against high-dose FV challenge.

Conclusions: We present a potent vector combination that is highly effective for immunization against retrovirus infection.

P1877

Evaluation of baculovirus production in three insect cell lines for standardized gene delivery in humans and animals

M. Wilde,* M. Klausberger,* D. Palmberger,† W. Ernst* & R. Grabherr*

**Department of Biotechnology, Institute of Applied Microbiology, Vienna, Austria, †Division of Biochemistry, Department of Chemistry, Vienna, Austria*

Purpose/Objective: The Baculovirus and insect cell expression system has been efficiently used for the production of heterologous proteins and recently gained importance as gene-delivery platform for gene therapy and vaccination in humans and animals.

Aside the systems' benefits, there still remains a bottleneck in determining the baculovirus titer in a reproducible way. Usually, baculoviral products almost exclusively rely on the *Spodoptera frugiperda* (Sf9) insect cell line for titer determination. It has been shown that virus generated in Sf9 cells, which was subsequently titered on Sf9, High Five and the BTI-*Tnao38* insect cell line, yielded different results (Hashimoto *et al.*, 2010). We propose that there exist differences in respect to the cell line used.

Materials and methods: The above mentioned 3 insect cell lines BTI-*Tnao38*, High Five and Sf9 were infected with various baculovirus constructs. Viral titer was determined on all the three cell lines by plaque assay and endpoint dilution assay. Real-time PCR was performed to determine the overall number of viral particles.

Results: Comparison of the three insect cell lines showed cell line dependent effects. Differences were found in respect to infection with different Multiplicities of Infection (MOIs) and subsequent harvesting at various time points. The baculovirus envelope protein gp64 was found to be less present in virus generated in BTI-*Tnao38* and High Five cells compared to Sf9.

Conclusions: Cell line dependent variations are suggested to function as basis to gain further insights on determination of the accurate dose of baculovirus-derived vaccine and gene-therapy products and may support the manufacturing of a baculovirus reference material for inter-laboratory comparison.

P1879

Genetically engineered chimeric molecules targeting influenza A viral antigen

N. Mihaylova,* N. Kerekov,* J. Prechl,† N. Ivanovska* & A. Tchorbanov*

**Immunology, Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria, †Immunology Research Group, Hungarian Academy of Sciences, Budapest, Hungary*

Purpose/Objective: The use of live and attenuated strains of microbes and viruses for vaccination comprises the risk of evoking B and (or) T cell epitopes possessing undesirable characteristics. This necessitates the application of epitope-specific vaccines. DNA vaccination using naked DNA encoding viral antigens has the potential to induce both humoral and cellular immune responses as live attenuated viral vaccines do. We hypothesized that sequences encoding an epitope of virus hemagglutinin (IP) attached to sequences encoding a scFv antibody fragment against co-stimulatory cell surface receptors (complement receptors 1/2 on mouse B cells or FcγRI on human monocytes) would result in the *in vivo* expression of a chimeric viral peptide with increased immunogenicity.

Materials and methods: Gene and protein engineering; Protein expression; DNA immunization; ELISA; Cytotoxic assay.

Results: The DNA constructs were engineered by linking of sequences encoding the scFv antibody fragment against the appropriate receptor and IP peptide representing a conserved epitope of influenza A virus hemagglutinin. Each DNA construct ends with either human oncogene Fos or Jun. We have inserted the DNA constructs into protein expression vector system and used them as naked DNA vaccine. Serum antibodies against the viral peptide from DNA injected animals were measured with ELISA. The cell-mediated immune response induced in the animals was evaluated using a cytotoxic assay.

An immunization with a DNA plasmid containing the described construct induced a strong anti-influenza cytotoxic response lasting for more than 6 months. After prime-boosting with protein chimeric molecule we obtained anti-influenza cytotoxic and antibody response.

Conclusions: Immunization of mice with pure DNA, encoding the antigen of interest attached to a scFv antibody fragment to positive receptors, followed by prime-boosting has been successfully used to induce protective immunity against a model pathogen. An analogous type of engineered molecule could be used for the treatment of other experimental viral or bacterial infections and different peptide epitopes could be used.

P1880

Glycosylation matters: role of viral hemagglutinin *N*-glycosylation in immunogenicity

J. Hütter,* J. Rödig,† D. Höper,‡ U. Reichl,† P. H. Seeberger,* E. Rapp† & B. Lepenies*

**Biomolecular Systems, Max-Planck-Institute of Colloids and Interfaces, Potsdam, Germany, †Bioprocess Engineering, Max-Planck-Institute for Dynamics of Complex Technical Systems, Magdeburg, Germany, ‡Friedrich-Loeffler-Institute, Institute of Diagnostic Virology, Greifswald-Insel Riems, Germany*

Purpose/Objective: One of the major players in influenza virus virulence is the glycoprotein hemagglutinin (HA). Most influenza vaccines target HA to elicit protective immunity. Innovative influenza vaccine production in mammalian cell lines as an alternative to conventional virus propagation in chicken eggs gets more and more into focus. Besides virus strain and subtype, the host cell line used for influenza virus production determines HA *N*-glycosylation. Due to an increasing demand for cell-line based influenza vaccines it is of special interest in which way differential glycosylation of viral proteins affects their immunogenic properties.

Materials and methods: In this study, we investigated the impact of the differential *N*-glycosylation patterns of two influenza A PR/8/34 (H1N1) variants on immunogenicity. Splenocytes from TCR-HA transgenic mice (all T cells express a TCR$\alpha\beta$ specific for the $HA_{110*120}$ peptide presented by $I\text{-}E^d$ MHC class II molecules) were stimulated with MDCK cell-derived (M-variant) or Vero cell-derived (V-variant) influenza virus preparations. Cytokine production and the expression of T cell activation markers were analyzed to determine the impact of HA *N*-glycosylation on immunogenicity. Next-generation pyrosequencing validated the congruence of the potential HA *N*-glycosylation sites and the presence of the $HA_{110-120}$ peptide. Additionally, influenza virus preparations were natively deglycosylated by a mixture of endo- and exoglycosidases to confirm that observed effects were glycosylation-dependent. Furthermore, mice were immunized with the fully glycosylated as well as the deglycosylated influenza glycovariants.

Results: TCR-HA transgenic splenocytes stimulated with the V-variant up-regulated the T cell activation marker CD69 faster and produced significantly more IL-2 than cells stimulated with the M-variant. Similar results were obtained *in vivo*. Co-cultivation assays with dendritic cells (DCs) and T cells indicated that this difference in immunogenicity was mediated by $CD11c^+$ DCs. Native virus deglycosylation dramatically reduced cytokine production by splenocytes.
Conclusions: In conclusion, we show that influenza HA *N*-glycosylation markedly affects immunogenicity. This finding might have important implications for cell-line based influenza vaccine design.

P1882

Identification and generation of CD8 T-cell subsets required for vaccine protection against Ebolavirus

N. Sullivan,* C. Asiedu,* M. Baily† & D. Stanley*
**National Institutes of Health, Vaccine Research Center, Bethesda, MD, USA, †National Institutes of Health, National Institute of Allergy and Infectious Diseases, Fort Belvior, VA, USA*

Purpose/Objective: The objective of the studies described is to define T-cell responses that are required for vaccine protection of nonhuman primates (NHP) against lethal Ebolvirus challenge. These data are used to guide development of vaccines that generate both rapid and durable T-cell based protective immunity.
Materials and methods: Single-shot vaccines based on replication-defective adenovirus 5 (rAd5) induce potent antigen-specific humoral and cellular responses against Ebola virus and protect NHP challenged 4 weeks post vaccination. Depletion of $CD8^+$ T cells eliminates protection, demonstrating that rapid generation of T cell responses is necessary for virus clearance. We used vaccine vectors derived from several adenoviruses (human and chimpanzee) with unique receptor usage and APC targeting, and that exhibit various degrees of protection against Ebola to elucidate the development, magnitude, and phenotype of $CD8^+$ T cells needed for protection.
Results: We present data demonstrating that the magnitude of vaccine-induced $CD8^+$ T cells does not predict protection. We show, rather, that immune protection requires the generation of a specific subset of effector T-cells defined by their pattern of intracellular cytokine secretion (quality); survival associates specifically with $CD8^+$ T cells that produce a combination of two cytokines, TNF-alpha and IFN-gamma. In contrast, 'polyfunctional' T cells that secrete these cytokines in combination with IL-2 and are thought to represent optimal immunologic memory are rare or absent from vaccines that protect against Ebola challenge.
Conclusions: The need for effector T cells that can mobilize rapidly is consistent with the biology of Ebola virus which is tropic for all tissues and fatal within 10 days of exposure in nonhuman primates, but presents a challenge for development of a vaccine that provides both rapid immunity and durable memory. We show strategies to overcome this problem in vaccine development and define the dynamics that govern generation of long term effector T cell-based protection.

Identification of immunodominant T cell epitopes from anthrax protective antigen for inclusion in a rationally designed sub-unit based vaccine

S. Ascough,* R. J. Ingram,† J. A. Musson,‡ M. Doganay,§ L. Baillie,¶ E. D. Williamson, J. H. Robinson,‡ B. Maillere,†† S. Sriskandan* & D. M. Altmann***
**Department of Infectious Diseases and Immunity, Imperial College, London, UK, †Centre for Infection and Immunity, Queen's University Belfast, Belfast, UK, ‡Institute for Cellular Medicine, Newcastle University, Newcastle upon Tyne, UK, §Department of Infectious Disease, Erciyes University Hospital, Kayseri, Turkey, ¶School of Pharmacy and Pharmaceutical Sciences, Cardiff University, Cardiff, UK, **Defence Science Technology Laboratory, Porton Down, Salisbury, UK, ††CEA, Service d'Ingénierie Moléculaire des Protéines, Gif Sur Yvette, France*

Purpose/Objective: A major determinant of *Bacillus anthracis* pathogenicity is a binary exotoxin composed of Protective Antigen (PA) and 1 of 2 subunits, Lethal Factor (LF) or Edema Factor (EF). The PA protein, which consists of four domains, remains the most extensively characterised of the anthrax toxins, and was an early focus of work to identify an antigen that provided protective immunity to anthrax. However, to date, studies have focused almost exclusively upon serology and the number of PA antigens that have been defined as T cell immunogens is very limited.
Materials and methods: Using a panel of humanised HLA-DRB1*0401 transgenic mice, we have defined HLA-DR restricted CD4+ T cell responses to the immunodominant epitopes of PA presented following immunisation. PA antigen-specific T cell hybridoma panels were also screened for recognition of the immunodominant peptides. This was correlated with the responses of two human cohorts; individuals vaccinated with the Anthrax Vaccine Precipitated (AVP) vaccine and patients recovering from cutaneous anthrax infections.
Results: Although a number of immunodominant CD4+ T cell epitopes were identified, the response was predominantly biased towards an epitope located in the C terminus domain IV of PA, which is essential for PA binding to receptors on the host cell surface. HLA binding studies also revealed that this peptide bound across a number of common HLA-DR alleles with remarkably high affinity.
Conclusions: Based upon this data we therefore selected the immunodominant PA epitopes for inclusion in an epitope-string vaccine construct, which was evaluated in HLA transgenic mice challenged with live *B. anthracis*. The protective effect observed indicates that the identification and inclusion of CD4+ T cell epitopes will be central to the success of future 'next generation' vaccines against bacterial pathogens such as *B. anthracis*.

P1885

Identification of RNA-based vaccine adjuvants through systematic fragmentation of the Influenza A nucleoprotein sequence

L. M. Kranz,* M. Diken,* K. Melber,† S. Kreiter* & U. Sahin*
**Immunotherapy Development Center (IDC), TRON − Translational Oncology at the University Medical Center Mainz, Mainz, Germany, †Preclinical Management, BioNTech AG, Mainz, Germany*

Purpose/Objective: The purpose of the study was to identify viral RNA sequences with high immunostimulatory potency selected based on cytokine induction in human peripheral blood mononuclear cells (PBMCs) and selective TLR induction.
Materials and methods: Various RNA sequences of different length derived from Influenza A virus nucleoprotein (NP) gene were tested fortheir potential to stimulate PBMCs and HEK293 cells transfected with human TLR3, 7, 8 and 9 (TLR-HEK cells). All RNA fragments

were applied in equimolar concentrations. PBMCs were transfected with cationic liposome-complexed RNA and IFNa as well as TNFa secretion was determined by ELISA 16 h post transfection. Transfection of TLR-HEK cells with a plasmid carrying a luciferase reporter gene under the control of an NFkB-inducible promoter allowed simple and sensitive monitoring of TLR signaling induction. TLR-HEK cells were transfected with RNA complexed with liposomes and NFkB induction was measured by standard luciferase assay 16 h post transfection.

Results: Among three fragments of equal length (525 nt) together representing the full-length NP sequence, A2 led to higher amounts ofIFNa and TNFa secretion from PBMCs than the two flanking fragments (A1 and A3). Comparison of A2 with the full-length NP sequence in TLR-HEK cells showed higher stimulatory capacity of A2 as revealed by higher orders of luciferase induction in TLR3 TLR-HEK cells. No increased induction of TLR signaling was observed in TLR7, 8 and 9 TLR-HEK cells. In order to investigate whether the higher stimulatory potential of A2 was due to its diminished length or rather to specific regions within the sequence, three subfragments of equal length (175 nt) were tested in TLR3 TLR-HEK cells. Whereas TLR3 induction by two subfragments, A2-2 and A2-3, remained below that of A2, subfragment A2-1 was able to reach the same level as A2. Most interestingly, upregulation of luciferase gene expression after addition of the other two subfragments to A2-1 was superior to A2 alone.

Conclusions: These results imply that the nucleotide sequence determines the extent of immunostimulatory properties of RNA fragments rather than their length. Further investigations on the nature of such sequences may help to design optimized RNA-based vaccine adjuvants.

Immunogenicity of DNA vaccines encoding simian immunodeficiency virus antigen targeted to dendritic cells in rhesus macaques

M. Tenbusch,* R. Ignatius,† G. Nchinda,‡ C. Trumpfheller,‡ A. M. Salazar,§ K. Töpfer,¶ U. Sauermann,¶ R. Wagner, D. Hannaman,†† K. Tenner-Racz,‡‡ P. Racz,‡‡ C. Stahl-Hennig¶ & K. Überla***

**Molecular and Medical Virology, Ruhr University Bochum, Bochum, Germany, †Institute of Tropical Medicine and International Health, Charité – University Medicine of Berlin, Berlin, Germany, ‡Laboratory of Cellular Physiology and Immunology, The Rockefeller University, New York, NY, USA, §Oncovir Inc., Washington, DC, USA, ¶Unit of Infection Models, German Primate Center, Göttingen, Germany, **Geneart, Regensburg, Germany, ††Ichor Medical Systems, San Diego, CA, USA, ‡‡Laboratory for AIDS Research, Department of Pathology and Körber, Bernhard Nocht-Institute for Tropical Medicine, Hamburg, Germany*

Purpose/Objective: Targeting antigens encoded by DNA vaccines to dendritic cells (DCs) in the presence of adjuvants enhances their immunogenicity and efficacy in mice.

Materials and methods: To explore the immunogenicity of this approach in non-human primates, we generated a single chain antibody to the antigen uptake receptor DEC-205 expressed on rhesus macaque DCs. DNA vaccines encoding this single chain antibody fused to the SIV capsid protein were delivered to six monkeys each by either intramuscular electroporation or conventional intramuscular injection co-injected or not with poly ICLC, a stabilized poly I:C analogue, as adjuvant.

Results: Antibodies to capsid were induced by the DC-targeting and non-targeting control DNA delivered by electroporation while conventional DNA immunization at a 10-fold higher dose of DNA failed to induce detectable humoral immune responses. Substantial cellular immune responses were also observed after DNA electroporation of both DNAs, but stronger responses were induced by the non-targeting vaccine. Conventional immunization with the DC-targeting DNA at a 10-fold higher dose did not give rise to substantial cellular immune responses, neither when co-injected with poly ICLC.

Conclusions: The study confirms the potent immunogenicity of DNA vaccines delivered by electroporation. Targeting the DNA via a single chain antibody to DEC-205 expressed by DCs, however, does not improve the immunogenicity of the antigens in non-human primates.

P1888

Immunological analysis of 35 new antigens of *M. paratuberculosis* in mice infected with *M. paratuberculosis*, *M. avium*, *M. tuberculosis* and *M. bovis*

V. Roupie,* S. Viart,† D. Cappoen,* M. Govaerts,‡ J. J. Letesson,§ R. Wattiez† & K. Huygen*

**Immunology, Scientific Institute of Public Health, Brussels, Belgium, † Department of Proteomics and Microbiology, University of Mons, Mons, Belgium, ‡Bacterial Diseases, Veterinary and Agrochemical Research Center, Brussels, Belgium, §Facultés Universitaires Notre Dame de la Paix, Unite de Recherche en biologie moleculaire (URBM), Namur, Belgium*

Purpose/Objective: To evaluate the immunogenicity and the specificity of 35 novel *M. paratuberculosis* proteins in mice experimentally infected with *M. paratuberculosis*, *M. avium*, *M. tuberculosis* and *M. bovis*.

Materials and methods: Eighteen of these 35 candidates were identified in standard *M. paratuberculosis* biofilm cultures (surface pellicle) on Sauton medium (Leroy *et al.*, 2007) and 11/35 were identified in latency models based on Sauton cultures submitted to different stress conditions (hypoxia, acidic pH, nutrient starvation or non-toxic NO). Proteomic and immuno-proteomic analyses were performed on culture filtrates and bacterial pellets. Finally, 6/35 were identified using an *in silico* analysis of *M. paratuberculosis* genome.

The 35 genes were cloned in *E. coli* expression plasmid pQE-80L (Qiagen) and IPTG-induced histidine-tagged recombinant proteins were purified by affinity chromatography on immobilized nickel-chelate (Ni-NTA) columns.

Mice were infected intravenously with *M. bovis* AN5 and with three luminescent strains *M. paratuberculosis*, *M. avium* ATCC 15769 and *M. tuberculosis* H37Rv obtained by transformation with pSMT1 plasmid.

At day 1 and 2, 5, 8, 12, 20 and 28 weeks after infection, mice were killed and organs were individually analysed for bacterial burden by luminometry and by/or standard plating. Spleen cell IFN-γ production following *in vitro* stimulation with the 35 proteins and serum antibody levels were measured by ELISA as described before (Roupie *et al.*, 2012).

Results: Among the 35 proteins, 11 induced an IFN-γ production as early as 2 weeks post-infection and this number increased to 26 at 20 weeks post-infection. IFN-γ responses were negative in response to nine proteins.

Among the four species, *M. avium* was the most virulent strain as reflected by very high bacterial numbers in spleen, lungs and liver. *M. tuberculosis*/*M. bovis* bacterial burden was highest in lungs, whereas highest MAP numbers were detected in liver.

Conclusions: The immunogenic antigens identified in this study may be relevant for early, specific diagnosis of bovine paratuberculosis and for MAP vaccine development.

P1890

Immunotherapy of bladder cancer with BCG cell wall skeleton encapsulated sub-200 nm nano particles

T. Nakamura,* M. Fukiage,* M. Higuchi,* A. Nakaya,† I. Yano,† J. Miyazaki,‡ A. Joraku,‡ H. Akaza,§ T. Ito,¶ H. Hosokawa,¶ T. Nakayama¶ & H. Harashima*

*Faculty of Pharmaceutical Sciences, Hokkaido University, Sapporo, Japan, †Japan BCG Laboratoy, Central Laboratory, Tokyo, Japan, ‡Department of Urology, Tsukuba University, Tsukuba, Japan, §Laboratory for Systems Biology and Medicine Research Center for Advanced Science and Technology, Tokyo University, Tokyo, Japan, ¶Department of Immunology, Graduate School of Medicine, Chiba University, Chiba, Japan

Purpose/Objective: Intravesical administration of live BCG is a gold standard for therapy of carcinoma *in situ* and superficial carcinoma. Live BCG seems to infect to tumor cells and induce immune responses against tumor cells. In other words, it is essential for induction of efficient antitumor immune responses that live BCG is taken up by bladder tumor cells. Although an effective therapy, the serious side-effects associated with using live mycobacteria for treatment, such as fever, granulomatous infection, sepsis and even death, pose a significant concern. Therefore, it is necessary to develop a more active but less toxic immunotherapeutic agent.

BCG cell wall skeleton (BCG-CWS) is an adjuvant component of live BCG and has been expected as bladder cancer vaccine instead of live BCG. However, BCG-CWS has problems in pharmaceutical preparation and low cellular affinity because of poor solubility, strong-negative charge and huge molecular weight. Thus, delivery systems are needed to deliver BCG-CWS into bladder tumor cells. In this study, we incorporated BCG-CWS into octaarginine-modified nanoparticles (R8-NP), our original delivery system, for the pharmaceutical properties and delivery into bladder tumor cells. In addition, we also investigated the antitumor effect of the nanoparticles against bladder carcinoma.

Materials and methods: The BCG-CWS incorporated R8-NP (R8-NP/CWS) was composed of phosphatidylcholine, cholesterol, stearylated octaarginine and BCG-CWS. Cellular uptakes of R8-NP/CWS into mouse bladder carcinoma cells (MBT-2) were evaluated by flow cytometer and confocal laser scanning microscopy. Antitumor effect against MBT-2 in mouse model was performed by inoculating a mixture of R8-NP/CWS and MBT-2 cells. Rat model which naturally developed bladder cancer was prepared by feeding carcinogen. After bladder tumor developed, R8-NP/BCG was intravesically administered.

Results: R8-NP/CWS was <200 nm in diameter and water-soluble preparation. R8-NP/CWS was efficiently taken up by MBT-2. Moreover, R8-NP/CWS significantly inhibited tumor growth in mice bearing MBT-2. Finally, R8-NP/CWS was intravesically administered to the rat model. As the consequence, R8-NP/CWS significantly inhibited the growth of bladder cancer.

Conclusions: In conclusion, the R8-NP/CWS is a promising drug against bladder carcinoma instead of live BCG.

P1891

Impact of a novel conjugation method on the efficiency of CD40mAb-antigen conjugate vaccines *in vivo*

T. Sultana,* O. J. Wilkinson,† A. W. Heath,* D. M. Williams† & J. Carlring*

*Infection and Immunity, University of Sheffield, Sheffield, UK, †Chemistry, University of Sheffield, Sheffield, UK

Purpose/Objective: The interaction of CD40, expressed by antigen-presenting cells, with CD154, expressed by activated T cells, leads to the initiation of humoral and cell-mediated immune responses. Antibodies against CD40 (CD40mAb) act as CD40 stimulants mimicking T cell help. Conjugation of CD40mAb to antigen enhances the immunogenicity of the antigen by up to 1000-fold and improves anti-tumour protection following vaccination.

Conjugates made in our previous studies using sulphydryl-maleimide coupling were poorly-defined and heterogeneous, containing both high and low molecular weight (MW) products. We hypothesize that a purer, low MW conjugate would be a more effective vaccine. To address this we have investigated the use of an alternative conjugation strategy that employs click chemistry and have compared this to our previous methods.

Materials and methods: CD40mAb was chemically crosslinked to the model antigen ovalbumin (OVA). (1) In the standard method, CD40mAb was treated with *N-Succinimidyl* S-*acetylthioacetate* (SATA) introducing a protected sulphydryl bond and the antigen was maleimide-activated using Sulfosuccinimidyl-4-(*N*-maleimidomethyl) cyclohexane-1-carboxylate (SMCC). (2) In the click chemistry method, CD40mAb was functionalised on lysine residues with an alkyl cyclooctyne and reacted with azide functionalised antigen to form a stable triazole. Click chemistry conjugates were separated via size-exclusion chromatography (HPLC) into several fractions, primarily very high MW conjugate and low MW conjugate. The components of unfractionated conjugate and fractions were analysed by Western blotting and sandwich ELISA using anti-rat IgG to capture and anti-OVA to detect. Flow cytometry on CD40 transfected L929 fibroblast cells was used to assess binding to native CD40.

Results: Western blotting showed both CD40mAb and OVA were present in high and low MW material, indicating conjugate formation. We show that low MW conjugates were >30 fold more efficient when compared to the higher MW conjugates in the sandwich ELISA described above. Murine studies comparing pure high and low MW conjugate for immunogenicity and protection against OVA expressing B16 melanoma tumours will be presented.

Conclusions: Low MW conjugate shows promise as a more potent vaccine construct.

P1892

Induction of HIV-1 neutralizing antibody and cell-mediated immune responses by using multimeric E2 scaffolds co-administered with DNA

M. Trovato,* S. Krebs,† J. P. Jaworski,† C. Smith,† W. Sutton,† G. Waagmeester,† R. Sartorius,* L. D'Apice,* P. De Berardinis* & N. L. Haigwood†

*Institute of Protein Biochemistry, C.N.R., Naples, Italy, †Oregon National Primate Research Center, Oregon Health & Science University, Beaverton, OR, USA

Purpose/Objective: It is widely believed that induction of both broadly neutralizing antibodies (bNAbs) and cell-mediated immunity are crucial for a successful HIV-1 vaccine. In order to elicit both humoral and cellular immune responses against HIV-1 we generated multimeric scaffolds, based on the acyltransferase component (E2) of the pyruvate dehydrogenase complex of *Geobacillus stearothermophilus*, displaying antigenic determinants from the HIV Envelope (Env) glycoproteins gp120 and gp41.

Materials and methods: E2 self-assembles into 60-mer virus-like particles (VLPs) with 60 copies of an antigen on each scaffold. The HIV-SF162 V3 and MPER regions were expressed as *N*-terminal fusion to the E2 core. To increase solubility, Env-E2 VLPs were refolded from inclusion bodies with equimolar amounts of E2 in stepdown dialysis. The assembled 60-mer particles were purified by size exclusion chromatography and were >90% pure, as assessed by SDS-PAGE and Western blot. Identity was confirmed by 447-52D and 2F5 binding to Env-E2 monomers. Env-E2 multimers were tested alone and in combination with HIV-SF162 Env (gp160) plasmid DNA in rabbits and in mice. NAbs were measured using TZM-bl assay; T-cell

responses were determined by dextramer staining, intracellular cytokine staining and thymidine proliferation assays.
Results: Immunization of rabbits with V3-E2 VLPs co-administered with DNA elicited strong V3-specific NAb response after two immunizations in 6 weeks. Co-immunization of V3-E2 VLPs plus DNA elicited V3-dextramer specific CD8+ T cells producing IFNg in mice. Rabbits immunized twice or more with DNA plus MPER-E2 VLPs rapidly generated strong NAbs, and a subset was specific for 2F5 epitope. Immunization of mice with MPER-E2 plus DNA induced CD4+ T cells that specifically proliferated and produced TNF-alpha.
Conclusions: Combination VLP plus DNA approach elicited strong anti HIV-1 Env NAb responses and cell-mediated immune responses. Our results further substantiate this novel strategy of co-immunization with scaffolds and DNA for vaccination against HIV-1, and indicate that this approach could represent an adaptable and efficient platform by which to direct immune responses toward conserved regions of Env.

P1893
Induction of the enduring T cell memory against *M. tuberculosis* on vaccination with peptide of 16 kDa antigen linked to Pam2Cys

J. Agrewala,* U. Gowthaman,* V. Singh,* S. Jain,* S. Chodsetti,* K. F. Siddiqui,* R. K. Gurran,* P. Parihar,* P. Gupta,† U. D. Gupta,† W. Zeng‡ & D. Jackson‡
**Immunology, Institute of Microbial Technology, Chandigarh, India, †Animal Experimentation Facility, Central JALMA Institute for Leprosy and Other Mycobacterial Diseases, Agra, India, ‡Department of Microbiology and Immunology, The University of Melbourne, Parkville, Vic., Australia*

Purpose/Objective: In TB-endemic populations, one of the main reasons for the failure of BCG vaccine is the obstacle caused by environmental mycobacteria in its processing and presentation to T cells. Usually, peptides do not require extensive antigen processing since they directly bind to major histocompatibilty complex molecules and can be presented to T cells. Therefore, peptide vaccines can surmount the problems associated with BCG failure. Therefore vaccine that does not require extensive processing can be quite successful in TB-endemic regions. Hence we have developed a construct by linking promiscuous peptide of *Mycobacterium tuberculosis* to Pam2Cys, a Toll-Like-Receptor-2 agonist. This vaccine has self-adjuvanting property, elicits long-lasting T cell memory and provides better protection than BCG.
Materials and methods: Protection studies in mice and Guinea pigs. Animals (7–10/group) were immunized as described above and rested for 75 days. Animals were then exposed to *M. tuberculosis* H37Rv through aerosol route at 100 CFU (mice) or 30 CFU (Guinea pigs) and sacrificed 30 days later. Mycobacterial burden in lungs was estimated by CFU plating. For histopathological analysis, formalin fixed tissues were processed and stained with hematoxylin and eosin.

Staining for surface markers on DCs and T cells. Cells were harvested and incubated with Fc block and stained with anti-mouse fluorochrome/biotin labeled mAbs for 30 min/4°C. Usual steps of washings were followed after the each incubation. Cells were fixed in 1% paraformaldehyde. The data were acquired using FACS-Aria II.

T cell Proliferation. It was monitored by 3H-thymidine incorporation and CFSE-dye-dilution assay.

Cytokines secretion: These were estimated by ELISA and intracellular-cytokines-staining.
Results: The vaccine construct can be targeted to dendritic cells to secrete cytokines, induces and enhances the expression of costimulatory molecules and increases their antigen presentation ability and help to T cells. Vaccine can bind directly to major histocompatibilty molecules and imparts enduring Th1 memory response and elicits better protection than BCG in the mouse and Guinea pig model of tuberculosis. It surmounts major histocompatibilty barriers and evokes immune response irrespective of genetic polymorphism of healthy individuals, tuberculosis patients and their contacts.
Conclusions: Lipidated peptide has self-adjuvanting property and activates both innate and adaptive arm of immunity. It generates enduring T cell memory response and induces better protection than BCG. Hence this lipopeptide can be a potent future vaccine candidate against tuberculosis.

P1894
Influence of vaccination strategies on IgG Fc glycosylation

M. Ehlers,* A. Winkler,† C. Hess,† A. K. Lorenz,† M. Berger‡ & D. Petzold*
**Institute for Systemic Inflammation Research, University of Luebeck, Luebeck, Germany, †Laboratory of Tolerance and Autoimmunity, German Rheumatism Research Center, Berlin, Germany, ‡Central Institute for Laboratory Medicine and Pathobiochemistry, Charité, Berlin, Germany*

Purpose/Objective: Induction of IgG antibodies after vaccination plays an important role in the protection against pathogens. Antibodies can neutralize the interaction of the pathogen with a specific receptor on target cells but are also involved in the elimination of the pathogen. The pathogenic potential of IgG antibodies is thereby highly dependent on the IgG subclass and on IgG Fc glycosylation. IgG Fc defucosylation highly increases the effector function of IgG antibodies to recruit killer cells in tumor therapy and IgG Fc de-galactosylation and de-sialylation increases the inflammatory potential of IgG antibodies as described e.g. for arthritis patients. We sought to examine the IgG Fc glycosylation after different vaccination protocols.
Materials and methods: We administered chicken ovalbumin (OVA) under different vaccination protocols to mice and analyzed OVA-reactive IgG Fc glycosylation. The pro- or anti-inflammatory function of differentially glycosylated anti-OVA IgGs was further investigated *in vivo*.
Results: Stimulation with antigens under inflammatory conditions induces de-sialylated IgGs. In contrast, tolerance induced immunosuppressive sialylated IgGs that were sufficient to block antigen-specific T and B cell responses, DC maturation and inflammation.
Conclusions: Our data show that a pro-inflammatory IgG Fc glycosylation pattern is highly dependent on the vaccination protocol.

P1895
Innate and adaptive immune responses to plant-based influenza H5 virus-like-particle vaccines by murine splenocytes

K. Young,* A. Brewer,* M. A. D'aoust,† M. Couture,† N. Landry,† L. Vezina† & B. Ward*
**Host Resistance, McGill University Health Center Research Institute, Montreal, Canada, †Medicago R&D Inc., Sainte-Foy, Canada*

Purpose/Objective: A novel H5N1 influenza vaccine candidate has been developed, based upon H5-bearing virus-like-particles (VLP) produced in tobacco plants (*Nicotiana benthamiana*). These VLP have demonstrated strong immunogenicity in both pre-clinical and clinical models, but their mechanism of action has still not been fully characterized. The immunologic microenvironment generated by innate responses to vaccination has been shown to greatly influence subsequent adaptive immune responses. The goal of this study was to characterize both the early innate and adaptive H5-specific cytokine responses in mouse splenocytes elicited by these plant-based VLP.
Materials and methods: To study innate responses to H5 VLP, splenocytes from H5-naïve 6–8 week old female Balb/c mice were isolated and exposed to 10 mg/ml H5 VLP. For adaptive immune responses, 6–8 week old female Balb/c mice were given two doses of

H5 VLP (2.5 μg/ml based on H5 content), 3 weeks apart. At study termination, harvested splenocytes were stimulated with recombinant H5 protein (5 μg/ml). In both models, culture supernatants were sampled at various times post-stimulation and cytokine/chemokine levels were measured by multiplex ELISA.
Results: *In vitro* stimulation of antigen-naïve mouse splenocytes by H5 VLP induced a predominantly pro-inflammatory response, with significant increases in five cytokines/chemokines (IL-6, MCP-1, TNF-α, MIP-1α, and CCL5) versus unstimulated controls. For adaptive immune responses, influenza-specific cytokine analysis focused on IFN-γ, TNF-α, and IL-2 levels, as these cytokines have been associated with better disease outcome in different models. Splenocytes from the vaccinated mice secreted high levels of IFN-γ and IL-2 in response to H5 protein restimulation but no TNF-α was detected. Secretion kinetics varied between the different cytokine/chemokines.
Conclusions: This work suggests that plant-based influenza H5 VLP vaccines elicit an early pro-inflammatory cytokine/chemokine response in splenocytes isolated from antigen-naïve mice. These innate effectors may serve to prime for a more potently anti-viral adaptive response upon re-exposure to influenza antigens, characterized by high levels of IFN-γ and IL-2.

P1896
Interaction between OAdV7, a novel ovine adenoviral vector and human immune cells

R. Tang,* A. Brooks,* G. Both† & J. Taylor*
**School of Biological Sciences, University of Auckland, Auckland, New Zealand, †Broadvector Limited, North Ryde, Sydney, Australia*

Purpose/Objective: Identification of adenoviral isolates of non-human origin has fostered development of vectors with vaccine potential that overcome the problem of pre-existing immunity in the human population that may limit clinical applications. Ovine adenoviral isolate, OAdV287 (OAdV7), the prototype of the genus Atadenovirus, has been characterized as a gene delivery vector. Previously we reported the use of recombinant OAdV7 as a vaccine for inducing an antitumor immune response in a mouse model and showed immunization with OAdV7-OVA prevented and retarded tumor growth in prophylactic and therapeutic tumor trials, respectively. Here we present data describing the impact of OAdV7 vector on human immune cells.
Materials and methods: Monocyte-derived Dendritic cells (mono-DCs) were treated with OAdV7 or hAdV5 for 48 h and transduction was assessed by the percentage of eGFP+ cells. For DC maturation, DCs were stained with antibodies for surface markers CD80, CD86, CD83 and HLA-DR and analyzed by FACS. Supernatants from DCs incubated with viral vectors were analyzed for cytokine concentration using CBA.
Results: Mono-DCs incubated with OAdV7 were successfully transduced using a high multiplicity of infection (MOI). Treatment of Mono-DCs with OAdV7 produced up-regulation of co-stimulatory markers CD80, CD86 and activation marker CD83, HLA-DR. Induction of DC maturation was greater with OAdV7 treatment than with hAdV5 although with hAdV5 transduction appeared greater at the same MOI. Cytokine analysis showed that OAdV7 induced secretion of TNFα, IL-6, IL-12/23 p40 and IL-12 from treated mono-DCs.
Conclusions: This is the first report on the ability of OAdV7 to transduce and activate human antigen presenting cells. The data justify further studies to evaluate the utility of this vector for tumour immunotherapy.

P1897
Lipooligosaccharides study of *Neisseria meningitidis*: the immunotype L2 expression in relation to serogroups in Brazil

E. De Gaspari, M. R. Fabiana & T. B. Elza
Immunology, Adolfo Lutz, São Paulo, Brazil

Purpose/Objective: The profile of antigen expression among meningococci is important for epidemiology surveillance and vaccine development. *Neisseria meningitidis* may be classified according to the lipooligosaccharide immunotypes. The types of LOS expressed by a bacterium may influence the behaviour and the fate of the strain. Our study represents the opportunity to focus on a particular aspect of the imunotypes of *N. meningitidis* strains of L2 immunotype epitope present in serogroups A, C, W, Y and B of Brazil .
Materials and methods: To this end two new mouse monoclonal antibodies (MAbs) have been produced against *Neisseria meningitidis* lipopolysaccharide (LPS). The MAbs were reactive against outer membrane antigens and present bactericidal activity. They were tested against different meningococcal strains 118 strains of serogroup A, 66 strains of serogroup C (1972−1974) 293 strains of serogroup B (1992) and 120 strains (2011−2012) of B, C, W135 and Y by Dot-ELISA .
Results: The MAbs were reactive against different meningococcal strains 118 strains of serogroup A, 66 strains of serogroup C (1972−1974) and 293 strains of serogroup B (1992) meningococci by Dot-ELISA. The prototypes and subtypes of B:4:P1.15, B:4:P1.9, B:4:P1.7, B:4:P1.14, B:4:P1.16, B:4:NT and B:NT:NT were detected in *N. meningitis* B serogroups. The strains C:2a:P1.2 and A:4.21:P1.9 were dominant in the C and A serogroups respectively. FACS analysis showed that the MAbs immunotypes recognized LPS immunotypes on the surface of *N. meningitidis*. The immunotype L_{379} was strongly expressed in 90% of *N. meningitidis* B compared with 67% in serogroup C and 18% in serogroup A, whereas L_1 and L_8 were weakly to moderatly expressed by 7% and 15% in serogroup B and 3% serogroup A and was not expressed in serogroup C. Interestingly the prevalence of imunotype L2 is related to serogroups A and B analyzed. Our results demostrated that the expression of LPS (immunotypes) in the *N. meningitidis* Brazilian strains studied is heterogeneous and related to serotypes present in diferent immunotypes.
Conclusions: Our study represents also the opportunity to focus on a particular aspect of the L2 immunotype strains of serogroup A, C B, W135 and Y of Brazil . Consequently, it can be hypothesized that these strains have a compensatory system explaining their ability to cause invasive disease. The explanation may be multi-factorial, as MenB possesses a whole battery of possibilities to escape the host's immune system as capsular switching event.

P1899
Microneedles mediated delivery of tumour antigens to Langerhans cells *in vivo* is an effective vaccination strategy for tumor immunotherapy

M. Zaric,* O. Lyubomska,* O. Touzelet,* U. Power,* C. Scott,† R. Donnelly† & A. Kissenpfennig*
**Centre for Infection and Immunity, Queens University Belfast, Belfast, UK, †School of Pharmacy, Queens University Belfast, Belfast, UK*

Purpose/Objective: Dendritic cells (DCs) are professional antigen presenting cells capable of generating strong T cell dependent primary immune responses, including cytotoxic CD8 T cell responses, necessary for effective anti-tumour immunity. Recently, several studies have highlighted the complexity of the cutaneous DC network, indicating that due to the high number of DCs present in the epidermis and dermis, the skin might represent the ideal site for vaccine delivery.
Materials and methods: In this study, we used polymeric dissolvable microneedle arrays (MNs) laden with a model antigen (ovalbumin)

encapsulated nanoparticles (NPs) to target specific skin DCs subsets and explore CTL immune responses.
Results: We confirmed that following *in situ* uptake, skin derived DCs were able to deliver NPs to cutaneous draining lymph nodes where they consequently induced potent activation of antigen specific IFN-γ secreting- CD4+ and CD8+ T cells. Moreover, we validated functional relevance of the induced immune responses in murine models of Sendai and melanoma. We further investigated the capacity of different skin DCs subsets to cross-present antigen after OVA-NPs immunization through MNs. Although Langerin+ dermal DCs induced minor OT-I T cell proliferation, Langerhans cells (LCs) constituted the main subset capable of cross-presentation. We confirmed a critical role for LCs in the immunization process when depletion of LCs at the time of MNs immunization dramatically reduced the proliferation of antigen specific CD8 T cells. Furthermore, we investigated the contribution of LCs for the generation of antitumorimmune responses after MNs immunization and found that depletion of LCs significantly reduced the tumour protective effect.
Conclusions: Therefore, we show that direct targeting of antigen to the specific skin DCs subsets, in particular LCs, through MNs vaccination can be successfully utilized to induce robust antitumourimmunity.

Modulation of experimental Sjögren's syndrome and diabetes via mucosal vaccination with fusion proteins derived from cholera-toxin and heat shock protein 60 kDa

S. Ledahl,* P. Vogelsang,* R. Jonsson,* N. Lycke† & N. Delaleu*
**Broegelmann Research Laboratory, The Gade Institute, Bergen, Norway, †Mucosal Immunobiology and Vaccine Research Center, University of Gothenburg, Gothenburg, Sweden*

Purpose/Objective: Cholera-toxin based CTA1-DD and CTA1R7K-DD direct immune responses due to their differential enzymatic activity. The aim of the study was to investigate their potential in modulating spontaneous diabetes and Sjögren's syndrome (SS) in non-obese diabetic (NOD) mice via heat shock protein 60 kDa peptide aa437−460 (aa437-460) fusion proteins.
Materials and methods: NOD mice were immunized intra-nasally with fusion proteins at 7-weeks of age. Untreated NOD and BALB/c mice were used as controls. Alterations in antigen presenting cell (APC) and effector cell populations were analyzed by flow cytometry 1-week post immunization. Diabetes incidence was determined from 12 weeks of age onwards and SS disease phenotype was assessed at 7-, 11-, 21 and 24-weeks of age.
Results: In NOD, neither significant change of cell population sizes nor of co-regulatory receptor and ligand expression levels were observed in response to vaccination. Mice administered with CTA1R7K-aa437-60-DD exhibited accelerated and increased diabetes incidence, whereas vaccination with CTA1-aa437-460-DD caused the opposite effect. Regarding SS, salivary and lacrimal gland secretion capacity at 11-, 21- and 24-weeks of age remained unaffected.
Conclusions: In contrast to previous results, the cholera toxin-based fusion proteins did not induce expansion of specific APC populations. Irrespective of this lack in immune adaptation, the diabetes incidence curves suggest that modulation of autoimmunity is peptide dependent and reflects the inherent properties of aa437-460. In addition, the results also reflected a difference in fusion protein function. The similarities in exocrine gland function between treated groups compared to untreated NOD and BALB/c controls probably reflect that overt disease has yet to manifest itself. However, target organs have been collected and prepared for histological assessment of inflammation and potentially microarray analysis; these will be used for determination of adjuvant effect.

P1901

Mouse model and protein candidates- finding an effective vaccine against *Chlamydia trachomatis*

T. Müller, L. Pfeiffer & T. Miethke
Institute for Medical Microbiology Immunology and Hygiene TU Munich, Klinikum rechts der Isar, München, Germany

Purpose/Objective: *Chlamydia trachomatis* caused genital infections are one of the most frequent sexually transmitted diseases worldwide with more than 90 million new cases occurring each year. Typical disease sequelae include cervicitis, endometritis, salpingitis, but also abortion and infertility. Recurrent infections increase the likelihood of these complications. Although chlamydial genital tract infections can be cured with antibiotics, a definitive control of *C. trachomatis*-caused diseases (STDs) is only possible through the development of a safe and efficacious vaccine.
Materials and methods: Therefore we try to establish the necessary mouse model using the *C. trachomatis* strain UW-3/Cx, serotype D. Furthermore, to produce the effective vaccine, we define, clone, express and purificate the required proteins and finally test them *in vivo*. A number of immunogenic antigens have been tested for their ability to induce protection; we decided to use the major outer membrane protein (MOMP) at one hand and the polymorphic outer membrane proteins (Pmps) on the other hand. Firstly, we tested the antigens alone and secondly in combination with a variety of immunostimulatory adjuvants. For investigating *C. trachomatis* infections we had a closer look on different mouse strains (Bl6/Balb/c/C3H), which we infected with different amounts of chlamydial infection forming units (IFUs).
Results: After 7 days of infection the mice, which were infected with 2×10^6 or more (IFUs) showed a plain redness and thickness of the uterus horns and the tubes. These macroscopically visible clinical signs of disease will be used to evaluate the success of the vaccine. Furthermore, the clearly enlarged lymph nodes will serve as source of B-, T- and antigen-presenting cells to investigate the immunologic reaction provoked by the infection and induced by the vaccine.
Conclusions: In summary, the aim of this project is not just to reduce the bacterial load after infection with *C. trachomatis*, but to prevent disease and to induce long- term immunity.

Novel RSV genetic vaccine based on chimpanzee Adenovirus and MVA vector is safe and highly immunogenic in rodents and primates and fully protects cotton rats from RSV challenge

M. Esposito,* A. Pierantoni,† F. Grazioli,‡ A. Abbate,‡ V. Ammendola,‡ S. Capone,* S. Colloca,‡ A. Folgori,* A. Nicosia,§ R. Cortese¶ & A. Vitelli†
**Immunology, Okairos Srl, Naples, Italy, †Respiratory Disease Department, Okairos Srl, Naples, Italy, ‡Vectorology, Okairos Srl, Naples, Italy, §CSO, Okairos Srl, Naples, Italy, ¶CEO, Okairos Srl, Naples, Italy,*

Purpose/Objective: Respiratory Syncytial Virus (RSV) infection is the main cause of hospitalization of infants and young children in industrialized countries. RSV affects also the elderly where treatment of infection is only supportive. Thus, RSV vaccine will have a tremendous impact and might be used in all infants and other risk groups.

We generated several replication incompetent chimpanzee-derived Adenovirus (ChAd) for the delivery of vaccine antigens. ChAd vectors are insensitive to pre-existing immunity and have been validated in Phase I and IIa clinical trials where they showed good safety, immunogenicity and efficacy. ChAd can be used in heterologous prime/boost regimens with Modified Vaccinia Ankara (MVA) vectors encoding for the same antigens leading to high immune responses.

Materials and methods: To induce a full spectrum of RSV-specific immune responses including neutralizing antibody and CD8+ T cells, we generated ChAd and MVA vaccine vectors encoding for the F, N and M2-1 RSV antigens. The vaccine was tested in pre-clinical animal models including mice, non-human primates (NHP) and cotton rats by different regimens and routes (intramuscular and intranasal), including mucosal delivery by intranasal spray in NHP. T cells responses were assessed by *ex-vivo* IFNg-ELISpot and Intracellular Staining assays, while humoral responses were tested by ELISA and Neutralization assay.
Results: The vaccine induced high levels of local and systemic T cell immunity in mice and NHP (up to 7200 and 13 500 SFC/10^6 splenocytes or lung cells and 8000 SFC/10^6 PBMC, respectively) with no signs of toxicity. High titers of neutralizing antibodies were induced in both species with levels exceeding by 100 fold those measured in protected human adults and infants.

In cotton rat model, the vaccine completely prevented replication of the virus in the lung and in the nasal cavity. Lung histopathology analysis showed that the vaccine was safe and didn't induce enhanced respiratory disease. GLP toxicology study in mice showed no vaccine related safety concern and GMP grade RSV genetic vectors have been prepared and are ready to be tested in clinical trials.
Conclusions: These data demonstrate that our RSV genetic vaccine is safe, induces a full range of immune responses in mice and NHP and fully protects cotton rats from RSV challenge.

P1903
Novel vaccine strategy for ocular surface infections using conjunctiva-associated lymphoid tissue as a route of immunization: local and systemic responses to model antigen

A. Inic-Kanada,* S. Belij,* M. Stojanovic,† E. Marinkovic,† I. Stojicevic,† J. Montanaro,* S. Schlacher,* E. Stein,* N. Bintner* & T. Barisani-Asenbauer*
**OCUVAC – Centre of Ocular Inflammation and Infection Laura Bassi Centre of Expertise, Institute of Specific Prophylaxis and Tropical Medicine, Medical University of Vienna, Vienna, Austria, †Research and Developmet, Institute of Virology Vaccines and Sera, Belgrade, Serbia*

Purpose/Objective: Ocular surface infections include several blinding disorders that affect the cornea and conjunctiva at the front surface of the eye. Since antimicrobial therapy has shown its limitation to protect from reinfection and vision threating sequels (i.e. Trachoma) also partially protective vaccines against ocular surface pathogens would impact ocular morbidity. As mucosal immune responses (e.g. nasal, oral, gastrointestinal) are most efficiently induced by the administration of vaccines onto mucosal surfaces, we aimed to assess the efficacy of the ocular mucosa with the conjunctiva-associated lymphoid tissue (CALT) as a mucosal route of immunization. The aim of the present study was to elucidate local and systemic immune responses after CALT immunization using a model antigen.
Materials and methods: BALB/c and C57BL/6 mice were immunized via conjunctiva with tetanus toxoid (TTd) as a model antigen (100 μg/mice, 5 μl were applied onto conjunctiva). Two percentage glycerol and merthiolat-inactivated *B. pertussis* were used as adjuvants. Subcutaneously immunized mice were used as a 'gold standard' (100 μg/mice, 100 μl). Three immunizations were performed at 2 weeks interval and the evaluation of local and systemic immune response was done 2 and 8 weeks after the last immunization. Protection assay against tetanus toxin (2 LD_{50}) has been done a month after the last immunization.
Results: We have found TTd-specific IgG and IgA in tears and sera of both mice strains, as well as, IgG positive TTd-specific cells. It was shown that the amount of TTd-specific antibodies in mouse sera strongly correlated with the presence of TTd-specific B cells in draining lymph nodes. Eight weeks after the last immunization, the levels of anti-TTd IgG and IgA in the sera of BALB/c mice were higher than in C57BL/6 although C57BL/6 exhibited more prominent IgA concentration in mouse tears. *B. pertussis* displayed adjuvantic properties when added to TTd as it was revealed that TTd-specific IgG and IgA immune responses in this mice group were the highest in both mice strains. Mice were challenged with a lethal dose of tetanus toxin by the intraperitoneal route. Immunization via conjunctiva resulted in 33% survival of C57BL/6 mice that received TTd adjuvanted with *B. pertussis*.
Conclusions: Conjunctival immunization induced TTd-specific local and systemic immune response, as well as a partial protection against systemic lethal challenge with tetanus toxin in C57BL/6 mice.

P1904
On the role of antigen stability in antigen cross-presentation

D. Knittel, A. Savatier & M. Léonetti
**CEA-Saclay, DSV/IbiTec-S/SPI/LIAS, Gif Sur Yvette, France*

Purpose/Objective: It has been previously shown that antigen (Ag) stability controls Ag presentation to $CD4^+$ helper T cells (Thai *et al.*, J Immunol., 2004) and thus influences antibody production (Delamarre *et al.*, J Exp Med., 2006). The aim of this study is to examine whether Ag stability also influences Ag cross-presentation.
Materials and methods: A model Ag containing the SIINFEKL $CD8^+$ T cell epitope covalently coupled to a 27-residues-long protein with three disulphide bonds was chemically synthesized, folded and purified by HPLC. A derivative differing by the absence of one disulphide bond was also synthesized. 3D structure was then assessed using circular dichroism. Susceptibility to proteolysis was examined using cathepsin L and cathepsin S. Susceptibility to reduction was examined using TCEP. The effect of Ag stability on cross-presentation was studied *in vitro* using two different approaches. First, the two derivatives were examined for their ability to trigger proliferation of splenocytes from transgenic mice expressing the SIINFEKL-specific TCR. Second, they were compared for their ability to activate a SIINFEKL-specific T cell hybridoma after cross-presentation by the JAWS II dendritic cell line.
Results: Circular dichroism experiments indicate that the two derivatives share the same overall structure. However, they differ in their susceptibility to proteolysis and to reduction. Thus, the three disulphide bonds containing protein is less susceptible to enzymatic degradation and to TCEP reduction than the derivative with the disulphide deletion. Differences were also found when cross-presentation was examined. Thus, the three disulphide bonds containing protein stimulates T-cells ten times less efficiently than the derivative with the disulphide deletion.
Conclusions: Our results show that two proteins differing by only one disulphide bond don't have the same cross-presenting capacity; the less stable one being more efficient than the more stable one. These preliminary results suggest that the stabilizing interaction network of proteins might modulate CD8 T-cell stimulation.

P1905
Prediction and identification of the potential immunodominant epitopes of herpes simplex virus type II glycoprotein D

Y. Li,* X. Wang,† Y. Wang,* Y. Pan,* J. Liao,‡ D. Yin† & G. Xie†
**Laboratory of Medical and Pharmaceautical Biotechnology, Huadong Research Institute for Medicine and Biotechniques, Nanjing, China, †Department of Pharmacy, Anhui University of Traditional Chinese Medicine, Hefei, China, ‡School of Life Science and Technology, China Pharmaceutical University, Nanjing, China*

Purpose/Objective: This study aimed to determine the immunodominant epitopes (B cell epitopes) of herpes simplex virus II (HSV-2) glycoprotein D (gD) via software algorithms and experiments.

Materials and methods: B cell candidate epitopes of gD2 were predicted with the software DNAstar, Biosun, and Antheprot. Their three-dimensional structures were predicted by moe2008 software . The predicted peptide epitopes of gD2 were synthesized chemically. Subsequently, the antigenicity and immunogenicity of these peptide epitopes were examined by EIA and Western blot experiments. All conjugates of these peptides with the carrier protein BSA were used to immunize mice. The specificity of their antisera were investigated by EIA and Western blot. The ability to neutralize HSV-2 infectivity *in vitro* was investigated by a 50% plaque reduction assay on antiserum raised against each peptide.
Results: Four B cell candidate epitopes of gD,2 namely, peptides 6−18 (DPSLKMADPNRF), 223−232 (FIPENQRTVA), 255−267 (PELSDTTNATQPE), and 276−287 (ALLEDPAGTVS) of gD2 (1−290), were predicted and selected. The selected peptides have antigenicity and could react with the antibodies to gD2 (1−290). All conjugates of these peptides with the carrier protein BSA could induce mice to produce specific antibodies. The EIA and Western blot results showed that the antibodies against each of the four peptides reacted with the parent gD2 (1−290) and can neutralize HSV-2 infection *in vitro*. The antisera against peptide 6−18 of gD2 (1−290) showed the strongest neutralization activity, which has not been reported until now.
Conclusions: The immunodominant epitopes of gD2 screened by software algorithms and validated by experiments have good antigenicity and immunogenicity, may be used in viral diagnosis and vaccine design against HSV-2.

Probiotic bacterium, *Lactobacillus gasseri* SBT205,5 can enhance antigen-specific immune responses in oral mucosa

T. Ochiai,* T. Kobayashi† & M. Yamamoto*
**Oral Immunology, Nihon University School of Dentistry at Matsudo, Matsudo, Japan, †Megmilk Snow Brand Co. Ltd, Milk Science Research Institute, Saitama, Japan*

Purpose/Objective: Probiotics are normal inhabitants of the gastrointestinal tract of man and are widely considered to exert a number of beneficial effects in many diseases. Probiotic strains have been used because of their potential therapeutic effects, and have been studied extensively. However, the mechanism by which they modulate the immune system is poorly understood. Periodontal disease has been suggested as a risk factor for systemic diseases. If the cascade of harmful immuno-inflammatory reactions could be reduced by the use of probiotics, probiotics could be have the potential to bring substantial health benefits for humans. In this study, we assessed the adjuvant effect of a probiotic strain, *Lactobacillus gasseri* SBT2055 (*L. gasseri*) for antigen-specific immune response.
Materials and methods: *Lactobacillus gasseri* were gastrically administered to 7-weeks-old BALB/c mice for 5 weeks. Three weeks after the initial administration, mice were immunized sublingually with 40-kDa outer membrane protein (40 k-OMP) of *Porphyromonas gingivalis* plus cholera toxin as mucosal adjuvant once a week for 2 weeks. Seven days after the last immunization, plasma, saliva, and nasal washes (NWs) were collected, subjected to ELISA and observed antibody (Ab) titer.
Results: Interestingly, *L. gasseri* treatment elicited significant increased levels of 40 k-OMP-specific S-IgA Ab in saliva and NWs. In addition, significant increased levels of 40 k-OMP-Specific IgG Ab were detected in plasma of these mice.
Conclusions: These results suggest that the administration of *L. gasseri* to the gastrointestinal tracts can induce the mucosal immune responses not only in the gastrointestinal tract but also in the oral cavity, which may have clinical implications for preventive or therapy of periodontal diseases.

P1907

Prophylactic treatment with IgY antibodies against influenza viruses does not interfere with the normal development of adaptive immunological memory against influenza

K. O. Grönvik,* R. Feinstein* & R. J. Webby†
**Virology Immunobiology and Parasitology, National Veterinary Institute (SVA), Uppsala, Sweden, †Department of Infectious Diseases, St. Jude Children's Research Hospital, Memphis, TN, USA*

Purpose/Objective: To develop new forms of intranasal-oral immuno-therapy by using IgY antibodies to control seasonal and pandemicinfluenza.
Materials and methods: Laying hens were immunized into the breast muscle with the high pathogenicity avian influenza (HPAI) H5N1 inactivated influenza viruses emulsified in Freund's complete adjuvant. After 4 weeks they were given a second injection with viruses in Freund's incomplete adjuvant. Eggs were collected commencing 2 weeks post second immunization and IgY antibodies were extracted from one volume of pooled egg yolks with nine volumes of super Q water. Balb/c mice were treated intranasally with 50 μg of IgY antibodies plus different concentrations of influenza viruses and were scored for the changes of weight as a sign if disease.
Results: Intranasal administration of specific IgY to mice protected against lethal infection of H5N1 avian influenza virus in 100% of the animals if administered at the same time as or 1 h prior to viral challenge. Interestingly, IgY against H5N1 also blocked viral invasion by H1N1 PR8 influenza virus during *in vitro* and *in vivo* challenges, demonstrating that IgY to H5N1 can indeed cross protect against infection with H1N1.

When mice, initially protected by IgY antibodies against H5N1, 3 months later were re-infected with a 100 times higher dose of H1N1 PR8 virus no reduction of weight was observed indicating the development of a good immunological memory to influenza viruses in these animals. *In vitro* challenge of immune T cells from such mice with antigen presenting cells, APCs, from infected lung showed that different populations of lung APCs induced different patterns of pro-inflammatory IFN-γ and IL-17. Also, influenza infected lung cells promoted TH cell independent proliferation of specific $CD8^+$ memory T cells.
Conclusions: The heterogeneity of the IgY response to viruses in chickens generates antibodies with broadly protective activity against influenza viruses and prophylactic treatment with IgY anti-influenza can be used to control influenza viral infection without interfering with the development of adaptive immunological memory resulting from a quiescent infection or a conventional vaccination.

P1909

Scientific investigations of trivalent influenza vaccine-induced adverse events in the paediatric population: role of innate immunity

D. Becher, S. Rockman, A. Dyson, S. Koernig, A. B. Morelli, S. Camuglia, J. Bodle, M. Barnden, P. Schoofs, M. Pearse, & Maraskovsky
CSL Limited, R&D, Melbourne, Australia

Purpose/Objective: During the 2010 Southern Hemisphere (SH) influenza season, there was an unexpected increase in the number of febrile reactions reported in the paediatric population (<5 years) in Australia shortly after vaccination with the CSL 2010 SH Trivalent Influenza Vaccine (TIV) compared to previous seasons CSL TIVs or other licensed 2010 SH TIVs. The rapid onset was suggestive of an innate immune response to the CSL 2010 SH TIV. A series of scientific investigations were initiated to identify the root cause of these adverse events (AEs). The primary objectives were: (1) investigate the immunogenicity/reactogenicity of the CSL 2010 SH TIV as compared to

previous season and comparator vaccines; (2) Identify vaccine components that may have contributed to the AEs; (3) identify surrogate parameters that can be used to prepare future TIVs which are safer and more effective in the paediatric population.
Materials and methods: *In vitro* cytokine/chemokine assays following stimulation of adult and paediatric whole blood, as well as mammalian cell lines such as the HEK293 cell based NF-κB reporter assay and various Toll-like receptor (TLR) transfectants, profiling of molecular signatures using microarrays, and *in vivo* studies in rabbits, ferrets, new born rats and rhesus non-human primates (NHPs).
Results: Various TIVs (approved commercial TIVs as well as re-engineered TIVs) and their individual monovalent pool harvest (MPH) components were examined. Detailed investigations eliminated bacterial-derived pyrogens and the method of inactivation. In addition, the role of neuraminidase was not found to be a significant contributing factor. The various *in vivo* and *in vitro* analyses indicated that the CSL 2010 SH TIV was, generally, more stimulatory and induced more potent gene signatures than previous seasons CSL TIVs or comparator 2010 SH TIVs. The *in vitro* assays also identified the B/Brisbane/60/2008 strain (and to a lesser degree the H1N1 pandemic A/California/07/2009 strain) to induce cytokines/chemokines and NF-kB activation. Interestingly, the induction of these signals was associated with a heat labile, viral-derived component.
Conclusions: The current working hypothesis is that the increase in febrile AEs reported in Australia after vaccination with the CSL 2010 SH TIV may be due to a combination of both the introduction of three entirely new strains in the CSL 2010 SH TIV, and differences in the manufacturing processes used to manufacture CSL TIVs compared to other licensed TIVs on the market.

P1910
Single step spray-dried polyelectrolyte microparticles enhance the antigen cross-presentation capacity of porcine dendritic cells

B. Devriendt,* K. Baert,* M. Dierendonck,† H. Favoreel,* J. P. Remon,† B. G. De Geest† & E. Cox*
**Virology Parasitology & Immunology, Ghent University, Merelbeke, Belgium, †Department of Pharmaceutics, Ghent University, Ghent, Belgium*

Purpose/Objective: Vaccination is regarded as the most efficient and cost-effective way to prevent infectious diseases. Vaccine design nowadays focuses on the implementation of safer recombinant subunit vaccines. However, these recombinant subunit antigens are often poor immunogens and several strategies are currently under investigation to enhance their immunogenicity. The encapsulation of the antigens in biodegradable microparticulate delivery systems seems a promising strategy to boost their immunogenicity. Here, we evaluate the capacity of polyelectrolyte microparticles (PEMs), fabricated by single step spray-drying, to deliver antigens to porcine dendritic cells and how these particles affect the functional maturation of dendritic cells (DCs).
Materials and methods: PEMs were loaded with either BSA-FITC or F4 fimbriae, a bacterial adhesin purified from a porcine-specific enterotoxigenic *E. coli* strain, by co-spray-drying with the PEM constituents, the polyelectrolytes dextran-sulphate and poly-L-arginine and the sacrificial template mannitol. *In vitro* generated porcine monocyte-derived dendritic cells were incubated with these PEMs and their ability to internalise antigen-loaded PEMs and their phenotypical and functional DC maturation was assessed by confocal and live cell imaging, flow cytometry, proliferation assays and cytokine ELISAs.
Results: In confocal images we detected multiple particles per cell in >80% of the examined DCs, indicating that the resulting antigen-loaded PEMs were efficiently internalised by porcine monocyte-derived DCs. F4 fimbriae-loaded PEMs (F4-PEMs) enhanced CD40 and CD25 surface expression by DCs and this phenotypical maturation correlated with an increased secretion of IL-6 and IL-1β. More importantly, F4-PEMs enhance both the T cell stimulatory and antigen presentation capacity of DCs. Moreover, PEMs efficiently promoted the $CD8^+$ T cell stimulatory capacity of dendritic cells, indicating an enhanced ability to cross-present the encapsulated antigens.
Conclusions: Our results confirm recent data obtained in rodent models that single step spray-dried PEMs boost the immunogenicity of vaccine antigens and could accelerate the development of veterinary and human subunit vaccines based on polyelectrolyte microparticulate delivery systems to protect against a variety of extra- and intracellular pathogens.

P1911
T cell epitope distribution in viruses reveals patterns of protein biosynthesis

C. M. Diez-Rivero & P. A. Reche
Microbiologia I (inmunologia), Facultad Medicina, Universidad Complutense, Madrid, Spain

Purpose/Objective: Development of T cell epitope vaccines is handicapped by the cost and difficulty associated with T cell epitope identification. Therefore, there is need for defining strategies that can speed translational vaccine research. Here, we tried to define a system for prioritizing protein antigens for vaccine design by investigating epitope distribution patterns.
Materials and methods: We used χ^2-statistics to analyze whether known CD8 T cell epitopes of Hepatitis C Virus, Human Immunodeficiency Virus-1 and Influenza A virus are distributed in the viral proteomes according to the size/length of the source proteins. We also analyzed the distribution of peptides predicted to bind to several human MHC I molecules using χ^2-statistics. Finally, we investigated the correlation between epitope distribution and sequence conservation.
Results: We found that epitopes are not distributed homogeneously by the size of the source proteins in any of the viruses. Specifically, structural proteins pack significantly more epitopes than those expected by their size. Moreover, we showed that such non-homogeneous distribution cannot be accounted by underlying MHC I-peptide binding preferences nor it is related to sequence conservation.
Conclusions: Overall, these results support the prioritization of structural antigens for epitope identification and vaccine design.

P1912
Targeting monocytes using a novel liposome based delivery system

S. S. Jensen,* P. T. Johansen,* J. E. Wern,* M. Gad,* J. R. Henriksen† & T. L. Andresen†
**Bioneer, Immune Targeting, Copenhagen, Denmark, †Danish Technical University, DTU-Nanotech, Copenhagen, Denmark*

Purpose/Objective: Targeting specific cells of the immune system is a promising approach to improve the therapeutic index of immune modulating compounds. Monocytes play essential roles in inflammatory conditions in both systemic and local inflammation. Furthermore, monocytes can upon stimulation by innate activation of inflammatory cytokines differentiate into potent antigen presenting cells like macrophages and dendritic cells. The purpose of the current project is to target liposomes specifically to monocytes and thereby modulate their activation, differentiation and migration in inflammation and vaccine development.
Materials and methods: Liposomes with different biophysical properties were generated using phospholipids and modified lipids. Liposomes were prepared using the lipid film hydration method and extruded to reach an average size of 100 nm. Liposomes containing the fluorescent marker rhodamine were incubated with human PBMCs

and also used in whole blood assays, and the immune cell subsets were subsequently analysed for liposome association using FACS analyses.
Results: One of the liposome compositions tested showed a marked association with CD14 positive monocytes after only 15 min incubation in whole blood, whereas other types of liposomes associated with both monocytes and B-cells. The monocyte association was dependent on the age of the whole blood, indicating that factors in the blood were required for an efficient specific targeting process.
Conclusions: A specific liposome formulation showed strong association with CD14 positive monocytes after incubation in whole fresh blood for only 15 min. The targeting technologyis currently being explored further for suppression of monocyte function in relation to systemic and local inflammation, as well as for targeting to monocytes *in vivo*, with the aim of stimulating monocyte differentiation into antigen presenting dendritic cells able to raise an antigen specific immune response towards cancer or infectious antigens.

P1913
The effect of antioxidants on the development of antigen presentation cells

Y. Yang, Y. Liu & J. Tsau
**School of Pharmacy, National Taiwan University College of Medicine, Taipei city, Taiwan*

Purpose/Objective: This study attempts to investigate the effect of reactive oxygen species (ROS) on the differentiation of the antigen presenting cells, including dendritic cells and polymorphonuclear leukocytes (PMN).
Materials and methods: The *in vitro* experiments were carried out by co-culturing the dendritic cells (DCs), the most potent antigen presenting cells, or the Gr-1+ cells from the bone marrow of C57BL/6J mice, with the L121-vaccine adjuvant-treated EL4 cells in the present of antioxidants, including catalase, tempol (4-hydroxy-2,2,6,6-tetramethylpiperidine-1-oxyl), and butylated hydroxyanisole (BHA), followed by analysis of the expression of the costimulatory molecules in the DCs. The production of ROS in the cells was detected by 2',7'-dichlorofluorescene diacetate (DCFDA) and hydroethidine (HE). The *in vivo* experiments were performed in the C57BL/6 mice by immunizing the animals with the vaccine adjuvants containing ovalbumin (OVA), with or without pretreatment with the antioxidants. Animals were sacrificed on day 10 after immunization, and cells from bone marrow and spleen were isolated. The expression of the costimulatory molecules in DCs were determined by staining the cells with flurochrome-conjugated antibodies, followed by flow cytometric analysis.
Results: Our results showed that treatment with antioxidants reduced the MHC II expression and the production of H_2O_2 and $O_2ø$ in the CD11c+ splenic DCs both *in vitro* and in the L121-vaccine adjuvant treated animals. The population of the SSC-hi, Gr-1(+) cells in bone marrow in the vaccinated animals, pretreated with the antioxidants, was elevated at the expense of the lineage-2 (+) populations, accompanied by a significant reduction in the production of reactive oxygen species.
Conclusions: Data obtained in this study showed the potential roles of the reactive oxygen species on the differentiation of myeloid antigen presenting cells in the vaccinated animals.

P1915
The effect of vaccination with recombinant *L. donovani* and *L. mexicana* gamma glutamyl cysteine synthetase by different routes of administration on host immune responses

B. Doro, M. Wiese, A. B. Mullen & K. C. Carter
Immunology, University of Strathclyde, Glasgow, UK

Purpose/Objective: Human leishmaniasis is a spectrum of diseases caused by protozoan parasites of the genus *Leishmania*. Drugs existing for the treatment of leishmaniasis have been unsatisfactory. Ideally a vaccine could prevent infection and would be a feasible control method as infected individuals are resistant to clinical re-infection. In this study the ability of recombinant *L. donovani* and *L. mexicana* gamma glutamyl cysteine synthetase (γGCS) to induce a protective immune response in BALB/c mice was determined.
Materials and methods: Animals were immunised by different routes with the recombinant proteins and the effect of vaccination on production of parasite-specific IgG1 and IgG2a was determined using an ELISA assay. In addition the effect of immunisation on cytokine production by *in vitro* stimulated splenocytes from immunised mice was determined.
Results: Immunization with g GCS inducing significantly higher titers ($P < 0.05$) comparing to control group.
Conclusions: Vaccination induced significant Th1 and Th2 immune responses after single dose treatment.

P1916
The nature of protective immune response elicited by fructose 1, 6-bisphosphate aldolase against *Streptococcus pneumoniae* in mice

S. Goldman-Elhaik,* S. Dotan,† A. Lilo,* A. Ohayon,* R. Ellis,‡ R. Dagan§ & Y. M. Nebenzahl§
**Microbiology and Immunology, Ben Gurion University of the Negev, Beer-Sheva, Israel, †Protea Vaccine Technologies and NasVax Ltd, Protea, Ness Ziona, Israel, ‡4Protea Vaccine Technologies and NasVax Ltd, Protea, Ness Ziona, Israel, §Pediatric Infectious Disease Unit, Soroka University Medical Center, Bear Sheva, Israel*

Purpose/Objective: Fructose Bisphosphate Aldolase (FBA) was previously shown to be surface-localized pneumococcal adhesin with age-dependent immunogenicity in children and recombinant FBA (rFBA) elicited protective immune response against *Streptococcus pneumoniae* in mice. To evaluate the nature of the protective immune response, the cytokine profile elicited by rFBA immunization was explored.
Materials and methods: BALB/c mice were immunized with rFBA in the presence of CFA and IFA in booster immunizations. $CD4^+$ T-cells, obtained from rFBA-immunized mice, were co-cultured with rFBA-treated naïve antigen presenting cells. $CD4^+$ T-cells proliferation and cytokine profile was determined by ELISA. Survival was monitored daily following inoculation of mice with bacteria pre-incubated with antiserum against rFBA.
Results: Immunization with rFBA resulted in significant $CD4^+$ T-cells proliferation and cytokine secretion. IFNγ and IL-17 levels increased gradually and peaked at 72 h (h), while IL-2 level peaked at 12 h and declined thereafter. IL-4, IL-5, IL-10, IL-12p70 and TNFα levels peaked at 48 h and decreased or maintain their level at 72 h. In addition, antibodies to rFBA, IgG1 and IgG2A subtypes, neutralized bacterial virulence and prolonged the survival of mice.
Conclusions: These results demonstrate the involvement of Th1/Th2/Th17 family of cytokines in the protective immune response elicited by rFBA to *S. pneumoniae*.

P1917

Transcriptional response to ISCOM-Matrix at the site of administration and in the draining lymph node in pigs

V. Ahlberg,* K. L. Bengtsson,† P. Wallgren‡ & C. Fossum*
*Biomedical Sciences and Veterinary Public Health, Swedish University of Agricultural Sciences, Uppsala, Sweden, †Isconova AB, RnD, Uppsala, Sweden, ‡Animal Health and Antimicrobial Strategies, National Veterinary Institute, Uppsala, Sweden

Purpose/Objective: ISCOM vaccines induce a balanced Th1/Th2 response, long-lasting antibody responses and cytotoxic T lymphocytes. Accordingly, in a recent human phase I study of influenza vaccination, the ISCOM-Matrix (Matrix M™) increased both the humoral and T cell-specific responses while still being well tolerated. The mechanism of action for ISCOM-Matrix is still largely unknown, thus the early immune response to ISCOM-Matrix was evaluated *in vivo*. The pig was chosen for the study due to immunological similarities to man, such as the organisation of monocytes, macrophages and DCs into subpopulations. Also the distribution of TLRs and the type I IFN response in the pig resemble those in human.
Materials and methods: Pigs were intramuscularly injected with 150 mg ISCOM-Matrix (Matrix M™) and sacrificed after 24 h. The Affymetrix GeneChip Porcine Genome Array was used to measure the early transcriptional response at the injection site and in the draining lymph node.
Results: After ISCOM-Matrix treatment, 594 genes at the injection site and 362 genes in the lymph node were differentially expressed (fold change >2; $q < 0.05$). Gene-set enrichment analysis revealed interferon-regulated genes (IRGs) to be significantly enriched in both tissues analysed, and at the injection site a gene signature for the cell type 'plasmacytoid dendritic cells' was enriched. In the draining lymph node, more than 40% of the up-regulated genes were IRGs. Of the 76 IRGs up-regulated, only *CASP1* and *DUSP5* were up-regulated in both tissues. Furthermore, genes encoding the cytokines osteopontin (*SPP1*), IL-10 and IL-18 were up-regulated at the injection site, and in the draining lymph node IL-1β was up-regulated but IL-18 was down-regulated.
Conclusions: The gene signature induced by ISCOM-Matrix was strongly characterised by an interferon-related response, although notably different IRGs were expressed at the injection site and in the draining lymph node. Elucidating these different responses might provide insights into the mechanism of action for the ISCOM-Matrix and its immunomodulatory effects. The pig will be a useful experimental tool in these further studies.

P1918

Understanding and manipulating chemokines and their receptors to improve vaccine adjuvant design

J. Stephen, R. A. Benson, A. R. Fraser, G. J. Graham, R. J. Nibbs, P. Garside & J. M. Brewer
Institute of Infection Immunity and Inflammation, University of Glasgow, Glasgow, UK

Purpose/Objective: New and improved adjuvants are essential for the development of novel vaccines. However, we have a very limited understanding of how adjuvants work *in vivo*, even for adjuvants in widespread clinical use, such as Alum. Our previous work has shown that the injection site responses to Alum are required for adjuvant activity, although this requirement is transient and becomes dispensable within 2 h of administration. We therefore characterized the cells and molecules of the inflammatory response induced at the site of Alum injection during this timeframe.
Materials and methods: Chemokine and chemokine receptor expression at the site of alum injection was determined using Taqman® Low Density Arrays. The effect of alum on cell recruitment to injection sites was determined using flow cytometry.
Results: Alum injection was found to induce expression of several inflammatory chemokines, including CXCL1, CXCL2, CCL5 and the chemokine receptor CCR5 within 1−2 h of administration. Consistent with this expression pattern, *in vivo* phenotyping of the cells recruited to the site of injection within 2 h of Alum administration revealed a significant early influx of neutrophils compared with controls. Our studies are now focussing on the role of neutrophils in mediating the immune response to alum and the potential to alter or enhance the effects of alum through chemokine and chemokine receptor modulation. Specifically, we aim to determine the impact chemokines and their receptors have on antigen presenting cell function and subsequent T and B-cell responses.
Conclusions: As chemokines and their receptors are one of the key regulators of immune cell movement and immune responses, manipulation of these molecules represents a potential mechanism for altering or enhancing adjuvant function and the subsequent adaptive immune response.

P1919

Vaccine development in prion diseases

V. Čurin Šerbec,* K. P. Hartman,* T. Vranac,* S. Koren,* M. Kosmac,* A. C. Venturini,* M. Ghielmetti,* N. Škrlj† & M. Dolinar†
Blood Transfusion Centre of Slovenia, R&D, Ljubljana, Slovenia, †Faculty of Chemistry and Chemical technology, University of Ljubljana, Ljubljana, Slovenia

Purpose/Objective: Prion diseases are fatal neurodegenerative disorders caused by the abberant accumulation of misfolded cellular prion protein (PrP^C) conformers, denoted as infectious scrapie isoform PrP^{Sc}. B- and T-cell tolerance are the main obstacles for an effective immune response to the incorrectly folded self-protein or to PrP of other mammals. The development of a potential anti-TSE passive or active vaccine thus represent a major problem. The possible ways of active and passive vaccine will be discussed.
Materials and methods: Three synthetic peptides, composed of 13 amino acids were chosen from the primary structure of human PrP and covalently bound to KLH in order to provoke the immune response in BALB/c mice. Monoclonal antibodies (mAbs) were produced by hybridoma technology and after stringent selection, one of them was chosen for humanisation which was done by using variable domain resurfacing approach guided by computer modelling. Mouse and humanized single-chain antibody fragments were expressed in bacterial cells using pMD204 expression vector. In futher studies, it was linked to apeptide, which enables crossing the blood-brain barrier. Different ways to induce anti-idiotypic responses were studied in xenogenic, alogenic and syngenic experimetal systems.
Results: PrP^{Sc}-specific IgG mAb was prepared, which recognizes a new, recently discovered fragment in TSE infected brain, PrP226*, which can be detected without PK digestion of brain tissue and could represent a form of PrP^{sen}. To examine a passive vaccine, scFv fragment of PrP^{Sc}-specific mAb was prepared in humanised form and it was linked to a peptide which enables crossing of the blood-brain barrier. As a new challenge in prion research, anti-idiotypic mAbs were prepared as a possible way to exercise an active vaccine, by using a panel of mAbs for stringent selection and an overview of the immunogenicity of the prion peptides was done.
Conclusions: In our studies, we were able to show that anti-idiotypic antibodies can be induced by careful selection of the antigen and the screening procedure. Besides, humanised scFv fragments of monoclonal antibodies, linked to a peptide, can cross the blood-brain barrier and can also be a model for the treatment of other neurodegenerative

diseases. The application of various epitopes, represented by a mixture of PrP peptides, or by a multivalent vaccine, should also be considered in future studies.

P1920

WHV preS1 elicits protective and virus-neutralizing antibodies in woodchucks

O. Brovko,* A. Schumann,* M. Lange,* S. Urban,† X. Zhang,* M. Lu,* A. Walker* & M. Roggendorf*

**Virology, University Hospital Essen, Essen, Germany, †Molecular Virology, University Hospital Heidelberg, Essen, Germany*

Purpose/Objective: Chronic Hepatitis B virus (HBV) infection remains a serious health threat leading to cirrhosis and hepatocellular carcinoma. Current safe and effective prophylactic HBV vaccines consist of recombinant particles built by the small HBV envelope protein (S-HBs). They successfully reduced HBV related morbidities. However, these types of vaccines do not elicit an immune response in 5% to 10% of normal recipients. In addition, vaccine-induced immune escape mutants have frequently been described. Recently it has been shown that the preS1 domain of the large HBV surface protein (L-HBs) is involved in the initial binding, fusion and entry into hepatocytes and possesses HBV neutralizing epitopes. The ongoing debates about additional protective effect of preS1 domain are limiting the usage of promising preS1-containing third generation HBV vaccines.

Woodchucks are the natural host of woodchuck hepatitis virus (WHV) and are frequently used animal models to study the infection course, treatment and vaccination against Hepadnaviral infections. In present study we examined the capacity of synthetic WHV preS1-derived peptides to elicit protective antibodies against subsequent WHV infection and to neutralize infection *in vitro*.

Materials and methods: Three groups of naïve woodchucks were immunized with preS1-GST protein, myristoylated or non-myristoylated preS1 peptides. Animals were inoculated intravenously with 10^6 WHV genome equivalents 2 weeks after the last immunization and monitored for markers of infection. Neutralizing capacity of α-preS1 specific antibodies was tested in *in vitro* Hepatitis D virus (HDV) neutralization assay.

Results: Immunization with all synthetic WHV preS1-derived sequences protected woodchucks from WHV infection and α-preS1 specific antibodies efficiently neutralized HDV infection of primary woodchuck hepatocytes. The neutralization capacity of α-preS1 antibodies was depended on peptides modification. The natural *N*-terminal myristoylation of preS1 reduced the protective effect most likely due to sterical shielding of important epitopes.

Conclusions: The results demonstrated that the α-preS1 specific antibodies are neutralizing and protective. The third generation HBV vaccines containing preS1 domain should be regarded as the HBV vaccine of choice.
